The integration of FMS with robotics in the modular construction field has several benefits. One of the main advantages we can obtain from the combination of these two, is increased production and efficiency. The use of robotics in this field enables the production process to be smoother and uninterrupted, even when faced with fluctuations, as robots can adapt to the varying speeds and production requirements. Additionally, with robotics the speed with which a product can be produced has improved, as digital designs and virtual modelling of the manufacturing process reduce the time between product design and delivery (Bahrin et al., 2016). This combination of FMS and robotics provides a powerful tool for the modular construction industry to optimize production and increase overall efficiency.

Optimization for modular construction topics has become increasingly important as the construction industry looks to build faster while also balancing the need for efficiency. In some cases, the focus on speed can be beneficial, but in many others, it may not align with the actual demand of a manufacturing plant and the variability in demand on a daily basis. Implementing flexible manufacturing systems (FMS) with robotics can address these challenges by increasing production and efficiency, allowing for adaptation to different speeds and production times as well as reducing the time between product design and delivery (Smids et al., 2020). Additionally, the integration of FMS and robotics can help to optimize operations and reduce downtime, leading to greater efficiency and cost-effectiveness (Bahrin et al., 2016)

The integration of flexible manufacturing systems (FMS) with robotics has several benefits in the field of modular construction. One of the most significant advantages of combining the two is reaching non-stop production. With the use of robotics, these can be adapted to speed changes and respond quickly to the current demand and fluctuations of the manufacturing facility, resulting in a production that is targeting the efficiency it needs.

One of the main obstacles to integrating lean in the modular construction industry is increased variability (Innella et al., 2019). FMS allows for quick adaptation to changes in demand, making it possible to handle varying levels of product variety and quantity. When combined with robotics, this flexibility becomes even more powerful, as the robots can respond quickly to changing production requirements and conditions. This leads to improved production performance, use of assets, and overall competitiveness in the market.

Moreover, the use of robotics in FMS can reduce the need for manual labor, leading to increased safety and reduced risk of injury. The integration of robotics also leads to improved equipment utilization, shorter work-in-process and set-up times, faster throughput and lead times, smaller batches and lower inventory, and reduced manpower requirements (Magalhães et al., 2022). Additionally, robotics systems can be quickly reconfigured to perform various tasks and multiple tasks (Pedersen et al., 2016), reducing the setup time and making them more flexible to handle a variety of manufacturing needs. While CNC systems are well suited for applications that require high precision and repeatability, robotics systems offer greater flexibility, programmability, and adaptability to changing manufacturing needs.

In conclusion, the combination of flexible manufacturing systems and robotics in modular construction presents numerous benefits, including increased production speed and efficiency, improved system performance and competitiveness, reduced need for manual labor, and increased safety and equipment utilization when producing panels for modular buildings. By leveraging the benefits of both FMS and robotics within modular construction, the industry should be able to better manage the fluctuations they have to face day by day and improve overall production efficiency.

CONCEPTUAL LEAN FRAMEWORK

The challenge addressed in this paper is that modular construction has a continuous change in demand, on a day-to-day basis, as is illustrated in Figure 3 which showcases an example of the variability of demand across a small period (months) for a modular construction facility. The ability to respond and adapt to changes in demand is essential to stay competitive and following lean principles. Furthermore, this variability also creates inefficiencies relating to overproduction at the system and line levels, incurring wasted efforts to deal with inventory or delays (Aziz & Hafez, 2013). Thus, a fluctuating demand requires a flexible and agile approach to production and a system that can adjust to these changes in real time is ideal to minimize wastes related to production timing.

To address this challenge, the integration of robotic flexible systems within modular construction is considered a strategic approach. A conceptual theoretical framework is developed to represent the relationship between flexible manufacturing systems (FMS) and robotics in modular construction. The focus of this study is to determine the feasibility of incorporating flexible robotics systems into modular construction processes.

A visual conceptual framework is a visual representation that outlines the key relationships among variables in a study. In such a framework, the independent variable is manipulated or changed in an experiment, the dependent variable is the variable that is being measured and is expected to change as a result of the manipulation of the independent variable. The moderator variable is a variable that influences the relationship between the independent and dependent variables, while the mediator variable is a variable that explains the relationship between the independent and dependent variables. The control variable is kept constant in an experiment to prevent it from interfering with the results and to isolate the effect of the independent variable on the dependent variable (Swaen & George, 2022).

In this conceptual framework illustrated in Figure 2. The relationship between the independent variable (robotics) and the dependent variable (modular construction flexible manufacturing systems) is understood through mediator variables. These variables act as intermediaries to explain how the independent variable impacts the dependent variable. The mediator variables selected in this framework are real-time adjustments, accuracy, equipment utilization, set-up times, varying speeds, reduced manpower, and implementation cost. These variables were selected as a result of the literature review to provide a thorough understanding of the impact of robotics on modular construction flexible manufacturing systems.

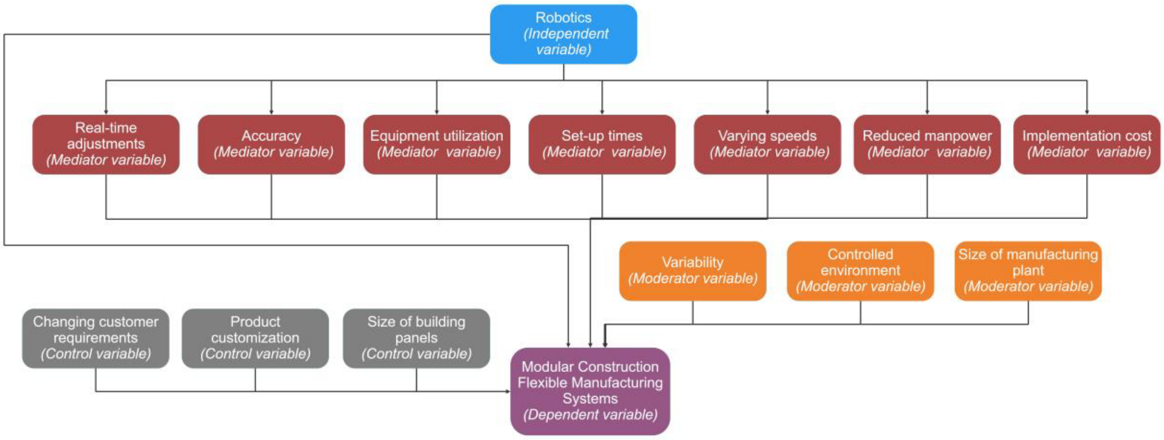

Figure 4: Conceptual Framework Robotics – Flexible Manufacturing

The selection of these specific mediator variables in the present study was based on a previous research article that established the connection between lean concepts and robotics (Cardenas et al., 2022). Specifically, the paper proposed a matrix model that described how the design parameters for a robotic cell in offsite construction interact with major lean wastes. This matrix model identified various design parameters related to robot selection criteria, production requirements, and cell requirements, which were identified through extensive literature reviews and observations of industrial robotic cells.

The variable "equipment utilization" in the framework is linked to the robot selection criteria of the matrix, as the choice of the robot can affect the efficiency and productivity of the production process. The variable "varying speeds" is linked to the production requirements of the matrix, as the speed of the production process can be affected by factors such as robot speed and cycle time. The variable "real-time adjustments" is linked to the cell requirements of the matrix, as the design of the cell and the robots used can affect the ability to make real-time adjustments to the production process. The variable "reduced manpower" in the framework may is linked to lean waste, as the use of robots can reduce the need for human labour and potentially reduce waste.

Real-time adjustments highlight the ability of robotics to make on-the-spot changes to production processes, while accuracy measures the precision of the production process. Equipment utilization, set-up times, and varying speeds demonstrate the efficiency of the production process. Reduced manpower and implementation costs provide insight into the impact of robotics on the workforce and overall cost of production. Together, these mediator variables help to illustrate the relationship between robotics and modular construction flexible manufacturing systems.

These variables have the potential to alter the level of flexibility in manufacturing systems. Variability in the manufacturing process is particularly important as it can significantly impact the flexibility feature. When variability is high, it can pose a challenge to the flexibility of manufacturing systems, whereas low variability scenarios may offer more flexibility. The level of control in the environment and the size of the manufacturing plant are also important factors that can impact the level of flexibility.

Furthermore, time is considered a control variable because it is held constant to prevent interference with the results. Although time is not the primary focus of the study, it can still impact the results. In the context of flexible manufacturing, a set period of time is used to produce a certain number of panels. However, demand can change unexpectedly, and the production process may need to be adjusted accordingly. This adjustment in production time can impact the flexibility of the system as it affects the production rate and the ability to adapt to changing demands. Hence, it is crucial to carefully manage time in flexible manufacturing systems to ensure that they remain efficient and flexible even in changing conditions.

The focus of this study is on the importance of flexibility in modular construction, as opposed to solely focusing on productivity. In the context of lean production, flexibility is valued more highly than productivity as it allows for the necessary amount to be produced at the right time. The current state of CNC systems in modular construction, which execute repetitive tasks in a fixed order and lack adaptability to changes, results in overproduction and is considered waste in the lean philosophy (Chahal & Narwal, 2017). Our proposed system offers a solution that prioritizes flexibility and the ability to produce the necessary amount at the necessary time, aligning with the principles of lean production.

CASE STUDY

This study compares the production of a cross-laminated timber (CLT) panel for modular construction using a robotic machining cell and a CNC machine. The study aims to determine which manufacturing process is more efficient and adaptable to changes in product design and production sequence.

The CLT panel has a variety of geometrical shapes for windows and doors, as well as additional features unique to CLT building techniques for modular construction. A previous robotic design for CLT machining is used to obtain simulated results (Villanueva et al., 2021), whereas the same CLT panel is then simulated in Fusion 360, illustrated in Figure 6 using a CNC machine to compare the two manufacturing processes. The specifications considered for the CNC simulation are a working area of 13500mm width, 1956mm height and 4648mm depth. Additionally, a rapid traverse speed of 63.5 MPM, cut speed of 35.5 MPM, a rapid traverse of 1.058 mm/min, max feed ratio of 0.592 mm/min, feed rate ratio of 100% and a tool change time of 15 seg.

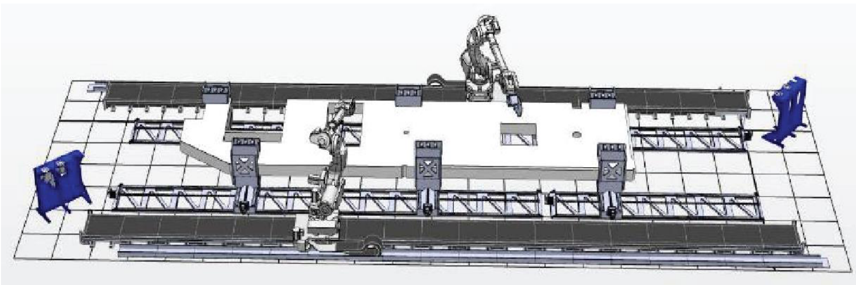

Figure 5: Robotics Simulation (taken from Villanueva et al., 2021 with permission)

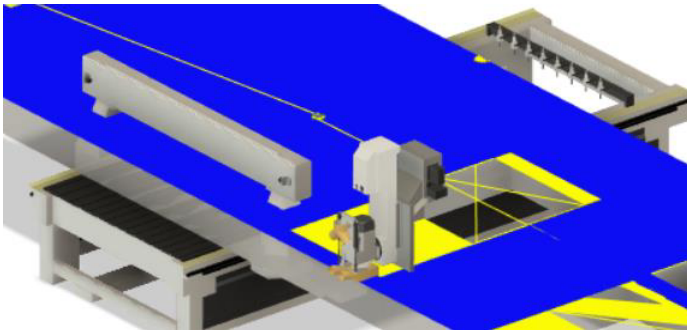

Figure 6: CNC Machining Simulation.

According to the findings of the study, the production of the CLT panel using the robotic machining cell took 18 minutes and 20 seconds (Villanueva et al., 2021), while the CNC machine took 36 minutes and 1 second to produce. The robotic machining cell is nearly twice as fast as the CNC machine, resulting in a significant difference in production time. This difference is due to the robotic machining cell's flexibility, which is programmable and adaptable, allowing it to quickly switch between different operations and make real-time adjustments. The multitasking capability of the robotic system allowed it to perform multiple operations at the same time, increasing its efficiency even further.

Assuming we have a manufacturing facility capable of producing 500 building panels per week, with a daily capacity of 100 panels. The actual demand for building panels, on the other hand, can vary greatly from day to day, so the facility must be able to adapt to changing demand. For instance, the demand for building panels is higher than expected on Monday, with a requirement of 125 panels. To meet this demand, the facility increases Monday production to 125 panels and decreases Tuesday production to 75 panels. The demand drops to 80 panels on Wednesday, so the facility adjusts its production accordingly. By the end of the week, the facility had produced 500 panels, meeting weekly demand while also being able to respond to day-to-day fluctuations in demand.

Using the information from the simulations, it is possible to produce 500 building panels per week with a daily capacity of 100 panels using the robotic machining cell. The robotic machining cell's 18 minute and 20 second production time per panel would allow the facility to produce approximately 200 panels per day, which is more than the expected daily demand of 100 panels. This provides a buffer for the facility to respond to daily fluctuations in demand. The robotic machining cell would be able to quickly adapt to the increased demand on Mondays and produce 125 panels in a single day without sacrificing panel quality. The robotic system's adaptability and flexibility allow it to quickly switch between different operations and make real-time adjustments, reducing setup time when compared to the CNC machine.

In contrast, the CNC machine, with a production time of 36 minutes per panel, would struggle to meet the increased demand on Monday. Changing tooling or setting up the machine for a new operation can be time-consuming, reducing the machine's overall flexibility and efficiency. The CNC machine's ability to respond quickly to changes in demand is limited by inflexible programming and the need for specific tooling and material options. As a result, the use of the robotic machining cell, with its quick production time and adaptability, enables the manufacturing facility to adapt to changes in demand and ensure that it can meet its production goals while remaining efficient and cost-effective. The ability to respond to changing demand is critical for any manufacturing facility's success, and the use of a robotic machining cell allows for such adaptability and efficiency.

The ability to adapt to changing demand is critical for the success of any manufacturing facility, and the use of a robotic machining cell enables such adaptability and efficiency (Javaid et al., 2022). The robotic machining cell's flexibility allows for simple process adjustments and quick adaptation to changes in product design and production sequence. This adaptability is a critical feature of a flexible manufacturing process, which is required to deal with variations in demand and product design.

As a result, the case study strongly advocates for flexibility over productivity in manufacturing processes, particularly when dealing with variations in product design and manufacturing sequence. The flexibility of the robotic machining cell over the CNC machine allows for rapid adjustment of production processes and adaptation to changes in demand and product design. The study's findings suggest that the use of robotics in manufacturing processes is an asset in the constantly changing world of industry, where the ability to respond to shifts in demand quickly and effectively is critical for success.

CONCLUSIONS

The integration of robotics into flexible manufacturing systems (FMS) in modular construction holds great promise for the future of the industry. The purpose of the paper was to present a theoretical framework for investigating the relationship between FMS and robotics in modular construction and found that the integration results in increased modular construction flexibility. The paper considered various moderator and mediator variables and concluded that a flexible manufacturing system is an essential component of Industry 4.0, with the potential to improve system performance and competitiveness.

Despite some challenges associated with the implementation of robotics in modular construction, the benefits of increased productivity, reduced dependence on labor, improved responsiveness to changing demand, and improved product quality make it a promising technology. Combining FMS with robotics in modular construction can increase production and efficiency, help to optimize operations, and reduce downtime. However, the high cost of acquiring and maintaining robots and the lack of technical expertise may limit the widespread adoption of robotics technology. To maximize the benefits of robotics integration in modular construction, it is important to carefully consider the costs and benefits and to invest in the necessary technical expertise to ensure a successful implementation.

One of the most important contributions of this study is the creation of a framework that incorporates novel mediator variables that have not previously been investigated in the context of FMS implementation. Furthermore, this study contributes to the understanding of the relationship between FMS implementation and overall manufacturing performance by emphasizing the importance of considering not only technical but also demand variability factors. While this study provides useful insights, further research is needed to understand how these mediator variables interact and how they can be effectively managed in practice.

VISUAL MANAGEMENT IMPLEMENTATION STRATEGY: AN ANALYSIS OF DIGITAL WHITEBOARDS

Bárbara Pedó[1], Algan Tezel[2], Lauri Koskela[3], Patricia Tzortzopoulos[4], Carlos Torres Formoso[5], Elena Vrabie[6], and Stuart Robinson[7]

ABSTRACT

Visual Management (VM) is a communication strategy in which a visual workplace for close-range communication is created by using easy-to-understand sensory devices. It is adopted to increase process transparency and self-management capacity. VM discussions have been mostly device-centred to date, being concerned with the development of new devices, or understanding the impact of different VM attributes for different purposes. Explorations of VM as a strategy have been limited. This paper outlines the key elements of one part of an overall VM strategy, namely the implementation strategy (i.e., planning, introducing, executing, monitoring, and controlling, maintaining, and improving, and removing). It is based on an empirical study on the use of a specific type of VM device (i.e., digital whiteboards) at an infrastructure engineering design and consultancy company in the UK. The main sources of evidence were surveys with key representatives of the company and participant observation in the development and implementation of the device. Findings indicate that adopting VM through a systematic implementation strategy with coherent plans and actions is important to enable its successful application. Moreover, some future research opportunities are pointed out, such as to expand and evaluate the definitions proposed, and to test them in different contexts and device types.

KEYWORDS

Visual Management, Strategy, Digital Whiteboards, Lean, Design Management.

INTRODUCTION

Visual Management (VM) is a key element of the lean production philosophy and refers to a management strategy to increase transparency and self-management capacity at a workplace (Tezel et al. 2016). It is realised by employing VM devices that enable close-range, sensory (i.e., visual, auditory, olfactory, gustatory, and tactile) communication for different purposes.

Transparency can be defined as the communication ability of work elements with human beings (Formoso et al. 2002). The reliance on written and text-based communication in VM should be limited (Galsworth 2005). VM devices should be easy to understand and accessible at the point of use. Information must be integrated into the workplace, increasing information availability (Greif 1991; Galsworth 1997).

VM is widely used in the implementation of lean in the Construction industry, where diverse types of devices have been used (e.g., visual boards, *kanban* cards, *andon* boards). VM discussions in construction have been driven by the lean construction community, and it is colloquially dubbed as a "lean communication system" (Tezel et al. 2016). Previous studies have proposed new VM devices as outcomes of action or design science research efforts (see for instance Brady et al. 2018), while others have assessed different types of VM devices according to functions, benefits, requirements, and purposes (see for instance Tezel and Aziz 2017; Pedó et al. 2022; Brandalise et al. 2022). Therefore, most existing VM discussions are centred around VM devices or practices. This is not surprising, as devices represent the more tangible and practical side of VM.

However, the application of VM is not limited to companies involved in the implementation of lean philosophy, as it can be employed outside a lean background. In fact, VM can be regarded, in essence, as managerial communication strategy. Therefore, research on VM from a strategic perspective at an organisational level is required.

This paper reports on initial findings of research aiming to understand the dimensions and elements of one part of an overall VM strategy, namely an effective VM implementation strategy. To the best of our knowledge, VM implementation strategy elements have not been clearly outlined in the literature to date. This is done by analysing the design, introduction, and use of a specific type of digital VM device at a large engineering design and consultancy company from the UK.

The discussions start from the VM device, and move to the company's VM strategy, indicating whether some key implementation strategy elements have been adopted. The need for a VM strategy was emphasised in a digital and dynamic context, where a more structured approach is required for the development and implementation of digital VM (e.g., digital whiteboards). Thus, the main contribution of the paper is the understanding of the key elements that need to be defined for an effective VM implementation strategy, considering the context of digital civil engineering design projects.

VISUAL MANAGEMENT

Using sensory stimuli to manage people is not new. Signals, banners, and signs have been used in armies or for managing mega projects for millennia. However, the term VM has crystallised as a concept in the last 45 years with the diffusion of the lean production philosophy in different sectors (Tezel et al. 2016). Alongside containing some more established VM devices in its toolbox, lean practitioners also recommend not copy-pasting VM devices and experimentation with VM for different contexts and information needs (Dallasega et al. 2022).

The literature has explored VM in different settings. For instance, Hirano (1995) showed how VM devices can create workplace order. Greif (1991) demonstrated that VM devices can contribute to different managerial efforts in a "visual factory". Liff and Posey (2004) extended those examples beyond factory shop floors and into other work settings such as hospitals and offices. Galsworth (2005) proposed a VM device classification system and an implementation framework. Theoretical discussions emerged from those initial, practical VM discussions. Attempts at explaining the mechanisms of VM devices through the concepts of affordances (Beynon-Davies and Lederman 2017) or boundary objects (Bell and Davison 2013) have also been explored in the literature.

In construction, Formoso et al. (2002) illustrated how VM can increase process transparency on construction sites. The adaptation of some conventional VM devices from manufacturing to construction sites has also been reported (Kemmer et al. 2006; Jang and Kim, 2007). The use of VM in construction design management has been also investigated (Tjell and Bosch-Sijtsema 2015). The functions (Tezel et al. 2016) and requirements (Pedó et al. 2022) of VM for construction have been discussed. Although some indications of VM as a management strategy can be found in previous studies (Nicolini 2007; Tjell and Bosch-Sijtsema 2015; Tezel et al. 2016; Brandalise et al. 2022), the discussions have mostly focused on VM devices and practices to date.

VM AS A STRATEGY

Beyond the development of visual devices, the literature suggests that implementing VM requires tasks such as evaluating information needs (Hirano 1995; Galsworth 2005), analysing the readiness of the work setting and elements for a VM device (Tezel et al. 2015), monitoring and evaluating the practical use of devices (Greif 1991), devising improvement and maintenance measures for the VM devices (Nicolini 2007), and capturing new VM ideas from users (Galsworth 1997; 2005). Nicolini (2007) and Brandalise et al. (2022) argued that a VM practice encompass both VM devices (the visual work of a VM practice) and the non-visual work involved in the use of the devices. A VM system is a group of visual practices working together (Brandalise et al. 2022) in order to create a visual work environment (Galsworth 2005).

Therefore, VM can be defined as a strategy for creating a "visual workplace" enabling self-management of people through VM practices (Greif 1991; Tezel et al. 2016). Being a strategy, it encompasses plans and several decisions (Galsworth 1997; 2005), such as: the purpose of the VM, the types of VM devices to be used, how people will be trained and incentivised to use the VM devices, how those devices will be created, standardised, maintained, controlled and improved, and how the devices will be linked with other production system elements and with each other.

The authors of this paper assert that decoupling VM devices and those hidden activities is necessary for a better understanding of the VM concept and successful VM applications in practice. The lack of a VM strategy, i.e., the absence of those hidden activities, may limit the effectiveness of a VM system, considering that VM will be developed as a set of random, incidental, and isolated practices which result from a trial-and-error implementation approach.

According to Chia and Holt (2009), a strategy, or a consistency of action, can also emerge from non-deliberate interventions to support immediate concerns with absence of goals specified in advance. This, for instance, can clarify aspirations, constituting a recognisable strategy with enough consistency when analysed in retrospect. A strategy does not necessarily imply something deliberately pre-thought, and positive outcomes can emerge serendipitously as a result of actions without a strong coordination effort (Chia and Holt 2009). Thus, strategies (and visions) can be a result from a combination of deliberate and emergent actions (Mintzberg, 1987).

The latter can also be developed as a consequence of bottom-up actions, mostly focused on the details, i.e., through trial-and-error, in which a pattern could be recognised as suggested by Mintzberg (1987). A strategy can also be defined as a plan, describing how goals can be achieved, or as a decision or a system of elements, as suggested by Galsworth (2005), in which the different options selected can lead to future situations, as they interact and could impact each other. A strategic plan is a formalised approach towards strategic decisions (Mintzberg, 2000) to work out the implications of a strategy (Mintzberg, 1987). In fact, different types of strategies might be required to support VM, however this paper's focus is on the implementation strategy.

Based on the literature, elements of a VM implementation strategy have been proposed, i.e., 1) planning, 2) introducing, 3) executing, 4) monitoring and controlling, 5) maintaining and improving. In the planning (1) element, decisions related to the readiness of the system need to be made, including actions such as: observe the process (Valente at al. 2019) and identify the problem or opportunities; analyse and identify user and VM requirements (Pedó et al. 2022); define visual attributes (Valente at al. 2019) by identifying patterns, coding, naming conventions or templates. The introducing (2) element of the strategy refers to training (Pikas et al. 2022) and is important to gain users' buy-in and give them autonomy to use and own the practices and devices. Implementing or executing (3) requires integration with the company system, e.g., linking with other existing VM practices and systems, as well as integrating with managerial routines (Valente at al., 2019) and identifying the types of integration and communication (Brandalise et al. 2022; Pedó et al. 2022) by pinpointing the number of users, information flow, and whether interactions are happening at the same or different location and time. By monitoring and controlling (4), the practical use of the VM devices should be assessed, as argued by Greif (1991), by adopting structured approaches for capturing users' feedback, solving problems, and managing change. Maintaining and improving (5) the device, as outlined by Nicolini (2007), was also identified as a relevant element of the strategy.

WHITEBOARDS AS VM

VM is also an approach for communication between individuals so that differing perspectives are considered towards developing shared understanding (Lindlöf 2014). (Physical) whiteboards have been shown as effective visual means of conveying concepts and ideas, facilitating discussion and collaboration among stakeholders (Shae et al., 2001), as well as establishing a common ground (Gergle et al. 2013). It is important to understand the intricate relationship of VM practices and users' cognitive processes (Valente et al. 2019), as visual aids can enhance comprehension.

In addition, in the design of digital systems, the coordination requirements are frequently ignored, such as the cognitive work of coordination and the dynamic interactions (Maguire 2019). Digital whiteboards, however, provide a flexible visual (and virtual) platform, akin to a white canvas, that enables the creation of artefacts to support remote communication and collaboration (Gumienny et al. 2013; Pikas et al. 2022). Digital whiteboards can support new routines, procedures, and activities by making it easy to pull information when required from an information field, i.e., there is an easy access to information at any time, place (or space) and device (Pikas et al. 2022).

RESEARCH METHOD

Case study was the research approach adopted in this investigation because it is suitable for studying phenomena in a real-life context, in which researchers have no control over events (Yin, 2003). The case study was part of a Knowledge Transfer Partnership (KTP) project aimed to improve collaboration between academia and industry. This project explored the integration of lean construction and digital design at an international civil engineering design and consultancy company, focused on the highways and rail sectors.

Digital whiteboards are the focus of this investigation, which were devised and disseminated through a bottom-up approach and emerged to support immediate concerns without specified goals. The case was used to recognise and refine key elements in a VM implementation strategy. Digital whiteboards were selected for this case study due to the fact that the platform presents the potential to cope with the dynamic interactions and collaboration in the context, and this is even more relevant when discussing the different elements of a VM implementation strategy. This is an ongoing research work, and more data from the company will be collected about its strategy. Moreover, there are limitations in considering data from the implementation of a single VM type (i.e., digital whiteboards).

The study had three main stages: (1) problem understanding and solution development, i.e. implementation of digital whiteboards, i.e. Miro (www.miro.com) and Mural (www.mural.co), (2) assessment of the digital whiteboard implementation through users' feedback , i.e. survey, (3) reflection upon the solution and critical analysis. The authors were directly involved in the introduction and use of the digital whiteboard. The main sources of evidence are: (1) survey with key company users (27 responses); (2) participant observation, as the researchers were involved in many applications and collected feedback throughout the implementation process; and (3) document and digital whiteboard interface analysis.

The survey had three sections (see Table 1): (1) general information; (2) user experience in using the digital whiteboards (Likert scale); and (3) challenges, benefits, and future opportunities. In the second section (2), respondents were asked to evaluate ten statements concerning the digital whiteboard characteristics on the 5-point Likert scale (strongly agree, agree, neutral, disagree, or strongly disagree). The key aspects explored are associated with the requirements for digital VM proposed by Pedó et al. (2022): simplicity, standardisation, availability, accessibility, flexibility, traceability. The challenges, benefits, comments by the respondents, and improvement opportunities captured from the survey were compared with the key implementation strategy elements proposed in this paper, supporting the refinement of the elements. This was complemented with the authors' observations of the use of the digital whiteboards. The survey responses were clustered according to the VM strategy elements, exemplifying, and expanding its definition.

Table 1: Survey Questions

Section	Questions
1	1.1 What is your role or position? 1.2 Overall, how would you rate your experience with digital whiteboards? 1.3 How would you rate the user-friendliness of digital whiteboards interface? 1.4 Why did you start using digital whiteboards? Please identify the key reason or purpose 1.5 What are the key functions of the digital whiteboard? Please select at most three options 1.6 How useful is the digital whiteboard to you considering the functions you identified? 1.7 How often do you use a digital whiteboard? 1.8 Have you had any training for using a digital whiteboard? 1.9 Who creates the digital whiteboards templates?
2	2.1 Easy and clear to use and understand the objective or function 2.2 Board templates are available and adopted 2.3 Information is standardised and consistent throughout the board 2.4 Easy to find the information because there is no excess of information 2.5 Easy to find information when required (at the right time e.g., during a meeting) 2.6 Easy to access the board because it is located in the right place, or its link is shared with the team when required 2.7 Easy to adapt the template 2.8 Easy to adapt and update the information 2.9 Easy to organise, store and backup the boards 2.10 Easy to track the information owner and changes
3	3.1 What are the perceived challenges and barriers of using digital whiteboards? 3.2 What are the perceived benefits of using digital whiteboards? 3.3 What other technologies or trends could be facilitators for the implementation and integration of digital whiteboards with existing technologies and processes? 3.4 Considering that you have used digital whiteboards extensively, how likely are you to recommend it to your friends and colleagues?

RESULTS

The starting point was a practical problem identified by the company, which had decided to implement VM and digital solutions across to increase efficiency, to deal with the challenges related to the design disciplines' fragmentation and lack of process transparency. Moreover, most design teams interactions were held in virtual environments due to the Covid-19 pandemic, affecting ways of working and collaborating. Thus, the idea of managing collaborative remote design work through digital VM was the starting point for this investigation.

The implementation of digital whiteboards was done across different sizes and types of design projects and teams, and for different functions. The digital whiteboards supported dynamic interactions, involving uncertainty, negotiation, and collaboration to establish common objectives. The key functions identified were related to planning, process mapping, and brainstorming, representing 68% of the survey responses (Figure 1 shows the interface of two VM practices using digital whiteboards as the medium to implement it). These were followed by continuous improvement and lessons learnt, representing 12% of the responses. The key purpose for starting the digital whiteboards adoption was to aid collaboration and support continuous improvement (60% of the responses), followed by knowledge management and sharing information. The previous knowledge on how to use, the top-down support, and the platform availability and easiness of use also influenced its implementation. Thus, the whiteboard dissemination for other uses was also facilitated due to the fact that the teams became familiar with the whiteboard interface and its functionalities.

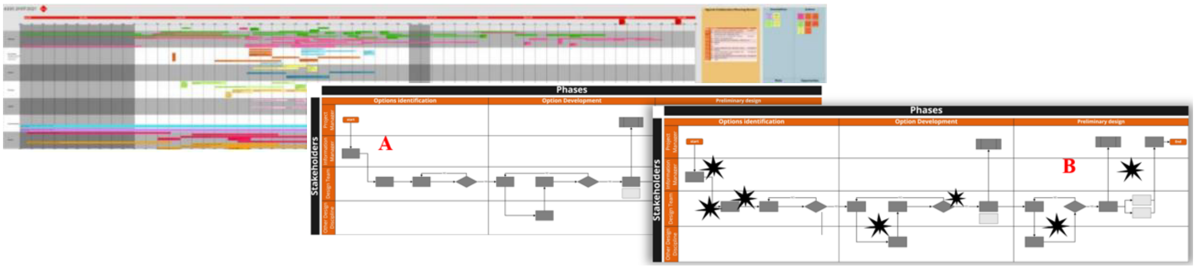

Figure 1: Digital Whiteboard Interface for 'Planning' and 'Process Mapping' Applications.

Most participants (68%) had not had any training on digital whiteboards. Nevertheless, the majority (78%) answered 'great' or 'excellent' for the user-friendliness of the digital whiteboards interface. In addition, 82% of participants answered 'great' and 'excellent' for their experience in using digital whiteboards, and the majority (85%) answered 'useful' and 'extremely useful' for the usefulness of the platform related to the key functions identified. Thus, 96% would likely or very likely recommend the platform to colleagues.

Most of the users can be described as BIM or digital managers and coordinators (30%), technical directors (22%), BIM or digital leads (19%), designers or engineers (11%), and others (18%), such as GIS coordinators or leads. There was daily and weekly frequency of use (17 responses out of 27), and the templates were usually developed by the continuous improvement practitioner or digital / BIM leads, not by the users.

Considering the user's experience in adopting the digital whiteboards for different functions, the comprehensibility, accessibility (right place), availability (right time) and information flexibility aspects were outlined as positive characteristics of a digital whiteboard (see Figure 2). The majority of the survey participants answered 'agree' or 'strongly agree' to 'easy and clear to use and understand the objective or function' (85.2%), 'easy to find information when required (at the right time e.g. during a meeting)' (70.4%), 'easy to access the board because it is located in the right place, or its link is shared with the team when required' (92.6%), and 'easy to adapt and update the information' (81.5%). In contrast, traceability and template flexibility were highlighted as negative or neutral aspects, considering most of the participants answered 'disagree' or 'neutral' to 'easy to adapt the template' (59.3%), 'easy to track the information owner and changes' (59.2%).

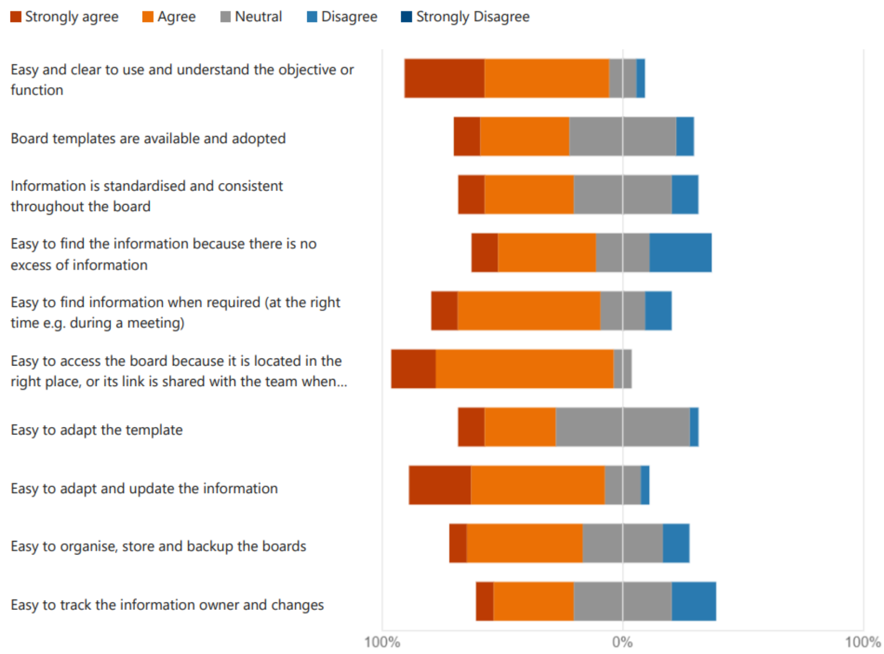

Figure 2: Users' Experience with Digital Whiteboards.

DISCUSSION

Table 2 presents the key VM implementation strategy elements (i.e., planning, introducing, executing, monitoring, and controlling, maintaining, and improving), based on the literature review, and refined considering the survey results and participant observations, i.e., the researchers' insights and observations as a source of evidence. The paper suggests that the VM implementation strategy elements proposed follow the plan definition or strategic planning, as suggested by Mintzberg (2000), however, they impact each other and some of the definitions could be analysed and interpreted through the decision lenses, in which there is a system of elements to consider as argued by Galsworth (2005), e.g., whether manual, digital or hybrid VM should be adopted or whether it should be implemented in production, administrative or management activities.

The 'planning' element relates to analysing the readiness of the work setting and elements for a VM device implementation (Tezel et al. 2015). It was emphasised by the challenges faced by the team members associated with the early identification of technical and system requirements, as well as with the early identification of the visual attributes. The team highlighted the need to have a plan regarding the correct number of licences (and financial implications), and permission in place before using the platform, as the lack of a full licence could restrict the adoption of some functionality. Setting up the boards' access and restrictions in early stages of the implementation was also identified as a key aspect, as this could avoid issues related to the security of information. The assessment of the need, process, problem, and opportunities is also a relevant aspect of the planning as identified by one of the users, avoiding the introduction of unnecessary boards. This is also related to an early identification and analysis of the VM application purpose and requirements. The definition and agreement on the visual device attributes (Valente et al. 2019), such as content and format, as well as identifying and prioritising relevant information (Hirano 1995; Galsworth 2005) was outlined as fundamental when working with a digital whiteboard, as the excess of information or space to work could be overwhelming for its users and it could become very disorganised. In addition, a clear and disciplined way of using such dynamic devices is a must have and it should be agreed in the planning stage (with room for improvement if required). It was suggested by one of the survey respondents that having a governance process in place could provide support in overcoming those challenges by consolidating and standardising the digital whiteboard management process. One of the participants also identified the time required to develop [and maintain] the board as a challenge, which underlines the need to consider ideating, prototyping, evaluating, and selecting appropriate solutions when possible.

Table 2: VM Implementation Strategy Elements Refined.

VM strategy elements	Definition	Output	Source
Planning	Analyse the readiness of the system and users, by considering its processes, VM purpose, user and system requirements, problems, and opportunities (e.g., emerging technologies), visual and non-visual attributes, and prototype possible solutions.	Planning strategy including cost and implementation plan	Literature review and researchers' insights/observati on
Introducin g	Train users, provide guidance, facilitate initial applications, and handover to them.	Training and ownership-building plan	Literature review and researchers' insights/observati on
Executing	Integrate in the company system by linking with existing VM practices and systems, as well as integrating with managerial routines, and communication and collaboration practices.	Execution plan	Literature review and researchers' insights/observati on
Monitoring & controlling	Monitor and evaluate the practical use of VM devices, outline certain criteria for control, capturing the users' feedback through standard approaches defined by the company.	Evaluation plan	Literature review and researchers' insights/observati on
Maintainin g & improving	Identify key elements of the device or practice that needs to be adjusted or improved.	Maintenance and Continuous Improvement plan	Literature review and researchers' insights/observati on
Removing	Identify practices that need to be removed from the system due to different reasons	Exit strategy	Researchers' insights/observati on

The 'introducing' element of the VM implementation strategy refers to the effort required prior to the device implementation in order to ensure the users understand its purpose and how it works. It is not only related to training, but also associated with the initial support with its implementation aspects (Pikas et al. 2022) and facilitation required until the users feel confident in using and owning the device, when it can be handed over to the users. As stated by one of the respondents: 'willingness to adopt new digital tools sometimes limits people or their awareness. Sometimes there is a strong resistance from people to change as '[...] they are not prepared to adapt, change or flex to a situation'. This highlights the cultural challenges and emphasises the need for change management, including training, guidance, and ownership-building activities, before the platform implementation. Also, updates to the platform interface or functionality, as well as in the standards, might only be understood by the users with guidance. This would increase their awareness of the platform interface and its functionalities, but also the VM relevance and impact in their own tasks. Ensuring all staff know how to use the platform properly and acquire experience on it to gain the maximum benefit is required.

'Executing' focuses on the integration of the VM practice into the company systems by linking it with existing VM practices and the managerial routines, as suggested by Valente et al. (2019). Identifying the types of communication (i.e. face-to-face, asynchronous distributed, asynchronous, synchronous distributed, and hybrid synchronous distributed & face-to-face), as well as the number of users and the type of interaction (e.g. one to one or many to one, as suggested by Brandalise at al. 2022) is essential to define the level of digitalisation of a device, e.g. if the device should be manual, digital or hybrid in order to meet the users' requirements. The digital whiteboards were often implemented considering an asynchronous distributed or synchronous distributed collaboration, as well as a high number of users. However, the digital whiteboard adoption through face-to-face or hybrid synchronous distributed and face-to-face approaches is still considered a challenge by the company members due to the staff lack of previous experience and knowledge on how to use it.

The integration of the digital whiteboard into the company processes was facilitated by its user-friendly interface (i.e., clear to use and understand its objective), easy access (stored in the cloud and accessible via website without the need to download apps), and all information being available in one place. In addition, the board templates and information flexibility encouraged its application for different functions, e.g., planning, process mapping or brainstorming. They enhanced collaboration through an efficient connection between the users, by allowing them to access the space and interact to each other in a similar way they would interact face-to-face.

The 'monitoring & controlling' element emerged as a relevant aspect of a VM implementation strategy and it was emphasised by the digital whiteboards due to their flexible and dynamic character. Information management was a challenge identified by the company members, as information could be easily changed without any notification, requiring even more coordination and structure. Regular backups and version control were also found to be essential for the monitoring and controlling process, even this could be considered challenging. A better integration of the digital whiteboard with other existing platforms commonly adopted by the company (such as Task Planner in Microsoft Teams, SharePoint, the scheduling software, or Excel) was suggested as an improvement by the users to support the control activities, as tracking of historical tasks was still considered a challenge. Thus, great benefits could be achieved through a better integration across other software already adopted by the company. As future opportunities, the teams also identified programming, e.g., to automate tasks, as a high-potential aspect that could support this integration.

On the other hand, the users also stated that information was centralised, acting like a source of truth, and avoiding having multiple revisions of documents due to the collaborative nature of the work. Digital whiteboards allow everyone to use the same board at the same time remotely, in a virtual space, and make changes simultaneously, highlighting the importance of the controlling and monitoring elements of a VM implementation strategy. In addition to this, capturing the users' feedback through standard and regular approaches defined by the company, e.g., a survey or the method of plus and delta, or management's observation were also identified as good practices to monitor the current implementation, as well as to identify improvement opportunities and guide future applications. In short, how the users interact with a VM device, and whether they use some or all parts of it as intended should be monitored and controlled, as argued by Greif (1991), with predefined mechanisms. This also includes adopting certain criteria and indicators for the control.

The 'maintaining & improving' element is related to identifying key elements of the device or practice that needs to be adjusted or improved, as well as to creating a maintenance and improvement plan to support those changes, corroborating with Nicolini's (2007) suggestion for devising improvement and maintenance measures. Due to the flexibility and collaborative nature of the whiteboards, it is easy for users to diverge from standard templates, adapting existing templates or using other areas of the boards, which can make it difficult to easily identify relevant information, as stated by one of the respondents. As argued by another team member, over a period of time, the boards become a massive information repository as it is very easy to add information by different people. The amount of time required to update the boards could also become a challenge. Thus, keeping the board structured and maintained is even more relevant, highlighting the importance of the board owner's role to do the housekeeping from time to time. Regular lessons learned shared on its adoption were observed by the researchers as a best practice to support continuous improvement and capture new VM ideas of people, as suggested by Galsworth (1997; 2005). To this end, VM devices can be subject to the Plan-Do-Check-Act (PDCA) continuous improvement cycle. Idea capturing activities, such as workshops, brainstorming and benchmarking sessions, suggestion boxes/boards, can also be adopted.

The ‘removing’ element is about recognising when a VM practice is not achieving the desired outputs and removing it from the system. This could happen due to different reasons, e.g., when the practices are obsolete or not aligned with their purpose, when the context changes, or due to the end of a project or activity. Without harming the users’ view of the strategy and affecting their work, a VM device exit plan should be in place. This includes a communication plan with the users for the reasons of removal, the timeframe for removal, what is going to happen to the information recorded on the VM device to be removed, alternative information channels to substitute the VM device to be removed, new arrangements between the management systems and routines and the VM device to be removed, and future actions in line with the lessons learnt after the removal.

An emergent expansion of the VM device application, through trial-and-error, was noted; people started to adopt the digital whiteboards for different functions and purposes, as the teams became familiar with the whiteboard interface and its functionalities, facilitating its dissemination for other uses. In order to support spontaneous innovations, like the digital whiteboards, an emergent and flexible strategy should be considered where only a few elements could be implemented, e.g., monitoring & controlling, maintaining & improving, and removing. However, as soon as a spontaneous innovation is recognised, the other elements of the VM implementation strategy could also be adopted (such as planning, introducing, and executing), and a deliberate or planned strategy could be devised. This corresponds to the bottom-up approach to VM, which often yields to effective VM solutions for people’s information needs, if managed properly (Galsworth 2005).

CONCLUSIONS

VM is often perceived as an intuitive concept executed over sensory devices. This is a limited view to VM, and partly due to the seemingly effortless effectiveness of sensory communication. However, to be able to implement VM as a strategy for creating a visual workplace catering to different contexts and needs, coherent plans and decisions should be in place. These include the VM implementation strategy elements which were explored in this paper at an engineering design organisation as a case. The findings showed the need to understand and address the strategy elements for a successful VM implementation, the absence or deficiencies of which could lead to various challenges and questions during the implementation.

Digital whiteboards are expanding the scope of VM application and the need for a VM implementation strategy has been emphasised to cope with the dynamic interactions in the analysed context. In practice, some of the strategy elements (e.g., colour scheme to be used in VM devices as part of defining visual attributes during the planning) could be adopted as a standard for many VM devices within an organisation. Some of the VM strategy elements still need to be reviewed and tailored for each VM device or practice separately (e.g., integrating with company systems and managerial routines during the executing). The proposed VM strategy elements are initial and by no means definitive. Future research can look at expanding and evaluating definitions and implementation of the strategy elements for different contexts (e.g., construction sites, facilities operations), for different VM purposes (e.g., information sharing, controlling, and limiting human actions), and for different VM device types (i.e., manual, digital or hybrid). The VM strategy elements can be further investigated for the top-down and bottom-up implementation modes. The strategy definitions can also be expanded and broken down to tactical level practices or other choice elements.

ACKNOWLEDGMENTS

The authors would like to thank the InnovateUK, the company and the survey participants for their time and support.

WORKSHOP FOR LEARNING VISUAL MANAGEMENT IN JAPAN: A REPORT

Koichi Murata[1]

ABSTRACT

This paper provides a report regarding a visual management workshop conducted for business persons in Japan from September to December 2022. The aim of the workshop was to aid the participants in solving their problems via the visual management theory developed.

Based on literature review, recent research trends pertaining to visual management show that the concept has disseminated widely. Nonetheless, the presence of various related studies with different contexts suggests the insufficient understanding of the concept. Hence, academics must endeavour to explain the details of visual management in a unified manner such that it can be applied more effectively. The purpose of this study is to address such issues based on the workshop above, as well as to describe and discuss the state of the workshop.

For the study, the plan–do–check–action (PDCA) cycle, which is a well-established problem-solving process used in various fields, is applied. This paper summarises the workshop based on four categories: planning, implementation, evaluation, and discussion (based on the PDCA cycle). Data obtained from the workshop include relevant materials, observations from the workshop, as well as interviews with the participants.

The conclusions obtained are as follows: First, participants from various industries with their respective issues can participate in the workshop. Second, the outcome of the workshop, i.e., the understanding that visual management connects people, instead of being a tool, is recognised by all the participants.

KEYWORDS

Visual management, lean education, workshop, PDCA cycle, Japan context.

INTRODUCTION

Visual management is a core lean management methodology used to increase operational transparency. People's lives and work involve various operations. A public transportation system is an ensemble of operations that allow people and vehicles such as cars and trains to move at comfortable speeds. The function that provides alerts regarding abnormalities on the transportation system is equipped with signals that protect pedestrians from iron lumps. Hence, visual management provides transparency to various operations. In addition, in the digital age, smartphones are used to publicise one's interests and behaviours. In addition, digital platform providers that offer these services are equally interested in such information as users and are striving to improve service quality as well as develop new products. Clearly, visual management demanded in many situations.

To understand visual management more comprehensively, the concept must be theorised and disseminated widely to society. Various studies have been conducted regarding the former. Tezel et al. (2015) and Valente et al. (2019) presented various examples and discussed their

[1] Professor, Department of Industrial Engineering and Management, Director, Operation and Production Management Laboratory, College of Industrial Technology, Nihon University, Chiba, JAPAN, koichi.murata30@nihon-u.ac.jp, orcid.org/0000-0003-4344-806X

common denominators. Similarly, Murata et al. (2010) proposed a horizontal expansion system via a detailed case analysis. Additionally, studies have been performed to interpret cases using affordance theory (Beynon-Davies et al., 2017), of which the latter will likely be included in lean management courses in universities. Furthermore, visual management workshops, consulting services, and books are available.

The purpose of this paper is to provide a report on the workshop, "Tsudanuma Mieruka Juku", which was conducted from September to December 2022 (Herein, "Tsudanuma" is the name of the area, "Miekaka" means visual management, and "Juku" means workshop in Japanese). The laboratory associated with the workshop, in which lean management is investigated, is where visual management workshops for business persons are designed and operated. The purpose of the workshop is to contribute to society by applying the results obtained from a university to the local community. The target is business persons in the area where the university is located. The main features of this workshop are as follows: First, the participants are not specific to one industry or company. The organisers of the workshop attempt to embody the fact that the concept of visual management is of widespread social interest. Second, a particular perspective management theory is used (Murata, 2021). The program is structured around one theory for diverse participants, which is the first feature. Although most of the participants are aware of the practical use of visual management, the robustness of the concept is tested in the workshop. This paper presents the results of this workshop to provide a more comprehensive understanding.

In the next section, recent trends in studies pertaining to visual management as well as the visual management theory used in this workshop are expounded. Section 3 describes the research method, and Section 4 provides the results obtained. Section 5 presents the overall overview.

LITERATURE REVIEW

RECENT VISUAL MANAGEMENT STUDY

Recent studies pertaining to visual management can be classified into four categories: 1) Description and consideration of usage situations; 2) evaluation and use of toolboxes; 3) effect of usage history; and 4) integration with other theories.

The first is the description and consideration of the usage scene of visual management. Some papers describe several cases comprehensively, where the role of visual management in each case and barriers to the introduction are expounded (Kurpjuweit et al., 2019; Tezel et al., 2017; Tjell et al., 2015).

The second is the evaluation and use of toolboxes for visual management. Tools for visual management abound. Owing to the progress in digital technology, visual management continues to evolve. Hence, studies related to each tool have been performed. Singh et al. (2021) attempted to determine the tool (among 12 tools) that was the most applicable. Bateman et al. (2016) focused exclusively on communications boards and conducted two years of utility survey.

The third is the effect of usage history, which pertains particularly to nurses. Williamsson et al. (2019) classifies users into nondaily, start, and daily users, and measured their usage effects. Dalain (2020) categorised the history of VM usage into less than 5 years, 5-10 years, 10-15 years, and 15+ years, and investigated the effect of tool usage on work performance.

The fourth is integration with other management concepts, which aims to determine the applicability of visual management by considering its integration with other concepts. According to Brady et al. (2018), visual management may effectively enhance one's ability to execute plans in project management. Additionally, the relationship between performance management and continuous improvement (Eaidgah et al, 2016) as well as the contribution of visual management to change management (Eriksson et al, 2018) were considered.

Based on the studies above, the following two conclusion can be inferred.

First, the concept of visual management is pervasive. The fact that related studies were conducted from various perspectives indicates the abundance of cases in this field. This is also supported by the fact that visual management is a management concept in which the useful tools have not been clarified.

Second, the understanding of visual management is insufficient. As observed by Williamsson et al. (2019) and Dalain (2020), different users perform differently at work, which suggests the nonexistence of unified understanding regarding this concept. This is partly due to the complexity and ambiguity of the concept.

Based on the above, academics must endeavour to explain the concept of visual management in a unified manner such that it can be used more effectively. It means that they make an effort to discuss how to disseminate and teach visual management.

Framework Learned in the Workshop

The theory used in the workshop, which is used to explain visual management in a unified manner, is based on Murata (2021). It is developed based on control theory and describes the internal structure of visual management. Based on this theory, the following three basic principles are provided in this workshop:

- Principle 1: Someone and someone else
- Principle 2: Why, what, how
- Principle 3: Sometimes I

Principle 1: Someone and Someone Else

Visual management is a tool that connects a person with another. When developing this tool, one must first ensure that a person is connected to another. Additionally, customers' requirements must be considered when developing products and services to ensure that they benefit from visual management. Henderson (1991) noted visual communication involves *boundary object*. Star et al. (1989) described that *boundary objects* are *both adaptable to different viewpoints and robust enough to maintain identity across them*. Also, good visual management is a *conversation for action* (Flores, 2012) that needs no interpretation and provokes desired behaviour. "Someone and someone else" imply a person and another person; however, it can also imply a human and a machine or a machine and another machine. The two connected entities have their own roles. One is the information sender and the other is the information receiver. However, the roles are not fixed. Similar to the two sides of a coin, the roles of each may be exchanged. Although two entities may know each other well, they must be re-understood.

Principle 2: Why, What, How?

This principle is applied to develop three elements, "reactions", "message", and "transmission" in a tool for practical visual management. It comprises the following three questions. They do not aim at promoting visual management. They just think about a component of a visual tool:

- Why do you see?
- What do you see?
- How do you see?

The first question reveals the reason for developing the tool, i.e., the necessity for visual management. In this regard, one considers the type of change that can be expected from the newly created interaction via visual management. After visual management is introduced, it appears that the type of change is "reactions" from a person, which must be investigated comprehensively. For the second and third questions, the specifications of the tools must be considered. The second question clarifies the "message", which is typically hidden prior to the development of the tool. However, its connection must be clarified. In the case of the pedestrian traffic light development in Figure 1, a “message” developed from the second question is about whether pedestrians should or should not cross. The third question clarifies "transmission". How to convey a message developed? There are many types of a traffic light in the world. Not only the physical method, but also the timing, environment, amount of information, combination of various methods, and the degree to which the opponent resonates differ.

Principle 3: Sometimes I

Principles 1 and 2 pertain to visual management tools and their users, i.e., visual management. Principle 3 is the designers' perspective of visual management. The manufacturer of a product or service contributes significantly to purchase decisions. What type of life do designers lead? Understanding the thoughts involved in developing visual management will promote its use. When the pedestrian traffic light is red, Japanese people wait until it turns green. But the British will cross if there is no car. Let's assume that the designer has extensive experience in developing pedestrian traffic lights. A designer's daily life and life influence the development of visual management.

Among the three principles, Principles 1 and 3 are related to people, whereas Principle 2 is associated with tools. Since the former two principles involve people, they provide a description of management based on people. Additionally, although Principles 1 and 3 pertain to meta-level knowledge and are used for designing visual management, the items to visualise in any area are not specified. Hence, they are general principles that are applicable to various visualisation targets.

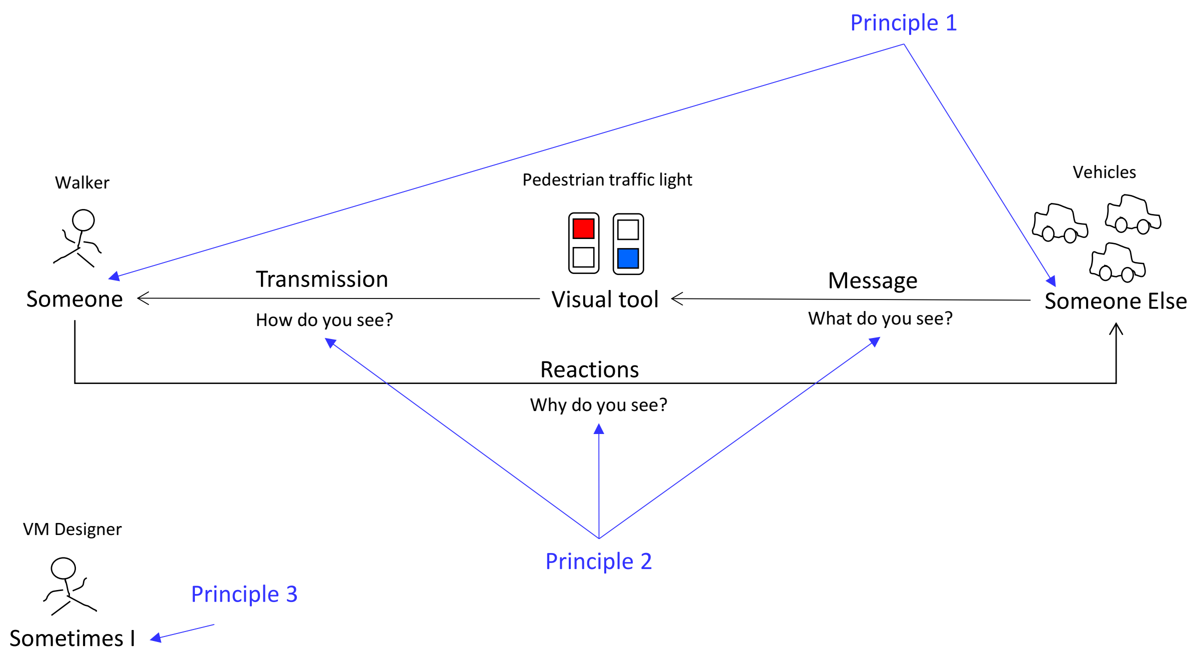

Figure 1: An example of pedestrian traffic light by the theory used in the workshop

RESEARCH METHOD

This study was performed based on the plan–do–check–action (PDCA) cycle, which is a typically used problem-solving method in quality control. In fact, it is well established and applicable to many areas other than quality control (Chakraborty, 2016; Kholif et al., 2018; Pietrzak et al., 2015; Realyvásquez-Vargas et al., 2018). In the PDCA cycle, continuous learning can be expected by continuously rotating the processes involved. The planning, implementation, evaluation, and discussion of the workshop are discussed herein based on the four processes of the PDCA cycle.

Workshop Planning (Step 1-Plan)

In this step, the organiser plans the workshop. This paper describes the purpose, expected results, implementation period, program, etc. pertaining to the proposal prepared for budget acquisition, as well as provides an overview of the workshop. Consequently, the configurations and conditions in which visual management is learned can be understood.

Workshop Implementation and Evaluation (Step 2-Do and Check)

This step describes the implementation and evaluation of the workshop. The current author is the main instructor of the workshop. The contents presented herein are objective information obtained directly from lectures.

The data obtained from the workshop include the profiles of the participants, the participation status in the workshop, as well as the themes of each participant and their outlines.

Additionally, data are obtained from evaluating the workshop from the perspectives of the participants. This is performed after the workshop is completed. The evaluation method is a questionnaire, in which multiple questions regarding the workshop process as well as visual management theory are posed, and answers are obtained in a multiple-choice format. In addition, the participants are interviewed to qualitatively obtain their impressions of the workshop. Thus, knowledge will be gained by observing the participants and exchanging opinions with them during the workshop.

Discussion of the Workshop (Step 3-Action)

This step considers the data obtained in Steps 1 and 2. Additionally, future issues identified from the workshop are considered and discussed based on visual management theory described in Section 2.

RESULTS

Workshop Planning (Outcome of Step 1)

According to the workshop proposal, the workshop will provide opportunities to learn visual management theory via a mini-lecture and an informal practice for business persons (5 years or more of working experience) who will lead their company in the future. One of the purposes of this workshop is to develop the ability to identify problems using management resources and to foster communication with colleagues for solving them.

The expected results are as follows: The first is to provide the understanding that visual management is not merely a tool, but represents human and technical ability to identify the essence of a matter. The second is to achieve positive awareness in terms of the thought process and attitudes toward daily work and foster the Kaizen mindset. The workshop comprises four sessions, each of which is conducted once a month from September to December 2022. The first three are online workshop and the final one is a face-to-face workshop. The topic of each workshop is as follows: Part 1 - Basic theory of visual management: three principles of design; Part 2 - Visual management strategy in the era for digital transformation: Digital visual management; Part 3 - Nishida's philosophy and the future of visual management: Feeling and one step mind; Part 4 - Final presentation by all participants.

In addition, individual meetings are conducted prior to each session.

IMPLEMENTATION AND EVALUATION OF WORKSHOPS (OUTCOMES OF STEP 2)

Implementation of the Workshop

Initially, six people applied for the workshop before it was conducted, and all of them participated until the final presentation. The affiliations of the participants were as follows: two persons in the manufacturing industry, a person in the retail industry, a person in the real estate industry, a person in tax accounting, and a person in the public sector. Four males and two females participated in the workshop, and their ages ranged from 20 to 50. The theme of each participant was as follows:

Participant 1: Continuous management for several visual displays

In this theme, the participant considers the life cycle management of several visual displays used for plant operation. In particular, the incorporation of display maintenance into normal operations is considered.

Participant 2: Innovation in the manner by which meetings are conducted

In this theme, the participant considers the manner by which a meeting is to proceed. After solving the problems in meetings with multiple participants, the participant considers the manner by which a meeting is to be conducted with minimal loss. This theme pertains to communication when a task is performed.

Participant 3: Visual management for connecting operators and users

In this theme, the participant identifies a method to improve the motivation of operators in a factory, which involves consideration into the requirements of product users. In particular, the participant uses an example of a girlfriend who prepares bento (lunch box) for her boyfriend as a metaphor.

Participant 4: Preparing posters for tax accounting office

In this theme, advertising strategies for attracting customers in the area where the office is located are examined. In particular, an appropriate poster is created.

Participant 5: Attempt to use visual management theory via analysis

This participant did not address the subject of his own work. Instead, the participant analysed the theory introduced in the workshop and attempted to understand and use the theory.

Participant 6: Management and operation method for rental buildings using a visual management design framework

In this theme, the efficiency of daily building management is analysed. Timely information sharing and reduction in personnel costs by adopting digital technology are proposed. The participant attempted to understand the theory more intensively based on the communication between a husband and a wife.

Evaluation of the Workshop

Table 1 shows the responses to the questionnaire provided to the participants after the workshop ended. In addition, descriptions provided by the participants regarding their overall impression of the workshop are provided herein.

Table 1: Questionnaire results

Questions	1	2	3	4	5
Q1 How difficult was the visual management theory? (1low ⇔ 5 high)	-	-	1	3	2
Q2 How useful was the visual management theory? (1low ⇔ 5 high)	-	-	1	3	2

Descriptions by participants

Participant 1:

When I first viewed the theory, I thought that it was extremely philosophical. It took me a while to understand it; however, after I understood it, I was able to apply it to my theme to obtain new solutions. We will focus on introducing it in the future.

Participant 2:

I appreciated the opportunity to communicate with the teachers individually.

Participant 3:

The more I thought about the theory, the more difficult it appeared to me. However, I gained some new knowledge, which I appreciated very much.

Participant 4:

I would appreciate more practical cases.

Participant 5:

I would like to learn from the textbooks that I have received. Unfortunately, it was difficult to understand the connection between philosophical and technical topics. The cases provided were few, and I did not know how to proceed.

Participant 6:

In my opinion, working professional will benefit from the lectures, even if they are longer in duration.

DISCUSSION (OUTCOMES OF STEP 3)

As mentioned in Section 2, academics should endeavour to explain visual management in a unified manner such that it can be applied more effectively. In this regard, the following aspects should be considered:

Versatility of the visual management theory provided

The participants participated in all workshops and provided a final presentation. The industries represented by the participants were manufacturing, retail, real estate, tax accounting, and public sectors. The themes were life cycle management for visual displays, meeting management, advertisement, supply chain management, and building management. Hence, the theory provided in the workshop presents a certain degree of versatility.

Trends in participants' understanding of the theory provided

From the answers to Question 1, many participants seemed to find this theory difficult. An analysis of the materials presented by the participants showed a tendency to focus on Principle 2 of the theory. This suggests that visual management is primarily recognised as a tool. Based on Principle 2, designing a tool is the final output of visual management. However, the aim of visual management design is to connect people. Principles 1 and 3 involve processes that deepen the understanding of users and designers. The essence of the theory explained in the workshop is that Principles 1 and 3 are prioritised before and after the realisation of Principle 2; hence, Principle 2 is used to design a visual tool. Many participants successfully applied Principles 1 and 3, although at different degrees.

Undesired effects of conceptual learning and the countermeasures

Based on the comments provided in the questionnaire, participant 5's opinion looks like negative. This participant requested the introduction of actual examples. However, after visual management theory was explained in the first session, the lecturer implemented to illustrate actual examples in a question-and-answers session during the lecture as well as through individual online meetings. The second and third sessions were delivered while considering technical and human aspects, respectively, of recent visual management. Instead of providing the necessary knowledge for designing these tools directly, recent progress and thought processes related to visual management were introduced. The planned intentions of the workshop deviated slightly from the requests of the participants. The author of this paper was workshop instructor and researcher. However, the merit of this dual role was not utilized. If the former communicated this problem to the latter and the plan was revised during the workshop, the resolution of the deviation might have enhanced the participant's understanding of the theory.

From the answer to Question 2, participants generally find this theory useful. Participants 1 and 3 expressed difficulties in understanding the provided theory; however, they gained new awareness in the process. A new concept is generally difficult to completely understand; consequently, a new thought process emerges. The participants' comments suggest that their impression toward this theory is positive.

CONCLUDING REMARKS

A report regarding a visual management workshop conducted in Japan was provided herein. In particular, the workshop was intended for business persons within a university area. The lecturer who participated in the workshop is the author of this paper. Information obtained from the workshop were organised, and the participants' understanding of the visual management theory provided were considered.

In lean management, visual management is a widely known methodology. However, to use it effectively, academics must endeavour to explain it in a unified manner. This was addressed in the workshop, and the results obtained were analysed.

Visual management is introduced to connect people and is not merely a tool. The workshop allowed the participants to understand the concept together. The results showed that they successfully acquired a unified understanding of visual management.

DEVELOPING AND TESTING COMPUTER- AND VIRTUAL REALITY-BASED TARGET VALUE DESIGN SIMULATIONS

Suryeon Kim[1], Zofia Rybkowski[2], and H. David Jeong[3]

ABSTRACT

Knowledge of fundamental lean construction principles and tools is often imparted through the physical playing of serious games and simulations. However, globalization and the emergence of the recent pandemic have created increasing demands for scalability, as well as for diverse player usability and remote implementation of the games. That said, there are challenges associated with transforming existing lean simulations to technology-oriented modes, such as computer- and VR-based formats. For example, while the potential of using advanced formats is promising, it is unclear if these versions offer an equivalent level of learning effectiveness as in-person play. This research reports on the development and testing of different forms of the Marshmallow Target Value Design (TVD) Simulation, including computer- and VR-based formats. Researchers administered and assessed post-simulation questionnaires, and the moderator effect of perceived usability was determined and analyzed. Results show that the computer-based format was more effective than the physical-based format for some TVD principles and that the VR-based format was more effective than the physical-based Marshmallow TVD Simulation for most TVD principles. For the computer-based format, usability moderated learning effectiveness. These results indicate that when developing a computer-based simulation, the usability of the simulation must be considered to ensure maximum effectiveness.

KEYWORDS

Serious games, simulations, target value delivery (TVD), computer-based simulation, VR-based simulation.

INTRODUCTION

Serious games and simulations, primarily designed for educational purposes other than entertainment, play a vital role in the testing and teaching of lean design and construction principles and methods (Bhatnagar et al., 2022; Tsao & Howell, 2015). They impart confidence about lean principles, and by creating a highly immersive environment, they make learning enjoyable. This pedagogical approach promotes engagement and creates links to applicability of instructional content by bridging the knowledge gap between theory and applications (De Freitas & Oliver, 2006; De Freitas & Levene, 2004). Serious games and simulations have been shown to students and practitioners to be effective in imparting lean construction principles

and tools—as well as in creating buy-in with participants. In fact the expansion of adoption of lean construction is likely responsible, at least in part, to the illustrative impact of serious games in both academia and industry (Bhatnagar et al., 2022).

Serious games and simulations have been—and still are—typically administered in a physical format, in which in-person interactions, active task involvement, and hands-on experience are maximized; these qualities been shown to improve learning (Rybkowski et al., 2021). However, as adoption of lean construction has expanded, projects have also become increasingly globalized to include multi-cultural stakeholders; pedagogical environments have become diverse and advanced, leading to the need to enhance scalability of serious gaming. The emergence of the global COVID-19 pandemic also heightened the demand to take gaming into digitized and remote formats (Rybkowski et al., 2021). Virtual formats offer the potential to accommodate varied geographical regions with greater accessibility. They also enable users to become highly immersed in the educational process (Schroeder et al., 2020).

While there are growing efforts to transform lean serious games and simulations into advanced learning environments, such as computer- and virtual reality (VR)-based formats, several areas must still be addressed. Firstly, there is a need to know whether different learning environments can promote the same amount of knowledge retention and learning effectiveness. Although there is a prevalent belief that learning with serious games and simulations offers similar cognitive effectiveness, differences in format may be significant in their capacity to provide effective learning (Ypsilanti et al., 2014). Furthermore some researchers have concluded that computer-based serious games and simulations do not always offer a positive impact on learning (Erhel & Jamet, 2013; Liu et al., 2020). Second, computer- and VR-based formats require a certain level of technological familiarity which significantly influences users' attitudes toward active involvement (Davis, 1989; Idris et al., 2015). The success of learning lies in actual involvement in the process, and users' negative attitudes may hinder them from learning (Tsai et al., 2015; Ypsilanti et al., 2014). To systematically investigate those areas, the development and testing of serious games and simulations in different formats are needed.

This research aims to develop and systematically test two formats of simulations: a computer (keyboard)-based Marshmallow TVD Simulation and VR (headset)-based Marshmallow TVD Simulation, which mimic the physical Marshmallow TVD Simulation's overall concept, framework, and rules. Two valid research questions, which will contribute to the current body of knowledge, were explored: (1) Are there differences in knowledge retention for physical- vs. computer- vs. VR-based formats? and (2) What is the effect of perceived usefulness and usability on knowledge retention for computer- and VR-based formats?

BACKGROUND

MARSHMALLOW TVD SIMULATION

Target Value Design (TVD) is one of the most effective lean processes that adapt the target costing concept to the peculiarity of the construction industry (Zimina et al., 2012; Engebø et al., 2021; Jacob et al., 2021). TVD is a management practice that aims to deliver a project within a specified allowable budget by promoting innovation throughout the project life cycle, increasing value and eliminating waste, and continuously improving a project's design in order to reach desired goals, thereby satisfying the client's values (Alves et al., 2017; Rybkowski et al., 2016; Zimina et al., 2012). Target Value Design is an adaptation of Target Costing for construction project delivery (Ballard, 2011; Zimina et al., 2012), constituting the design phase of Target Value Delivery (Hill et al., 2016).

The Marshmallow TVD Simulation is one of the full-blown lean simulations designed for practicing the TVD process. It simplifies traditional and TVD processes so participants can intellectually grasp the TVD framework (Rybkowski et al., 2016). The simulation consists of two rounds. In each round, participants build a tower that can hold a marshmallow at the top with supplied materials (e.g., drinking straws, uncooked spaghetti noodles, coffee stirrers, bamboo sticks, masking tape, and a marshmallow). The tower should be at least 60 cm (approximately 2 feet) tall and free-standing (i.e. not taped to the table). During Round I, participants build a tower without awareness of the unit cost of each material. After the first round is finished (within approximately 20 minutes), they count and report the unit amount of each material they chose to use to build their tower so that a typical Market Cost (an average of all towers) is established. Target Cost is then set to be 20% lower than the Market Cost, and an even lower “stretch goal” (Allowable Cost) is declared by each team. During Round II, participants again build a tower, but this time within the Target Cost (and potentially even their individually declared Allowable Cost). At the start of this round, they are given information about the unit cost of each material Amounts reached per team are collected on a spreadsheet and projected on a wall for all to see and discuss following play (Munankami, 2012; Rybkowski et al., 2016).

The Marshmallow TVD Simulation is a good candidate to be developed and tested in various modes, including physical-, computer-, and VR-based formats. Firstly, it requires a sense of spatiality. One of the requirements of the tower is that it must be free-standing, which means it must resist gravity. Computer- and VR-based formats can simulate gravity using three-dimensional software programs such as Unity™. Also, the 3D-format simulates reality, offering the opportunity for flexibility and therefore variety in tower design. Additionally, the simulation software can rapidly calculate total cost based on the fixed unit cost of user-selected materials. Finally, computer- and VR-based format simulations can be augmented with add-ins.

RESEARCH QUESTION DEVELOPMENT

This research involved development and testing of computer- and VR-based simulations of the Marshmallow TVD Simulation. Simulation development required transformation of the physical simulation. Testing and analysis of the learning effectiveness of the two simulations required determining the moderator effect of perceived usefulness and usability of the advanced formats. Two research questions were posed:

Research question 1. Are there differences in knowledge retention for physical- vs. computer- vs. VR-based formats?

Learning effectiveness refers to the extent to which a goal or task can be achieved. This research investigated whether the different simulation formats affect a users’ knowledge retention. It was investigated by evaluating instructional content after playing the simulations.

Knowledge retention was measured regarding: (a) mutual respect and trust; (b) mutual benefit and reward; (c) collaborative innovation and decision-making; (d) early involvement, (e) early goal definition; (f) intensified planning; (g) open communication; (h) appropriate technology; and effectiveness of the (i) organization and leader. These characteristics represented fundamental TVD principles intended to be conveyed through the Marshmallow TVD Simulation (Munankami, 2012), and were adopted for the consistent assessment of the three different simulation formats.

Research question 2. What is the effect of perceived usefulness and usability on knowledge retention for computer- and VR-based formats?

As computer- and VR-based formats adopt advanced technologies, a users’ attitude toward technology works as an essential factor in learning effectiveness. Serious games and simulations should be usable regardless of a user’s personal characteristics (Jordan, 1998). Two elements, perceived usefulness, and usability, determine the users’ attitude toward the technology (Davis, 1989). This research hypothesized that these qualities moderate knowledge retention in computer- and VR-based simulations, as shown in Figure 1.

Perceived usefulness refers to the degree to which a user believes using a particular technology and system will enhance their performance. Usability refers to the level of comfort users feel and how confident they are with the simulation's capacity for them to reach specified goals (Davis, 1989). These qualities are determinants of a good user experience (Diefenbach et al., 2014; Jordan, 1998) and they help guarantee the success of learning effectiveness in computer- and VR-based formats (Pal & Vanijja, 2020).

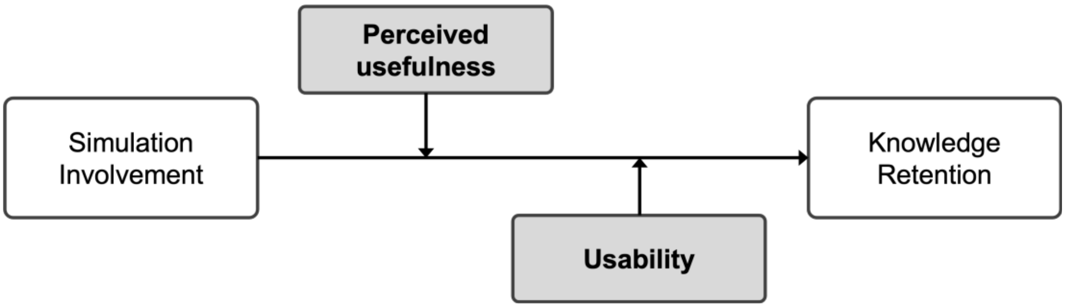

Figure 1: Conceptual Diagram for Research Question 2.

SIMULATION DESCRIPTION

COMPUTER-BASED MARSHMALLOW TVD SIMULATION

This research developed computer- and VR-based formats of Marshmallow TVD Simulation using Unity™. The 3D-software is often used for gaming and can: imitate the properties of materials with some sense of reality; simulate physical characteristics including movement and gravity; provide a user-friendly user interface; and allow multiple networking (Unity User Manual, 2020). The rules and goals of the physical format of the Marshmallow TVD Simulation were transformed into computer- and VR-based formats. Figure 2 shows how key scenes in each format were realized.

The computer-based format requires a three-button mouse (e.g. two buttons and a wheel), as well as a keyboard. Users can select objects in the scene, rotate, place, and delete the object, turn the camera, and zoom in and out with the mouse and keyboard. The computer-based format also provides a graphical user interface that allows users to interact through graphical icons in the scene.

VIRTUAL REALITY MARSHMALLOW TVD SIMULATION

The VR-based Marshmallow TVD Simulation requires users to wear a VR headset and operate controllers. There are two buttons in each controller: the grab button and the trigger button. Grab buttons are located near a user's palm and allow them to grip and release an object. Trigger buttons are operated by index fingers and enable users to activate functions such as a "gravity test" in the VR environment. To a large extent, motions and actions are similar to playing in a physical environment, so users can intuitively understand their manipulations. In the VR-based format, the following were included: a graphical user interface, a panel itemizing materials, costs, and test/return buttons.

SIMULATION TESTING

A post-simulation questionnaire was conducted to investigate the two research questions. Students majoring in construction science, architecture, and civil engineering were recruited; 32 and 26 responses were collected in computer- and VR-based formats, respectively.

Following play, participants were asked to score on a scale of 1 (lowest) to 5 (highest) their perception of the simulation's ability to impart the following key TVD concepts: (a) mutual respect and trust; (b) mutual benefit and reward; (c) collaborative innovation and decision-making; (d) early involvement of key partners; (e) early goal definition; (f) intensified planning; (g) open communication; (h) appropriate technology; and effectiveness of (i) organization and leadership. These data were compiled and compared to identify whether there are statistically significant mean differences between various formats. Previous experimental data from Munankami (2012)'s physical format were used as a control group for the first research question. For the second research question, participants were asked about their perceptions of the simulations. They evaluated the perceived usefulness and usability of the simulations.

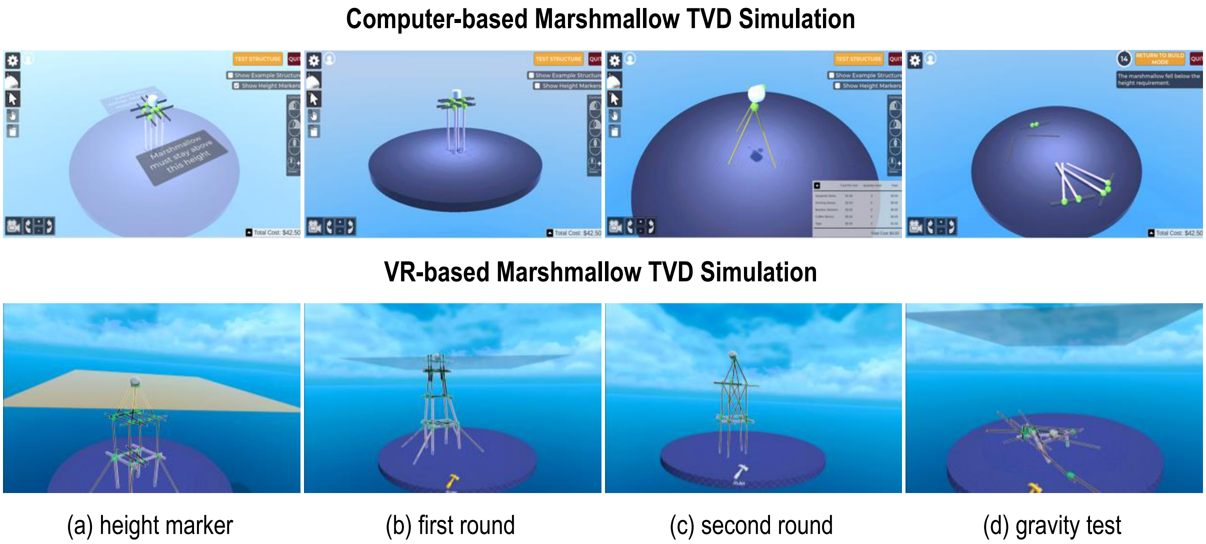

Figure 2: Computer (keyboard)- and VR (headset)-based Marshmallow TVD Simulations

ANALYSIS AND RESULTS

RESEARCH QUESTION 1. ARE THERE DIFFERENCES IN KNOWLEDGE RETENTION FOR PHYSICAL- VS. COMPUTER- VS. VR-BASED FORMATS?

A one-way analysis of variance (ANOVA) was conducted to investigate whether the computer- and VR-based Marshmallow TVD Simulations show a similar or even better understanding than physical simulation.

From the ANOVA, a significant effect of different simulation formats was observed on seven out of nine TVD principles; (a) mutual respect and trust [$F(2, 103) = 6.286$, $p = .003$], (b) mutual benefit and reward [$F(2, 103) = 3.367$, $p = .038$], (c) collaborative innovation and decision-making [$F(2, 103) = 4.967$, $p = .009$], (e) early goal definition [$F(2, 103) = 14.629$, $p < .001$], (f) intensified planning [$F(2, 103) = 8.613$, $p < .001$], (g) open communication [$F(2, 103) = 4.739$, $p < .011$], and (i) organization and leader [$F(2, 103) = 3.763$, $p = 0.026$].

A Tukey HSD test was used for post hoc comparisons of the seven TVD principles to compare each of the different formats to every other format; that is, the test compared understandings of TVD principles from physical- and computer-based, physical- and VR-based, and computer- and VR-based formats. Overall, results indicated that the mean score for the VR format was significantly different from the computer-based format, implying that the VR simulation can more effectively impart the principles of TVD than the physical simulation. The computer- and VR-based formats did not significantly differ in conveying TVD principles except for (e) early goal definition. Early goal definition was most effectively imparted in the VR-based version, followed by computer-based and physical formats (Table 1).

Two TVD principles, including (d) early involvement of key partners and (h) appropriate technology, did not show statistically significant differences. The result means that those two principles can be imparted effectively regardless of the simulation format used. In summary, the VR-based format is superior to other formats in imparting fundamental TVD principles. Some principles can be effectively imparted regardless of the simulation formats, others can be more effectively transferred to a VR-based format. Computer-based and physical-based formats showed very similar levels of effectiveness.

Table 1: Result of Tukey HSD Test

TVD Principle	Mode (I)	Mode (J)	Mean Difference (I - J)	Std. Error	Sig.
(a) Mutual respect and trust	VR	Physical	.579	.164	.002
(b) Mutual benefit and reward	VR	Physical	.442	.173	.032
(c) Collaborative innovation and decision-making	VR	Physical	.492	.156	.006
(e) Early goal definition	VR	Physical	.752	.152	<.001
	Computer	Physical	.552	.142	<.001
(f) Intensified planning	VR	Physical	.686	.166	<.001
(g) Open communication	VR	Physical	.489	.159	.008
(i) Organization and leader	VR	Physical	.556	.207	.022

(Note: Only statistically significant results from the Tukey HSD test are included above.)

RESEARCH QUESTION 2. WHAT IS THE EFFECT OF PERCEIVED USEFULNESS AND USABILITY ON KNOWLEDGE RETENTION FOR COMPUTER- AND VR-BASED FORMATS?

A moderation analysis was used to determine whether the relationship between users' involvement and knowledge retention was influenced by or moderated by usability and usefulness. Four moderation analysis models were created for this research: (1) usability's moderator effect in computer-based format mode; (2) usability's moderator effect in VR-based format; (3) usefulness's moderator effect in computer-based format; and (4) usefulness's moderator effect in VR-based format. Among the four models, the usability's moderator effect in computer-based format showed statistically significant results, as shown in Table 2. The results indicate that the usability of a computer-based format reduces the positive relationship between users' involvement and their understanding of TVD principles (R^2 = .311, $F(3, 28)$ = 4.499, p = .043).

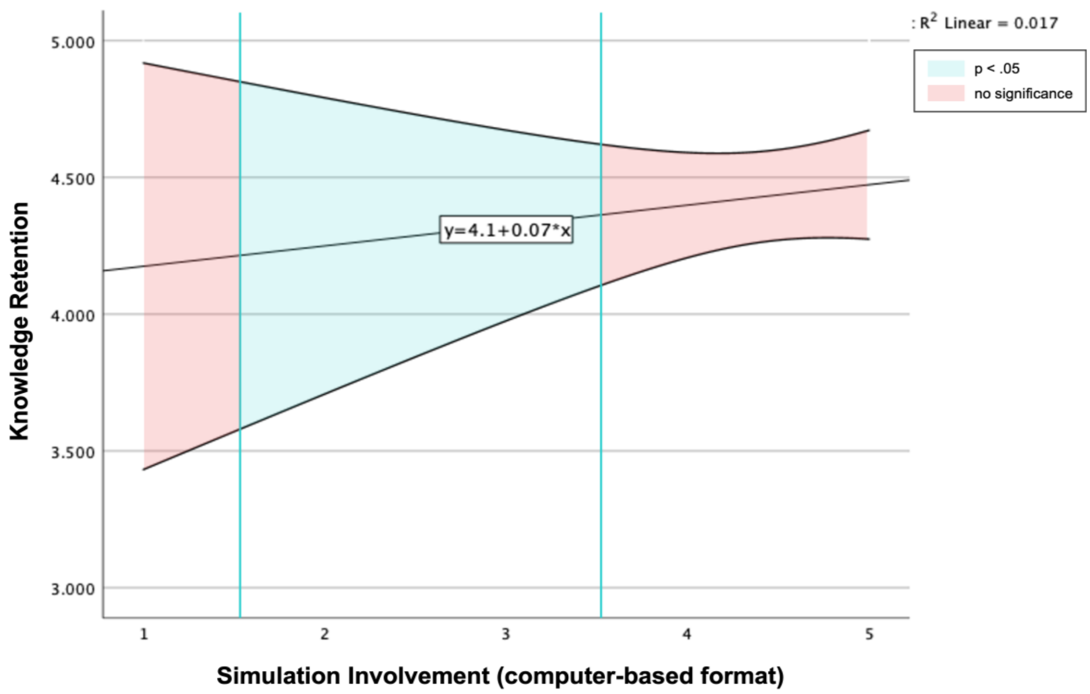
Johnson-Neyman interval further investigated the range of usability where the moderator effect is statistically significant. As a result, the moderator effect of usability on the relationship between the involvement and understanding of TVD principles was significant, from 31.25% to 68.75%; if further increased, there is no moderating effect of usability (Figure 3). The result implies that if the usability is between 31.25% and 68.75%, the effectiveness of the computer-based format can decrease even though there is a positive correlation between the users' involvement and their understanding of TVD principles.

Previous studies have reported that the success of serious games and simulations lies in the active involvement of users playing them, and the more actively and intensively involved the learning process, the better the understanding that emerges (Ropes, 2013; Ypsilanti et al., 2014). However, depending on the usability of the serious games and simulations, specifically in the computer-based format, effectiveness can be changed. Thus, it is crucial to improve the usability of the computer-based simulation to guarantee the maximum level of learning efficacy.

Table 2: Moderation Estimates

	Coeff	SE	t	p	LLCI	ULCI
(1) Usability's moderator effect in the computer-based format						
Involvement	1.629	.741	2.198	.036*	.111	3.147
Usability	1.634	.717	2.280	.031*	.166	3.102
Involvement × Usability	-.334	.158	-2.121	.043*	-.657	-.011
(2) Usability's moderator effect in the VR-based format						
Involvement	1.107	1.122	.987	.334	-1.220	3.434
Usability	1.117	1.100	1.015	.321	-1.165	3.400
Involvement × Usability	.272	.240	1.134	.269	-.770	.226
(3) Usefulness's moderator effect in the computer-based format						
Involvement	.740	.527	1.404	.171	-.340	1.820
Usefulness	.769	.544	1.412	.169	-.347	1.885
Involvement × Usefulness	-.143	.114	-1.252	.221	-.377	.091
(4) Usefulness's moderator effect in the VR-based format						
Involvement	.320	.901	.355	.726	-1.549	2.189
Usefulness	.409	.927	.442	.663	-1.513	2.332
Involvement × Usefulness	-.040	.196	-.204	.840	-.445	.366

*(Note: * signifies statistically significant relationship.)*



Note: X-axis indicates the level of simulation involvement (1: least involved, 5: actively involved). Y-axis indicates users' knowledge retention (1: very low understanding, 5: very high understanding). Usability has a moderator effect in the range highlighted in blue (involvement 1.56 – 3.41).

Figure 3: Johnson-Neyman Plot - Usability's Moderator Effect in Computer-based Format

DISCUSSION AND CONCLUSION

This research investigated the effectiveness of different simulation formats, namely physical-, computer-, and VR-based formats, on a users' knowledge retention. Computer- and VR-based formats of Marshmallow TVD Simulations were developed and used to investigate two research questions.

Empirical results indicated that the VR-based format is superior to other formats in imparting fundamental TVD principles, while some TVD principles, including early involvement of key partners and appropriate technology, can be imparted effectively regardless of the simulation format. Physical- and computer-based formats showed similar effectiveness in imparting TVD principles except for early goal definition. In addition, the usability of a simulation can moderate the learning effectiveness of the computer-based format. From this we learned that developers need to guarantee a high level of usability, specifically when engaging users in a computer-based format.

This research provides insights that can be instructive for future serious game and simulation developers. Simulation developers, especially those who intend to develop a computer-based format, should take care to improve usability to maximize learning effectiveness. This research identified the relatively unexplored area of moderator effectiveness for perceived usefulness and usability. By extending the results to other serious games and simulations, different modes can be adopted to be effective for a wider range of participants.

INCORPORATING PSYCHOLOGY OF LEARNING THROUGH THE MALABARES METHOD FOR EFFECTIVE IMPLEMENTATION OF THE LAST PLANNER SYSTEM

Cristóbal Plubins[1], Lispet Wesp[2], Cristobal Fermandois[3], Andrés Antúnez[4], Guillermo Tirado[5], and Rodrigo F. Herrera[6]

ABSTRACT

This study investigates the impact of teaching through a method developed by a chilean company, Malabares Consultores, based on psychology of learning theories and in the adherence to the Last Planner System methodology. It takes a qualitative and descriptive approach to the teaching of LPS by implementing this so-called the Malabares method, that is a compound of six key factors, as is described in the present document. The study shows the evolution of this method in three stages of development, where the learning obtained in each stage is analysed as well as the adjustments made to improve it. The results show that through the security, confidence and willingness to learn of the participants, added to the gamification of the contents, a link is generated between teacher and student that allows the LPS methodology to be transmitted very effectively both to the person and to the company a la whole. On the other hand, transversal participation from the entire team, including administrators and on-site managers, added to an implementation program that trains work teams at their own workplaces, supporting teams in generating the planning habit under de LPS in the long term, are proven to be crucial to success. The study provides evidence for the effectiveness of the Malabares method in the construction industry and concludes that it offers a valuable approach to implementing the LPS, emphasizing the importance of continuous improvement within the method development example itself.

INTRODUCTION

The need to change to survive is observed and understood in both plant, animal, and human nature, as well as in competitive organizational environments. Plants and animals must adapt to their habitat conditions, available resources, and predator threats. Humans must learn to live in an increasingly inclusive and technologically advanced multicultural society. Companies

must figure out how to compete and meet the new needs of people, the changing society values and the other companies threats (Hamel, 1996; Yoon et al., 2019). Facing these diverse realities, change results from the transition of an individual or group of individuals from their current condition to a new one that allows them to face aspects of their environment that they could not in their current state (Hamel, 2000).

The change or changes, in the case of human beings, and therefore in the organizations that they make up, can be conducted and achieved through the teaching-learning process, which in turn can occur in different ways according to how the person processes the information he receives and how he transforms it into knowledge, either reflecting or experiencing it in a concrete way. Finally, this process can be promoted and even ensured with the use and planning of methodologies, that is, with strategies, procedures and actions ordered in such a way that they allow the achievement of the objective of facilitating student learning.

Regarding organizations, the change requires learnings to adapt its methods and policies at the level that is necessary, to effectively be profitable in the face of the market and self-conditions (the only path that does not mean ceasing its activities of course). This need for change may not be evident or may not necessarily have to be resolved in the short term, but the organization should be aware of the possible need in the long term (Drucker, 2012). You can be in a healthy health condition today, but given the dizzying social, technological, and competitive changes, the current condition may not guarantee survival in future social, technological, or competitive contexts. Thus, the need for change, or at least the ability to change, presents itself as a relevant and interesting aspect for any organization that aspires to continue operating tomorrow (Abraham, 2012).

But, how to prepare for this change, and how to effectively carry it out? Nature takes its time, evolutionary changes take hundreds, thousands, and even millions of years. It is humble for humans to understand that their own changes cannot happen overnight (Commoner, 2020). There are things that should be approached gradually and sustained over time to see positive and permanent results (Abraham, 2012). Strict diets that seek results in a few days often have negative effects and eventually lead the person to a worse situation than the original (Sidor & Rzymski, 2020). Sudden implementations of new work methods in an organization make it difficult for workers to understand, adhere to, and use these, leading to the failure of their implementation or to the turnover of their workers, affecting the human group that makes up the organization (Bortolotti et al., 2015). Changes must be approached gradually, to give the organization time to be able to change, being one of the first conditions that the members of the organization, at its different levels and hierarchies, are open to change. It is about generating a culture that allows it to effectively implement the specific changes required in various situations (Drucker, 2012). Given this context, the Lean philosophy and the concept of continuous improvement are conceived as a way of being, thinking, and doing that, when implemented and rooted in an organizational culture, contributes to an organization as a whole being more efficient, effective, and flexible (Bhasin & Burcher, 2006; Pellicer et al., 2015).

Lean philosophy and continuous improvement are considered key elements in generating a culture of change within an organization (Dave et al., 2013; Howell et al., 2004). The question now arises, how to introduce this philosophy in an organization, both in its work methods and operation and in its group of collaborators? It must be gradually introduced to ensure its correct understanding, adherence and permanence at both individual and organizational levels (Alsehaimi et al., 2014). Intensive inductions for the entire work team do not guarantee effectiveness, as they can confuse and the natural tendency will be to return to the familiar, in this case, to how things were done before the induction (Salazar et al., 2019). The implementation process of a new work methodology in a group must consider not only the introduction of this new knowledge but also its sustained implementation over time, ensuring the necessary accompaniment and adjustments that may be required based on the results obtained (Dave et al., 2015). Finally, it is about developing a continuous improvement process in the use and growth of the new knowledge by the organization (Hu et al., 2016).

Learning styles are the result of the combination of two ways in which individuals process information from lived experience. The first way to process information is by living the experience in a direct and concrete way, involving emotions through challenging and short activities with quick results. The second way to process information is through abstract experience, when the individual reads or someone tells him something. In addition, two ways of transforming information into knowledge are identified in people, the first occurs in the reflective student, who analyzes experiences from many different points of view, and the second occurs by concretely experiencing the information received, where the individual puts into practice the new knowledge acquired.

The mentioned is complemented by other theories on the nature of human learning at the individual level that emphasize the importance of concepts such as meaningful learning, which means that new knowledge must be linked to the individual's interests, and situated learning, which is when the new knowledge must be put into practice in the individual's real-life activities so that they can demonstrate its impact and usefulness. In both cases, learning is achieved by giving meaning to what is being learned, whether at a personal or work level.

In addition, the "teacher's work" becomes key to using the learning potential in the human being, since it is the teacher who best perceives the different styles and ways of learning of their students, generating techniques and environments suitable for learning. the learning and change that is sought based on the people with whom one is working. The teacher will act as a mediator between the experiences, the environment and the new learning, generating a security, bond and trust in the environment to encourage all these variables to combine harmoniously in people (Feuerstein, 1980).

Today, the so-called Malabares method, developed by the company Malabares Consultores, is formally defined as the integration of six factors that, applied correctly, make it possible to modify people's work habits. It has been proven in the implementation of the Last Planner System (LPS) in companies of the construction industry in Chile, and also in the implementation of other Lean methodologies. These factors are: (1) A space of security and confidence; (2) Learning “here and now”; (3) Transversal participation of the organization; (4) An implementation program through trainings, training sessions and accompaniments; (5) Interactive dynamics for meaningful learning; (6) Long-term work program that ensures adherence to the methodology. With the above, the method permeates the work teams, generating a positive experience and a long-term adherence and permanence of the methodology in everyone, both in individuals and the company, which ultimately contributes to the necessary ability to survive in the changing and competitive environment of today's business organizations, particularly in the construction industry. The purpose of this work is to present and describe this method from its conception to the proven success of its use today, to contribute, as a case study, to the teaching-learning processes of this and other methodologies.

RESEARCH METHOD

The aim of the study is to demonstrate the impact of the Malabares method on adherence to the Last Planner System (LPS) methodology and to verify changes in adherence indicators resulting from the method's application over time. The study employs a qualitative approach to study phenomena and subjects within their contexts and find meaning in them based on people's own interpretations. The study is descriptive, analyzing the characteristics of the training process and the profiles of the participants using the Malabares teaching method as the phenomenon under investigation. The authors seek to verify effective adherence to the LPS methodology and describe the impact of the Malabares teaching method on this adherence .

The population studied consists of collaborators from companies trained by Malabares and collaborators from Malabares itself who have witnessed the changes and results obtained from the training developed over time. A non-probabilistic sample was used, with convenience sampling for trained companies that agreed to participate and purposive sampling for members of Malabares who participated in the trainings and witnessed adherence in the trained teams. The trained companies are among the most relevant in the construction industry in Chile, including one operating in the stock exchange, and their collaborators mostly hold managerial positions or are area managers with experience in construction, planning and team coordination, and have previously implemented methodologies, including LPS. The Malabares collaborators are a team of people from the areas of engineering, psychology, communication and academia, with 10-20 years of individual professional experience in their respective fields and at least 3 years implementing the methodology. The co-founders, Andrés and Guillermo, have 15 years of experience in LPS and active teaching, respectively.

The study utilized semi-structured in-depth interviews as well as existing documentary data on the results of the training and implementation of LPS by Malabares. The in-depth interviews were designed based on Mertens' typology, which aimed to obtain background, opinions, and expressions of feelings from the subjects of the study. The documentary information had two main sources: the results of adherence and permanence of LPS measured by the companies themselves, and Malabares' own information gathering through evaluations of adherence to the methodology during periodic visits. This evaluation involved scoring key steps of the meetings, commitments, and fulfillment of tasks by the work teams, with possible outcomes of 0%, 50%, and 100% depending on the execution and achievement of the objectives.

Through this research methodology, the effectiveness of the Malabares method in different implementations was evaluated by comparing expert opinions and empirical data. The study established three stages in the life of the Malabares method: the initial stage, the transition stage, and the current stage, with each exhibiting different characteristics and results. To present the findings, graphs were included for each stage, showing the results of the evaluation of adherence to the methodology of different works during the accompaniment stage (three cases per each accompaniment stage).

THE “MALABARES” METHOD

For the past 9 years, Malabares Consultores has been working to implement the last planner system (LPS) in the construction, real estate, and other industries in Chile. Their approach aims to promote learning, adherence, and long-term retention of this new knowledge. The results of Malabares' work over the years have demonstrated concrete and lasting benefits such as better effective communication within the teams, greater efficiency in meeting planning, and adherence and persistence of new knowledge at both the individual and company levels.

Malabares' implementation of the LPS initially focuses on three planning instances: the Master Plan, Intermediate Plan, and Weekly Plan. The Master Plan provides a strategic vision of the project, identifying deadlines, activity sequences, and milestones traditionally presented in a Gantt chart format. The Intermediate Plan analyzes the activities of the project from a horizon of 4-6 weeks, identifying the detailed sequence of each activity, the necessary resources and the restrictions to guarantee that all the conditions are available so that the deadlines of the project can be met. Finally, the Weekly Plan is a short-term weekly schedule expressed as an expected progress schedule, which is then analyzed by the responsible parties to create a credible engagement schedule. The philosophy of "continuous improvement" is introduced with the commitment program that is reviewed and validated during the Intermediate and Weekly Planning meetings, where the fundamental root causes of unfulfilled commitments are identified and corrective actions are established to prevent recurrence. The goal of Malabares' implementation is to enable teams to apply the concepts and tools of the LPS and establish the weekly use of Intermediate and Weekly Planning meetings.

ORIGIN OF THE "MALABARES" METHOD

Malabares Consultores S.A. was founded with the goal of teaching the LPS methodology to construction companies in Chile through a pedagogical approach that uses games. The founders had previously observed unsuccessful attempts to teach and implement the LPS methodology through traditional methods, where people struggled to understand and apply the concepts. One of the co-founders, an industrial civil engineer, had experienced this firsthand while working on teams that attempted to use the LPS methodology. Despite being convinced of its benefits, he found that there was a lack of an environment that promoted easier and more effective teaching at a conceptual level while visualizing and concretizing the practical application of what was taught. On the other hand, the other co-founder, a psychologist, believed that people could learn and apply any work methodology if they were in a favorable environment with reduced stress levels and if the content taught made sense to them. These two perspectives led to the idea of using play experiences to teach the LPS methodology, encouraging the participation of the entire team. As the psychologist explained, "the engineer believed in the method, and I believed in people". The goal of using this approach is to ensure that the teams can grasp and internalize the concepts of the methodology and apply them effectively to their work, resulting in improved teamwork and adherence to the LPS methodology.

THE SIX KEY FACTORS OF THE "MALABARES" METHOD

The method can currently be described in six key factors, those that arise from the initial purpose of its founders and are consolidated with the passage of time and the continuous improvement developed on the implementation process itself. They are described below:

(1) A space of security and confidence: Malabares Consultores emphasizes the importance of establishing rules at the start of workshops, such as arriving on time and actively listening to others. These rules provide a sense of security and care for all participants, and also values the experience and knowledge of the participants, encouraging mistakes as a natural part of the learning process. Trust is established through empathetic listening and validation of comments. As the group bonds, humor and laughter are encouraged to lower barriers and promote learning. To prepare the workspace, tables are set up with paper, markers, sticky notes… and candies.

(2) Learning "here and now": The importance of attending with a willingness to learn is explained to the participants, asking them to concentrate on what is being discussed and the experiences that are being shared. This also means surrendering to the dynamics, wanting to play, move, share and open up to others. To encourage participation, induce the game and reward those who answer correctly, chocolates are distributed among the participants.

(3) Transversal participation of the organization: This is key in trainings, where entire real teams, including managers, administrators, field professionals, supervisors, warehouse, technical office, and subcontractors, are invited to participate in the same learning space. This generates positive bonds during training and then taking them to the field. When everyone participates in the presentation of new knowledge, language and meaning align, and technical concepts, for example the "restrictions", are understood and used throughout the organization.

(4) An implementation program through trainings, training sessions and accompaniments: This 3-step program aims to provide the necessary theoretical and practical knowledge to apply the LPS methodology on site. Participants are trained in the necessary tools to carry out intermediate and weekly planning stages, such as the "analysis sheet" or the "weekly program", and then are taught a step-by-step methodology, considering the different roles and responsibilities of each member of the team. Accompaniments consist of scheduled visits to the planning meetings, evaluating adherence to the methodology, with six to ten visits per team.

The program spans over several months, with training in the first months and accompaniments in the following months.

(5) Interactive dynamics for meaningful learning: To enhance the learning experience, gamification is used within the logical thinking process designed for the participants to explore and discover the meaning of the adopted work method. Two facilitators are always present during the workshops and training sessions: Facilitator No. 1 is the theoretical expert who ensures complete delivery of methodology content, while Facilitator No. 2 ensures active participation and comprehension among all attendees. The use of games and activities helps participants to engage with the material in a meaningful way, leading to greater understanding and retention of the knowledge presented.

(6) Long-term work program that ensures adherence to the methodology: The sixth factor stems from the actual experience of Malabares' application and modifications to the method. This factor is related to the objective and the needs of the companies to ensure that what has been learned is maintained over time, which implies changes in the habits of the teams, for which time is required. The program considers the learning time of each team, which is why the implementations, in their current version, have a duration of 6 to 12 months, where the facilitators, according to their experience, identify the different support needs of each team.

The evolution of the Malabares method in its constant development and how it has impacted the evaluations of adherence to the methodology that are carried out in the program's accompaniment stage will be presented below. Although the changes have been constant, two key modifications over time are identified, which mark 3 stages with characteristics and their adherence results over time. The application of these 6 factors throughout the 3 stages called Initial, Transition and Current Implementation will be discussed.

INITIAL IMPLEMENTATION

The LPS programs carried out by Malabares Consultores from 2016 to 2019 are considered as an initial stage. In this stage, what in now called the Malabares method was only the idea that focusing a training on the learning processes of people with a theoretical content that made sense to them, would ensure changes in habits and use of what was learned. The participants' reception of this new way of teaching was one of total uncertainty.

Both the 1st factor, the idea of generating a safe and trusting space for learning, and the 2nd factor, inviting them to become aware of learning "here and now", were implemented from the beginning and as described in the definition of the method. The 3rd factor, regarding the transversal participation of the team, is a requirement that arises from Malabares, who proposes the participation of everyone (subcontractors, specialists, support areas, etc.), however, it is up to the organization to decide if it finally includes all the related parties or not. On the other hand, it is noted that a real impact is generated in participants commitment when heads and managers attend the workshops. The 4th factor, the implementation program itself, considering the stages training, training sessions and accompaniments, in the first implementations of the LPS for construction companies' teams, were structured with 18 hours of training, divided into 4 modules and then 4 “training sessions”. Finally, there are 2 surprise visits, initially called “monitoring”, to actual team meetings on site for the Intermediate Planning and Weekly Planning meetings. The goal of these visits was to ensure that the meetings are being held regularly on the days and at the times established, and that the tools learned in the training are being implemented. The program as a whole was 60% training, 27% training sessions and 13% monitoring if we consider the time dedicated for each stage, and in general lasted 2-3 months. Regarding to 5th factor, in the initial stage the interactive dynamics for meaningful learning were focused on situations outside the construction. In a safe and trusting space, games and laughter come easily. In the trainings, participants are given costumes and props that are specific to working with Malabares that they would not normally use, especially in a work environment, such as the use of a clown nose every time a participant had to present a concept, which makes the training more fun and less intimidating. The 6th factor, the long-term work program, had not yet been developed at this stage.

The greatest discovery in this initial stage was the link between facilitators and participants that is generated in the trainings. The importance of opening the bond or link in all the initial contact instances in order to teach the theoretical content that is required later on. With the certainty of having found the way to generate the "knowledge transfer bridge" between the participants and the facilitators, there was room to make other modifications.

The results of the evaluations also showed that, although good immediate adherence was achieved by the team, with team members remembering the main concepts of the LPS and the use of the tools (evidenced by an individual test), there were drops in evaluation due to two main reasons: the teams do not have a clear idea of how to apply everything learned to real work situations; and it is difficult to remember the structure of the meetings and replicate them weekly. The surprise visits at the monitoring stage induces the teams to carry out the meetings, but does not ensure the quality, leading in some cases to the practice of these only to comply with the Malabares visit and not to observe real progress with the execution of these (like a student who prepares to get a good grade, but not to really learn the content of the evaluation).

While the playful mode meets the objectives of favoring the learning environment, favoring communication and reducing barriers to changes in work practices, it has a deficiency in achieving that the methodology begins to be applied in a real work situation, so it is concluded that the training should, without completely losing the playful focus, be more focused on the real applications of the methodology and not on fictitious examples unrelated to work. Also, it is concluded that tools must be included to help maintain the adherence to the methodology achieved with the training stage throughout the entire project and not lost and returned to the previous work practices, which are precisely the ones being sought to change and for which the clients decide to develop the implementation of the LPS. The surprise monitoring system, as mentioned, ensures the execution of the meetings but not their quality. Thus, the logical conclusion is that the team visits should aim not only to evaluate the permanence, but also to improve the quality of the content of the meetings and their efficiency, contributing to the effective change in the team's work culture by visualizing the discrepancies that are obtained, thus giving meaning to the new knowledge in their daily work.

Figure 1 shows the results of the evaluation of LPS adherence in three construction projects (at five consecutive evaluation moments) where the initial stage method was applied. The x-axis shows the number of the evaluation for each work, the space between evaluations is from 1 to 3 weeks. The evaluated works are high-rise housing and may correspond to teams in different companies (I1, I2, I3, respectively).

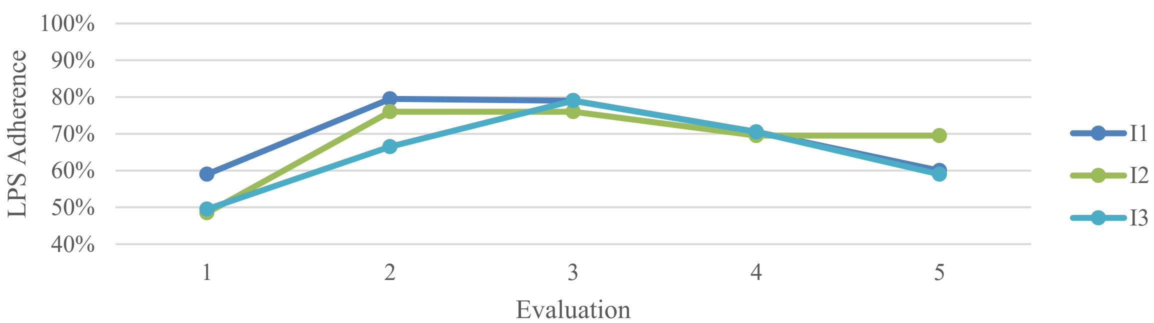

Figure 1: LPS adherence of three construction projects. Initial Implementation

TRANSITION IMPLEMENTATION

The transition stage covers implementations mainly in years 2019-2020. During this stage, the importance of generating a space of security and confidence (1st factor) and of learning "here and now" (2nd factor) was maintained. The participation of actors from different disciplines and positions within the organization (3rd factor) was reinforced and called to be fulfilled. The observations made on the initial stage and the results of the teams create the need to induce changes in the Interactive dynamics for meaningful learning (5th factor) and structure of the implementations (4th factor), aiming to reduce the negative impacts mentioned.

The structure of the Malabares' LPS implementation is now 12 hours of training divided into 4 modules of 3 hours each, 5 training sessions focused on preparing and executing Intermediate Planning and Weekly Planning meetings and 4 accompaniment sessions to strengthen the persistence of adherence to the methodology. The program was divided into 40% training, 47% training sessions, and 13% accompaniment based on the time dedicated to each stage. Increasing the hours of training sessions will result in more personalized teaching, better tool utilization, and earlier realization of the benefits of the methodology. Since it is crucial to prepare for meetings, such preparations should be included in the training sessions as well. The aim is to ensure that team members understand their roles and responsibilities, development and validating the planning information in advance of the meeting, rather than developing it during the meeting itself. The new iteration adds a stage of "accompaniment," consisting of 4 monthly interventions where the Malabares team supports the construction team in the preparation and meeting instances, ensuring better results, unlike the previous surprise visit, which only measured results. Additionally, the items evaluated in this accompaniment are modified to consider not only the step-by-step structure of the meeting but also the main preparation instances that must be respected to ensure the information is ready for presentation. All the applied changes affect the duration of the implementation in approximately one month.

According to the 5th factor, trainings themselves maintained a playful and participatory approach, but changed the games and dynamics that lead the participants to completely fictitious situations to simulations of equally fictional situations but within a construction context that LPS will later be applied in. Thus, the games and activities always talk about construction meetings, field activities such as excavation or concrete structures, and weekly building works programs. Before trainings, participants are asked to go to the field and look for changes in their work such as unused materials or idle times and then expose and develop ideas in the training that are completely adjusted to the project reality.

During the implementation of the LPS methodology, team adherence decreases over time, although there is stabilization and slight improvement during the accompaniment stage. Practical applications of the methodology are learned in trainings and replicated in project development with the support of Malabares, but when the accompaniment stage begins, some fundamental concepts are not clear to all team members, leading to tool abandonment. However, the extension of Malabares' team participation in the work helps maintain the team's application of the methodology, reversing the trend of decreasing adherence and leading to an improvement trend. Individuals from the work teams make personalized contributions, but these are not always shared with the rest of the team, especially in field teams.

After this iteration, it is concluded that the application of playful dynamics with examples applied to real work conditions helps teams understand how the tools of the methodology should be applied to the cases they will see in their work, but it is not a good option for participants to internalize the basic concepts of the LPS individually first. To improve the results of the implementation, it is first necessary to ensure that the team members understand the fundamental concepts of the LPS well, and then to apply these to real work cases. It is concluded and reinforced the idea of maintaining the accompaniment stage for the teams, even dedicating a greater number of hours to this stage and increasing the number of months in which the

Malabares team will continue to work with the teams until stabilizing the adherence indicators. Thus, the need for the 6th factor, long-term work program, is conceived.

Figure 2 shows the results of the evaluation of LPS adherence in three construction projects (at nine consecutive evaluation moments) where the transition implementation method was applied. The x-axis shows the number of the evaluation for each work, the space between evaluations is from 1 to 3 weeks. The evaluated works are high-rise dwellings and may correspond to teams in different companies (T1, T2, and T3, respectively).

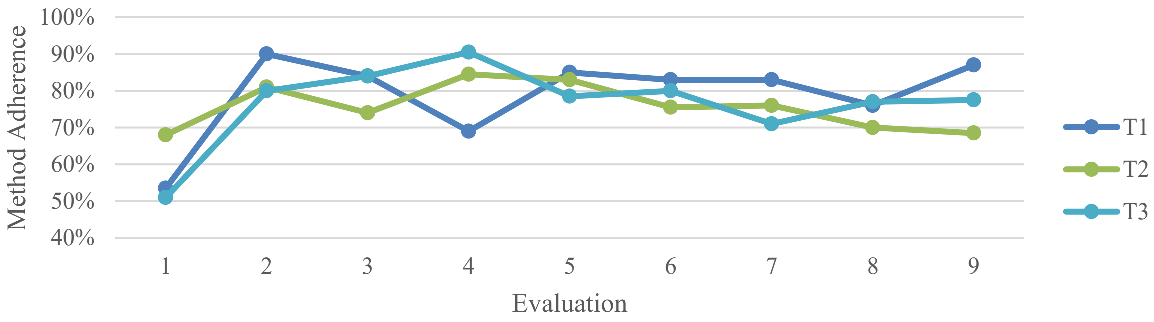

Figure 2: LPS adherence of three construction projects. Transition Implementation

CURRENT IMPLEMENTATION

The current stage started in 2021 and is implemented until these days. The current training of Malabares is characterized by returning to the more playful roots of the method, reserving the examples applicable in real-life work situations for the training stage, and then developing sustained support for several months. In this stage, the focus on generating the facilitator-student bond through the space of security and trust (1st factor) and learning "here and now" (2nd factor) is paramount. Regardless of the culture of the company or the characteristics of the people who attend the implementations, positive emotions are contagious, and everyone is open to play, to enriching discussions and to sharing experiences. Interactions between people are essential, giving the necessary time to each type of learning. Regarding the transversal participation of the agents involved (3rd factor), it remained the same as in the previous stage. Managers, supervisors, and supervisors are indispensable in the presentation of the complete program, where they support and validate the program itself to be implemented.

At this stage the complete program lasts 12 months, convinced of the importance of supporting the teams in adopting the habit in the long term (6^{th} factor). The new structure of implementation program (4th factor) currently contains the following: 6-hour instruction divided into two 3-hour modules, where the aim is to teach the main concepts of the method and its application to fictional cases. 2 training sessions for the Intermediate Plan and 2 for the Weekly Plan. Accompaniment until completing 12 months of implementation in the team, which are maintained as instances where the construction team is supported to prepare the meeting and then evaluate it, pointing out opportunities for continuous improvement in front of each evaluation. The participation of each stage in this program is: training 12%, training sessions 31% and accompaniment 58%. The current composition of the program takes better care of the characteristics of the learning process of the participants, giving space for those who have different ways of learning to become users of the methodology.

The 5th factor in the current implementation program incorporates all the experience gained during these almost 10 years. All the dynamics of the training are aimed at getting the participants to reflect on the reasons behind the theoretical concepts, for example: Why to plan? Why to live a Lean culture? Why be aware of continuous improvement? Each answer to these questions is shown applied in their daily work and personal life through games, examples and analogies. So later, they feel the need and possibility of generating the change because they know and validate the benefits it brings. Also in the current stage, new work instances are added with execution teams on the ground in continuous improvement meetings of 30 minutes, where the goal is to assess improvement opportunities observed by the field teams, to seek solutions applicable by the team, and to propose action plans to implement the improvement.

In this stage, work teams have similar level of adherence to previous cases and even better, but, unlike previous cases, with the transition to the training and accompaniment stages, a tendency to improvement or stabilization is maintained in high levels of adherence. The continuous improvement work with the field teams allows for an assessment of multiple improvement opportunities, in many cases unknown to the administrative professionals in the team, which are reported to the rest of the team along with solution proposals, which denotes proactive and positive work from the field teams in favor of good execution of the work. Although at the time of this study, the implementations of this method have not yet concluded, it is observed that in the evaluations of the support stage, a trend towards improvement is maintained without abrupt drops compared to previous implementation stages. Applying what was learned to real-life cases, which are closer to the work conditions of the teams, is also key to good implementation, if it is started once the fundamental concepts underlying these practices have already been learned and internalized by the team. Finally, in cases where significant deviations from the method are observed in the team, it is concluded that an immediate alignment should be made with the team to adjust group adherence.

Figure 3 shows the results of the evaluation of LPS adherence in three construction projects (at three consecutive evaluation moments) where the current implementation method was applied. On the x-axis is the number of the evaluation for each work, the space between evaluations is from 1 to 3 weeks. The evaluated works are high-rise housing and may correspond to teams in different companies (C1, C2, and C3, respectively).

CONCLUSIONS

The implementation of the Last Planner System methodology under the method created by Malabares Consultores has proven to be efficient and lasting over time, since it allows for substantial and profound changes, generating a new way of understanding and seeing different situations, breaking paradigms and building new ones, thanks to the fact that it takes into account the environment in which people find themselves, whether at work or personally, the experiences of each participant, their biology in terms of the intellectual capacity of each one, among other factors.

Interventions in a learning environment are never the same, because the contexts and the people who learn are different. The Malabares teacher takes into account the different types of learning that each student has and through various dynamics achieves the participation of all, with which a greater diversity, points of view and experiences are obtained around the new knowledge that is being taught and to its application in real daily work. Different activities and games are developed where the abilities of each one help the learning of the other, since they are put in situations and roles to which they are not used, where they have to listen, read, act, teach, reflect together and achieve the adequate synergy for learning and the sense of what is transmitted. This not only serves to better "understand" the subject, but also to generate an environment of trust and bonds between all the participants, which is finally transferred to the actual work on site, where people manage to connect what they have learned during the training. and apply it in their daily activities, and at the same time consolidate a work team that learns and advances as a whole.

It should be noted that the main limitation of the study is that although quantitative data was used, most of it was qualitative, so a much more detailed quantitative study of the adherence results could be developed in the future, and thus validate the Malabares method more accurately. All in all, it is possible to affirm that the six key factors through which the Malabares method is expressed can be useful for any type or area of knowledge, not exclusively LPS, that it is necessary for a team or commercial organization to acquire. Finally, the case presented in this study can be expressed as an example of continuous improvement in itself, this being a key concept within the Lean philosophy, and a necessity for the survival of human beings and companies.

In summary, the implementation of LPS with the Malabares method has shown that an effective way to teach this methodology and achieve good adherence to the team is by creating a close bond between people, as well as a pleasant and relaxed environment, regardless of hierarchies within the team and organization. Constant support over time, not only in training, but also in monitoring workers in the field, is essential for long-term adherence to the Last Planner System methodology. Learning effectively lasts over time thanks to the creation of new cognitive structures, mental maps and significant memories. Malabares believes in people, in their abilities and that it is never too late to face new challenges, and he puts this into practice with great passion in all his interventions.

TEACHING AND TRAINING EFFORTS OF ACADEMIA AND INDUSTRY TOWARDS LEAN CONSTRUCTION IN INDIA

Prashanth Kumar Sreram[1,2] and Albert Thomas[3]

ABSTRACT

Lean construction is gaining traction in India. While there are a few companies which have become first movers and gained advantages of lean implementation in construction projects, there still are many companies which still need to adopt lean construction. At this juncture, the role of academia and industry is vital for accelerating lean implementation. However, the studies indicating lean teaching and training efforts are limited in the Indian context. Therefore, research is conducted to explore how Indian construction companies are adopting lean and how academia is contributing to lean construction, which is the aim of the study. Multiple research methods are used to obtain information on lean implementation. The results indicate that organisations have started lean implementation mainly for cost and time benefits, but there is a difference in training their employees and trade partners. Academia is teaching lean construction majorly as an elective than as a compulsory course. Further, measures to accelerate lean implementation in India are proposed. Overall, this paper presents the efforts of industry and academia towards lean implementation in India and is a source of information for construction companies in emerging and developing economies wishing to initiate the lean journey.

KEYWORDS

Lean construction, collaboration, education, process, change.

INTRODUCTION

One of the largest industries in the world on a global scale is construction. Around 7% of the world's working population is employed there. Every year, more than $10 trillion is spent on construction products and services, which is equal to 13% of the GDP. According to Invest India (NIPFA (n.d)), an official Government of India database, India's construction industry is anticipated to contribute about 9% of the nation's GDP and employ 51 million people. By 2025, it is anticipated to reach USD 1.4 trillion as one of the major economic sectors in the world is constructed. The industry supports 7% of the world's working population and has an impact that extends far beyond its borders by creating the buildings where we live, work, generate our energy, produce our materials and goods, and travel. However, compared to other sectors, the

construction industry's productivity has been appallingly low for decades (Ramaswamy & Kalidindi, 2009).

Adopting Lean tools and principles can help the construction industry improve its operational efficiency, promote collaboration with business partners, and thus enhance its ability to deliver projects as per the commitments made to customers more consistently. Moreover, it would help the organisations improve their overall business performance. Similarly, introducing any new philosophy requires sufficient training efforts, either through in-house training or academic institutions (Moradi, Sormunen 2013, Raghavan et al., 2014, & Bayhan et al., 2019). However, the research in this direction is limited in the Indian context. Therefore, this research work aims to understand the current level of efforts in teaching and training in India. Further, the following research questions were focused upon: How typical or different is the lean implementation in Indian construction companies? and How are the companies and academia engaging in lean training and teaching?

This study summarises the journey of lean implementation in a few client, consultant and contractor firms in India and provides an overview of the current situation from the perspective of lean implementation engineers and academicians and is helpful for researchers and practitioners in developing countries.

LITERATURE REVIEW

In order to understand the current status of lean implementation, the International Group for Lean Construction (IGLC) and Lean Construction Journal (LCJ) are the primary sources of literature. A keyword such as "India", "Lean construction", and "Lean implementation" were used to search for the literature in the IGLC conference papers. Various researchers across the globe have studied lean implementation.

Smith & Ngo, 2017 studied lean implementation by finishing contractors in the United States and observed that Last Planner System (LPS) was the most common tool used. The driving force for lean implementation is cutting costs and reducing schedules. Mossmon (2009) has mentioned that the need for lean education is one of the reasons for no more implementation in the UK. In the case of Brazil, Valente et al., 2020 have observed that in a case study company, various initiatives like participating in lean conferences, using LPS, encouraging continuing education, and lean training for partners as the main success factors for lean sustaining. Forbes et al., (2021) have presented case study examples of lean education initiatives by US-based Owners, Architect, Engineering, and Construction (OAEC) stakeholders based on semi-structured interviews.

In the Indian context towards lean implementation, Karanjawala & Baretto, 2018 have provided case studies of implementing lean at multiple project sites in India. Raghavan et al., (2014) have identified that in Indian construction, lean implementation is subject to factors like site and organisational culture, planning and engineering expertise, and site and top management support, based on the experience of working with a contractor and client firm in India, Kalyan et al., (2018) have proposed that lean tools at the site level, as a bottom-up approach and then that can be complemented with a top-down approach that builds awareness, empathy, and knowledge at the leadership level. Further, Anandh et al., (2018) have observed that lean implementation through academia could be much higher in India and have suggested measures to add Lean construction in India.

The above literature indicates that there are studies on lean implementation in various countries, including India. However, in the Indian context, the existing literature is reported primarily by the institute/organisation implementing lean as their experiences, which is a perspective from the top level. Further, studies indicating teaching and training efforts similar to Forbes et al., (2021) are unavailable, and there is a need to take a bottom-up approach of enquiring from the project level (Arbulu & Zabelle, 2006). Therefore, there is a need to understand the views of the people who are implementing lean at sites and also from the faculty who are teaching lean. Accordingly, the study aims to explore how Indian construction companies are adopting lean and how academia is contributing to lean construction. Further, the objective is to identify potential commonalities and differences in lean education (training and teaching) and measures to accelerate lean implementation in India. The research necessitates using multiple research methods to achieve the study's aim and objectives.

RESEARCH METHODOLOGY

Multiple research methods, such as desk research, survey form, and case studies, were used to achieve the purpose of the study, with qualitative case study methodology, as a combination of different data collection methods (Pinfield, 1986; Anderson, 1983). Using multiple methods has many advantages, such as increasing the creative potential of the research, and it also allows for covering more details and findings (Kathleen, 1989).

Purposive sampling was used to identify the respondents who are currently implementing lean. Purposive sampling is a non-random sampling technique which is helpful for the researcher in an exploratory study where the researcher finds out who can and will provide information through practice, knowledge, and experience (Etikan et al., 2016). One of the authors participated in Indian Lean Construction Conference (ILCC) held at Hyderabad, Telangana, India, during 15-17 December 2022 to identify the respondents from the companies and academic institutes participating in the conference and approached forty attendees for participating in the survey.

Fifteen participants have agreed to participate in the survey. However, instead of the interview, there was a need for more time as they were busy at the conference and agreed to share their inputs through the web-based survey form. Further, the company/institute where the participant's work is considered a case study example. The selected companies and academic institutions are known for their leadership in lean construction and are playing a pivotal role in the Indian Lean Construction Excellence (ILCE) community in India.

The research methodology involved a structured questionnaire survey (web-based) with open-ended questions for obtaining input from the respondents from the case study companies and educational institutions. Further, the company information is obtained through desk research. The desk research method is used for referring to ILCC conference proceedings, souvenirs, magazines covering lean construction aspects in India, being the members of ILCE, in order to be through with the lean journey of the case companies. Further, a qualitative content analysis was performed on the raw data provided by the respondents. The goal of qualitative content analysis is to summarise the informational elements of the data (Altheide, 1987 & Sandelowski, 2000). As per the request of the repondents, the company names and respondent names are anonymised.

DATA COLLECTION AND ANALYSIS

For data collection, a web-based survey form using Microsoft Forms was created and sent to the willing participants with the following questions (as referred to and modified by Forbes et al., (2021)). Further, the last question was added to seek inputs on measures to be taken for accelerating lean implementation, considering the benefits of lean implementation.

How did your company get started with lean? And why?

How did you personally become involved with lean implementation?

How are you training your employees/subordinates? What do they read? What games/simulations do they play? Any other innovative way of training your employees?

How much time does your organisation devote to training employees for Lean? Is training a “one-time” or "recurring"?

To what extent do you train your trade partners (subcontractors/labourers/clients/suppliers/any other)? Who among your trade partners should be trained more and why?

Has lean been incorporated into your company's guiding principles/values/processes? If so, how?

Any other suggestions for accelerating lean implementation in India?

Regarding the academicians, the objective is to identify the teaching efforts in Lean construction. Therefore, the following questions were asked:

Students at which level (Undergraduate/postgraduate) you teach and at what level they should be taught Lean! Why?

What do the students read? What games/simulations do they play?

Any other suggestions for accelerating lean implementation in India?

A total of ten industry professionals and five academicians responded to the survey. The details of the respondents from the construction companies are provided in Table 1. The industry respondents' experience in lean ranges from 0.5 to 7 years, and their total experience ranges from 2 to 16 years.

Table 1: Details of the respondents from the industry

Company	Respondent Id	Designation	Work Experience (in Years)	Experience Practicing Lean (in Years)	Company Core Market	Company Type
A	1	Project Manager	13.0	0.5	Buildings	Owner/Client
B	2	Regional Lean Manager	8.0	7.0	Buildings, Malls, Airport	Consultant (PMC)
B	4	Planning Manager	16.0	4.0	Buildings	Consultant (PMC)
C	3	Planning Engineer	6.0	6.0	Infrastructure	Contractor
C	6	Senior Engineer	7.0	2.0	Infrastructure	Contractor
D	5	R&D Engineer	2.0	2.0	Infrastructure & Buildings	Contractor
E	7	Assistant Manager	5.5	1.5	Infrastructure	Contractor
E	8	Assistant Manager	7.5	2.0	Buildings	Contractor
E	9	Assistant Manager	4.5	1.0	Buildings	Contractor
F	10	Deputy Manager	2.0	2.0	Buildings	Contractor

Similarly, academicians' details are provided in Table 2, along with the institute they teach. The academicians are teaching lean construction from a minimum of 3 to a maximum of 10 years. Further, the academicians in the range of assistant professors, professors, and heads of the university, from four different institutions have provided the inputs for the survey. Further, in Table 3, the details of the case study companies are provided. It can be inferred that lean implementation started in 2008. The companies are long-standing, with more than fifty years of existence in the construction industry.

Table 2: Details of the respondents from the academia

Academia ID	Academia Type	Respondent	Designation	Overall Experience (in Years)	Experience in Teaching Lean (in Years)
Academia A	University	1	Professor	22.00	6.00
Academia B	Institute for Postgraduation	2	Professor	40.00	10.00
Academia B		3	Assistant Professor	14.00	3.00
Academia C	University	4	Head	35.00	10.00
Academia D	Engineering College	5	Assistant Professor	15.00	3.00

Table 3: Details of the Companies with Lean Implementation

Company	Company Category	Lean Implementation in India	Brief Description
A	Owner/Client	2022	Set up in 1953 as an infrastructure construction firm to undertake the construction of government projects. In 1986 the company diversified and ventured into private real estate development.
B	Consultant (PMC)	2007	100+ years old US-based construction company providing Project Management Consultant Services in India.
C	Contractor	2008	One of the well-known companies in the Infrastructure sector, namely, marine structures, surface transport, Oil& gas, hydro & underground, and urban infrastructure. Set up in 1959
D	Contractor	2013	It was started as a small contractor in 1956 to construct irrigation systems in southern India. In its 66 years, the company has grown in scale and strength, covering all infrastructure and residential projects in India.
E	Contractor	2008	Buildings vertical of a construction company founded in 1938, regarded as a professionally managed Indian multinational construction company engaged in Technology, Engineering, Construction, and Infrastructure Projects.
F	Contractor	2010	It was established in 1865, offering ‘turnkey solutions’, from ‘concept-to-commissioning’ across the entire spectrum of urban infrastructure.

EFFORTS OF CONSTRUCTION COMPANIES FOR LEAN IMPLEMENTATION

The case companies' lean implementation journey and the respondent answers based on the qualitative content analysis have been summarised in the below sections.

Lean journey commencement

The lean journey has begun in client organisation company A, aiming to increase productivity. The consultant organisation company B, being a US-based organisation, has lean in its operational standards. The operational standards provide standard work breakdown structure, procedures, workflows, and templates that standardise our work across projects and regions/countries.

The contracting organisations C, D, E, and F have different reasons for lean implementation. Company C has begun lean due to emphasis on early completion of the projects. The primary motivation for Company D to begin the lean journey is to get information transparency among stakeholders on the project's progress. Company E has targeted wastage reduction, rework and thus cost reduction, for which lean is being implemented at project sites. Company F adopted lean to reduce hidden costs and optimise the construction activities' timeline. Further, it is to be noted that ILCE has acted as a facilitator-cum-catalyst for lean implementation in the contractor companies, namely C, D, E and F. While companies C, E, and F are founding charter members of ILCE from 2008, Company D joined ILCE in 2013 as they became aware of lean construction through a professor at Indian Institute of Technology, Madras (IITM).

The reason for respondents' involvement in lean implementation is majorly the management decision and part of roles and responsibilities. However, there are a few exceptions. Respondents 8 and 9 from company E are selected for the company's Lean implementation program. The lean implementation process in company E is as follows: 1. Select a site for lean implementation, 2. Identify lean champion(s) in the specific site, 3. Provide the documents and access to the lean repository (use cases), 4. Be at the site for a week to check and correct the implementation, 5. Obtain weekly/monthly reports to see the improvement and benefits.

Respondent 10, from company F, is part of a lean journey because of doing the course on "Lean project delivery" during the postgraduation in construction management, and Respondent 5 has done the final year project on Lean Construction, which has fetched the role of "Lean Coordinator" at company D.

To summarise, motivation for lean implementation by case companies is to gain cost and time savings, and the driving force is top management. Further, lean tools used for productivity improvement, waste reduction, and increased transparency about the progress.

Lean training for the employees

Company A's training efforts are minimal as they are in the very early stage of lean implementation. Currently, only one training is conducted for two employees in LPS so that they can implement it. However, the company management plans to take up further training based on the success of LPS implementation.

Respondent 2 from company B was given stepwise training initially with an emphasis on what precisely lean is for commencing the journey with willingness. There are training modules for employees at basic and advanced levels. Further, company B has a University Knowledge Network for different sets of training conducted online and in person.

Company C uses Silent Squares simulation and E-Learning courses on Lean to train employees. Company E has two different training programs for Lean Champions and the project team separately and is provided at the start of lean implementation at a project level. The various tools and processes that have been fixed to be implemented are explained to the employees through these two training programs with the help of the company's case studies from other similar projects. Company F has engaged only selected employees with the National Programme on Technology Enhanced Learning (NPTEL) based Introduction to Lean Construction course conducted by Prof. Koshy Varghese and Prof. Raghavan N from IITM.

Compared to all the companies, Company D, though it started its lean journey in 2013, five years later than companies C, E, and F, has developed a specific training plan as follows:

employees take the NPTEL "Introduction to Lean Construction: Module 1 - Basics" course which is mandatory, followed by internal training with their Lean experts (employees whose experience in Lean implementation is more than five years) in a virtual mode with the help of presentations and case studies from the company project sites. Further, Company D has a "Villego" Simulation Kit, which was outsourced from "The Change Business- UK", a Lean Consultancy, for the Last Planner System.

Concerning the training frequency, the common aspect of all these companies is that the management encourages these employees to attend the training workshops and conferences held by ILCE. However, the in-house training frequency as per the respondents is based on the need of the hour at the site level rather than a recurring and scheduled event, except for company C where the training frequency is once a quarter for everyone. Further, as part of its lean implementation program, Company E imparts training whenever a new member joins the program.

Overall, the efforts on employee training towards Lean Construction differs for each company. Only one of the case companies has a defined training plan and one has defined training frequency whereas all others treat training employees as per the need of the hour.

Lean training for trade partners

The trade partners for the construction companies are trade partners (subcontractors, workers, clients, and suppliers. The training for the trade partners is significantly less across the companies. Companies A, C, and F currently do not have any training programs for trade partners. However, the respondent from company A feels that there should be a particular focus on training workers. The respondents from companies C and F believe sub-contractors are to be trained to introduce the benefits of implementing the lean.

Company B trains the trade partners, at-least on weekly mass training. Company D has yet to train the external project players (sub-contractors, clients, suppliers, and consultants). However, training the workers on Lean tools like 5S (Sort, Set in Order, Shine, Standardize, and Sustain) & 3P (Production Preparation Process) with sign boards in *their regional language*. Further, Company E trains the workers through the lean champions and site engineers involved in the specific activity in which lean is implemented. Further, the respondents from company E feel that all the workers, including subcontractor's supervisors, are to be trained, and even the material suppliers/ vendors should also be provided virtual training as they do not visit the site.

As the current training efforts are targeting internal employees, training trade partners is limited. At this juncture, the respondents opine that subcontractor supervisors, subcontractors, and workers are to be imparted lean training for maximising the benefits.

The Lean as part of the organisation's guiding principles/values/processes

The company's approach to adding lean to the existing systems is different. Company E has incorporated lean management as a section in the project quality plan (PQP), which makes adopting tools and practices an auditable point. Moreover, this enables the project teams to adopt these practices. At Company C, mainly 5S, root cause analysis (RCA), LPS and Value Stream Mapping (VSM) are strictly implemented at construction sites to improve project activities continuously. Company D has done mandatory training for all employees on Lean construction with a well-defined training plan.

Further, Company D has made Lean implementation one of the key results indicators (KRI) of the employee performance appraisal system. Further, Company F has incorporated LPS as an integrated part of IMS (Integrated Management System) processes. Company B has incorporated the pre-construction phase as part of the project management plan so that the implementation during the construction phase can be made easy and handy. Company A, being in the initial stages of implementation, has yet to plan for now but is interested in adding it to the company's process, provided LPS implementation is successful.

The approach to incorporate Lean into company's existing policies is different by the companies. Each have chosen a different approach as explained above. However, it is interesting to note that Lean is being injected into the companies existing process one way or other. Table 4 provides the summary of the lean implementation, teaching and training efforts, ways of introducing into companies existing process illustrating the similarities and differences across the companies.

Table 4: Summary of Training Efforts of the Construction companies

Company	A (Client)	B (Consultant)	C (Contractor)	D (Contractor)	E (Contractor)	F (Contractor)
Company Lean journey	Productivity improveme nt	Operational standard	Early completion	Information transparen cy on project progress	Wastage and rework reduction	Hidden costs reduction and optimising time
Respond ent's lean journey	Manageme nt decision	Part of the Roles and Responsibili ty-ty	Manageme nt decision	Project work on Lean Constructio n-n	Lean Implementati on team	Course on Lean project delivery
Training employe-es	Very limited training so far	Corporate university – basic and advanced levels	Silent Squares simulation and E-Learning courses	Well-defined mandatory training plan & Villego	Two programs – for Lean champions and the Project team at the start of the project	NPTEL course for the selected employee
Time devoted to training	Nil	Need basis	Quarterly	Need basis	Need basis	Need basis
Trade partners trained	None	Mass training for all trade partners	None	Workmen	Workmen	None
Lean in Company processe -s	None	Project managemen t-t Plan	5S, VSM, RCA, LPS mandatory	Mandatory training and lean implementa tion as KRI	Project Quality Plan for Audit	LPS as part of IMS

EFFORTS OF ACADEMIA FOR LEAN TEACHING

The respondents representing the four academic institutions have provided their inputs on how they have been contributing to the lean implementation, and the summary of the teaching efforts, and the resources used for teaching are provided in the sections below.

Lean teaching for students

The students at Academia A are being taught at the postgraduate level with a subject titled "Lean Construction". Further, the course is being delivered as an elective, which the students choose. However, the respondent from Academia A feels the course could be introduced as a higher-level elective at the final year undergraduate level. Moreover, the university has made a collaboration with UK based university for a project titled Collaborative Online International Learning (COIL) project to create awareness about lean and sustainability. Similarly, Academia B also offers a course on Lean construction at the postgraduate level, except that it plans to make it a core/compulsory course.

Academia C offers courses in the built environment. The builders/developer organisations have been provided with training on saving materials and time costs. In this process, the institute started adding topics on lean construction, which the builders/developer organisations accepted well. Therefore, Academia C has been teaching lean construction practices as an elective in two of their master of business administration programmes for the last five years. Academia D offers all engineering courses. However, the institute has started offering specialisation in Lean Construction Technology as part of the graduate-level civil engineering course. The Lean construction courses are delivered in the third and final year of the bachelor of engineering course.

One out of the case academic institutions has introduced Lean Construction at the undergraduate level, whereas rest of the institutions have been teaching at the postgraduate level. Further, the course at postgraduate level is being offered as an elective as an alternative construction project management method.

Resources used for Lean teaching

Training the students at academia A and B is based on the concepts in the textbooks on lean, journal papers or online material. Further, games involving card games, aeroplane games, and pattern development games are used for teaching Lean Construction. Occasionally role-play games are used to simulate the construction scenarios. At Academia B, the students are given lean concept theory linked with practical application through case studies. Further, Academia A and B have hosted ILCC conferences and engaged students as volunteers, encouraging them to see the practical application of Lean Construction. Multiple lean awareness exposure games and lean software are used to train and teach the students at Academia C.

Overall, games, books, journals and case studies are major part of the resources used for teaching.

SUGGESTED MEASURES FOR ACCELERATING LEAN IMPLEMENTATION IN INDIA

Lean was introduced to India fifteen years back by IITM and ILCE in 2008-2009 (Raghavan et al., 2014). However, the number of contracting parties reporting lean implementation is less compared to the number of construction companies in India. Considering the advances in technology adoption requirements, there is a need to fast-track the lean implementation (ILCE (n.d)). Therefore, the respondents, being lean trainers and lean implementers, were asked to provide their suggestions for accelerating lean implementation in India.

The measures suggested by the respondents are: 1. Marketing in the industry by showcasing the success stories and their positive outcomes with the Tier II & Tier III contractors, 2. Devising Lean construction-based courses jointly by construction companies and educational Institutes, 3. Integrated Project Delivery (IPD) or Relational contracting approach for construction project delivery. 4. Engaging with public policy decision-making authorities more frequently for mandating Lean Construction - Introducing lean implementation as a prequalification criterion, 5. Improve Lean knowledge and awareness of clients in India, 6. Introduction of the lean rating and lean certification, 7. Sharing of incentives with the trade partners for promoting lean adoption, 8. Increasing the training of frontline workers and supervisors, and 9. Use of computer simulations to enable the selection of lean tools for better decision-making and implementation. Further, majority of these measures are considered as enablers of lean construction (Bayhan et al., 2019 & Moradi, Sormunen 2013)

In this context, the role of organisations is crucial for conducting specific training dedicated workshops and monitoring their incremental progress over a period. ILCE has been connecting the industry and academia by conducting ILCC conferences at the academic institutes to promote Lean in India. Further, academia should also bring in a compulsory course (rather than as an elective) on lean construction in undergraduate and postgraduate courses for all disciplines, so that lean awareness is ensured at the entry level of the construction industry.

CONCLUSIONS

The study has used multiple research methods to understand the efforts of industry and academia towards lean education and training in India. A total of fifteen respondents from six companies and four educational institutes have provided valuable inputs on how lean is being implemented and the training and teaching efforts. It has been observed that the primary motive for lean implementation is to get cost and time savings, and the top management is driving the lean implementation. Therefore, creating further awareness and marketing Lean should attract more construction companies to adopt lean.

The company's approach towards implementing Lean in existing company procedures is varied. However, all the approaches presented in this study can be referred to by the companies in developing countries and adapt to which one best fits their organisational setup. Further, the true success of Lean implementation is possible only when there is a significant cultural change brought among all the project stakeholders, focusing on suppliers/vendors, subcontractor supervisors, and frontline workers.

There is a need to show the clients the potential benefits of Lean by contractors and advocate implementation beyond contractual obligations. It would eventually have significant benefits for all the stakeholders in the Construction Ecosystem. The research is helpful to both researchers and practitioners to gain further insights on lean implementation and teaching/training in India and is a source of information for the potential construction companies wishing to implement Lean construction.

LIMITATIONS AND FUTURE WORK

The number of respondents from each company/institute is limited. There could be construction companies not presenting at the conferences, not joining the ILCE, but implementing Lean on a full scale. Therefore, a survey of nationwide construction companies will facilitate further understanding. While the research has obtained data saturation representing each organisation, increasing the number of respondents from each organisation, conducting qualitative interviews, and longitudinal studies would provide further insights into the teaching and training efforts and validate the suggested measures for accelerating lean implementation in India.

ACKNOWLEDGMENTS

We want to thank ILCE, and all the construction companies, academicians and survey participants for their valuable input in this research work. We also thank the anonymous reviewers for their review, which has helped in the overall improvement of the research paper. We would also like to thank IGLC for providing this opportunity.

HOW TO NAVIGATE THE DILEMMA OF VALUE DELIVERY: A VALUE IDENTIFICATION GAME

Salam Khalife[1] and Farook Hamzeh[2]

ABSTRACT

Delivering value on projects is one of the fundamental concepts in lean construction through the Transformation-Flow-Value (TFV) theory. The concepts of transformation and flow are thoroughly explained through the lean construction literature, and various educational games are offered to support the understanding of the flow concept including work-flow variability, takt time, waste elimination, pull systems, and efficient planning. The concept of value, however, tends to be more complicated where researchers are continuously trying to better understand value delivery on construction projects. The International Group for Lean Construction conference offered research on Target Value Design as well as games to reap knowledge about project value. This paper provides additional support to understand the value concept and its characteristics through a proposed educational simulation game. The game demonstrates how designers identify requirements on projects, how various parties value different things, and how to potentially deal with conflicting requirements. The game helps students and lean practitioners in understanding the process of eliciting perceived value on a project and achieving shared understanding through proper communication between different parties. This would help in managing projects in a way that delivers higher value for the different stakeholders, thus achieving successful projects with higher satisfaction rates.

KEYWORDS

Value and design management, serious games simulations, collaboration, benefits realization.

INTRODUCTION

The early definition of value in construction has focused on understanding and achieving client's needs or client's objectives (Bertelsen & Emmitt, 2005). However, different stakeholders on a project have their own interests and needs, thus formulating a different value perception (Haddadi et al., 2016). Accordingly, research had looked into separating the value of interests into external and internal value (Emmitt et al., 2005). External value represents the client value, and internal value is defined by and between the design and delivery team (Emmitt et al., 2005). Additionally, the client in this case represents different stakeholders including the users of the building, the owner, and investors. Not to forget, the surrounding neighbourhood and community needs are part of the client's complex system. Given this complexity, it is difficult to conceptualize and define value. User's and owner's value must be aligned and the design team shall need effective processes to create value on projects (Haddadi et al., 2016).

Moreover, value on projects has distinct characteristics being dynamic or changing over time, subjective, and stakeholder specific (Christoffersen, 2003). Regarding the latter,

[1] Ph.D. Candidate, Construction Management, Civil and Environmental Engineering Department, University of Alberta, Edmonton, Canada, khalife@ualberta.ca, orcid.org/0000-0003-1907-4547

conflicting requirements among stakeholders on projects is a major issue when delivering value. Drevland et al. (2017) discussed ethical dilemmas when delivering value on projects, where questions on whose value to prioritize "the good of the client versus the good of wider society" or "the good of the developer versus the good of the buyer". Thus, this adds up to value complexity and confusion. Accordingly, research is still investigating ways to simplify the concept and propose methods and tools to understand how to deliver value on projects.

The problem amplifies when talking about novice lean practitioners and designers. They usually do not have a clear idea about the concept of delivering value on projects nor the complexity of the design process, specifically the early ideation phase. In an attempt to help resolve this issue, and to provide a clearer picture of the value concept, this research adopted the active learning path by proposing a value identification educational game. Target Value Design (TVD) games have been proven to be effective in learning important principles relating to TVD and improving overall value while considering a target cost (Jacob et al., 2021). Such games has been proven to act as useful pedagogical techniques to teach challenging concepts in lean construction while increasing students' enthusiasm (Hamzeh et al., 2017). A growing use of these games have been identified using a systematic review conducted by Bhatnagar et al. (2022) proving their effectiveness. In this study, 96 lean games were identified and only one game relates to value capture and value management (beyond TVD games) and this game was categorized as slightly discussed. While the concept of value is still considered vague, this suggests that there is a need for such research to help in better understanding value and consequently delivering it and achieving higher satisfaction on projects. This paper contributes to the growing field of using simulation games as tools for learning lean concepts by specifically focusing on the value identification component. Achieving a better understanding of the ambiguities inherent in our concepts of project value can provide an opportunity for achieving higher value.

THE VALUE CONCEPT

VALUE DISCUSSIONS IN THE LEAN COMMUNITY

The international lean community has been involved in research about value delivery since the inception of the lean construction group. From the early start of lean philosophy, Koskela (1996) admitted that practitioners do not really understand how value is generated during a project and called for challenging theoretical research. Customers have expectations and requirements, and designers or suppliers would need to provide value through their product or services. Yet Koskela (1996) described the internal mechanism of this two-way connection as a black box. Ballard & Howell (1998) explained how thinking about value alters the traditional conversion model in design which requests the customer to clearly present their complete or fixed design brief. Contrary to that, designers need to elicit customer's desires, explain their consequences, and negotiate customer's ends and means (Ballard & Howell, 1998). Additionally, Leinonen & Huovila (2000) in their paper *the House of the Rising Value,* they indicated the difficulty, yet the importance, of creating value. They suggested in their study a tool that provides realization of project performance based on project definition. It can be combined with quality function deployment tool which helps creates requirements from needs. The paper highlighted that methods to enhance value creation are available but still not fully exploited and difficult to deal with.

Since then, researchers invested time and efforts to assist the construction industry in general and the lean community specifically with finding answers and improving knowledge about the value concept and associated methods.

In fact, from the repository of the IGLC conference, for the years between 1996 and 2021, more than forty papers are categorized under the *value generation* topic providing insights and research evolution on the value topic. Salvatierra-Garrido et al. (2012) performed a literature review to explore the value concept within the IGLC conference proceedings from years 1993 till 2011. They spotted that the value concept is still ambiguous due to the various interpretations of its meaning and due to its subjective nature. Also, the research noticed the focus on delivering value at the project construction level by reducing waste and praised the efforts to fulfil customer's requirements.

In general, going through a good deal of the lean construction literature, the following approaches were offered as basis for identifying and improving value on projects:

- Collaboration as basis for project delivery: collaborative decision-making, early involvement of downstream players in design, intensified planning, and open communication to produce a clear brief.
- Cross-disciplinary coordination and intensified design with multiple professionals.
- Co-location; productive work environment: specifying the right pace, meeting frequency, meeting agendas, interactive design sessions, big room with right people, freely share concepts and ideas.
- Bring problems to surface, have candid conversations, and proactively change course of action.
- Carefully selecting teams: based on mindset and alignments, based on prequalification.

The proposed value identification game focuses on the first point and intends to provide assistant with producing the value proposition list (also called the value attributes list).

WHY LEARNING ABOUT PROJECT VALUE IS IMPORTANT

Researchers and practitioners have expressed interest in learning about the concept of delivering value on projects as indicated above. The lean community had offered a specific category in the international group of lean construction conference named *Value generation*, which reflects the importance of investigating the topic beyond making it merely about project construction processes and minimizing waste. The briefing process still suffers from unstructured methods (Leinonen & Huovila, 2000), therefore learning about value identification would help in structuring the briefing exercise more. Moreover, during the lean course, as soon as the educator reaches sessions about early design phases and the wicked design process, confusion is noticed. The silent squares game helps students learn about the importance of collaboration to minimize rework in design. Yet, focusing on the value identification is still needed.

In the business world, a value proposition canvas had been introduced to produce products that meet customers' needs by understanding their problems. Construction projects are no different. Architecture and engineering professionals need to produce projects that meet different stakeholder's needs including those of the customers, end-users, and communities (Pirozzi, 2019). Learning about the value concepts and how to identify value from the early beginning will help practitioners in minimizing iterations in design. Nonetheless, designers need to keep their options open. This is called Set-based design in lean, and part of it is related to delivering higher value by keeping flexibility and not locking design early during the project design (Ballard, 2000). We are trying to focus on the fact that design is not a onetime *shot*, design evolves as needs also evolve with the progression of the project. Design thinking is a problem-solving approach used to create design solutions that focus on user's needs. It involves several steps to reach a satisfactory design solution including: empathy, ideation to generate a wide range of ideas by brainstorming, defining, prototyping, divergence and convergence, then testing to refine the solution based on feedback (Efeoglu et al., 2013). Identifying value relates to the first two steps of the design thinking approach.

Moreover, learning about project value will help in understanding that hidden needs exist. Wandahl (2004) explained the four windows for requirements and needs on projects (Figure 1). The first includes what is known for both the client and the design/delivery team. The second is what is not known to the client but know to the team. The team in this case helps the client by asking questions and making requirements clear. The third window includes what is known to the client but not known to the team. Here, the client should inform the team about their desires and expectation by simply telling them. The hardest part is window four where requirements are unknown for both the client and the team. It takes a lot of collaboration on projects through workshops, questions, researching, and transparent engagement to try to reveal those hidden needs.

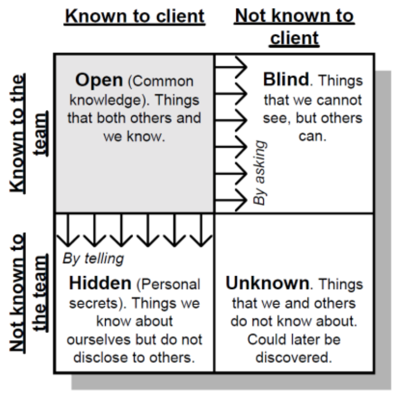

Figure 1: Johari Window retrieved from (Wandahl, 2004).

THE VALUE IDENTIFICATION GAME

GAME DEVELOPMENT AND LEARNING OBJECTIVES

The authors developed the value identification game or Value ID game to help novice designers and project managers in understanding the concept and the process of identifying value on construction projects. This preliminary step of identifying value would help in subsequently delivering higher value during the project phases. One of the authors has been teaching lean construction for more than ten years now and the value topic always raised curiosity among students. The idea of developing this game was thus inspired in the classroom. Yet, the actual development of the game was when the authors got involved in the design of a housing project and sensed the confusion among practitioners as well regarding dealing with requirements and value identification. The game was then developed and tested in a class setting a few times and then presented in front of lean experts to get feedback. The adjustments in the game based on feedback are specified in the relevant sections herein.

Thus, questions about project ideation and value definition were raised; How to identify owner's needs? Users' needs? Community's social needs? Environmental needs? How to make these needs work in conjunction with each other? How to deal with conflicting requirements? And how to really understand what is behind the client's requirements? The design production is related to storytelling, designers need to elicit the needs of different parties, research the different alternatives and options, and then innovate to uniquely produce the preferred design. In response to these inquires and to understand the general idea of value identification, the authors proposed this game to facilitate drawing connections to the importance of understanding value and having a clear vision from the beginning. Specifically, the authors highlight the three main learning objectives of this game:

- Learning Obj.#1: Deepen knowledge of the value identification concept and value characteristics on construction projects.
- Learning Obj. #2: Augment understanding of project owners as a system and that the system has many and varied statements of value that might include conflicting requirements on projects.

- Learning Obj.#3: Gain the ability to communicate efficiently and come up with proper questions to elicit information from project owners and customers.

Additionally, after playing the game, participants should be able to (Learning outcomes):

- Learning outcome #1: Identify value propositions on a project based on project goals and client's needs and translate them into design solutions/criteria.
- Learning outcome #2: Evaluate different design alternative against the value propositions.

The following sections explain the game rules and roles. Then later in the paper, the discussion section will relate between the mentioned learning objectives and outcomes and the results of the game.

GAME ROLES, RULES, AND THE STORY

The game includes four steps. In the first step, the game facilitator invites students to team up and form a design team of 4-5 people. We ask participants to select different roles: one to two architects, one structural/civil engineer, one electromechanical engineer (MEP) and a contractor. Based on their background, they need to provide suggestions about the general design. But first, the facilitator needs to present to participants a script that includes a general description of the owner's vision – and end-users' preference if applicable – about the project. This script acts as the design brief for the project. In our case, we opted to experience the game on a two-floor private villa. The owner, which is basically the end-user in this case, offered their vision of the project. The owner submitted a short design brief, and we shared it with participants during the two trials. The text reads as follows: "*The house is located in a mountainous area facing the ocean. The owner is interested in sustainable designs and solutions. The owner has a lean thinking background. The owner would like to connect with nature. The owner has a tight budget.*" We mentioned that the 'owner has a good position in society'.

Next, the facilitator asks participants to discuss with their team what is considered of value for the project based on the description of owner's requirements or the general vision provided. In other words, the participants need to come up with suggestions of how the brief description could be translated into value propositions and design requirements. Each team should agree on the top five value criteria that need to be achieved during the design to have a project compatible with the client's vision. The team shall write the five design value criteria on the evaluation card provided – or in the google sheet provided (Figure 1). It is important that the facilitator recommends that participant be specific when listing the value criteria. As a modification, and based on the two trials we conducted, we suggest adding another column and splitting the brainstormed ideas into value propositions and design specification. The design specifications are translation of the value propositions. The team converts these value propositions into design solutions or technical solutions. For instance, a value proposition can be having natural light as a way to connect to nature, then the design solution related to this value could be designing large windows. When participants start to list the value propositions and the translated design solution, they would come across conflicting requirements. Going back to the example, having large windows to connect with nature will not be specifically sustainable since it would lead to pressure on the heating and cooling systems. The participants will need to figure out how to better resolve the conflicting design solutions through alternative design ideas.

Value Identification Game (V.ID) - Evaluation Sheet — *Group 1*

Design Criteria - Group A

	Step 1- Fill in the selected Design Value Criteria	Design Option 1	Design Option 2	Design Option 3
1	Natural material	7	10	10
2	color of material	4	9	10
3	use of glass for having nice view	8	8	10
4	use of solar power	1	8	9
5	Cost Effecient	5	7	8
	Total Grade	25	42	47

Step 2 -Evaluate options based on the criteria
Grade each design from 1-10

NOTES

Figure 2: Value Identification Card (Google sheets)

In the second step, the facilitator presents three design options for the suggested villa. Each team will need to evaluate the design options against their list of design value criteria. The scale used was 1-10, where 1 indicates the presented design option poorly reflects the design value criteria and 10 represents an extremely compatible design with the listed criteria. The team calculates the total score per design option out of 50, which is the sum of the grade number given for each of the criteria. The three options need to have a similar representation, so all three designs need to be presented in 2D and 3D. Preferably, the north side shall be revealed beside the plans as this would help in deciding about sustainability and energy-related concerns. A sample illustration for the three options is presented in Figure 3. The samples were collected from *pinterest.com* website. The purpose of these samples is to give an idea of what might be a good fit for the game. Any design would do, the important thing to keep in mind again is the story behind these designs and how to conduct the discussions after receiving the evaluations.

Option 1 | Option 2 | Option 3

Figure 3: Sample Illustration of the Design Options (not to scale)

In the third step, the facilitator elicits the scores per design option from each team. One representative from each team shall give an overview of the brainstorming process that helped in developing the value criteria based on the design brief. Afterwards, in step four, the facilitator will ask some questions to open a discussion and will need to talk about the story behind this exercise.

The discussion shall include two questions: (a) What did you notice during the teams' discussions on value identification and scoring the different options? And (b) what are some efficient ways that might improve the process of identifying value, revealing hidden needs, and improving satisfaction on projects? These two questions can generate ideas, specifically regarding collaboration among the different design disciplines and asking the right questions to reveal needs and design style.

As for the story behind this exercise and the design options, the facilitator shall explain that the options are design alternatives for the same project and were done in chronological order. Option one was the first design the architect provided to the client. The architect assumed that given the client's position in society, they would want a luxurious villa. The architect explained that the material used could be affordable to minimize cost. The architect wanted to impress the client. Therefore, option one needs to be the wildest. Obviously, this design option will still be over budget and does not match the lean thinking the client has. At this point, the client did not know what exactly the alternative should be but indicated that a simple design would do. Then, option 2 would be suggested. The design is now simple with huge windows opening to enjoy the mountainous views. The client realized one problem with this design which is the absence of balconies and terraces on the upper level. The design also would be costly for the heating and cooling systems. Thus, the designer reimagined the project as depicted in option 3, where balconies and windows with louvers were provided.

CLASSROOM SIMULATION

The first run of the proposed game was conducted by the authors as a simulation exercise in a lean construction graduate class at the University of Alberta. The selected project for this first trial was a real case study the authors were involved in. The options were the actual design alternatives. The four steps explained earlier were conducted.

After the teams were done with listing value propositions, rating the options, and discussing their thoughts, the authors explained that these options are design alternatives for the same project and read out the story. This was the AHA moment for the students. It was then clear for them that iterations in design are inevitable, yet to reduce these, design teams need to conduct deep conversations with the owner and collaborate early on the project. The authors then explained about the value concept and how to reach a shared understanding of what is of value on projects.

Students Input

We invited students to engage in discussions based on multiple questions after the game concluded. One question asked students to congregate a value criterion that they perceived as the owner's hidden value (implicit need) and explain their selection. This triggered a discussion about the meaning of hidden needs or implicit value criteria. It was confusing to students at first, but the authors explained that the more questions the design team asks, the more implicit needs are revealed. We usually refer to the design thinking bootcamp from Stanford, indicating "*Engaging with people directly reveals a tremendous amount about the way they think and the values they hold. Sometimes these thoughts and values are not obvious to the people who hold them. A deep engagement can surprise both the designer and the designee by the unanticipated insights that are different from what they actually do - are strong indicators of their deeply held beliefs about the way the world is."*(Plattner, 2010).

Another question was raised and intended to gather strategies that students think are important for understanding the clients' requirements and enhance delivering value on projects. Responses included:

- Early involvement of different design professionals and contractors
- Open communication and collaboration
- Ongoing open discussions; pick owner's brain
- The use of visuals and providing sample design styles

Finally, the authors asked students what were some characteristics of value that they might have picked up from this exercise. In this discussion we highlighted the dynamic nature of value where designers need to keep in touch with the owner/end-users and update them on the progress as some needs develop with the proliferation of more information (Khalife & Hamzeh, 2019).

LEAN CONSTRUCTION EXPERTS' SIMULATION

The authors presented and played the value identification simulation game with a group of lean experts and enthusiasts to further test the effectiveness of the developed game. This group gathers monthly for the purpose of testing and playing educational simulation games related to lean concepts under the name APLSO: Administering and Playing Lean Simulation On-line. The advantage of playing the game with this group is conducting a plus-delta session after the game to highlight the advantages and the deltas or areas that need improvement. These are highlighted in Table 1. More deltas were recorded but were not mentioned because they are already incorporated into the game, examples: consider putting everything in the same level of presentation, include a 3D perspective with all options, and include roles for the team members.

Table 1: Pluses and Deltas on the value game received from the APLSO Group

Pluses	Deltas
Original game design	1. Add cost/ influence graph?
Like the story behind it	2. Cost is not a criterion, but a constraint; so best not to include this as a criterion or it will create confusion in the lean community.
Liked the lesson behind it- owners need some input from designers to learn what they want	3. Owner has information and designer has missing information; therefore, need to build a bridge between the two; example: have a table with both their input
The game generated good discussion	4. Need two groups: tangible versus intangible
Different team members have different perspectives	5. More information on the site and energy efficiency/ mechanical systems

About the deltas, the points one and two answer each other. During the discussions, one of the attendees suggested adding cost or influence graph to the options, yet another participant from the lean experts said that cost should not be a criterion. If the game included cost, mostly participants will focus on that as the basis for their decision among options, therefore it was not logical to include it. Delta 3 cannot be incorporated because the goal of this exercise is to get the design team to discuss more with the limited information at hand. For delta 4, it would be hard to make one group focus only on the intangibles. In the end even intangible value criteria need to be translated to tangible design solutions. That is why we suggested splitting evaluation card into value propositions and design solutions. As for delta 5, this might be a good suggestion for future trial and implementation. The authors could add few information without being very specific so participants would not get affected by comparing numbers.

DISCUSSION

The value identification game is meant to be part of the lean simulation games that help in teaching lean concepts. The value concept is part of the wicked problems in the project definition phase, where wicked problems in design are associated with stakeholder needs and values (Whelton & Ballard, 2002). Therefore, to help students in understanding the value concept and the associated hurdle with identifying stakeholders needs, the value identification game is proposed. Based on two trials and feedback from lean experts and practitioners, the game was modified and presented. In this discussion part, the authors highlight the common points identified from the game trial discussions:

- At the start of the game, there was still a misunderstanding of how to translate the requirements into value propositions. After the discussions, participants had the AHA moment.
- The design brief is considered a mechanical outcome, we would rather want a value outcome on projects where human-centred design is essentially the target.
- Team alignment is part of the project value concept, where teams needed to collaboratively agree and brainstorm ideas in this game. People not agreeing on value definition is already value loss on projects.
- The more in-depth discussions took place, the more ideas were generated. Collaboration is the key.
- Players go through definition, development, negotiation, evaluation, so they move from the value definition to value alignment phase, then later value delivery can take place.
- Designers need to avoid projecting personal thoughts; instead, designers need to coordinate their perception of design.
- Participants need to clarify the tangibles that reflect the value propositions, since the only thing provided to them is the design of the house without any further input from the owner.
- In reference to the Johari window, the game focuses on the third quadrant and touch base on the fourth. The participants will be trying through this game to extract more information based on the available description. It is good to include the Johari window at the end so participants can relate to what they are doing in the game.

To sum up the take-aways from the game, Figure 4 is provided as part of the presentation that the facilitator could provide participants with by the end of the game.

Figure 4: Value take-aways from the Game.

Finally, based on the discussions in the two trials, the authors could assess that the learning objectives were met. Participants had gained more knowledge about the value identification exercise after the game, and they learned about the value being dynamic from the story behind this game. Participants also came across conflicting requirements. The facilitator highlighted the need to ask questions and collaborate to elicit more information than what is provided usually by owners and participants learned about this strategy. It might be relevant to mention the design thinking approach and human-centered design with this game. Design thinking is known for investigating human needs, scoping, defining the problem at hand, personas understanding, user experience mapping and more. The game relates to the first two stages of design thinking: empathize and define. Emphasize is where the designer sees the world from the user's perspective, understands their feelings and motivation, and communicates their understanding. Define stage is where the designer collects ideas to present functions needed to solve problem at hand, similar to the approach in the game. Therefore, mentioning design thinking helps in establishing the connection and explaining that value needs to be delivered in any product not only construction projects.

CONCLUSIONS & FUTURE DIRECTION

This paper proposes a value identification game to help students and novice practitioners in understanding the concept of value and learn to define value propositions through interactive means and observations of different viewpoints. The game includes four steps starting with brainstorming ideas to elicit what is important on the project given the project brief and listing them as value criteria and design solutions. The team of different disciplines will need to coordinate and discuss if there are conflicting requirements identified. Then, the facilitator will provide 3 design options and ask the team to evaluate these against the value criteria listed. In step three, the different teams share ideas and see which option got higher scores. Step four constitutes the main discussion, where the facilitator tells the story behind the games and the options provided and asks provocative questions. Participants will learn that projects normally comprise conflicting requirements, which means they need to deal with these and be informed about the strategies to mitigate the conflicts. Through this game, the authors highlight the issue of hidden needs and the dynamic nature of customers' requirements and the value they perceive of the project. Collaboration and team alignment are also important takeaways from the game. Open candid conversations need to take place because even knowledgeable owners take time into the process to figure out their needs. This idea is often overlooked, and owners are expected to express their need upfront in the design.

After conducting the game in a graduate class setting and with lean experts, positive feedback was received, and possible future additions can be considered. On a final note, the authors had come across the recent trend in design. Artificial intelligence has found its way into developing design concepts using AI art generators. Recently, we have been witnessing design engines that use AI to generate design photos based on a set of words that describe the project. It kind of resembles the current game setting, where the design team are requested to filter out the design options based on the set of value attributes or value propositions inspired from the brief. A future version might be considered which includes comparing the effect of these AI generators and their adaptability to generate design solutions based on the keywords being the top value attributes identified.

Finally, lean philosophy has people at its heart. Value is deeply correlated with social impact, social justice, and equitable living. The game could be tailored to reveal such important ideas. The game conductor may opt to provide a hospital project as an example, or an elderly care center, or a rehabilitation center. The authors believe in visuals and interactions to highlight important ideas in connection with delivering value on projects.

DEVELOPMENT AND TESTING OF A DIGITAL LEAN TOOL TO SHARPEN MOTION AND TRANSPORTATION WASTE RECOGNITION

Yasaman Arefazar[1], Zofia K. Rybkowski[2], H. David Jeong[3], Jinsil Hwaryoung Seo[4], and Sayyed Amir Hossain Maghool[5]

ABSTRACT

There is a need to create ways to communicate opportunities for motion and transportation waste reduction and productivity enhancement that align with the visual management characteristics of those practicing within the construction industry. In this study, researchers aimed to evaluate the effectiveness of an interactive online simulation game that generates spaghetti diagrams as a tool for improving conceptual understanding of motion and transportation waste reduction, that could potentially be used by lean educators in the construction industry. The tool was developed using Unity™ and tested against a control group. To ensure the concept was relatable to participants across different roles, the commonly experienced activity of making spaghetti was chosen as the simulation scenario. Participant feedback from preliminary testing of the online simulation game indicated that the activity was enjoyable and appeared to heighten participant awareness of object placement. Metrics generated by the simulation—as well as post-play discussion—appeared to help participants perceive how elimination of motion and transportation waste can potentially improve their performance. The intent of the simulation is to spur post-simulation discussion with participants about identifying and reducing waste in their own varied processes such as job site operations and procurement.

KEYWORDS

Motion Waste, Transportation Waste, Lean Simulation, Lean Construction, Online Game, Serious Games, Spaghetti Diagram, Productivity Awareness

INTRODUCTION

Simulation games can be used in the classroom to promote learning, facilitate classroom instruction, and boost comprehension among students (Bhatnagar et al., 2022; Hamzeh et al., 2017). Furthermore, students expect university education to be entertaining and simulation games can impart learning in an enjoyable way (Kapp, 2012; Prensky, 2007).

A review of relevant literature suggests that a spaghetti diagram is a potentially impactful tool that can help reduce unnecessary movements. Kanaganayagam (2015) describes a spaghetti diagram as a method of visualizing the path of movement of an actor or object using a line. By identifying motion and transportation waste, spaghetti diagrams help organizations reduce superfluous labor and implement changes to organizational structure or workstation layouts (Senderska et al., 2017). Spaghetti diagrams are powerful tools to identify and reduce unnecessary motions. However, a major drawback is that traditional spaghetti diagrams are static and time-consuming to create, limiting their usefulness for dynamic environments such as construction sites. While vision-based approaches allow for real-time monitoring, they do not currently offer the ability to quickly generate spaghetti diagrams to visualize motion waste. This presents a significant opportunity for the construction industry to improve their processes by leveraging the potential of rapidly generated spaghetti diagrams. This research proposes that an online game generating spaghetti diagrams can potentially enhance the performance of the construction industry by presenting visual opportunities for reducing waste and improving productivity.

EXPERIENTIAL LEARNING AND SERIOUS GAMES

Experiential Learning, often referred to as involved, evidential, or situational learning, is a participatory, interactive, and practical style of learning (Hawtrey, 2007). It permits environmental interaction and exposure to varied and unpredictable processes (Gentry, 1990).

Experiential learning, in its more advanced forms, provides possibilities for "data learning" by requiring students to actively participate in the learning process and to engage in expression of their ideas, utilization of inductive reasoning, or collaboration within groups. In fact, when a participant transitions from the role of a passive listener to an active respondent, this process is known as experiential learning (Hawtrey, 2007).

This research is focused on game-based learning which is aligned with experiential learning. The serious game movement is a response to the need to combine play and meaningful content with advanced capabilities (Spires, 2008). Games in this category incorporate social themes or problems into the gameplay, giving players a fresh viewpoint through active participation (Johnson et al., 2012).

Several studies, including Cassidy (2003), Sacks et al. (2007), and Tommelein et al. (1999), have demonstrated that computer simulations can be more effective than traditional methods of instruction. However, to ensure effectiveness, it is essential to develop a user-friendly design with clear instructions and graphics which illustrate that which is to learned (Gadre et al., 2011; Kuriger et al., 2010). Additionally, feedback is critical for knowledge and skill improvement. Without accurate feedback, learners cannot draw reliable conclusions about that which have learned (Gentry, 1990).

SIMULATIONS AND GAMES IN LEAN EDUCATION

Lean philosophy has given rise to principles and a set of tools to help identify and eliminate waste embedded within processes through the practice of continuous improvement. Elimination of waste, addition of value, continuous improvement, and a culture of respect are the four cornerstones of Lean philosophy (Rybkowski et al., 2018). Although they were arguably built upon productivity theories from Frederick Taylor, Frank and Lillian Gilbreth, and W. Edwards Deming, among others, lean concepts are often summarized as part of The Toyota Production System (TPS). Koskela (2000) is credited with being among the first to apply Lean principles to the construction industry.

A central notion in Lean is waste reduction, which Toyota defines as "anything other than the absolute minimum quantity of materials, equipment, and labor required to add value to the product" (Alarcon, 1997, p. 1). Many authors define lean as a technique for reducing waste.

However, others have argued the actual purpose of reducing waste is to free up resources to enable maximizing value (Sundar et al., 2014). While others have since argued there are additional wastes, Taiichi Ohno originally listed seven: overproduction, time on hand, transportation, processing itself (e.g. overprocessing), stock on hand, movement (i.e. motion), and defective goods. Ohno contended that getting rid of these wastes would lower production costs and boost profits (Ohno, 1988).

Building operations can be optimized using Lean waste elimination principles and analysis of value-adding and non-value-adding activities. Simulation games can serve as a valuable tool to teach these principles and tap into Lean's potential in the field of construction and its business operations (Bhatnagar & Devkar, 2021).

Although Lean concepts such as flow, value, waste reduction, and value maximization are promising and have the potential to improve construction processes, a literature review suggests that the complexity of Lean philosophy and a lack of knowledge about Lean are considered potential barriers to the adoption of its principles in the construction industry (Demirkesen et al., 2019).

Simulation games provide a unique opportunity for hands-on learning, effectively bridging the gap between theoretical knowledge and practical applications in Lean philosophy. In fact, Lean pioneers Greg Howell and Glenn Ballard began experimenting with Lean Construction simulations as early as the 1980s. Simulation games have traditionally been utilized to teach outsiders about Lean building practices and processes, and have proven to be a valuable tool for promoting understanding and engagement with Lean concepts (Tsao & Howell, 2015).

Simulation games provide a dynamic and error-free learning environment that allows individuals to gain a deeper understanding of Lean principles through hands-on experience. By providing a realistic simulation of real-life scenarios, simulation games promote learning through physical activities and enable individuals to translate their knowledge into practical skills (Galloway, 2004). Visual representations of processes and metrics play a crucial role in helping players understand the consequences of their decisions and strategies in these games. By presenting data in a visually engaging manner, players can easily grasp the impact of their actions and make informed decisions to improve their performance. This enhances the learning experience and allows for a deeper understanding of Lean principles (Shannon et al., 2010).

SPAGHETTI DIAGRAM

A spaghetti diagram is a technique used to visualize the movement of an object in a system (Kanaganayagam et al., 2015). Due to the likeness of the results to cooked spaghetti, the tool was given the name spaghetti diagram.

Within the Lean manufacturing paradigm, spaghetti diagrams are commonly utilized as improvement tools (Gladysz et al., 2017). A spaghetti diagram can be used to identify movement durations, multiple movements and overlapping motions. Transportation and motion wastes are revealed using a spaghetti diagram, enabling the reduction of unnecessary labor, and modifications to organizational structure or workstation arrangements (Senderska et al., 2017).

These diagrams are a tried-and-true method for finding layouts that work better (Bicheno & Holweg, 2008). It is relatively simple to identify opportunities to decrease movement waste when the transportation routes are made clear. This visual transparency makes it possible to analyze each movement, revealing areas where motions can be improved. Staff members or workers are observed performing their duties, and the route they take is graphically traced onto a two-dimensional floor plan (Lean Consulting Group, 2016).

The spaghetti diagram is a valuable tool for enhancing our understanding of work processes, particularly when it comes to the distances travelled by production workers. Inefficient material staging arrangements resulting in waste from unnecessary and empty transportation can often be addressed through the rapid visualization of movement, even with modest technologies.

While traditionally hand-drawn, the development of software products is now facilitating the process of creating spaghetti diagrams. By capturing a worker's motions throughout the work cycle being studied and tracing them onto a two-dimensional plan, a spaghetti diagram can be created with greater accuracy and efficiency. Using software such as visTABLE® is a logical and practical approach to creating spaghetti diagrams and is certainly helpful during design of projects such as healthcare facilities where movements of healthcare workers should be minimized (Weber, 2022). While visTABLE® software is a logical tool for creating spaghetti diagrams, it currently cannot generate diagrams in real-time. To address this limitation, this research explores the effectiveness of a dynamic post-action spaghetti diagram incorporated into an online game in improving worker performance. One potential issue with using spaghetti diagrams is the possibility of altered behavior from workers who are aware of being observed. To address this concern, a dynamic spaghetti diagram can be constructed continuously and without the knowledge of workers being analyzed, providing a potential remedy to this drawback (Gladysz et al., 2017).

AWARENESS ENHANCEMENT

An expanding number of research studies support the use of visualization as a tool for problem solving and awareness enhancement. Visualization improves information comprehension by encouraging immediate linkage and perceived associations. In order to achieve this, information must be presented in a way that makes it easier for a user to process it and reduce the amount of mental adjustments needed (Livnat et al., 2005).

For example, in studies focused on raising energy awareness, visibility of energy consumption appears to play a crucial role. According to a survey by Hassan et al. (2009), increased visibility of energy use motivated users to reduce energy consumption. Additionally, a study conducted by Jachimowicz et al. (2018) showed that sharing energy use data with users resulted in energy savings between 0.81% and 2.55%. Sharing this kind of data with users appears to increase their awareness and alter the direction of their actions. When unbiased measurements make them more aware of their actions, users appear to better grasp what they are doing that jeopardizes a goal and what they need to change to reach that goal.

The use of visual management (VM) technologies has grown, and successful implementation instances have been recorded (Brandalise et al., 2022; Tezel, 2011). VM is a component of the Toyota Production System (TPS) and is frequently linked to lean construction (Koskela, 1992). Applications for visual management are designed to make information more easily accessible so that process participants can take appropriate action at the right time (Koskela, 2001; Liker et al., 1995). For example, the increasing ubiquity of BIM facilitates VM before actual construction. By analysing the frequency and intensity of a worker's actions, non-value-adding activities (waste) are easier to identify. Project managers, superintendents, and foremen can benefit from developing situational awareness, but it is arguably equally important for workers to develop this skill by offering them a before-and-after "snapshot" of their own movements (Ghimire et al., 2017; Reinbold et al., 2019).

RESEARCH GAP

The objective of this study was to examine whether exposing individuals to digitally generated spaghetti diagrams can enhance their personal awareness of value-adding and non-value-adding activities, and lead to a reduction in their own movements. However, the creation of accurate spaghetti diagrams is a skill that requires time and practice. Furthermore, existing diagrams are often static and fail to capture transportation dynamics (Gladysz et al., 2017). In response to this need, a real-time diagram-generating algorithm was incorporated into an online game developed for this research.

The following were the procedures and objectives of this research study:

Develop a real-time spaghetti diagram into an online game which can incorporate distance travelled; and

Collect feedback to determine whether or not the spaghetti diagram generated by the online game helps participants identify opportunities for enhanced productivity.

The research question was as follows: Will students and construction professionals enhance their performance (reduce motion and transportation) when exposed to visual spaghetti diagrams incorporated into an online game?

RESEARCH METHOD

The cross-platform game engine Unity® 3D by Unity Technologies was used in this research to develop a game to determine if a spaghetti diagram could heighten player awareness of opportunities to improve their productivity. Because AEC stakeholders perform a wide range of activities defined by their specific roles, the game was designed to engage participants in a universal activity that is widely relatable to actors across multiple fields and cultures—e.g. the act of making spaghetti (Arefazar & Rybkowski, 2022). The game was inspired by the authors' anecdotal observation that construction workers responded well to a video entitled "Toast Kaizen" (GBMP 2009); these workers argued the video was effective in helping them understand waste identification and elimination on-site because toast-making is a shared experience. The intent is that this simulation may offer a first exposure to participants to waste recognition with the expectation that the graphics could then be replaced with materials and activities related to a stakeholder's specific role, such as supply-chain management, material delivery and laydown areas, equipment placement, structural erection, bricklaying, roofing, etc.

The game was designed in such a way that it could be played using a laptop. The game was designed in 3D view and the view that appears in the game is the plan view. To stage the making of spaghetti, the game depicts a kitchen layout that includes kitchen appliances, utensils, and ingredients needed to make a full plate of spaghetti with meatballs. An avatar cook starts walking when the player clicks on a desired destination. When the cook is close to an object, the object will automatically light up, which signals that the cook can grab that object.

This game has a notable feature of tracking and recording the total distance the player's cook has walked. This information is displayed on the right side of the kitchen's layout after each scenario is completed. The game's objective is to deliver a cooked dish (spaghetti with meatballs) with the least possible distance traveled, and the order of activities is not crucial. Two versions of the simulation were available to players: the control version (Figure 1; orange background) did not provide access to a spaghetti diagram of the cook's movements, while the experimental version (Figure 2; green background) displayed a complete history of the cook's movements via a spaghetti diagram at the end of play. Both versions show players the kitchen, utensils, player's name, level played, travel distance, and elapsed time.

DATA COLLECTION

The research was approved by the Institutional Review Board by Texas A&M University and participants were emailed a consent form before play. The control group participants played the game without being shown a spaghetti diagram, while the experimental group was shown a spaghetti diagram of their path after each round. The experimental group participants' movements were tracked, and a spaghetti diagram was generated on the screen. During the first round, the kitchen layout was pre-set by the program and the layout was identical for each participant; however, during a subsequent round, participants were asked to make a decision about potentially modifying the layout of the kitchen by relocating a stove to one of three possible locations (A, B, or C) as shown in Figure 3.

After each round, the experimental group participants were asked to describe how they used the spaghetti diagram, if at all, to identify a strategy to improve their performance.

After completing the game, both groups were requested to provide plus/delta feedback which is a common tool in Lean philosophy to identify what is working well enough to be retained (plus) and what could be improved (delta). Their feedback was used to improve the game and fix potential deficiencies.

The null hypothesis (H0) and alternative hypothesis (H1) of this research were as follows:

H0: There is no significant difference in improved performance between the control group and the experimental group. Being shown a spaghetti diagram of the cook's path did not help the participants improve their performance.

H1: There is a significant difference in improved performance between the control group and the experimental group. Being shown a spaghetti diagram of the cook's path helped the participants improve their performance.

The researchers aimed to investigate the effectiveness of the spaghetti diagram in enhancing the participants' ability to identify opportunities to reduce motion. To achieve this goal, the study included two groups of participants: an experimental group of 30 individuals and a control group of 30 individuals. The researchers collected performance data from each participant in both groups and compared the results. To test the alternative hypothesis, the researchers employed an unpaired t-test as a statistical analysis method.

DATA ANALYSIS

Information related to the online game participants is depicted in Table 1. Students played the online game during in-person sessions. A live facilitator explained the rules and was available for the duration of the session to help participants with any questions they might have.

For the test session with online lean simulation experts called APLSO (Administering and Playing Lean Simulations Online), the facilitator explained the rules and instructions and randomly divided participants into two separate breakout rooms (i.e., control and experimental) using Zoom. Separate links to the game were sent to each group, and they were invited to play. Since learning to play the game effectively takes some practice, the researcher compared participants' performances between Levels (i.e. "rounds") 1 and 4. The difference between the average distances between Rounds 1 and 4 shows improved performance. The mean of the enhanced performance for the control group was -5.23 units. The negative value indicates that the travel distance was shortened (i.e., improved by 8.4%) in the latter round.

The experimental group played a version of the online game in which the spaghetti diagram was depicted at the end of play. The distance travelled and selected layout for each round was collected. According to Table 2, the difference of the average distances between rounds 1 and 4 shows improved performance. The mean of the enhanced travel distance performance for Group B (experimental) is -10.86 units. The negative mean suggests the cook's path in round 4 versus round 1 was shortened by 10.86 units (improved by 51.84%), which is greater than that found for Group A (control). A comparison of the averages of the improved performances between the two groups suggests that the participants who played the version with a spaghetti diagram showed greater improvement in terms of travel distance. Data collected from Group A (control) and Group B (experimental) are summarized in Table 2. The control group played a version of the online game in which participants were given access to their travel distances after each round; however, a spaghetti diagram was not made available to them.

Although the improvement in travel distance for participants using the spaghetti diagram was not statistically significant, data analysis revealed that the experimental group was more successful in identifying an optimized layout for the kitchen. Specifically, 70% of the experimental group participants chose layout C, compared to only 30% of the control group participants. This suggests that the spaghetti diagram was effective in helping participants understand that layout C, which involves placing the sink and stovetop closer together, would reduce wasted transportation and motion (as measured by travel distance).

Results of the paired t-test results are as follows:

The two-tailed P value equals 0.1261. This difference is not considered statistically significant. Therefore, the null hypothesis cannot be rejected and a spaghetti diagram of the cook's path did not help the participants improve their performance;

The mean of the Control Group minus the Experimental Group equals 5.63; and

A 95% confidence interval of this difference is from -1.633 to 12.96.

To further illustrate this point, Figures 4 and 5 depict examples of spaghetti diagrams that experimental group participants saw after playing each round. The spaghetti diagram in Figure 4 shows a total travel distance of 53.07 units for layout A, where the stove is located further from the sink. In contrast, the spaghetti diagram in Figure 5 shows a total travel distance of 42.89 units for layout C, where the stove is located close to the sink.

Interestingly, data analysis showed that layout C was the only layout where participants could minimize their travel movements. Moreover, the best performance among participants came from a participant in the experimental group. To determine the significance of this result, a Chi-Square test was performed, resulting in a chi-square statistic of 9.6 and a p-value of 0.001946. This indicates that there was a significant difference between the experimental and control groups in terms of choosing layout C, as shown in Table 3.

Figure 1: Spaghetti Kitchen Online Game (Control Version)

Figure 2: Spaghetti Kitchen Online Game (Experimental Version)

Figure 3: Stovetop Layout Options Given on Both Experimental and Control Versions.

Table 1: Online Game Participants and Dates

1	Students	37 graduate students taking COSC663 (Sustainable Construction) at Texas A&M University.	09/22/2022
		15 masters and PhD students from the Department of Construction Science at Texas A&M University	09/28/2022
2	Lean experts	8 Lean Experts from APLSO*	10/03/2022
		*Administering and Playing Lean Simulations Online (APLSO) is a voluntary, international online lean construction group that tests and gives feedback on novel online lean simulations.	

Table 2: Comparison of mean travel distances between control and experimental groups

	Group A (Control)	Group B (Experimental)
N	30	30
Mean	-5.2253	-10.8617
Standard Deviation	12.0122	15.8546
Standard Error of the Mean	2.1931	2.8946

The experimental group participants were asked to provide feedback on how they used the spaghetti diagram to identify strategies to improve their performance. The responses provided valuable insights into the benefits of using the spaghetti diagram, including:

Identifying and focusing on long travel distances;
Visualizing their movements through the spaghetti diagram;
Recognizing the importance of having utensils, stove, and sink located closer to each other to reduce unnecessary time and space requirements;
Optimizing the layout by placing the stove closer to the sink;
Organizing the retrieval of items in a logical order based on distance traveled;

Gaining a better understanding of their displacement and movements through the geometry of the spaghetti diagram and the repetitive lines, which showed where more attention was needed;

Designing a better path to improve their workflow; and

Identifying and eliminating wasteful movement.

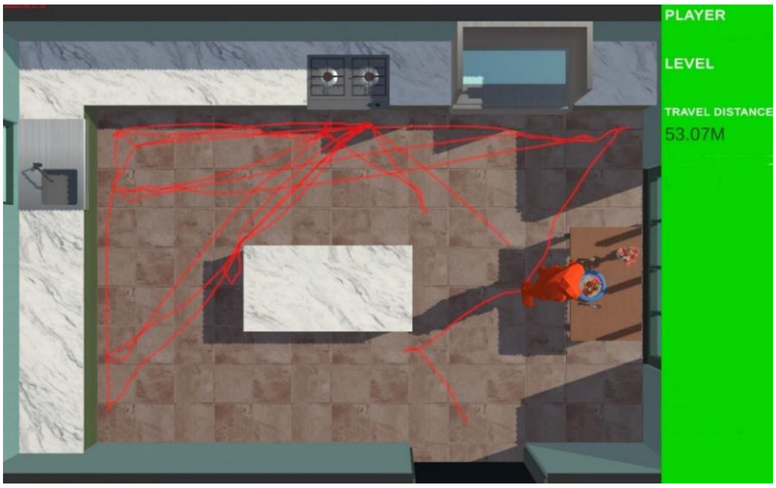

Figure 4: Example of spaghetti diagram in layout A.

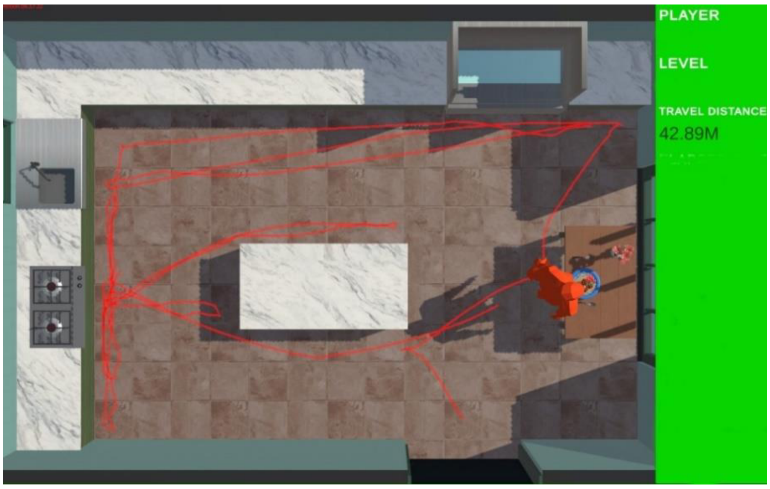

Figure 5: Example of spaghetti diagram in layout C.

Finally, feedback from participants of the online game was collected and examples of feedback included: *Plus*: Engaging graphics, fun to play, intuitive, useful; *Delta*: Add more options for rearrangement of appliances and create next stage of this game for construction.

Table 3: Number of times layout C was chosen by participants.

Type	Layout C	Other Layouts	Row total
Experimental Group	**21**	**9**	**30**
Control Group	**9**	**21**	**30**
Totals	**30**	**30**	**60**

These findings underscore the potential benefits of using spaghetti diagrams in optimizing workflow and reducing waste in a variety of contexts. Although further research is certainly needed to fully explore their impact, the study provides potential insights into their effectiveness in the context of layout optimization.

DISCUSSION

There are certainly limitations to this research. For example, different participant groups were combined due to time and resource limitations, and the sample sizes were relatively small. The researchers did not ask participant to share their background so there is no knowledge about which players may have more experience with Lean and waste identification than others. Another limitation of the research itself is that the game was primarily tested on university-level graduate students who plan to enter the construction industry. As such, the research represents a first-run study. Further research with on-site construction workers and project managers is needed to validate the simulation's effectiveness within the construction industry.

There are limitations with the currently designed game as well. For example, the designed online game cannot be played until the rules and instructions are explained to players. Instructions can certainly be shared through a pre-recorded video, for example, but there are benefits to having a live facilitator assist participants who may need additional guidance regarding moving and interacting with the objects. Playing should be followed up with discussions about potential applications to actual construction scenarios as the intent of using a commonly shared activity such as making spaghetti is to introduce participants to a fundamental lean concept that then can be applied to a task to which many participants can relate. For example, by using a software program, steel girders can digitally replace packages of spaghetti and cranes can easily be swapped with stove tops.

The ultimate goal of this work is to help users heighten their awareness of ways to improve workflows using the online game as a preliminary training tool to expose participants to their own movements. The intent is to help them self-identify wasted movement and therefore opportunities for productivity improvement when performing their own work. Because they are automated and internet-accessible, both the video and online simulation game offer the possibility of expanded geographic reach to potentially exceed what physical, in-seat simulations can do. This can offer a substantial benefit to multinational companies seeking to simultaneously train personnel in different parts of the globe.

CONCLUSION

Results from this research suggest that spaghetti diagrams, and other alternative ways to map construction processes, may be effective in increasing awareness of waste reduction and improving performance among those trained in the construction industry. There are opportunities for future research, including investigations into the applications of this simulation to actual construction scenarios. This could involve tracking and recording movements of workers or equipment and projecting them onto the ground in the shape of a spaghetti diagram for visual observation.

By adapting the online simulation game to depict construction activities on an actual project, with locations for material delivery, logistics, and laydown areas, there is potential to further enhance the game's effectiveness. Additionally, designing and testing the game in a three-dimensional (perspectival) view instead of a two dimensional (plan) view could provide valuable insights into its intuitiveness and effectiveness for those practicing in the construction industry. Overall, these findings offer exciting possibilities for future research and innovation in this field.

ACKNOWLEDGMENTS

The authors express their appreciation to the students of COSC 663 (Sustainable Construction), and MSCM and PhD students from Department of Construction Science at Texas A&M University, and the international research community of APLSO (Administering and Playing Lean Simulations On-Line) for their valuable feedback that helped in the continuous improvement of the Spaghetti Kitchen simulation.

EXPLORATION OF EDUCATIONAL BACKGROUNDS, PERSONALITY TRAITS, AND GENDER ON TENDENCIES TO COLLABORATE AMONG OWNERS, ARCHITECTS, ENGINEERS, AND CONTRACTORS

Vishnu Ramanath[1] and Zofia K. Rybkowski[2]

ABSTRACT

The construction industry is challenged by a lack of collaboration and trust, leading to an adversarial relationship among project stakeholders. With the introduction of Lean-Integrated Project Delivery (IPD) processes, collaboration has become a key strategy for increasing productivity. This research leveraged game theory and the Maroon-White simulation to explore whether there is any correlation between the educational background of owners, architects, engineers, and contractors and their tendencies to collaborate. It also explored whether there is a correlation between tendencies to collaborate based on various personality types as measured by Jung/Isabel Briggs Myers typology. Although results from this research are preliminary, university students studying to enter the OAEC stakeholder practices (Owner Architecture Engineering and Construction) showed similar rates of tendencies to collaborate. Correlation with personality types was inconclusive. However, multiple rounds of play often revealed long-term negative impacts when one team betrayed a collaborative agreement for its personal benefit. Also, although teams with females did not significantly modify the numerical results, facilitators noticed that women often openly voiced that a collaborative strategy would gain the most points, yet their suggestions tended to be dismissed by teammates. Further research is needed in this area.

KEYWORDS

Lean Construction, Maroon-White Game, simulation, integrated project delivery, IPD contract, collaboration, trust, betrayal, personality traits, gender.

INTRODUCTION

The construction industry is confronted by challenges such as a paucity of collaboration and trust, ineffective communications, and a lack of systems thinking. These attitudes are arguably partly responsible for adversarial relationships between Owner, Architecture, Engineering, and Construction (OAEC) [3] stakeholders (Elmarsafi 2008). Collaborative friction can lead to project delays, difficulty in resolving claims, cost overruns, litigation, and a win-lose climate that affects

[1] Graduate Student, Department of Construction Science, School of Architecture, Texas A&M University, College Station, TX, USA, vishnuramanath@gmail.com

[3] The acronym OAEC is used here instead of the more typical AECO to refer to Owner Architect Engineer and Contractor stakeholders. The (re)ordering is intentional to acknowledge the primary focus of the team in Lean-IPD is to align with the Owner's needs.

all the project stakeholders. It is therefore worthwhile to explore tendencies toward collaboration or non-collaboration among students who are being educated to enter OAEC-related practices.

Research shows that with the evolution of construction projects from Design-Bid-Build[4] to the Design-Build[5] and Integrated-Project-Delivery[6] (IPD) methods, the need for collaboration is high. Shelbourn et al. (2007) argues that with advancing methods, it is time for the construction industry to embrace new ways to improve productivity, mitigate litigations, and to deliver at its best the demands of the Owner. Also, the construction industry's success depends on the collective efforts of players from different companies and backgrounds. To achieve this, collaboration and trust among key players in the industry are critical.

Research suggests that for the implementation of Lean-IPD, collaboration plays an important role (Smith 2013). With lean manufacturing principles giving rise to lean construction, IPD processes have helped to improve collaboration levels among different key players (Mesa et al. 2019). Yet even with the implementation of IPD, lack of trust and collaboration among stakeholders still exists. One possible reason for deficits in collaboration is the uniqueness of each construction project; repeating partnerships do not happen often. Also, natural competitive tendencies can often spur on sub-optimization and subsequent long-term losses (Smith and Rybkowski 2013).

The objective of this research was to investigate the potential influence of the educational background of owners, architects, engineers, and contractors on tendencies to collaborate in the construction industry. Also, based on the assumption that extroverts may tend to collaborate more than introverts, the research attempted to determine whether this is true in the case of OAEC disciplines. Finally, the research serendipitously explored whether, when in competitive teams, women tend to collaborate more than men.

SIGNIFICANCE OF THE STUDY

Collaboration plays an important role in the success or failure of Lean-IPD. An understanding of cultural and educational tendencies towards collaboration or non-collaboration of stakeholders offers a glimpse into factors that might facilitate or impede collaboration. For example, by understanding if there are disciplines that have lower tendencies to collaborate, a college curriculum can be structured to address the importance of collaboration. Optimization of the whole over the parts is one of the key tenets of lean, and stakeholder understanding of it facilitates implementation of IPD.

THE NEED FOR INTER ORGANIZATIONAL COLLABORATION

Collaboration has been defined as the process of shared decision-making among independent parties, involving joint ownership of decisions and collective responsibility for outcomes (Boyle and Kochinda 2004). Collaboration includes supporting sustained teamwork by creating a culture that values personal integrity, giving power and respect to each person's voice, integrating individual differences, resolving competing interests and safeguarding the essential contribution each must make to achieve optimal outcomes (Sterchi 2007). To become successful at a job it is necessary to coordinate with others (Johnson and Johnson 2004). Collaboration can be the key to overcoming work-related obstacles (Vygotsky 1978).

Basic essential characteristics of a group setting should include the following: cooperation, conversation, teamwork, confidence and coherence (Greenlee and Karanxha 2010). Constructive conversation tends to bond team members together. Sarker et al. (2011) concluded that better interactions lead to higher levels of achievement.

---

[4] Design and construction are separate contracts; lowest construction cost is the criteria for final selection (Kenig 2011)
[5] Design and construction contracts are combined (Kenig 2011)
[6] Key parties are involved from the inception of the project and use a multi-party contract (Kenig 2011)

Inter-organizational collaboration has been shown to create a strategic advantage in most industries. According to Schifrin (2001), strategic alliances are a common business strategy in the US with 10,000 partnerships being created each year. In an industry such as construction, the conditions for the practice of inter-organizational collaboration are ripe. Opportunism by team players is readily available in most construction projects and generally comes at the expense of the other players or the project as a whole (John 1984). Research has also identified trust as one of the most effective ways to prevent opportunism (Walker 2003). When group members are familiar with one another, it can lead to an improved team environment, which shows tendencies to collaborate (Janssen et al. 2009; Stark and Bierly 2009). Inter-organizational collaboration has been studied across industries and has been shown to increase organizational capabilities and value generation through exchange of resources—thus contributing to an organization's competitive advantage (McEvily et al. 2003).

INTEGRATED PROJECT DELIVERY (IPD)-COLLABORATION

Integrated Project Delivery (IPD) is defined as a "project delivery approach that integrates people, systems, business structure and practices into a process that collaboratively harness the talents and insights of all participants to optimize project results, increase value to the owner, reduce waste and maximize efficiency through all phases of design, fabrication, and construction" (AIA 2007). IPD, in contrast to the traditional method of delivery, integrates all key players from the project's inception. It leverages early contributions and expertise through utilization of new technologies, allowing all team members to add value and to realize their potential for contributing to the project. IPD seeks to improve project outcomes through a collaborative approach of aligning the incentives and goals of the project team through shared risk and reward, early involvement of all parties, and a multiparty agreement (Kent and Becerik-Gerber 2010).

Collaborative working is considered by many to be essential if design and construction teams are to consider the whole lifecycle of the construction process (Shelbourn et al. 2007). Inherent within this agenda of new ways of working is a move toward collaborative working and its associated fields: concurrent engineering and lean production (Anumba et al., 2004). Collaboration is essential if design and construction teams are to address the entire lifecycle of the construction product and take account of not only primary functionality but also productivity, buildability, serviceability, and even recyclability (Kusiak and Wang, 1993). Cooperative relationships among the supply chain actors (referred to as partnering) are an important element of lean construction (Naim and Barlow, 2003; Green and May, 2005; Jorgensen and Emmitt, 2008), facilitating the integration of different actors' competences and efforts toward joint problem-solving. At the core of IPD are collaborative, integrated and productive teams composed of key project participants (AIA 2007, Mesa et al. 2019). Guided by principles of trust, transparent processes, and effective collaboration, the IPD teams build upon early contributions of an individual's expertise.

New technologies when utilized in conjunction with collaborative processes are demonstrating substantial increases in productivity and decreases in requests for information, field conflicts, and other forms of waste (AIA 2007). AIA claims Integrated Project Delivery is built on collaboration, which in turn is built on trust. With better collaboration, the key players focus more on the success of the project rather than on individual goals. Without collaboration, IPD will falter, and participants will remain in the adverse and antagonistic relationships that plague the construction industry (AIA 2007). Kulkarni et al. (2012) discovered that collaborative project delivery systems produce more reliable cost outcomes for public owners. One of the factors that can undermine implementation of IPD is fear of loss of individual interest. Huxom (1993) claims that the key disadvantages of collaboration are loss of control, flexibility, and glory. Despite these disadvantages, however, the benefits of collaboration override the disadvantages (Huxom 1993).

EDUCATIONAL INFLUENCE ON TENDENCY TO COLLABORATE

Collaboration has been studied substantially in a variety of fields. Borrego (2006) claims that engineers tend to view collaboration as an isolated division of labor and the views on collaborative relationships vary markedly between technical and social science fields. Also, Borrego et al. (2008) observed that the way an individual understands and appreciates the nature of knowledge affects the way he or she collaborates with colleagues in different academic disciplines. According to Lin and Darnall (2015), some organizations find it difficult to configure alliances for mutual benefit, resulting in the failure of half of strategic alliances.

With the advent of IPD, inter-organizational collaboration plays an important role. AIA claims that without collaboration IPD fails. In recent decades, collaborative working has focused on the delivery of technological solutions (Faniran et al. 2001; Karasu et al. 2022). There is a need for research on the human-related factors influencing the level of collaboration among the project stakeholders.

Borrego (2008) observed that the way an individual appreciates the nature of knowledge affects the way he or she collaborates with colleagues in different academic disciplines. Much of the research on the topic of influence of educational background on the level of collaboration has been conducted in the fields of health care, engineering, and social science. For example, Stacy (2007) claims that nurses have a better collaborative approach than physicians.

WOMEN AND TENDENCY TO COLLABORATE

According to research literature, women tend to be less competitive than men. Gneezy et al. (2003) found that women were less effective than men in competitive environments, despite the fact that their performance was similar to that of men in a non-competitive environment. Niederle and Vesterlund (2007) concluded that women tend to shy away from competition. In terms of group processes, Woolley et al. (2010), concluded that group collaboration is greatly improved by the presence of women in a group. In a study of group performances, Fenwick and Neal (2001) found that, on a management simulation task, groups with a greater number of women performed better than homogeneous groups.

In a meta-analysis comparing men and women in terms of task and interpersonal styles, Eagly and Johnson (1990) found that women were significantly more interpersonally oriented than men. The styles of males tend to be more autocratic than those of females (i.e., giving orders), whereas the styles of females tend to be more democratic than those of males (i.e. focus is on participation). In addition, when comparing all-female versus all-male groups, all-female groups demonstrate more egalitarian behaviors, such as equal amounts of communication among group members and shared leadership (Berdahl and Anderson 2005). While these findings may be undergirded by physiological and hormonal differences between males and females, results may also vary according to context and cultural practices.

GAME THEORY: PRISONER'S DILEMMA AND THE MAROON-WHITE GAME

The Prisoner's Dilemma has been defined as a paradox in decision analysis in which two individuals acting in their own best interest pursue a course of action that does not result in the ideal outcome. The typical prisoner's dilemma is set up in such a way that both parties choose to protect themselves at the expense of the other participant. As a result of following a purely logical thought process to help oneself, both participants find themselves in a worse state than if they had cooperated with each other in the decision-making process. The exercise explores the conflict between social incentives to compete versus those encouraging cooperation (Holt and Capra 2000). Research shows that when given the option to cooperate with another party or look out for one's own best interests, barring additional incentives, the selection of a cooperative move is unlikely (Axelrod 1981; James Jr. 2002; Smale 1980).

The Maroon-White Game is an example of prisoner's dilemma. The Maroon-White Game is a three-group non-zero-sum game. A non-zero-sum game describes a situation where one team scoring points does not necessarily mean that fewer points are available for the other teams (Von Neumann and Morgenstern 2007). This type of game is commonly used in situations where cooperation between teams is a possibility.

This study used the simulation, the Maroon-White Game (Smith and Rybkowski 2013), to explore whether the educational backgrounds of four different stakeholders (owners, architects, engineers and contractors) influence their tendencies toward collaboration. The Maroon-White Game helps reveal whether individualism is favored over collectivism or vice versa in an organization and in the industry in general. This research also explored whether women have a higher tendency to collaborate when compared to men and whether specific personality types as defined by the by Jung/Isabel Briggs Myers Typology test are more or less likely to collaborate.

RESEARCH METHODOLOGY

INTRODUCTION

This research asked the following question: Is there a correlation between educational background and tendency to collaborate (TTC), specifically among those preparing to enter OAEC practices following graduation? Also: Does personality type, defined by the Jung/Isabel Briggs Myers Type Indicator, make a difference? Does gender? To address these research questions, researchers invited fourth year undergraduate students at Texas A&M University to participate in the Maroon-White Game (Smith and Rybkowski 2013).

DATA COLLECTION

Courses at Texas A&M University in the four disciplines of Business, Architecture, Engineers, and Construction Science representing the Owners, Architects, Engineers, and Contractors in the construction industry were selected for participation.

A recruitment email was sent to instructors of courses in these disciplines asking their permission to administer the game in one of their classes. Participants were asked to sign off on an informed consent form, required by the Institutional Review Board (IRB of Texas A&M University). The game was administered to two (2) senior-level business classes, one (1) graduate-level business class, three (3) senior-level architecture classes, two (2) senior-level construction science classes, and one (1) senior-level civil engineering class. Also, the game was played with members of one (1) construction company during a separate facilitation.

RESEARCH TOOL: THE MAROON- WHITE GAME

Simulation games are commonly used for research and teaching in the field of Lean-IPD (Bhatnagar et al. 2022). The Maroon-White game was used to address the stated research questions and played according to instructions in Smith and Rybkowski (2013). The Maroon-White Game was derived from the Red-Black Game outlined on the College of St. Benedict website (CSB-SJU n. d.) and was facilitated as follows: The facilitator divides participants into three teams: A, B, and C, and writes a score chart (Figure 1) on a chalkboard, flip chart, white board, etc. or projects the chart on a wall for everyone to see. Each team is given two cards written with "M" (maroon) and the other with "W" (white). Teams are instructed to discuss their decision to simultaneously hold high either the M or W card when instructed to do so. The facilitator repeats only one phase: "The object of the game is to gain the maximum number of points." Participants successively play seven (7) rounds and after each round the score is recorded. Teams are permitted to send an ambassador to negotiate with the other teams' representatives starting from Round 3. If participants ask whether the maximum number of points is for the total group or individual teams, the facilitator simply states "both," and repeats: "The object of the game is to gain the maximum number of points."

If all teams declare "white" by the third round, the facilitator can invite each team to send an ambassador for a few minutes outside the room to negotiate on their behalf. The game is finished after seven rounds of play.

Figure 1: Maroon-White Game Scoring Chart

Discussion following play included asking the following questions: What is the best way to maximize your points? What did you learn from this game? How did a betrayal (if any) affect your decision as a team? Once the trust is lost by selecting white, what effect did it have on you as a participant? How can this game be applied to construction? What factors affect one's ability to maximize points?

For this study, the number of female participants and personality types was collected. The researchers acknowledge that the Jung/Isabel Briggs Myers Typology Test is just one of several recognized personality tests; however, as it is widely known and used, the test was selected and virtually administered to participants before the game as one way to determine the personality type of the participants. The test defines 16 personality types made from the following combinations: E (Extraverted) vs. I (Introverted); N (Intuitive) vs. S (Sensing); F (Feeling) vs. T (Thinking); J (Judging) vs. P (Perceiving) (Human Metrics n. d.).

DATA COLLECTION & ANALYSIS

Data collected included:

- TTC (Tendency to Collaborate) = (Number of Maroon Responses ÷ Total Number of Responses) *100
- The percentage of women in each team
- The percentage of extroverts per team.

The left and right tallies in Figure 2 represent the worst and most-commonly observed scenarios, respectively. The middle tally shows the results if the teams pursued a collaborative approach. If the teams collaborate in each round, the maximum points that each team could gain is 350–and the total points would be 1050. A fully collaborative approach maximizes both the individual team points and total points. Teams play seven (7) rounds to mimic a potential real-world scenario where individuals elect to trust or not trust other individuals and teams, based on prior experience with those actors.

Table 1 lists the average TTC observed for Business Seniors, Business Graduates, Construction Science Seniors, Civil Engineering Seniors, Architecture Seniors, and the construction company. Figure 3 compares their TTC, showing similar rates of TTC per discipline. TTC is the lowest for the construction company when compared to the average TTC across Business Seniors, Business Graduates, Civil Engineering Seniors, Construction Science Seniors, and Architecture Seniors at Texas A&M University. Teams A and B consistently declared white, while team C frequently declared maroon. The low TTC among many members of the construction company may be attributed to the fact that teams A and B worked daily with subcontractors on low bid projects and so were unwilling to extend trust (according to teams A and B) while team C was composed entirely of estimators who stated they trusted one another.

The average TTC for all the academic disciplines was found to be 36.34% and the TTC for the construction company was lower than the than the average TTC among disciplines by 12.54%.

Comparing only the disciplines across Texas A&M University, it can be observed from Figure 3 that the architecture senior students had the highest TTC with 39.15%. The business graduates and the civil engineering seniors had the second highest TTC with 38.09%. Construction Science seniors had the third highest TTC with 37.80%. The business seniors had the lowest TTC when compared to all the other disciplines with TTC of 28.56%, however this may simply reflect natural variation. Ultimately, there was no evidence that the level of collaboration is influenced by educational background. To verify whether gender plays any role in levels of collaboration, the percentage of females per team was calculated and their TTC was plotted in scatter plot. Figure 4 shows the scatter plot of percentage of women per team and their TTC.

TTC (left to right): (0/21) = 0% ; (21/21)*100 = 100% ; (6/21) = 28.5%

Figure 2: Possible Combinations and Commonly Observed Results.

Table 1: Disciplines and Their Average TTC (Tendency to Collaborate)

Group tested	No. of participants	TTC (mean %)
Business Seniors	44	28.57
Architecture Seniors	43	39.15
Construction Science Seniors	35	37.80
Business Graduates	16	38.09
Civil Engineering Seniors	14	38.09
Construction Company	13	23.80
	165	34.25

Note: The full set of results data for this research is available at Ramanath (2014). The mean TTC of student teams was 36.34%.

Because the percentage of female participants in each team was small (24% on average), it cannot be concluded that there is a difference in the level of collaboration based on the gender (Figure 4). However, if the women on the teams (the minority) had an intention to collaborate there is a possibility that the men on the teams (the majority) who did not wish to collaborate dominated. For example, it was observed that, in several instances, the individuals who suggested to collaborate while playing this game were females who were silenced, and their recommendation dismissed by teammates. We do not know whether the results would have been different had the teams been composed primarily of women. This needs to be further tested with larger sample sizes.

To verify whether the personality types play a role in the tendency to collaborate, the percentage of each personality type in each team was calculated and its TTC graphed in a scatter plot. From Figure 5 it can be seen that there is no significant statistical evidence to show that extroverts, intuits, feelers, and the judgers have a better tendency to collaborate when compared to the introverts, sensors, thinkers and feelers respectively. However, it cannot be concluded that personality types do not influence the tendency to collaborate. To validate the results, more research needs to be done on the personality traits and their influence on tendency to collaborate.

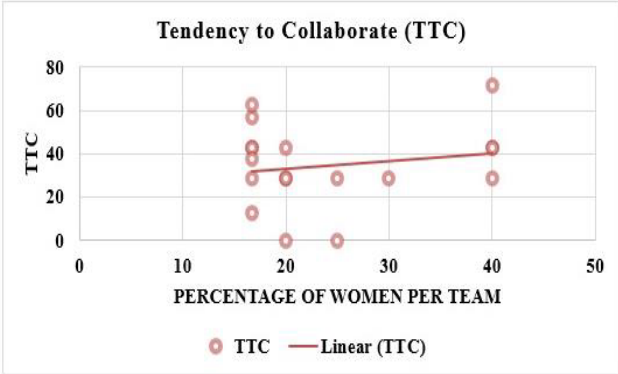

Figure 4: Percentage of Women per Team and Their TTC-Scatter Plot

DISCUSSION

A majority of the OAEC students from Texas A&M University appeared driven by competition during the initial rounds of the Maroon-White Game. It was observed they had an attitude of individualism over collectivism. It appears that natural competitive tendencies can often result in sub-optimization and long-term losses (Smith and Rybkowski 2013) and that these tendencies held true for the games administered. Researchers observed that an inability to collaborate with other teams prevented potential gains both in the short- and long-term. There seems to be a natural proclivity not to trust other teams in a competitive environment. The majority of participants chose "white" as their first choice during the game as they did not initially perceive the numerical benefit of collaborative thinking. Also, it was seen that the tendency to betray was often highest after gaining trust from other teams that agreed to declare "maroon." In other words, one team would often betray the other two teams even after all agreed that they would choose maroon. Subsequent to a betrayal, the other two teams would refuse to place themselves in a situation where they might be taken advantage of again, ultimately reaching the point where all three teams selected "white" during each round; teams even openly stated their intentions of doing so indefinitely. In fact, in only one (1) out of the ten (10) trials were teams able to regain collaboration following a betrayal. Because it is played in multiple rounds, the Maroon-White Game can be used to demonstrate to participants how natural tendencies to sub-optimize can substantially and negatively impact long-term gains, trust, and collaboration.

An unexpected outcome from observations of the M/W Game is that a formal, legally enforceable IPD contract is potentially preferable as it can help protect those who act with the expectation that others are trustworthy. This is because the "most common scenario" shown in Figure 2 illustrates how frequently one team chose to renege their verbal commitment to collaborate; most teams refused to collaborate during subsequent rounds following a betrayal. This recommendation differs from the partnering agreements popular in the 1990s where signed partnership agreements represented intentions to collaborate but did not hold legal standing.

Although this game is not an exact simulation of project delivery processes, it can arguably mimic the typical mindset of industry stakeholders and depict their typical decision-making processes. As discussed earlier, once the game was completed and outcomes discussed, a majority of participants agreed that collaborating maximized points and that they were sub-optimizing by not collaborating. The initial lack of trust and the betrayal impacted future decisions. This outcome demonstrated the need to develop sustained long-term relationships in the industry, and an integrous reputation to undergird trust. This game demonstrates that the tendency to sub-optimize can damage the development of a long-term sustained relationship. Interestingly, when Gandhi (2014) used the M-W game to test TTC of architecture students, he found a slight drop in students between their first and fourth year, suggesting a possible erosion of trust over time. Similarly, in this study, those working for a general contractor showed a lower TTC than the university students; this may also represent a further decline of trust once stakeholders enter the industry. Also, with respect to the general contractor, two of the three teams that worked daily with subcontractors[7] in the field argued their work "taught them never to trust" which helped explain, they said, why they insisted on declaring "white" and never "maroon" throughout the game. The only team that showed any tendency to collaborate explained that they were all estimators for the same company, so were accustomed to extending a level of trust between themselves.

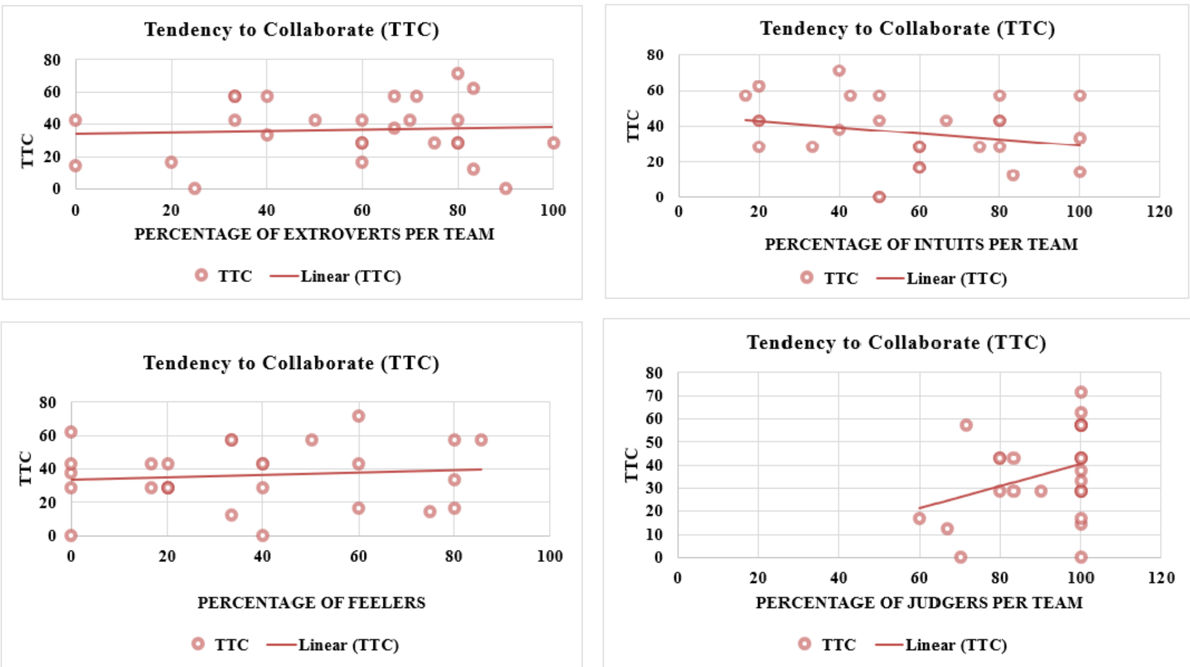

Figure 5: Percentage of Extroverts, Intuits, Feelers, & Judgers per Team and Their TTC

One important lesson from the game is that collaboration is important for sustaining long-term relationships. During the post-game discussion, participants stated the following factors that affected their tendency to collaborate: Absence of trust; lack of proper incentives; past experience; fear of betrayal; personality types; competitiveness; not seeing the long-term benefit; cultural differences; not knowing people enough or lack of a previous relationship; and favoring capitalism.

Recommended countermeasures to improve collaboration in the construction industry included: Change of mindset by playing games such as M-W; collaborative project delivery methods such as IPD; early negotiations; early and constant communication among stakeholders; setting expectations among stakeholders and informing them; mutual respect; and sustainment of long-term relationships to develop trust.

There were of course limitations with this exploratory research. For example, personality profiles of teams were collected in aggregate and individual correlations were not tracked per se. Also, prior collaborative work experience of participants was not tracked. Finally, larger sample sizes are needed to achieve statistical significance.

---

[7] The term "subcontractor" is used here rather than the preferred term "trade partner" because the former was the term used by the general contracting company that did not practice Lean-IPD at the time of play.

CONCLUSION

This research investigated the tendency to collaborate among different disciplines. The average TTC's for business seniors, architecture seniors, engineering seniors and the construction science seniors were found to be 28.57%, 39.15%, 38.09%, and 37.80% respectively. The average TTC of business graduate students was found to be 38.09%. The architecture seniors had a higher TTC compared to all other disciplines. However, overall differences in TTC were not highly significant.

Of special interest is the observation that an actual construction company had a lower TTC than the average of student groups tested. It would be helpful to study this phenomenon further to determine whether the outcome is generalizable to include other general contractors and if so, why this might be so. Finally, how might contractors perform that are already accustomed to Lean?

This research also provided a platform to verify whether gender influences tendencies to collaborate. Based on numerical results, it appeared that gender did not appear to have an influence on tendency to collaborate. However, these final numerical outcomes were at odds with facilitators' observations that several females attempted to recommend collaboration during play, but their recommendations were often dismissed or ignored. Further research in this area is worth pursuing.

This research also explored whether personality types play a role in the tendency to collaborate. By comparing the percentage of extroverts, intuits, feelers, and judgers in each team to their TTC, there was no statistical evidence to conclude that personality types have an influence in the tendency to collaborate. However, further research is required to statistically validate the results.

Finally, the research revealed the corrosive effect of a single betrayal on the decision of the other teams to continue to collaborate. Recovering to a state of collaboration and trust seemed extremely difficult as only in one case out of ten were the teams able to collaborate fully once trust had been betrayed.

Opportunities for additional future research include exploring how the M/W game might be used to identify readiness of teams for IPD. It would be worth investigating if the game can help heighten awareness among project team members about the benefits of developing a more collaborative mindset before embarking together on an actual Lean-IPD project. It would also be valuable to systematically test to see if there may be generalizable differences in the tendency to collaborate between females versus males.

OVERCOMING THE BARRIERS TOWARD WIDESPREAD ADOPTION OF PREFABRICATION: AN APPROACH INVOLVING EMERGING TECHNOLOGIES

Tran Duong Nguyen[1] and Pardis Pishdad-Bozorgi[2]

ABSTRACT

Today, prefabricated construction is rapidly expanding due to the development of factory-prefabricated components, fast construction site assembly, and sustainability. Despite the advantages, there are several problems, such as a lack of process standardization, poor communication and coordination, a lack of variety and transportation logistics, and a lack of trust and collaboration among stakeholders. Fortunately, the successful evolution of emerging technologies has facilitated growth in the building sector. By implementing literature reviews, this research aims to understand better the issues disrupting the widespread adoption of prefabricated construction and integrate innovative solutions and approaches to these issues. We will discuss prefabricated construction and its applications within the building sector by (1) comparing it to conventional construction method; (2) investigating the advantages and barriers toward widespread adoption of prefabricated construction; (3) developing an approach for applying advanced technologies in prefabrication, and (4) applying an approach to demonstrate how prefabrication overcomes conventional building issues. Our research suggests that an integrated approach combining advanced technologies during the prefabrication process will help solve the most significant problems that construction projects face, such as productivity, quality, safety, and sustainability. Additionally, the integration will provide a promising strategy to transform the construction industry from traditional to industrial.

KEYWORDS

Prefabrication, modular construction, off-site construction, Building Information Modeling, Blockchain.

INTRODUCTION

Modular or prefabricated construction is one of the advancing breakthroughs in the construction industry (NIST, 2015). However, the outcome could be more encouraging due to a lack of standardization, poor communication, a lack of collaboration among stakeholders, and the complexity of transportation logistics (Z. Zhang et al., 2022). One of the main reasons that holds back the advancement and widespread application of modular construction is the need for more standardization (Razkenari et al., 2020). However, most modern buildings attempt a complex and innovative design. These designs need further preparation and customization (Eastman et al., 2011). Due to their lack of industry experience, most modular construction companies need

[1] Ph. D student, Georgia Institute of Technology, Atlanta, Georgia, United States, dnguyen458@gatech.edu, https://darch221.wixsite.com/nguyentranduong, 0000-0002-0024-4828

[2] Ph. D, Associate Professor, Georgia Institute of Technology, Atlanta, Georgia, United States, pardis.pishdad@design.gatech.edu, https://bc.gatech.edu/people/pardis-pishdad-bozorgi, 0000-0003-4208-9755

assistance learning what is required on-site and how to proceed throughout the manufacturing phase. Moreover, there are several contracts because of the complexity and the many stakeholders involved in prefabrication (Razkenari et al., 2020). Also, their complexity has created confusion over time. The builders and suppliers keep facing their challenges and creating coordination and trust is a new challenge.

An answer to the need for coordination and trust among stakeholders in traditional construction practices has been the Integrated project delivery (IDP) method, along with a single Smart contract between various stakeholders. The same approach can be applied to solve a distinct set of problems in the modular construction approach since the foundation of these problems still needs coordination and trust among stakeholders. Technology such as BIM is commonly used to design projects. However, one critical approach is integrating the supplier and design teams right from the start so the feasibility of building the prefabricated blocks can be quickly done. The complexity of numerous contracts has limited each stakeholder's capacity and left no space for transparency. A single contract signed by all suppliers and builders prior to the start of the project is one solution.

Among construction technologies, BIM and Blockchain stand out as reliable and complete methods in construction because it is a potential instrument that helps stakeholders understand the advantages of prefabricated construction, allowing them to have better control. In conducting this review, this research attempts to answer the following key questions:
RQ1: What is the current state of prefabricated construction in research-related fields?
RQ2: What are the advantages and barriers of prefabricated construction compared to traditional building methods in terms of advanced technologies?
RQ3: What are the technological advancements or solutions in prefabricated construction from a research perspective?
RS4: How might emerging technologies promote prefabricated construction from a research standpoint?

The successful approach and widespread adoption of technology in prefabricated construction are the most promising strategies for transforming the construction mode from traditional to industrial. The purpose of this research is to examine the current barriers that are holding the prefabricated construction approach back and to bring solutions to those challenges using innovative technologies such as BIM and Blockchain. The authors hypothesize that advanced technologies assist in problem resolution in prefabricated construction.

METHODOLOGY

The authors conducted a literature review to find relevant data on the uses of emerging technologies as a solution to the barriers toward the widespread adoption of prefabrication. This study's methodology provides a set of data analyses to present the qualitative approach through concepts, experiences, and insight into scholarly publications. Initially, data was gathered from a variety of sources. The original search keywords are prefabricated construction, modular construction, off-site construction, emerging technology, Building Information Modeling, BIM, Blockchain, etc. The initial literature review identified research gaps and emerging trends in the construction industry's relevant modular or prefabrication topics. This step helped the researchers become familiar with the current state of knowledge and the constraints of a particular topic.

Additionally, the literature review attempted to answer the research questions raised below about applying technologies in prefabrication. The study provided basic knowledge on the uses of emerging technologies to solve the challenges in the prefabricated construction method and developed an approach for the data analysis. The research approach was used as a filter in the decision support framework, which will assist researchers in choosing technology for review. Lastly, the research applied the integrated approach for the applications of advanced technologies jointly to the prefabrication methods as a solution to the challenges that are consequences of the traditional construction methods, including BIM and Blockchain. The study delivered a research concept schema or a roadmap for academic researchers to analyze and discuss technologies using the suggested approach.

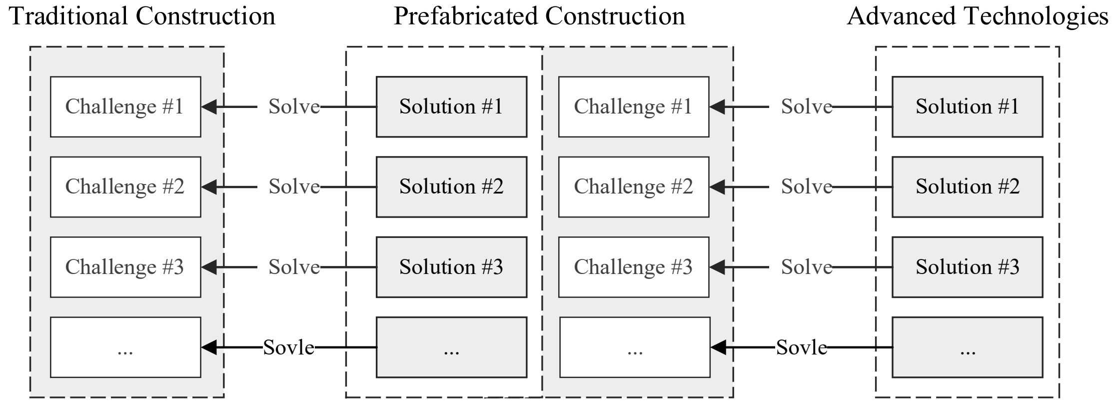

Figure 1: Proposed research conceptual schema

RESEARCH BACKGROUND

Several problems occur in the traditional construction method, one of them being sustainability, as 2.2 billion tons of construction waste are generated globally, of which 600 million are in the USA (*BigRentz*, 2021). Nearly 30% of all material delivered to the site ends up in the landfill. Construction costs rise, delays occur, and 98% of all construction projects incur cost overruns or delays (Tafesse et al., 2022). Time delays, productivity, and weather account for 60% of cost overruns (*Weatherbuild*, 2018). Safety is one factor that needs to be thoroughly enhanced regularly on the construction site, and it does not depend on physical health but on mental health. Noise pollution is abundant; 51% of all construction workers have experienced dangerous noise exposure, and approximately 14% of laborers have a hearing impairment (NIOSH, CDC, 2021). Construction methods and techniques also change with the seasons, so construction relies on clear weather; therefore, workers' livelihoods depend on weather conditions (Myers & Swerdloff, 1967). Longevity also plays a role, as it is easier to tear down than to renovate at the final phase of a structure's life, and it is harder to control quality (Tavares et al., 2021).

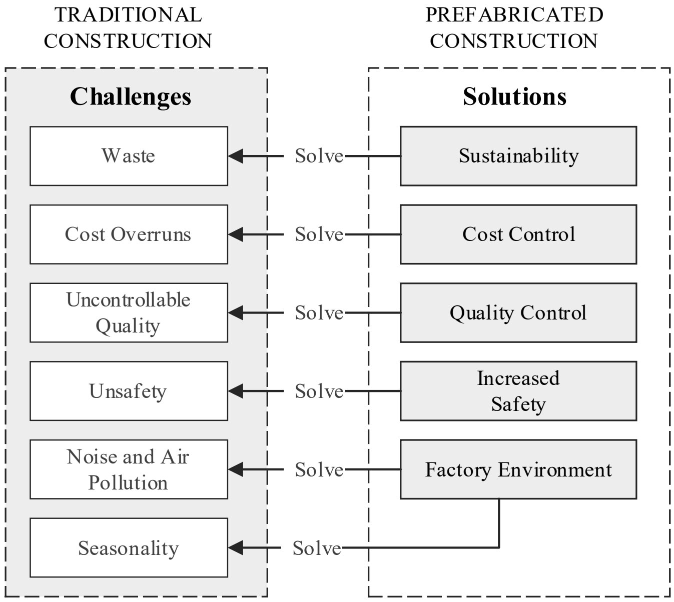

Figure 2: Traditional methods versus Prefabrication

Accordingly, the study suggests using prefabrication or modular construction to address these problems (Figure 2). The advantages of the modular method are quality assurance and predictable outcomes (S. Wu et al., 2022). Due to this factory environment, there is a reduction in noise and air pollution in the surrounding community, a smaller site footprint, and less material stored at the factory. We can work in any weather condition (Wilson, 2019). The costs are also reduced as they decrease by combining factory and site activities. Doing that can reduce the project duration and site assembly time. There is also a reduced labor requirement, which improves productivity (Zadeh et al., 2018). Safety also increases as there is better control of dangers to health and safety in an industrial environment, a 63% overall reduction in safety accidents, and a reduced chance of fall-related injuries (*Chubb North America*, 2020). Finally, wastage reduces as there is 52% less construction waste, 44% less energy consumption, and 9% less contribution to global warming (Z. Wu et al., 2021).

LITERATURE REVIEW

While prefabricated construction has numerous benefits, this practice still needs improvement and has some issues. They need more standardization in the process, which means more familiarity and expertise to implement prefabrication. Prefabrication demands accurate and trustworthy data as well as increasingly automated equipment. There needs to be better communication and coordination than there has historically been. There needs to be more cooperation between builders and their suppliers, and a lack of communication with vendors of off-site prefabrication requires risks of unanticipated expenses and flaws. All supply chain participants and companies should have (Lopez et al., 2022). Traditional construction gives us beautiful and aesthetic buildings, and there is a lot of variety in modular construction that needs more variety because complex designs involve more planning and custom designing. Everything is restricted to what can fit on a truck (Eliwa et al., 2020). Transportation also disturbs the smooth working flow of prefabrication, as difficulties arise from the movement of prefabricated components to prevent storage issues and idle time; fabricated parts need to be delivered only in order to prevent the supply chain from becoming more complex (Stroebele & Kiessling, 2017). Finally, stakeholders need more trust and collaboration because supplier companies typically carry the most risks, and factory follow-ups and performance monitoring are often done improperly. A systematic performance measurement system and real-time analysis are necessary to analyze and continually improve the manufacturing process due to the complexity of prefabrication, the significant number of stakeholders engaged, and the number and complexity of contracts (Chen & Samarasinghe, 2020).

Furthermore, Z. Zhang et al. (2022) successfully reflected the recent changes in the Australian prefabrication industry in particular and explored the benefits and challenges of implementing prefabrication from industrial perspectives globally.

Table 1: Benefits and challenges shared by academia and industry interviews, adapted from Z. Zhang et al. (2022)

	Benefits/ Solutions	Challenges
1	Time saving	Cost inefficiency
2	Better quality	Lack of skilled workforce
3	Energy saving	Lack of standardisation
4	Improved construction safety	Transportation & logistics issues
5	General cost benefits	Misconceptions
6	Reduce on-site work and labour	Inflexible for design change
7	Reduce on-site construction waste	Market demand
8	Addressing skills shortage	Site access
9	Lower production cost	Lifting safety

10	Less disruptive to neighbours	Protection during transportation
11	Relief housing demand	Compliance and inspection
12	Waste recyclability	Lack of automated adoption
13	Material saving	Bankability
14	Light weight of prefab. materials	Moisture control
15	Increase project certainty	Fire, thermal and acoustics testing
16	---	Payment process

Note: Table 1 showed summary results of the industry's perspectives on the challenges of using prefabrication. It provided a valuable reference for all parties in the prefabrication supply chain, to update their knowledge or understanding of the barriers toward widespread adoption of using prefabrication and their corresponding recommendations.

Through a literature review and interviews, Z. Zhang et al. (2022) classified the significant challenges into eight aspects related to feasibility, design, manufacturing, transportation, on-site construction, standardization, skills and knowledge, finance, and market. The authors summarized recommendations to tackle these barriers, particularly in adopting digital technologies in prefabricated construction. The application of cloud-based technology, the Internet of Things (IoT), BIM, and Blockchain, has been proven effective in improving information exchange, reducing uncertainties during logistics, and therefore improving the schedule performance of prefabricated construction. The findings could help local industries and governments develop roadmaps and policies promoting prefabrication. Similarly, Jin et al. (2018) implemented a holistic review approach incorporating bibliometric search, "*scientometric*" analysis, and in-depth qualitative discussion for reviewing and summarizing off-site construction literature published between 2008 and 2018. The authors proposed a framework to link current research areas in off-site construction to future research directions. The study found that sustainability, standardization, safety, and productivity are the performance measurements of prefabrication projects. Supply chain management, standardization, automation, fragmentation, and logistics are project delivery processes for off-site construction, considering the life cycle assessment approach. At the same time, the inclusion of multiple stakeholders and project parties in the design stage of a modular project is regarded as critical in some social and cultural contexts. The readiness of stakeholders to adopt off-site construction within a specific country or cultural context is crucial, as well as global cross-country comparisons. This review-based study provided both academic and practical implications. Scholarly, this study added to the body of off-site construction knowledge by focusing on developing off-site construction research in the last decade.

With the potential of applying digital technologies, the construction industry is at the point of a transformation driven by prefabricated construction. However, based on the detailed literature review, the authors have explored common challenges while implementing prefabricated construction. Some of the identified barriers include (a) lack of design, (b) lack of standardization, (c) poor communication and coordination, (d) transportation and logistics issues, and (e) lack of trust and collaboration among stakeholders.

Generally, the current research on prefabricated construction focuses on improving technology and addressing the barriers to the widespread adoption of prefabrication and its opportunities. The current studies aim to solve the challenges of prefabricated construction by applying BIM and Blockchain technology in different applications. However, combining these two technologies to collectively solve the challenges faced in the widespread application of modular construction is a new approach. Moreover, the values of integration and "*building trust among all the stakeholders*" from integrated project delivery are enforced by involving various suppliers, builders, architects, fabricators, engineers, and transporters right from the beginning. In such a case, the feasibility and duration of each sub-procedure can be accurately calculated.

Also, allowing them to coordinate through a Blockchain setup sets the steppingstone for developing a culture of trust and coordination.

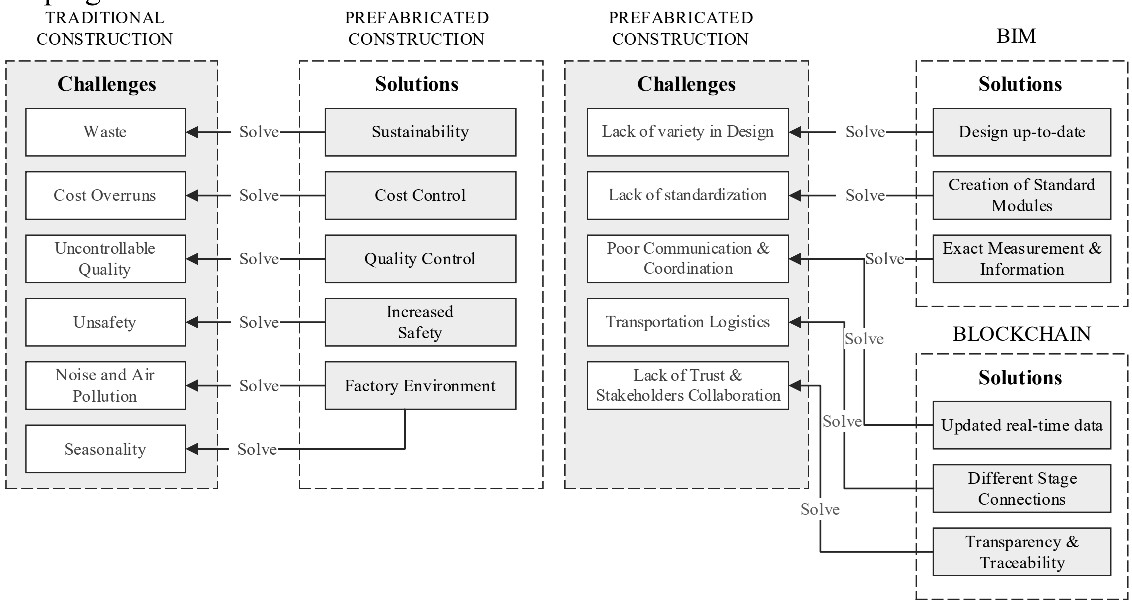

Figure 3: Proposed research conceptual schema to address the barriers toward widespread adoption of prefabrication in literature review.

DISCUSSIONS

Building Information Modeling (BIM) and Blockchain are emerging technologies that have the potential to advance prefabricated construction significantly. In combination, BIM and blockchain have the capability to greatly enhance the efficiency, quality, and transparency of modular construction, leading to improved outcomes for construction stakeholders. By leveraging these technologies, prefabricated construction can become more reliable, efficient, and cost-effective, making it a more sustainable option for a broader range of projects.

This section presents the relevant data found in the literature on the uses of BIM and Blockchain to aid the problems commonly raised in the prefabrication method.

BUILDING INFORMATION MODELING (BIM)

Originally, it took a remarkably long time for BIM to displace its predecessor, which at first started with hand-drafting, computer drafting, computer-aided design (CAD), and other computer-based systems. BIM is technically designed to increase information integration among project stakeholders significantly. Integrated information is the foundation and the source of integrity and insight, which allows an integrated team to make the best decisions for the project. By using visualization as a platform, BIM can help an integrated team create the aesthetics of a design and interpret the values of the building's owner and end users. Simulation is another primary use of BIM, which allows teams to evaluate alternative designs and strategic interventions to reduce risks and negative impacts. In addition to monitoring the initial cost, the team can now analyze energy consumption, workflow, natural light, and previously unmeasurable values like "*openness*" and "*connectedness*" (Martin Fischer et al., 2017). The Architecture, Engineering, and Construction (AEC) industry continues to push forward to build quicker, smarter, and more efficiently. As a result, using BIM has become crucial to achieving these goals of creating structures in a shorter timeframe while maintaining safety and sustainability. BIM is used in the world of prefabrication to make this construction more precise and efficient. While prefabrication has its issues, such as a lack of variety, standardization, and communication, BIM can be used as an effective method to ensure these issues are addressed and avoided.

BIM offers the unique ability to design with the intention of prefabricated, allowing for designs to be specified and designed around how they are to be sent directly to the shop and then from the shop to the site (Jang & Lee, 2018). In most cases, construction projects include errors only discovered once they are already on site due to a lack of communication between the AEC parties. Using BIM, these errors can be discovered quickly and designed in a way that they can visualize the building components, identify clashes, and then create shop drawings that either compensate for or fix the issue. This saves a tremendous amount of money in the later stages of construction when time is a crucial aspect of the project. To truly earn the benefits of BIM in prefabrication, the total collaboration between the architects and subcontractors is crucial to creating efficient prefabricated parts that include all the necessary mechanical, electrical, and plumbing (MEP) for the intended prefabricated structure. In the case of the 500,000 ft2 Miami Valley Hospital, a 12-story addition was added using prefabricated modular bathrooms, casework, headwalls, and workstations (*Architecture | NBBJ*, 2012). Architects worked countless hours with different MEP contractors, nurses, managers, and more to find the most efficient design while creating a usable and effective space. It was estimated that using this method increased productivity by 300% and saved more than two months off the 30-month project total. BIM helped achieve these feats by allowing the architects to find ways in which parts of the overall model could be designed for prefabrication and fit onto the truck for transportation.

BLOCKCHAIN

Blockchain has been around for a couple of years; however, its use within the construction industry has yet to be fully utilized. The use of Blockchain within prefabrication offers the AEC industry vital support in notarization-related applications to reduce the time for authenticating documents, transaction-related applications to facilitate automated procurement and payment, and source-related applications to improve the transparency and traceability of construction supply chains (Li et al., 2021). These solutions greatly help reduce typical issues within prefabrication, such as collaboration between multiple parties, shipping planning, and trust/ stakeholder collaboration. The Blockchain is a mode of Distributed ledger technology (DLT) where all the processes of business or construction can be verified and uploaded. It acts as a distribution network where no single authority is needed to maintain the verification of involved parties, giving stakeholders complete access to track construction history and check the recorded data conveniently (Li et al., 2021). Because of its highly trustworthy database, the Blockchain allows massive construction data to be kept impartially; in other words, an extensive range of information may be used in a traceable, secure, and sustainable manner (Li et al., 2021). We can then use Blockchain to create and automate various parts of the prefabrication process. An event completion, whether that be material arrival at the fabrication facility or completion of the fabricated item, would then trigger the next step within the automated contract to begin quality checks, time recording, payments, and so on. Within the supply chain, prefabrication can be difficult in terms of tracking regarding the status of the condition or location of the designated object. Blockchain offers the ability to track smart construction objects (SCOs) through their sensing, processing, and communicating capacities to facilitate information exchange among various construction resources (Lu et al., 2021). By attaching a Radio-frequency identification (RFID) or Quick response (QR) code to these SCOs, we can create checkpoints along the supply chain that automatically track these objects and update the Blockchain contracts with relevant and accurate data regarding the positioning and status of prefabricated items. Figure 4 shows a detailed SCO plan for construction processes with two types of models (Lu et al., 2021), which are model 1: a low-energy, single GPS sensor for location-based service in off-site logistics and model 2: high-frequency multiple motions and environmental sensors for off-site production and on-site assembly.

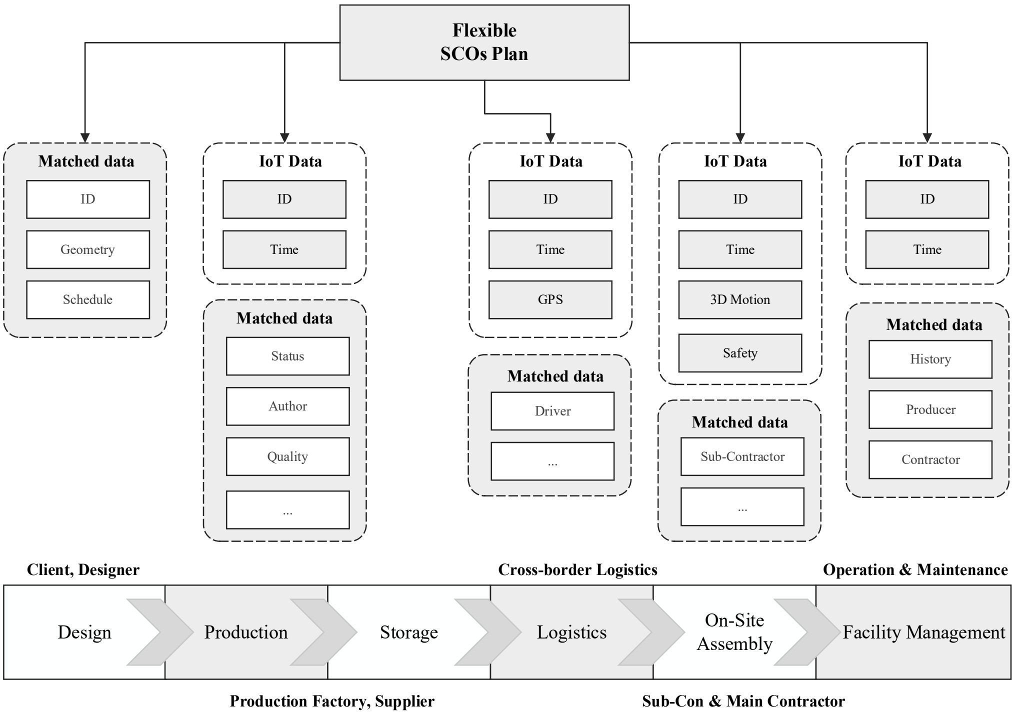

Figure 4: An SCO plan for construction processes: Off-site production, logistics, and on-site assembly services, adapted from Lu et al. (2021)

RESULTS & FINDINGS

The challenges or barriers mentioned earlier still exist in the prefabricated construction method. Figure 5 below illustrates how each of those five issues could be solved by implementing an integrated approach using BIM and Blockchain technologies during the prefabrication process.

First, the lack of variety is caused by complex designs requiring more planning and custom design with size restrictions so that the prefabricated fragments can fit in the truck for transportation (Eliwa et al., 2020).

Second, the lack of standardization in the prefabrication process demands more precise and trustworthy data, as well as more automated machinery (Rose Morrison, 2021). There is also a need for more familiarity and expertise in implementing prefabrication because workers need to be able to create documents accurately and efficiently. Using BIM helps analyze constraints to give maximum efficiency in designing project fragments that can be prefabricated and fit on a truck. It allows for the prefabrication of sophisticated systems such as irregular exterior paneling and MEP modules (Jang & Lee, 2018). BIM helps analyze the exact data, providing the exact measurements of the fragments the subcontractor requires for module prefabrication.

Third, poor communication and coordination are common among builders and their suppliers. BIM reduces discrepancies in a final model among both designers and manufacturers, shrinking the procurement schedule as an embedded BIM execution plan can facilitate design cooperation from the start of a project and any required adjustments or modifications on a model that can be incorporated before the proper production phase without adversely affecting the project and product duration and quality (Mostafa et al., 2020). Also, to aid the poor communication and coordination among stakeholders, Blockchain technology allows multiple shareholders to obtain smart connected product (SCP) status data in real-time while linking various stages, responding quickly to worrying occurrences, and reducing energy consumption (Li et al., 2021). Furthermore, by combining Physical asset tracking (PAT), Digital asset management (DAM), and Distributed ledger technology (DLT) contracts through apps, industry partners may leverage a variety of (current or unique) asset tracking and management systems and link them to smart contracts and Blockchain technology (van Groesen & Pauwels, 2022). Organizations are able to pre-set prerequisites on the Blockchain that allow customers to effortlessly engage in the Smart product-service systems (SPSS) chains for (1) notarization-related implementations to shorten the amount of time required for document authentication; (2) money transfer applications to support automated sourcing and payment; and (3) authenticity applications to enhance the traceability and transparency of construction supply chains (Li et al., 2021).

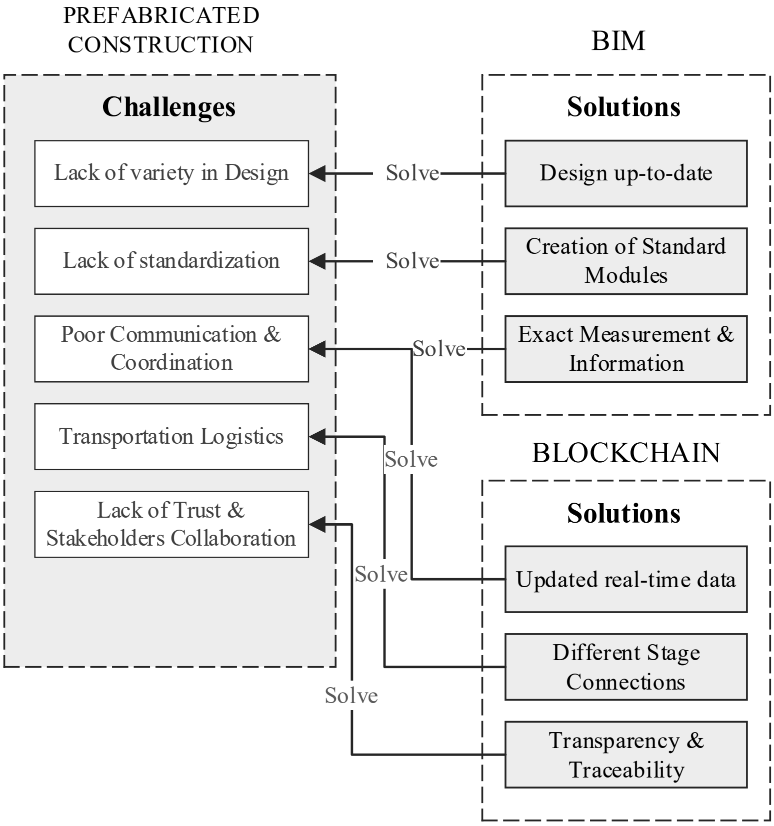

Figure 5: BIM and Blockchain technologies to aid Prefabrication challenges.

Fourth, transportation logistics in the prefabrication process are essential given the difficulties of transporting prefabricated components, such as reduced waiting time and warehousing concerns since the fabricated parts must be shipped just-in-time to prevent further intricacy within the actual supply chain (Stroebele & Kiessling, 2017). Lastly, the lack of trust and collaboration between stakeholders is quite common in the prefabrication construction method, given that, typically, supplier firms bear most of the risks and the need to effectively handle performance appraisals and follow-ups in the production process. The number of complex agreements is also impressively large due to their intricate nature and the many stakeholders engaged in prefabrication. A precise performance evaluation and real-time analysis system are required to monitor and constantly improve the manufacturing process (van Groesen & Pauwels, 2022). Blockchain technology creates traceability and transparency in a collaboratively managed register; its usage diminishes miscommunications and disputes among relevant parties; and it automates the evaluation of advancement and conformity to contractual responsibilities in arranging individually manufactured parts via geographic data tracking technologies. Additionally, QR Codes may be used to track the status of manufactured elements utilizing a mechanism of *"fabricated," "delivered," "ready for assembly," "assembled," "ready for verification,"* and "*verified*" (van Groesen & Pauwels, 2022).

Apparently, the widespread adoption of BIM has been considered a strategy to accelerate the growth of prefabricated construction following decades of slow advancement in the industrialization of construction (Bimal Patwari and Scott Pittman, 2022). The findings reveal potential solutions when applied to construction projects. BIM can address these challenges and provide technical support for the growth of prefabricated construction. Using Blockchain and Smart contracts in prefabrication improves supply chain transparency and traceability in automated procurement, payment, and document authentication. Thus, the construction industry has benefited from advanced digital technology, and the combination of BIM and Blockchain technology within the construction context will discover more benefits of prefabricated construction presently. It is suggested that BIM will help solve the most significant problems that prefabricated construction projects confront now, such as Lack of design and standardization, poor communication and coordination, transportation and logistics, and Lack of trust and stakeholders' collaboration.

FUTURE RESEARCH

This paper presents the investigations and literature review findings in the prefabrication field of the construction industry. Even though there have been few implementations of Blockchain in the construction sector, the study predicted that there would be significant benefits for latecomers. The many advantages of combining Blockchain with BIM were emphasized. Future research is needed to expand and enhance the application of innovative technologies in prefabrication, such as construction 3D printing (C3DP), Virtual reality (VR), Augmented reality (AR), and the Digital twin (DT). In addition, several current techniques or approaches are being considered for the integration of advanced technologies into prefabricated construction, such as Cloud-based computing, which stores data generated by BIM; integration platforms like BIM360; collaborative workflows as Integrated Project Delivery (IPD); Machine learning, and Artificial Intelligence (AI) which are being used to automate and optimize processes. Developing and implementing new technologies in the prefabrication industry that address supply-chain issues, safety concerns, and management challenges is necessary. There should be a need for suitable research methodologies to integrate various other technologies to ease the use of prefabrication in the construction industry, keeping the industry's traditional approaches in mind. In general, using advanced technologies in prefabricated construction offers many potential solutions but presents significant challenges that must be overcome to realize its potential fully.

CONCLUSIONS

This research contributes to the body of knowledge by addressing the barriers to the widespread adoption of prefabricated construction projects and developing an integrated approach for applying advanced technologies to the prefabrication process. Our research suggests that an integrated approach combining BIM and Blockchain technologies during the prefabrication process will help solve the most significant problems that prefabrication projects face, such as a lack of design, a lack of standardization, poor communication and coordination, transportation and logistics issues, and a lack of trust and collaboration among stakeholders' collaboration. Together, BIM and Blockchain can help to streamline the prefabricated construction process in terms of design up-to-date, the creation of standard modules, exact measurements, and information, updated real-time data, different stage connections, transparency, and traceability. Most significantly, the approach proposed in our research advanced the prior works by proposing a conceptual schema for addressing each problem highlighted in previous studies. In addition, this research demonstrates how prefabrication addresses challenges associated with traditional construction and how the challenges associated with prefabrication can be addressed through our proposed integrated approach involving technologies. This study benefits professionals and academics by providing a framework for comparative analysis and investigation into the benefits and drawbacks of various approaches. Although modular or prefabricated construction has a long history, adoption remains remarkably slow. After decades of limited development in the industrialization of construction, the widespread adoption of innovative approaches and emerging advanced technologies is now seen as a viable approach to accelerating the growth of modular construction in the near future.

PRODUCT AND PROCESS COMPLEXITY IN CONSTRUCTION: AN EXPLORATORY STUDY USING BILL-OF-MATERIALS (BOM)

Carolina Melecardi Zani[1] and Cecilia Gravina da Rocha[2]

ABSTRACT

Modularity has been applied in the automotive and computer industries to simplify production and supply chain management. Instead of coping with dozens of hundreds of parts, these are grouped into modules produced and delivered by suppliers, simplifying products assembly. Bill-of-Materials (BOM) is a technique used in manufacturing to map the modules that form a product at distinct hierarchical levels. Yet, to the best of our knowledge, such technique has not been widely explored in construction to assess the complexity involved in buildings production. This paper uses BOM in an empirical case (a house of approximately 400 square meters built in Southeast region of Brazil) to analyse (i) the total number of different modules forming a building and (ii) how these modules are distributed throughout the work packages for producing such building. The results show that the studied house is formed by (at least) 522 different modules, which are unevenly distributed across 18 work packages. Some work packages (e.g. concrete pillars and walls) have more than 200 modules whereas others (e.g. foundations) have less than 10. This suggests the potential for repackaging and organizing the delivery of modules as kits to ease production tasks.

KEYWORDS

Complexity, modularity, modules, work packages, work structuring

INTRODUCTION

Simplifying production and supply chain management is a core underlining reason for the adoption of product modularity in the manufacturing sector. Instead of coping with dozens of hundreds of product parts these are grouped into modules (sets of parts), which are produced and delivered by suppliers, simplifying the final product assembly. Baldwin and Clark (1997) report that the complexities of a vehicle require car manufactures to control a network of hundreds of suppliers in addition to a complex schedule and a large inventory as buffer. Thus, instead of managing the entire network of suppliers for producing each individual part, parts are organized and delivered as a smaller set of modules (e.g. Doran et al. 2007; Ro et al. 2007). An example is the cockpit module that includes several parts (air bags, heating and air-conditioning systems, etc), which is produced and delivered by a supplier responsible for coordinating the chain of suppliers involved in producing this module (Baldwin and Clark 1997).

Bill-of-Materials (BOM) describes the structure of a product in terms of its constitutive parts (termed here as modules) with the goes-into-relationship (also known as a parent-child relationship) among them (e.g. Chung and Fischer 1992, Cox et al 1992, Olsen and Saetre 1998, Matías et al 2008, Kashkoush and ElMaraghy 2016). BOM can be used to assess the extent to which the modules delivered are more or less aggregated and also the number of hierarchical levels that comprise a product architecture. Indeed, as recognized in the literature, modularity of a product and its constitutive modules can be analysed at distinct hierarchical levels. For example, Fixson (2005) examined such hierarchy from a functional viewpoint (namely, the functions performed by the product parts). He argues that the function of a hair dryer (the set of all components forming the product) at the highest level is to dry the hair whereas at the lowest level (of a single part such as screw), might be to hold part B in position C. Thus, not only functions (but also the corresponding physical parts or components performing then) can be analysed at distinct levels.

Inspired by the manufacturing industry, the construction sector has adopted information structures relying on BOM (Hussamadin et al., 2020). Most papers on the construction field related to BOM address (i) Building Information Modelling (BIM), or other technologies, to BOM management (e.g. Zhang, 2022; Song and Fischer, 2020; Mukkavaara et al., 2018; Boton et al., 2018; Song et al., 2017; Genge et al., 2015; Scheer et al., 2014) or; (ii) BOM focused on construction sustainability, such as life cycle assessment (e.g. Tavares and Freire, 2022; Roh et al., 2019; Zea Escamilla and Habert, 2017; Al-Ghamdi and Bilec, 2017) circular economy (e.g. Gillott et al., 2023), replacement of materials (e.g. Ortlepp, 2019; Zea Escamilla and Habert, 2017; Milaj et al., 2017), and other topics (e.g. Songcayauon, 2018; Winistorfer et al., 2005). Yet, these studies do seem not examine BOM from a product modularity viewpoint and their implications from a product and process complexity.

This paper seeks to address this gap by presenting an initial exploration on this theme. It aims to provide initial answers to the following questions: *How many modules (or physical chunks) form a building? How are these modules distributed throughout the work packages? What insights can be gained by connecting the modules forming a building (product view) to work packages (process view)?* In line with Da Rocha and Kemmer (2018), modules (identified in this study by applying the BOM technique) and work packages, refer respectively to the organization and breakdown of (i) a product and (ii) a construction process. Work packages are the outputs of work structuring, and define the organization of work chunks (namely, in what chunks will work be assigned to a production unit, release to the next production unit, in what sequence, etc) as detailed in Ballard (1999).

BILL-OF-MATERIALS

All modules that form an end product pertain to a hierarchical level, or in other words, every product can be decomposed into modules, which can be further decomposed into lower levels modules (Pahl and Beitz, 1996). The level to be considered can be defined according to the assembly sequence or the function performed by the modules and how it relates to the end product (Chung and Fisher, 1992). The hierarchical level is higher as it gets closer to the final product and its main function; therefore, the highest level is the entire product. The notion of decomposing a product in hierarchical levels has been presented in a number of early studies (e.g. Alexander, 1964; Christensen, 1992; Gulati and Eppinger, 1996; Simon, 1962). A technique that maps the assembly sequence of a product (and thus, the modules comprising such product at each level) is the Bill-of-Materials (BOM) (e.g. Chung and Fisher 1992, Van Veen 1992, Jiao et al 2000). In its simplest from, the BOM is a list or a visual display (e.g. tree map, fish bone diagram, list, etc) of all modules (raw materials, components, sub-assemblies, etc) needed to produce an end product.

The modules and how these should be connected are presented through goes-into-relationship (or a parent-child relationship). The “parent” is an (i) in-between product (grouping of modules at a particular level) or (ii) the end product, and the “child” are the modules forming either one of these. For example, in Figure 1, “prefabricated beam” (at level 1) is a parent for all the subsequent modules (at levels 2, 3, etc). “Concrete” is a child for the “prefabricated beam”, but also a parent for “grit”, “gravel, “cement” and “water”. Note that “grit”, “gravel, “cement” and “water” are also a child for the “prefabricated beam”, but in a lower hierarchical level. Figure 1 shows the parent-child relationship in list (a) and tree (b) formats. In the former such relationship is elicited via codes (numbers), whereas in the latter it is through lines connecting the modules at distinct levels. Such codes are not often used in trees representations (Van Veen, 1992). Yet, numbers are usually included to express the volume of modules at each level (Erens et al, 1992; Hegge, 1992; Van Veen and Wortmann, 1992; Stonebraker, 1996; Romanowski and Nagi, 2004, Liu et al, 2014). Distinct information elements can be presented in a BOM such as product definition, manufacturing instructions, engineering changes control, service parts support, liability or warranty policy, order entry facility, costing, and pricing (Mather, 1987). Yet, such technique can also be adapted as needed. Here it is used to map the number of different modules (but not volume) at levels 1 and 2, considering the building assembly or finished product (level 0).

GOES-INTO RELATIONSHIP (PARENT-CHILD) SHOWED BY NUMBERS

Figure 1: Example Bill-of-Materials as list (a) and tree diagram (b)

To illustrate the applicability of BOM in the construction sector, two examples from the literature are explored comparing BOM off-site (e.g. prefabricated components), more similar to the manufacturing sector, and BOM on-site, which is further developed by this paper. Cao et al. (2022) explore the advantages of BOM combined with BIM, in industrialized construction. Industrialized construction has high degree of repeatability and standardization, such as hotels, affordable housing, schools, hospitals and so forth (Bertram et al., 2019; Cao et al., 2022). This enables a trustful BOM, which in turn enables reliable management of resources. The referred authors propose a module library, using as a timber panelised building as an example. They argue that BOM is the key to information system, offering data with regards to designing, ordering, building developing, construction and maintenance. The BOM complements the BIM application, since BIM by itself is not capable of automatically manifesting the effect of a design change, unless the change violates a rigid constraint, such as a clash.

On the other hand, Hussamadin et al. (2020) highlight that construction is an ongoing process, unlike the assembly line in manufacturing production, in which new spaces are becoming available while work is being finished, leading to a more complex and dynamic relation between such process and the BOM. The authors explore five construction assets in three construction companies, showing that among the variation in workflow, more specifically, the space as the non-movable component, is a challenge of applying BOM to on-site construction and which makes the applicability of BOM more complex. Their study proposes some adaptations of such tool, highlighting the relevance of studies that adopts BOM applied to in-site construction, such as this one. Both studies (Cao et al., 2022 and Hussamadin et al., 2020) show that the complexity of the products (hereby understood as a high number of modules present in the final product) and assembly system can be assessed by the BOM. Such tool can provide support to management decisions by showing where the source of complexity arise from and help to rationalize the choice of product features and design alternatives. BOM involving can help assess complexity a priori without the need to for detailed information on the constructive system but instead just by looking at the number of modules across the BOM structure.

CASE STUDY

This investigation examined the budget sheet and the production schedule for House A developed by Company B, based in the city of São Paulo (SP), Brazil. Company B has been operating since 2001 and has delivered more than 200 buildings. Most of these are residential houses, but there are also some high-rise buildings and industrial sheds. The company provides a complete solution: it is involved in the product development, including the building design, its production and hand over to the end client. The majority of production tasks are performed by Company B but some such as the foundations and the water heating system are outsourced.

Company B is comprised of an average of ten teams with ten people each. Each team gets a different building to work on which are then swapped across teams. Usually, three people work in the office (the interns work both at the office and at the construction site) and seven in the construction site. The project coordinator, the civil engineer, and a construction coordinator work at the office but visit the construction site regularly. In the construction site are the electricians, hydraulic professionals, painters, etc.

Initially, Company B suggested three houses for this study. House A was selected because it had the most complete budget sheet and had been recently delivered at the data collection time, thus easing potential queries and clarifications around the information gathered. House A is a four-bedroom home with approximately 400 square meters. Besides the common amenities of a house, it also includes parking space for four cars, a gourmet area, a courtyard, and offices. This building was erected using traditional construction methods: cast in place reinforced concrete and ceramic bricks. The construction took place between May 2013 and April 2014.

DATA COLLECTION AND ANALYSIS

First, the budget sheet for House A was sent by Company B via email for its appraisal and assessment. An initial analysis showed that some modules were missing, so receipts for all purchases were requested. These were organized and added to the budget sheet. The first author then performed a one-week visit to the company. During this visit, a one-hour meeting was conducted by the first author with the director, the civil engineer intern, and the building contractor to gather data on the production schedule for House A. Additional receipts and purchase invoices were provided and tabulated, creating a complete budget sheet that produced the results presented in this manuscript.

A second meeting with the same staff was performed to gather data on the company, further details on the production schedule, and to clarify queries regarding some items of the budget. This meeting lasted one and a half hours. The production schedule devised by the first author was based on the realized tasks and actual durations, rather than plans and expected durations previously established by Company B. Thus, the work packages presented here were defined by the authors mainly based on the data gathered in the meetings, the duration of tasks, trades similarities, and crew changes.

RESULTS

The BOM (based on the complete budget sheet) shows that House A is formed by 522 different modules. Considering that a BOM is comprised of several hierarchical levels, the highest is the complete building (finished product), and the modules (or physical parts) arriving at the construction site (522) are located in level 1. Such number (522) does not entail repetitions (or quantities) for each module, which would be a subsequent step in applying the BOM technique. Some examples of modules include: nail (15x15), cement tile (2,44x0.5 x 4mm), steel bar (CA60 4,2mm 12m), rafter (5x5cm x 2,5m made of cambara wood), batten (2,3x7cm made of cedro arana wood), and batten (2,3x15cm made of cedro arana wood), among others. It is worth noticing that elements that have the same of function (e.g. batten) but have different dimensions (e.g. 2,3x7cm or 2,3x15cm) are treated as separate modules as they are physically different chunks. It is worth noticing that although BOM might resemble Work Breakdown Structure (WBS) in terms of the underlying logic (i.e. a systems' organization in terms of its constitutive parts), the former is specifically focused on the products and its comprising physical parts whereas the latter is more broadly applied to projects and its key stages.

Figure 2 shows the distribution of the 522 modules across the 18 work packages identified in the production schedule for delivering House A. Some modules such as nails, pipes, electric conduits, are used in more than one work package. Thus, the sum of modules in all work packages is 1020 and not 522 (in case each module was used in only one work package). There is an average of 57 modules per work packages yet with a high standard deviation as can be visualize seen in Figure 2. For instance, *WP1 – foundations* has 6 modules whereas *WP5 – concrete pillar and slab (2nd floor)* has 223 modules. Approximately 70% of the work packages have less than 50 modules, with the other 30% (concrete pillars and walls for both floors, fixtures and fittings, and electrical and hydraulic systems) have more than 150 modules. These four work packages (WP3, WP5, WP10, and WP17) account for 76% of the total number of modules. WP3 and WP5 have a large number of modules because rebar and wires arrive as separate items (rather than cut, folded, and pre-assembled kits for columns and beams). In addition, the pipes embedded in the walls also arrive as individual components rather than pre-assembled kits. The same applies to electrical and hydraulic systems; all wires and pipes are also delivered on site as separate components.

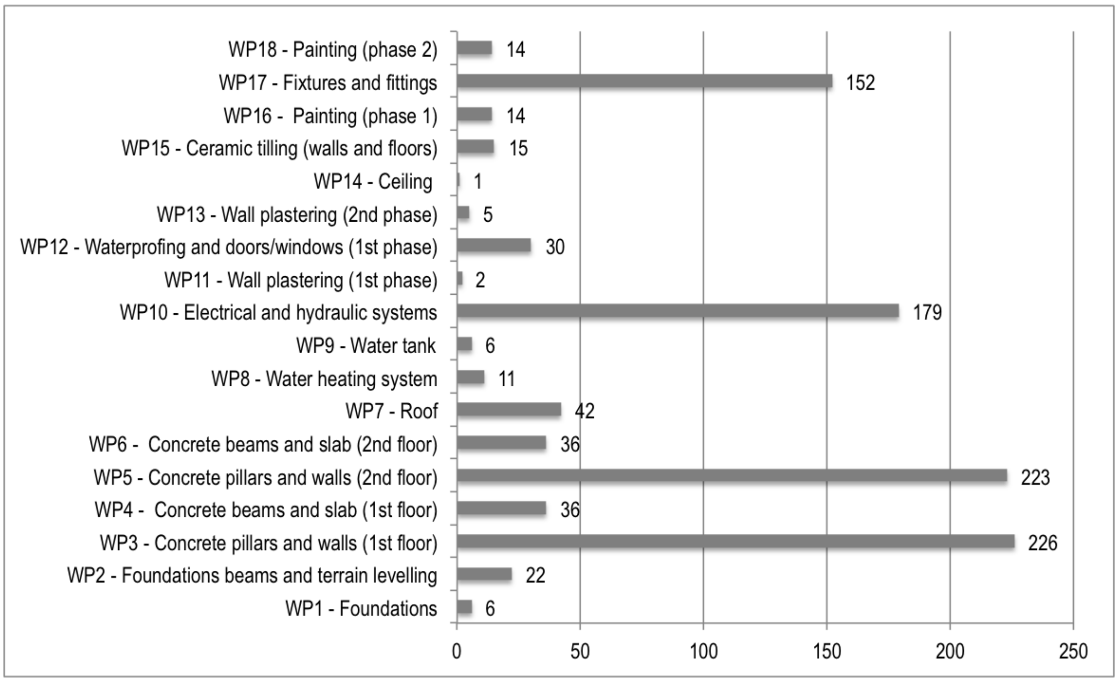

Figure 2: Distribution of modules for House P across the work packages

The 522 modules presented in Figure 2 are level 1 of a BOM (Figure 1), as they are the level immediately below the complete product (level 0) and which refers to the parts arriving at the construction. In this study, the modules at the immediately subsequent hierarchical level (2), namely, the number of parts (or sub-modules) forming each module at level 1 were also analysed. Table 1 shows the number of modules that are formed by two, three, four and five or plus sub-modules at level 2. Because House A is built using traditional construction methods, thus using concrete, steel, wood, bricks, etc (different strength, type, size, etc would be considered modules), the vast majority (79%) does not have sub-modules at levels 2 and below. Indeed, as shown in Table 1, less than one third of the modules is a sub-assembly, namely, has two or more modules at level 2 or below.

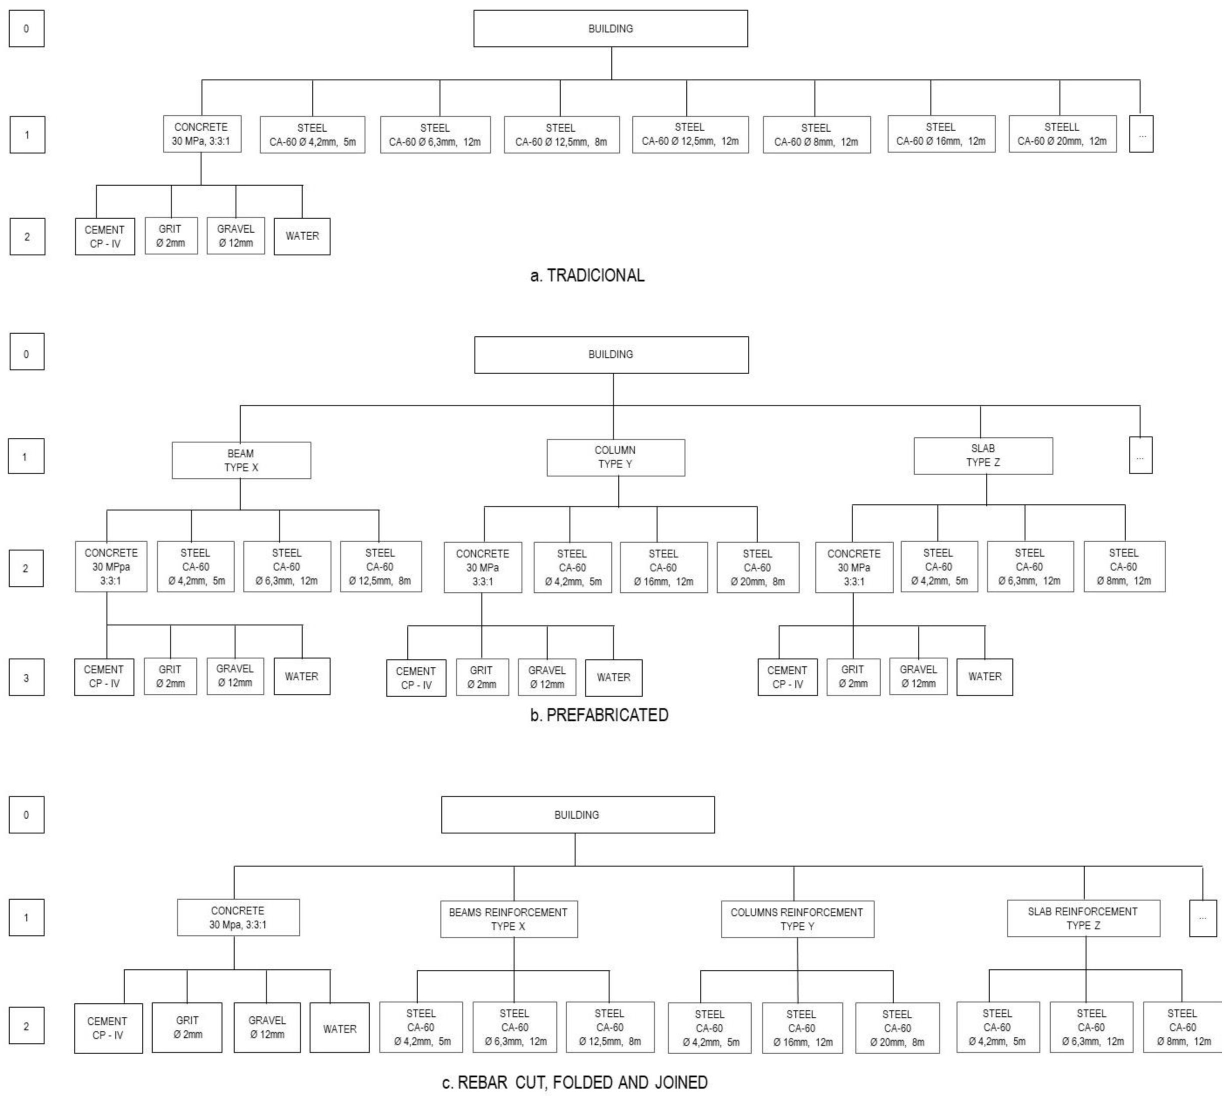

Figure 3: BOMs reflecting different construction methods

Differently, buildings erected using a prefabricated structural system (beams, pillars, and slabs produced off site) such parts (beams, pillars, etc) would be the modules at level 1, and concrete and steel would be modules at level 2 (Figure 3b). this would reduce the product complexity delt with at the construction site, measured by the number of modules at level (building assembly/erection on site). Opting for prefabricated steel reinforcement would result in a in-between alternative, with a smaller number of modules in level 1 in comparison to traditional construction (Figure 3a): steel parts and concrete would still be at level 1, but with a smaller number of different modules at this level (Figure 3c). This is because the steel elements would already be grouped into kits, such as reinforcement for beam X, Y, reinforcement for column A, B, etc instead of individual rebars.

Table 1: Percentage of modules at level 1 formed by 1, 2, 3, 4 or 5 or more modules (level 2 or lower)

Number of modules (Level 1)	Number of modules (Level 2 or lower)
411 (79%)	zero
10 (2%)	two
20 (4%)	three
5 (1%)	four
76 (14%)	five or more

DISCUSSION

The total number of different modules delivered at a construction can provide evidence of complexities in terms of product and process (on site production and supply chain). These can be further understood by assessing how these physical chunks are structured and organized by using the BOM technique and linking those to the work packages. This study seeks to introduce a notion already adopted in manufacturing (Baldwin and Clark 1997): to partition a product in modules (or production cells) to simplify production. Indeed, what constitutes a module is determined by the supply chain and the production system arrangement. Namely, a cockpit (and its constitutive parts) is a module (from the car assembler perspective) because it is delivered as a single part (or sub-assembly) to the car assembly plant. Thus, the number and nature of modules that arrive the construction site are tangible manifestations of a production system and supply chain arrangement, regardless of if the decisions around such arrangement have been formally made or not. Such rationale and notions seem underlined when considering prefabrication or modern method of construction.

Yet, they also apply to traditional construction even if the physical chunks are simple materials such as concrete, steel reinforcement, etc as in the case examined here. Indeed, this does not seem to be considered more broadly in construction as also noticed in Da Rocha and Kemmer (2018) under the Modular and Traditional design approaches. Based on the results of this exploratory study, the work packages for producing the structural, hydraulic, and electrical systems contain a large number of modules. These are prime candidates to be delivered as kits or sub-assemblies (rather than as a large set of different parts) to ease and simplify construction on site. This is in line with the principle to simplify by minimizing the number of (product) parts (Koskela 2000). A similar analogy was reported by Feloni (2014) when analysing the LEGO Group in the early 2000s. The number of piece types increased from 6,000 to 12,000 and nearly bankrupted the company ("a nightmare of logistics and storage"), meaning that every LEGO module was so unique that they no longer could be considered a module. In order to save the company, they went back to the previous 6,000 pieces. Therefore, in the construction context, precast elements (beams, columns, or slabs) could be used to reduce the number of modules at the construction site (Figure 3b). Also, pipes could be combined into pre-assembled piping systems.

Fitting and fixtures, which also account for a large number of modules, might not be delivered as sub-assemblies if the building is erected using traditional construction methods. Nonetheless, they can be organized and packaged as kits. For example, having a package with a mix of all the fitting and fixtures modules installed in a given room, rather than stocks organized based on the module type (e.g. stock of sinks, stock of tiles, etc). These alternatives just described (creating pre-assembled pipping systems and per room/zone packing of fittings and fixtures) look at re-organizing the product structure (which can be visualized using a BOM) to simplify production. The counterpart strategy is to re-organize the process, or in other words, to (re-)structured the work packages (e.g. Ballard 1999, Tsao et al 2000). For example, WP3, WP5, WP11, and WP17, which entail the assembly/combination of large number of modules, could be disaggregated in two or more work packages. This would enable the number of modules to be more evenly distributed across production units (i.e. a crew performing a set of production tasks, Ballard 1999) and work chunks (i.e. unit of work handed off from one production unit to the next, Ballard 1999). Clearly both strategies (product and process) can be jointly applied to reduce the number of modules and consequently production and supply chain/logistics complexity.

There seems to be an inverse relationship between (i) the number of modules at level 1 in the BOM and (ii) the number of modules in level 2 and/or lower levels, if one assumes a building is made by a constant/same set of modules, just changing their distribution across the BOM levels. In this study, there is a large number of different modules at level 1 in the BOM so these are not likely to be formed by several modules in level 2 and/or lower levels. This is indeed the case (Table 1): 79% of modules (level 1) are comprised of two or more modules in (level 2 or lower). Conversely, for fully modular buildings (e.g. formed by a small number of volumetric pods) there will be a small number of large modules (i.e. pods), which in turn are comprised by a large number of modules at lower levels. However, it is proposed here that an inversely linear relationship between number of different modules and the level of aggregation of physical part into sub-assemblies (or level of prefabrication) might not apply (Figure 4). Considering the case of a load bearing building erected with bricks, the number of modules for the enclosure system might be close to one (if only a few brick types are used for the entire system). The number of different modules is likely to increase if the system changes to a steel structure and dry walls, as a larger set of different physical parts is needed. Clearly, as the level of prefabrication increases and the building is delivered as a set of fully volumetric pods, the number of modules reduces again (right hand side of Figure 4).

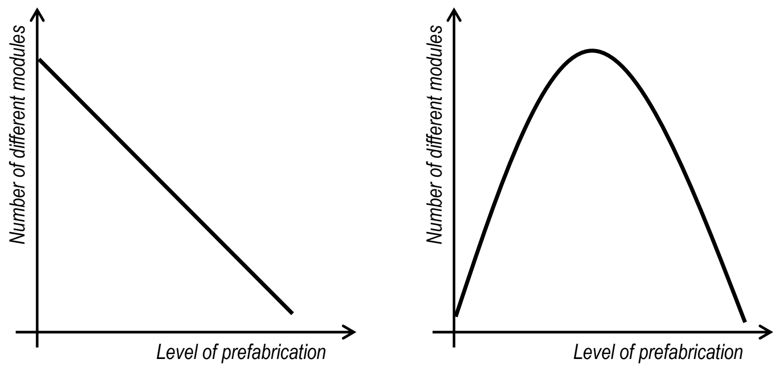

Figure 4: Linear and quadratic functions for

BOM can be used to understand a product breakdown thus also reflecting the complexities involved in operations (procurement, logistics/transport, and on-site construction/assembly). In terms of on-site activities, Tommelein (2006) presents the benefits against the detriments on adopting a modular approach on pipe spool models, which can be generalized for many other components in construction (e.g. doors and windows of various dimensions, supports and fixtures of different types, left- and right-handed mechanical equipment). The referred study shows that as the number of different spools pieces decreases, the production process gets easier. There is potential to a reduction on defects (and thus in rework) with the experienced acquired on repetitive work; there is less time needed to setup and change-over the production of spools; there is opportunities to facilitate flow, by applying the 5S, using right-sizing equipment and lining up work; inventory and supply chain management is also facilitated through the provision of flexibility in the system. These improvements particularly in terms of overall benefits to the system are created by adopting a modular approach.

Aligned with this finding, a previous study developed by MacDuffie et al. (1996) in the automotive sector shows that the disadvantages due to a lack of modularity goes beyond the costs: in such case greater scope of products variants and options have a significant adverse impact on total labour and overhead hours per produced car, assembly line downtime, minor repairs and major reworks, and inventory levels. In this work, they analysed 70 auto assembly plants worldwide. Further, Su et al. (2010) investigated assembly defects caused by operators mistakes by considering complexity factors such as design. The more similar, or modular the product, the fewer are the mistakes. In the manufacturing, the impact of high levels of product variety on complexity in design and manufacture has been explored through different lens (Roy et al., 2011; Samy and ElMaraghy, 2011; Hasan et al., 2018). This resonates with the findings by Fisher and Ittner (1999). The authors examine the impact of the variety of products on car assembly. The results indicate that the larger the number of modules, the greater the risk of errors, resulting in rework and low quality, mainly due to clustering errors and labour difficulties.

CONCLUSIONS

This paper presents an exploratory application of BOM in construction to assess the number of modules forming a building and how these are distributed across work packages. The results show that House A which is traditionally built is comprised by 522 different modules and that these are not evenly distributed across work packages. Most work packages have less than 50 modules whereas a few have more than 150. As discussed previously discussed, the number of modules seems to be closely connected to the method used and traditional construction might not lead to the highest number of different modules. This is because the modules are essentially simple raw materials or components that can be arranged and adapted in a number of different ways. This prompts an interesting discussion: bricks might be positive from a flow view, by minimizing waste associated with finding the correct part, errors in installing the wrong parts, etc as reported by Tommelein (2006). Yet, they are inefficient from a transformation viewpoint as walls are made by assembling small physical chunks, and which often require cutting and adjusting. On the other hand, a steel structure and dry walls system (proposed as an alternative to the brick system), might have opposing trends for the flow and transformation views just described. Fully volumetric pods on the other hand, seem to reconcile the two views by reducing waste relating to non-value adding activities while also ensuring that transformation is efficient.

This is an initial study looking at BOM and how this technique can be used for assessing product and process complexity. (i) The number of different modules (522) as well as (ii) their distribution across work packages (on average 57 but with a high standard distribution with most work package having less than 40 and some more than 150 modules) are relevant metrics in that regard. Yet, such numbers will become interesting in the context of the numbers encountered for other buildings (including other uses and typologies beyond a two-storey residential house examined here) and construction methods so that overall trends and patterns can be identified. In this sense, this is a truly exploratory as additional efforts (studies similar to this one) doing quantifications are needed to create a database for meaningful relationships and generalizable knowledge to be created around product and process complexity. For example, the hypothetical function connecting number of different modules and level of prefabrications could be corroborated or refuted once sufficient data is gathered and large-scale quantifications studies are completed. Another interesting analysis could be performed by collecting the data outlined here in addition to the quantity or volume of each different module (data not gathered in this study) correlated with the project performance measure to further provide insights on the impact of complexity. This would complement and expand the findings presented in Tommelein (2006) based on simulation, by having actual project data (the modules used in a project and its actual performance).

Finally, some limitations of this study should be highlighted. First, Company B did not have a clear production schedule and work structuring. These have been defined a posteriori by the authors. Thus, although care was taken in defining the work packages (use of company data, similarity of trade, etc) as highlighted in section 3.1, more reliable results are likely to be obtained for companies with a formal work structuring and schedule. Secondly, the budget sheet used for House A provided by Company B was not complete and had to be updated by the authors based on invoices. Here again, care was taken in gathering all existing receipts to create a complete budget. Also, the budget was scanned to ensure that main items (concrete, bricks, sink, tiles, etc) were not missing, but it is not possible to unquestionably assert it includes all modules. Thus, as an overall conclusion and ballpark figure, it is more appropriate to state that a two story traditionally built house of around 400 square meters is formed by (at least) 522 different modules.

FACTORS INFLUENCING CYCLE TIMES IN OFFSITE CONSTRUCTION

Fatima Alsakka[1], Haitao Yu[2], Farook Hamzeh[3], and Mohamed Al-Hussein[4]

ABSTRACT

In offsite construction, various factors contribute to variability in cycle times at workstations in production facilities, leading to imbalanced production lines. Understanding these factors is vital for implementing Heijunka, a fundamental lean principle that consists of levelling out the work schedule. This study presents a qualitative approach for identifying and understanding factors that influence variable cycle times at the workstation level. The application of the approach is demonstrated in reference to a semi-automated framing workstation in a panelised construction facility. A list of 36 potential influencing factors categorised into eight classes is first compiled based on observation of the process, a cross-functional diagram, and a review of relevant studies, and then discussed based on feedback solicited from personnel at the case framing station through a semi-structured interview. The approach, its application, and the results demonstrate the effect of expending effort on the identification and understanding of cycle time-influencing factors in improving the accuracy of cycle time analysis, thereby facilitating the implementation of Heijunka.

KEYWORDS

Offsite construction, lean construction, cycle time, influencing factors, Heijunka.

INTRODUCTION

MOTIVATION: THE HARE APPROACH

The offsite construction industry, also known as the construction manufacturing industry, is rooted in the broad shift of construction practice from traditional in-situ methods to manufacturing methods. One may intuit that moving towards manufacturing methods will inevitably pave the way for comprehensive and streamlined implementation of lean philosophy in construction. There is a degree of truth to this, as many offsite construction companies have sought to leverage the benefits of lean principles such as standardisation, waste reduction, continuous flow, production line balancing and others with the notable case of a panelised construction enterprise in Edmonton, Canada, applying these principles described in a recent study (Alsakka et al., 2022). Several studies have evaluated the benefits of implementing lean principles in offsite construction, including waste minimisation and workload and workforce density balancing in modular construction (Moghadam & Al-Hussein, 2013; Zhang, 2017), and

batch and inventory size reduction in precast construction (El Sakka et al., 2016), to name a few. In reality, however, the variable nature and other unique characteristics of construction make the implementation of lean manufacturing practices such as *Heijunka* (i.e., levelling out the work schedule (Liker, 2004)) inherently challenging . As argued by Ohno (1988) decades ago and reiterated by Liker (2004), "*the slower but consistent tortoise causes less waste and is much more desirable than the speedy hare that races ahead and then stops occasionally to doze. The Toyota Production System can be realized only when all the workers become tortoises*." The point here is not to advocate for slow production, but rather for steady production that reduces the likelihood of over- and under-utilisation of resources. The variability inherent in construction projects, however, forces workers and machines in offsite construction factories to follow the so-called "hare" approach. Let us consider, for example, a production line for fabricating wood house walls with one workstation dedicated to framing wall panels and another workstation dedicated to installing sheathing. Since walls are of different types, dimensions, and designs, the time it takes to frame a wall panel or install sheathing, if any, will vary depending on the wall type/design. As a result, if, for a given batch of panels, wall framing takes less time than sheathing installation, the workers at the sheathing workstation will be pressured to speed up their work to keep pace with the framers and keep the production line moving. If this batch is followed by a batch of interior walls for which no sheathing is installed, then the workers at the sheathing workstation will be under-utilised while the framers will be pressured to speed up their work to avoid starving the downstream workstations. In other words, the workers are pressured to function as "hares". Operators in offsite construction do endeavor to reallocate tasks among workstations in order to mitigate this effect, as described in Alsakka et al. (2022), but effective levelling of a production line requires detailed knowledge of the variable cycle times at workstations that is not readily available in current practice.

THE NEED FOR INFLUENCING FACTORS

Given this, researchers have employed machine-learning models trained to consider relevant influencing factors (or prediction variables) in order to estimate process time-related variables. For instance, Shafai (2012)—who argued that average task times should not be used to estimate the durations of highly variable tasks performed for manufacturing wall panels of different designs since the manufacturing time is contingent upon the unique design properties of each panel—built linear regression models for estimating the duration of each task (e.g., spray form insulation) as a function of the given panel's design properties relevant to the task at hand (e.g., number of studs, cut zone area, etc.). In another study, Benjaoran et al. (2004) used multivariable linear regression and neural networks to estimate the duration of production processes in a precast factory as a function of twenty influencing factors such as material weight and concrete strength. However, few studies are available in the literature that have followed this line of thinking for estimating process times or cycle times at the workstation level in offsite construction, although there are studies that have followed this paradigm for estimating other related variables, such as a study estimating man-hour requirements for structural steel fabrication jobs using linear regression (Hu et al., 2015), and another estimating the productivity of steel fitting activities in steel fabrication using artificial neural networks and simulation (Song & AbouRizk, 2008). Moreover, despite the critical role prediction variables play in determining the performance of machine-learning models, the identified studies either have not taken a systematic approach or have not thoroughly discussed the approach followed for identifying the factors that may have an effect on the time variables under study (i.e., task time, cycle time, man-hours, and productivity). The value of expending effort on such an approach is not only that it allows for the relevant influencing factors to be identified; it also helps modellers to gain knowledge about the process under study, in turn allowing them to follow a prescriptive approach for selecting and representing predictor variables (Kuhn & Johnson, 2019). In this manner, they can perform experience-driven modelling alongside empirically-driven modelling, thereby reducing the risk of overfitting to erroneous data patterns or of generating models that cannot be rationally interpreted, compared to an approach that relies solely on empirical data (Kuhn & Johnson, 2019).

STUDY OBJECTIVE AND CONTRIBUTIONS

In this context, there is a need for a structured approach for identifying factors that could influence cycle times in offsite construction. This study thus presents a qualitative approach for identifying factors that influence cycle times at the workstation level in offsite construction factories. The identification of these factors, it should be noted, is an important preliminary step when deploying machine-learning techniques to develop cycle time prediction models as part of the lean practice of production line levelling. The approach is demonstrated through its application to a semi-automated, wood-wall framing workstation in a panelised manufacturing factory in Edmonton, Canada. The study contributions are as follows: (1) shedding light on the significance of analysing cycle times at the workstation level in offsite construction factories; (2) presenting the implementation of a generic approach as a way of encouraging researchers and practitioners to expend effort on identifying the factors influencing cycle time, which are significant for the performance and interpretability of machine-learning models developed to predict cycle times or related process time variables for the purpose of optimising production lines and production schedules (in order to ensure more balanced and efficient production); and (3) providing a preliminary list of factors that could influence cycle times at semi-automated wood framing workstations in offsite construction—a list that could serve as a starting point for researchers or practitioners studying other types of framing workstations.

APPROACH AND METHODS

The study followed a three-stage qualitative approach that leverages the benefits of process mapping and semi-structured interviews to identify the factors exerting an influence on cycle times at a wood framing station. The approach is presented in a generic manner in this section, while the next section describes its application to the case framing workstation.

STAGE I: UNDERSTAND THE PROCESS

An adequate understanding of the tasks involved in a process, the resources allocated to it, the manner in which the tasks are carried out, the process inputs, and of the process outputs enables rapid identification of a number of factors influencing cycle time. Process mapping of the current state, in turn, is an effective means of gaining a thorough understanding of a given process. Process mapping generates an abstraction of the process, allowing for it to be better understood and demonstrated and its performance assessed (Giachetti, 2011). The steps followed in building a process map are described in detail in a previous study by Alsakka et al. (2022). Validating the accuracy of the process map with input from the workers actually assigned to the workstation under study is crucial. The case application described in the present study demonstrates the significance of this validation task. The framing machine is equipped with a cutting saw that is used to cut through the top- and bottom-plates of the panels. Throughout the period of observation that formed the basis of the process mapping, the operator at the framing workstation was manually operating the cutting saw for every wall panel. As a result, moving the cutting saw was recorded as a step in the framing process. However, consultations with the operator revealed that in fact the framing machine was in disrepair, and hence, the operator was manually performing a step that would normally be performed automatically by the machine. In other words, what seemed to the analyst to be a normal part of the process (based on observation alone) was in fact the result of equipment breakdown (i.e., a factor affecting cycle time at the workstation). This example underscores the importance of validating the process map based on consultation with workers on the production line as a crucial step in identifying the factors influencing cycle time.

STAGE II: COMPILE A LIST OF POTENTIAL FACTORS

Based on the results of the first stage, the analyst may identify a variety of factors that influence cycle time at the workstation with regards to various elements involved in the process. The analyst may start by specifying high-level classes that could encompass the different types of factors to be identified, since doing so helps to structure and, hence, facilitate the process analysis task. In this respect, a set of eight major classes is proposed in the presented approach—"product", "worker", "machine", "material", "workstation setup", "production line", "factory operations", and "external factors"—these classes having been preliminarily selected based on the authors' understanding gained during the first stage, then confirmed based on a review of the relevant literature (refer to the Case Application section). In relation to each of these classes, the analyst may identify factors that influence cycle time at the workstation. (Examples of factors that belong to different classes are described in the case application section of this paper.) In addition to the process map, a review of previous research that analyses cycle times, productivity, or related aspects of the process under study, or of similar processes in offsite construction factories, could help to identify additional factors and, possibly, additional classes (over and above the eight classes proposed). At that juncture, the analyst would have a profound knowledge of the process under study and would be well positioned to extract relevant factors from the literature. It is advisable to extract all factors that could potentially have an impact on cycle time at this stage as doing so can further bolster the understanding of the process, even if some of the factors are ultimately excluded at a later stage. The outcome of this stage is a group of classes comprising factors that may impact cycle time at the workstation under study.

STAGE III: SOLICIT WORKERS' INPUT ON THE FACTORS

As the cutting saw example described above demonstrates, the input of workers regarding cycle time-influencing factors is critical, since they are the most knowledgeable about the process. The workers' input may help the analyst to better understand certain factors, highlight significant factors, determine which factors are less important, identify additional factors, or identify relationships between different factors. Hence, upon compiling a preliminary list of factors in the second stage, semi-structured interviews can be conducted to solicit workers' input on the factors in the list. Semi-structured interviews, it should be noted, involve a mixture of close-ended and open-ended questions that are often followed with "why" or "how" questions (Adams, 2015). Semi-structured interviews are valuable when the interviewer (i.e., the analyst, in the context of this study) is interested in the independent thoughts of the interviewee (i.e., the worker) or when there are unknown but potential issues and the interviewer needs to pinpoint beneficial leads and pursue them (Adams, 2015). For each of the identified factors, the analyst may start by asking the worker if the factor affects or does not affect cycle time (i.e., a Yes/No question) and then asking follow-up questions such as "why it affects (or does not affect) cycle time", "how it affects cycle time (i.e., positively/negatively)", and "to what extent it affects cycle time (i.e., significance)". In the case application presented in this study, this approach was found to trigger valuable discussions that yielded useful insights.

Given that a fixed and limited number of workers are typically assigned to each workstation in offsite construction factories, it is possible that some workstations will only have a single worker. This means that there may be just a single worker who is deeply knowledgeable about the current state of the process under study in some cases. However, this would not be critical, as the factors would have been previously identified based on a detailed analysis of the process and previous research work and will be further analysed during the machine-learning process in which the factors will be used. In other words, there are multiple input sources for the factors.

CASE APPLICATION

This section presents the implementation of the described approach on a semi-automated wood-wall framing workstation located in a panelised construction factory. In a recent case study on this workstation, cycle times were found to vary significantly, ranging from approximately 1 minute to about 48.5 minutes (Alsakka et al., 2023). This wide range of cycle times underscores the importance of determining the factors that influence cycle times at such workstations.

STAGE I: UNDERSTAND THE PROCESS

The case framing workstation has a semi-automated wood-wall framing machine that performs three operations: nailing, drilling, and cutting. An operator loads the machine with framing elements when prompted by the machine to do so, and the machine performs the required operations. An automated material feeding system moves studs from their inventory location to a location at the framing workstation from which the operator can directly pull them. The components are made ready half a shift or one shift before they are needed, and are placed on a rack located at the framing workstation in the same order in which they will be required by the framer. Moreover, the top and bottom plates of wall panels are stored on a rack located next to the workstation in such a manner that the operator can directly pull the plates to their loading locations on the framing machine. Figure 1 shows the locations of the different elements.

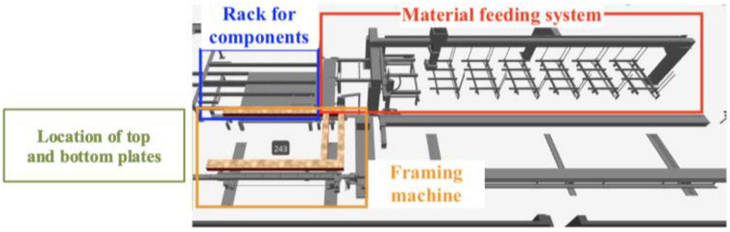

Figure 1: Virtual model of the framing workstation

Given that there are multiple resources (i.e., machine, operator, feeding system) interacting at the framing workstation to frame wall panels, cross-functional diagrams, also known as "swimlanes", were developed to aid understanding as to which tasks are performed by each resource. Cross-functional diagrams, it should be noted, are used to map the workflow of interrelated activities and resources that transform inputs into outputs, as well as to portray the relationships among the various resources performing actions (Damelio, 2011; Giachetti, 2011). A portion of the mapped diagram is displayed in Figure 2. The diagram was first mapped based on observation, and then verified and adjusted based on the operator's feedback.

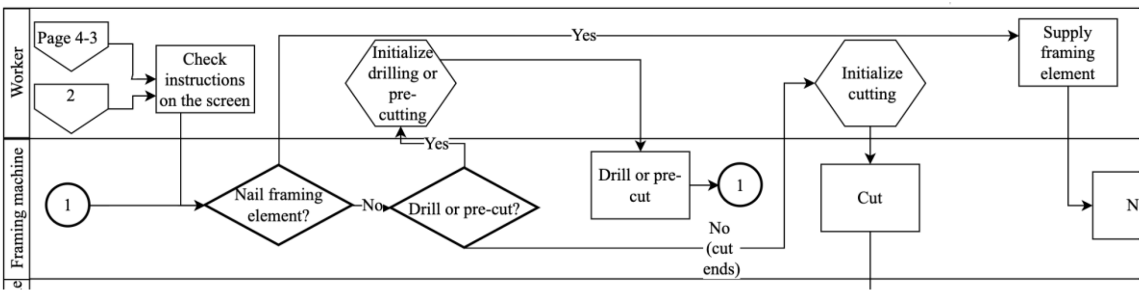

Figure 2: Portion of the framing workstation's cross-functional diagram

STAGE II: COMPILE A LIST OF POTENTIAL FACTORS

For each of the eight classes mentioned above, the factors understood to affect cycle times at the framing workstation were identified based on the authors' understanding gained during the first stage. This was followed by a review of the relevant literature to confirm the comprehensiveness of the classes identified. Because, as previously mentioned, only a limited number of directly related studies were identified, studies examining related metrics such as man-hour requirements and productivity were also reviewed. The factors identified in the relevant literature included, to name a few representative examples, (1) product-related (or design-related) factors such as [length, width, height, surface area,…] for the production of steel panels (Ayinla et al., 2019), [number of single studs, double studs, doors, windows, cut zones, drill holes, nails, screws,…] for the production of wood wall panels (Shafai, 2012), [number of fittings, cut-outs] for steel fitting (Song & AbouRizk, 2008), [number of bolts, length of weld, length of wide flange beams,…] for structural steel manufacturing (Hu et al., 2015), and [nominal height, weight, and width, concrete volume, finishing area, reinforcement weight, concrete strength,…] for precast concrete production (Benjaoran et al., 2004); (2) worker-related factors such as the number of workers (Benjaoran et al., 2004), and skill level (Song & AbouRizk, 2008); (3) material-related factors such as length and weight (Hu et al., 2015; Song & AbouRizk, 2008); (4) machine-related factors such as breakdowns and interactions of material handling systems (Song & AbouRizk, 2008); (5) factory operations-related factors such as work shift (Song & AbouRizk, 2008); and (6) production line-related factors such as activity precedence relationships, queuing, and rework (Song & AbouRizk, 2008). Finally, a list was compiled for 36 classified factors of which the cycle time at the case framing workstation may be a function. These factors are listed in Table 1 below. It should be noted that certain factors that, although may influence framing cycle time, are highly complex and may require a comprehensive analysis of their own (e.g., worker morale, work environment, worker wellness, pay, etc.) were excluded from the case study. It should also be emphasised that, while there may be factors that influence cycle times at framing workstations in other companies, or in other workstations at the case company, only factors influencing cycle time at the framing workstation under study were considered. For instance, the availability of tools and machines is a commonly encountered factor that influences cycle time, but these resources at the case workstation are not shared with other workstations and, hence, are always available. The input of the operator on these factors (presented in the following section of this paper) helps to further clarify meaning, and provide a preliminary justification for inclusion, for the listed factors.

STAGE III: SOLICIT WORKERS' INPUT ON THE FACTORS

At this stage, the operator's input was solicited (via semi-structured interview) concerning the list of potential factors. The operator consulted, it should be noted, has more than ten years of experience working at the framing workstation at the case company, making him highly knowledgeable about the process. The operator was asked whether or not, why (if applicable), and in what manner (if applicable) each of the listed factors affects cycle time. The operator indicated that some of the listed factors are correlated with other factors, which means that they hold information also held by other factors with regards to cycle time. The interview results are summarised in Table (found in the following subsection), where (✓) indicates that the given factor was considered by the operator to influence framing cycle time, (X) indicates that the given factor was not considered by the operator to influence framing cycle time, and (C) indicates that the given factor was considered by the operator to influence framing cycle time, but that the factor is correlated with another one. The operator's comments included in the table are based on written notes taken during the interview. (It should be noted that the comments as represented are a mix of the exact words of the operator and reformulations of some of the operator's input.) Factors for which no specific comments were made during the interview are denoted by a dash symbol in the "operator's comments" cell in the table.

RESULTS AND DISCUSSION

Based on the interview results, the majority of the factors identified in the first two stages were deemed to be relevant based on the operator's input. Accordingly, it was determined that these factors (highlighted in green in Table 1) should be left for the machine-learning process. During the semi-structured interview, the operator provided information that directly resulted in the exclusion of previously included factors, as it became evident based on this information that these factors (highlighted in red in Table 1) do not influence framing cycle time. Removing these factors would help to avoid unnecessary effort expended collecting data on factors that would have been removed during the machine-learning process anyway, as well as reducing the complexity of the machine-learning process. However, factors with respect to which workers may make subjective judgements were not excluded (even when flagged as candidates for exclusion) unless the machine-learning process confirms their irrelevance. For instance, the hypothesis underlying the wall panel design complexity factor is that it may take the operator more time to interpret the shop drawings and load the elements accordingly for more complex wall panels (since they typically require more framing tasks compared to less complex wall panels). Even though the operator indicated that this factor does not affect the time it takes to frame a panel, relying solely on their experience-based input may introduce bias, as it is difficult to assess how long it takes to interpret a shop drawing or load elements from different locations without a quantitative analysis. As such, these factors (highlighted in orange in the table) should be examined in the machine-learning process. Moreover, the operator identified two factors as being correlated with other factors. One of these was panel length (highlighted in yellow), which was indeed found to be correlated with the number of cuts. However, the panel length factor may hold additional information that is not captured by the number of cuts factor or by other factors. In fact, many of the previous studies in this area have used panel length as a factor (as discussed above), further supporting the hypothesis that it is an influencing factor. Additionally, panel length is correlated with the number of holes used for lifting, a consideration that the operator did not mention. This justifies the consideration of panel length as a potential influencing factor, as well as its inclusion in the final list of factors. The other factor identified by the operator as being correlated with other factors was the distance between the nail inventory location and the workstation, this factor being correlated with the nail gun refill factor. Reaching the nail inventory during the process of framing a wall panel was found to be 100% correlated with the nail gun refill factor, and for this reason the former factor can be excluded. Finally, the operator noted that adjusting the machine's opening to accommodate panels of different heights adds an extra step to the framing process for certain panels. Hence, the height difference between a panel and its preceding panel should be examined as an influencing factor. The framing sequence of panels should be also included in the final list of factors to account for any other correlations between cycle times of subsequent panels. Additionally, the operator mentioned that events occurring on certain days may affect productivity (Factor 21). Thus, the framing date should also be considered to better understand cycle times.

Table 1: Results of semi-structured interview

Class	Factors and operator's comments	Effect?
Product	**1. No. of single studs**: - **2. No. of double studs**: "They take more time to nail than single studs as they require more nails." **3. No. of L-shaped studs**: "They also take more time to nail than single studs as they require more nails." **4. No. of multi-ply studs**: "They take more time to nail than the previous three types of studs, and they take more time to nail with every additional ply." **5. No. of regular doors**: "They could take about 6 times longer to nail single studs." **6. No. of large doors**: "They could take about 10 times longer to nail single studs." **7. No. of garage doors**: "I need to do some manual work for garage doors, so they	✓

	take much longer than large doors." **8. No. of regular windows**: "They could about 6 times longer to nail single studs." **9. No. of large windows**: "They could take 10 times longer to nail single studs." **10. No. of cuts**: "Cutting takes about as long as nailing single studs." **11. No. of drill holes**: "The time needed to drill a hole is close to the time needed to nail single studs." **12. No. of blocks**: - **13. No. of components**: -	
	14. Panel length: "Longer panels typically comprise multiple wall panels that are grouped together. As such, they necessitate a higher number of cuts, but this effect is correlated with the number of cuts per panel."	C
	15. Panel height: "This factor may affect cycle time in two ways. First, for higher wall panels, all panel elements (e.g., stud) are heavier. Whether this factor affects or does not affect cycle time depends on each worker. Some workers may find it harder to lift and load longer elements while other workers may not be affected. Second, I should adjust the machine's width between panels of different heights. This task is not required when a batch of panels of equal height are framed sequentially. Moreover, before I can adjust the machine, I must be able to push the completed panel downstream which means that the downstream station must be available. This task adds additional time to the cycle time for certain panels."	√
	16. Panel thickness: "A thicker panel is composed of thicker elements (e.g., 2×6 studs versus 2×4 studs). First, thicker elements are heavier and may be more difficult to lift and load. Second, thicker elements require a larger number of nails."	√
	17. Availability of shop drawings: "Shop drawings are always made readily available before they are needed."	X
	18. Wall panel design complexity (It reflects the variety of framing tasks that the operator must complete for a wall panel): "Aside from the varying time required by each type of element (e.g., single stud versus door), having a panel composed of single studs only versus a panel with a mix of various elements does not affect cycle time as the same steps are followed to load each element and run the machine."	X
	19. Quality of shop drawings (i.e., dictates the frequency of errors + delay + rework time if any): "This factor has a high impact on cycle time. The framing machine cannot read drawings with errors. As a result, I have to stop the work, inform the drafter, and wait for the revised draft before work can be resumed."	√
Worker	**20. Work shift (i.e., morning vs. afternoon) (which could relate to fatigue)**: "This may have an effect, but it depends on each worker and the workstation. For instance, younger workers may work faster at the beginning of the day and start slowing down throughout the day. Meanwhile, older workers may be more consistent in their speed throughout the day. Moreover, when the workstation is semi-automated, the worker's pace may be dictated by the machine's pace, which increases consistency. Sometimes, however, random events may happen throughout the day, and workers could become mentally drained in the afternoon."	√
	21. The day of the week (which could relate to work motivation or fatigue accumulation): "Monday mornings may be less productive as workers return from weekends, which may involve disrupted sleep schedules, alcohol, etc. Tuesdays are more productive as workers become dialled in. Thursdays (given that the company has a four-day work week) may be also productive because workers are motivated to finish their work earlier and start their weekend. Regarding fatigue accumulation, this factor may be more critical in the summer as workers get tired more quickly in higher temperatures and may get less rest after work. This means that their bodies may recover less between workdays, which may lead to fatigue accumulation."	√
	(Note: the operator's comment on this factor was generic and is not applicable to the case workstation given the operator's long years of experience.	X

	22. Learning curve: "This factor has a high impact on cycle time, but it varies among workers. Some workers are fast learners and retain knowledge, while others constantly seek help from others, thereby increasing cycle times."	
Machine	**23. Breakdowns**: "Some breakdowns result in complete work stoppages while others may only cause minor interruptions. For instance, the nail gun may occasionally shoot double nails, requiring extra work to cut the defective nails each time it occurs. Although this extends the framing process, it does not entirely halt production. These issues may occur approximately once every two weeks. In contrast, machine failures that require complete shutdown may last anywhere from 15 minutes to an entire day, and may occur approximately once every six months.	√
	24. Errors: "The machine may result in errors (e.g., nailing defect); a couple of minutes may be spared per incident."	√
	25. Nail gun refills: "The machine's nail gun was replaced with a new one of a different brand, but the new one must be refilled more frequently. Nail refills add more time to the cycle time for certain panels."	√
	26. Motion speed: "The machine has a constant motion speed."	X
Material	**27. Material type**: "Different types of materials (e.g., Laminated strand lumber (LSL) versus Spruce wood) vary in weight (e.g., LSL is heavier than Spruce), and heavier elements may be more difficult to lift and load."	√
	28. Delays in raw material supply: "There are no delays related to raw material supply."	X
	29. Delays in material preparation activities (e.g., sub-assembling door openings): "Material preparation activities are completed one shift or half a shift before the material is needed."	X
Workstation setup	**30. Distance between material inventory location and installation location**: "I must reach the nail inventory location every time a nail gun refill is needed, but this factor is correlated with the "nail gun refills" factor. All the other materials are reachable from my work location."	C/X
	31. Distance between tools location and workstation: "All the tools are located in a way that I can reach them without travelling."	X
Production line	(Note: the framing workstation is the first workstation on the wall production line) **32. Delay at downstream workstations**: "While waiting for the downstream workstation, I could start setting up the machine for the following panel instead of standing idle."	√
Factory operations	**33. Workload – Sq. Ft. per day**: "If the workload is low, the workers may become slower. Meanwhile, high workload may have two outcomes depending on the worker; while some workers may become faster trying to finish the scheduled work during working hours, other workers may become overwhelmed with the increased workload which, in turn, adversely affect their productivity."	√
	34. Overtime shift: "It depends on each worker. My speed during overtime shifts and regular shifts is consistent if overtime shifts are occasional."	X
	35. Weekly cumulative overtime: "In case of multiple overtime shifts during a week, workers do not have enough time to recover and become less productive."	√
External factors	**36. Ambient temperature**: "When the temperature exceeds 20 °C, workers get tired more quickly and become slower since there is no air conditioning in the factory."	√

Following this approach, the modeller will have a set of factors that are highly likely to influence cycle time at a given workstation (highlighted in green), another set of factors that are likely to influence cycle time (highlighted in orange and yellow), and a third set of factors that show minimal or zero likelihood of influencing cycle time (highlighted in red). The modeller will also have a good understanding of how these factors could influence cycle time and, hence, will be better positioned to rationally interpret the performance and the results of a machine-learning model developed to predict cycle times at the workstation under study. This facilitates the development of prediction models that more accurately capture the complexity of the process under study. It is important to note that not all influencing factors will become part of the prediction model. Some factors may be excluded due to various reasons such as data unavailability, an insufficient sample size, or weak correlations with cycle time compared to other factors. The modeller will nevertheless have an awareness of the potential effect of the excluded factors on the results. To further demonstrate the importance of following such a systematic approach for identifying influencing factors, let us consider a brief overview of the results obtained for building a model that predicts processing times (excluding delay times) at the case framing workstation. A multi-layer feedforward artificial neural network model was trained and cross-validated (using a 10-fold cross-validation) using data collected on 172 wall panels framed at the case framing workstation. The case company estimates the capacity of the workstation in linear meter per minute (m/min), so only panel length was used as a predictor variable in the first model. Based on cross-validation results, the mean absolute error was found to be 2.18 min. Adding the geometric properties of the given panel (i.e., Factors 1–16 in Table 1) reduced the error to 1.94 min, resulting in an 11% reduction in the error. Moreover, considering the complexity, day, shift, temperature, height difference, framing sequence, and date factors further reduced the error to 1.80 min, resulting in a total error reduction of 17%. The details of this neural network model are not presented in this paper due to space limitations, but will be presented in a future paper. Nevertheless, this brief overview of the results serves to highlight the value of dedicating time and effort to identifying and understanding the factors that influence process cycle time; Having a comprehensive pool of influencing factors is vital for the development of more accurate prediction models. As such, following the same approach for identifying influencing factors and building prediction models for different workstations, the modeller gains a deeper understanding of what factors drive cycle time variability and becomes well positioned to analyse cycle times across workstations. This, in turn, can facilitate workload balancing across workstations to ensure leaner operations.

CONCLUSIONS

This paper presented a structured approach for identifying and understanding the factors influencing cycle times at workstations in offsite construction factories, an essential step toward more accurate analysis of cycle times across workstations for the purpose of balancing production lines. The application of the approach was demonstrated in reference to a semi-automated, wood-wall framing workstation in a panelised manufacturing factory in Edmonton, Alberta, Canada. A total of 36 potential factors categorised into eight classes were identified based on observation, a cross-functional diagram of the process, and a literature review. These factors were further investigated based on the input of the workstation operator solicited in a semi-structured interview, and the factors were further discussed in light of the interview results. A brief demonstration of their effect on the performance of an artificial neural network model was presented, where using more factors as prediction variables in the model reduced the mean absolute error by 17%. A detailed description of the neural network model will be presented in a future paper. In short, this study demonstrated the value of expending effort on the identification and understanding of the factors influencing cycle times at workstations in offsite construction. Doing so can be expected to aid in streamlining and improving the accuracy of cycle time analysis for the purpose of applying Heijunka and balancing production lines, thereby minimising instances in which workers find themselves playing the role of the “hare”.

EXPLORING OFFSITE CONSTRUCTION FOR THE CONSTRUCTION SECTOR: A LITERATURE REVIEW

James P. Broadhead[1], Emmanuel I. Daniel[2], Olalekan Oshodi[3], and Sa'id Ahmed[4]

ABSTRACT

The construction sector is one of the largest producers of Gross Domestic Product globally and yet has shown little innovation in the last 20 years. Offsite has been touted as cheaper, faster, higher in quality and more environmentally friendly than onsite construction. The purpose of this paper is to review the current research into offsite construction and determine the barriers to adoption and benefits facing offsite construction. A systematic literature review was undertaken to gather relevant knowledge surrounding the subject matter using a database search of Scopus. It was found that knowledge was the largest barrier to adoption and that transcended multiple stakeholders, from the selection of the appropriate delivery methodology, how to design for optimized fabrication and finally how to interface with the onsite requirements. The benefits are a higher build quality, shorter project duration as both site work and fabrication occur at the same time, improved safety, and less material wastage. The Barriers come from design freezes earlier in the process and inflexible design for customization later in the build.

KEYWORDS

Off-site construction, modular construction, prefabrication, advantages, disadvantages

INTRODUCTION

According to McKinsey report (2020), the construction industry globally represents about $10 trillion annually making the construction industry the largest sector globally accounting for 13% of the worlds spending. The construction sector has demonstrated an average growth of 1% year over year compared to 2.8% growth of the global economy. McKinsey estimates the productivity performance in the construction sector represents $1.6 trillion in potential value added that could be generated by higher productivity. At the same time, the sector has suffered from inefficiencies and persistently low levels of productivity, largely the result of a fragmented supply chain, which still hampers its ability to embrace innovation (Department of Business Innovations and Skills 2013). When looking historically over the construction sector performance has shown a consistent 1% growth over the last 20 years (Mckinsey, 2020). The risks in the delivery of construction projects remain high, it is very typical for projects to run over schedule (typically 20% over) and costs (up to 80% over). When combining the high-risk

factor with a low profitability, around 5% and that can be less depending on where in the value chain the specific construction company performs, construction companies are frequently the highest hit about insolvency (Mckinsey, 2020).

Based on the low growth and lack of efficiency, the construction industry is open to the risk of disrupters looking to capitalize on the $265m profit pool on the table. That profit pool could be further improved if projects can successfully shed risks. Industrialization in the (1970-1980), globalization (1990 -2000) and digitalization (2010-present) have all been key drivers of change in all other industries. As these drivers hit the construction industry, and are continuing to play a role, it is expected that disruption is likely within this sector (Mckinsey, 2020).

One solution that follows the key drivers to change and presents an opportunity for disruption within the construction sector, is the adoption of offsite construction (Mckinsey, 2020). Goddier and Gibb (2007) define offsite construction as the 'manufacture and pre-assembly of components, elements or modules before installation at their final location'. In a modern context prefabrication or offsite construction, which includes modular construction, refers to the pre-fabrication or fabrication of individual units that are assembled on-site to construct the final building (Jang, Ahn and Rob, 2022) (Marte Gómez *et al,* 2021).

The Prefabrication industry has been under review by different bodies of research and concluded it is faster by 34% cheaper by 19% and a higher quality than conventional construction (Shahzad, Mbachu and Domingo, 2015). A recent study has pointed to offsite construction to improve project efficiency (Steinhardt *et al*, 2016). Industry literature produced by the Modular Building Institute (MBI) touts the benefits of site construction to be further reaching adding to the benefits to include improved worker safety, reduced wastage, and offsets labour shortages (MBI, 2021).

Lou and Guo (2020) found that offsite construction is a complicated system that has multiple stakeholders influenced by different drivers. Inefficacies in design, transportation, storage, manufacturing, building installation and onsite construction all negatively influence construction costs.

The global offsite industry generated $130.4 billion in 2020 with expectation of forecast growth to $235 billion by 2030. As a market share this value places offsite construction at 1.3% (Market wise). Globally the adoption rate varies by region. The market share is very similar within the UK, Australia and the US representing prefabrication as less than 5% of the elements for housing compared to 84% in Sweden, 15% in Japan and 20% in the Netherlands (Cerro, 2021). This is also supported by the Journals reviewed with nine of the twenty-six studies coming from the UK and nine from Australia compared to none from Sweden or the Netherlands indicating that studies into barriers for adoption are not warranted and the value proposition is well established.

Goddier and Gibb (2007) research focused on the construction industry in the UK in 2007, the rate of evolution albeit slow in the construction sector has moved on in the last 15 years it opens up the content to questions regarding relevance today. Cerro (2018) work is more recent and focuses on the United States citing an affordable housing challenge with a lagging supply of homes indicating that adoption rate of innovative practices is still lagging, furthermore Cerro (2018) points to learning from Sweden, Japan and the Netherlands based on adoption rate. Steinhardt *et al*, (2016) researched the structure of the industry and what type of businesses were successful missing the advantages and disadvantages to adoption. Shahzad, Mbachu and Domingo (2015) reviewed 66 completed projects to assess their performance in New Zealand, however, this work did not look at the barriers to adoption. Lou and Guo (2020) only focused on costs for projects in China.

Based on the potential for efficiency gains and risk reduction in an industry that carries such a large profitability this research aims to identify the existing benefits and barriers to offsite construction to help inform why the adoption rate is so low in some regions and not in others.

The construction market value is there and has remained very stable, which also begs the question why disruption is not more prevalent within this sector. Thus, this paper seeks to undertake a systematic review of current literature studies and further answer the following set of research questions:

RQ1. What is the current knowledge surrounding the barriers adoption of offsite construction?
RQ2. What is the current understanding of the benefits to offsite construction?

METHOD

Several types of literature review can be identified in the existing knowledge. According to Clark et al. (2021), narrative review and systematic review are the main types of literature review. When compared with narrative review, systematic review provides comprehensive and rigorous analysis of the existing knowledge on a selected topic (Tranfield et al., 2013). This research method has been used to analyse the existing knowledge on apprenticeship (Daniel et al., 2020) and public private partnership (Tang et al., 2010), among others. In the current research, the systematic review was done in three stages. The initial stage identified the key papers of interest based on a database search of Scopus. The second stage involved limiting relevant and excluding irrelevant information in the search criteria. The final stage was conducted by reviewing the content and analyzing for relevance against the research aims and objectives.

Based on the research questions, a list of key terms was identified for the literature search. The shortlisted terms were further analyzed to identify additional words commonly used in different geographic regions. For example, 'Offsite' is used in the UK as supposed to Malaysia where the use of "Industrialized" is more common. The initial search data set was used as a scoping study to identify other key words that may appear on additional studies that would be otherwise excluded from the search criteria.

The research team decided to remove conference papers due to limited online access. The journal papers included in the study's sample have been peer reviewed and this process validates the findings emerging from those studies. The benefit of secondary research is that the breadth of data available is very extensive compared to a limited primary research approach. By accessing Primary sources, the intent is to access the original research into the field and by focusing on peer reviewed journals the quality will be controlled. The roman emperor and philosopher, Marcus Aurelius had a similar thought when in 160 he said:

"Nothing has such power to broaden the mind as the ability to investigate systematically and truly all that comes under thy observation in life"

Scopus database was selected as it contains the largest abstract database of peer-reviewed literature. With multiple search criteria options it is very useful in identifying the key studies of focus as these primary sources of information are updated on a regular basis. A potential limitation of the study is the use of only Scopus as the research database and may miss some research studies as a result that are available on other databases. The thinking in only selecting Scopus was to limit study duplication and potential over complication of the research data by trying to work through multiple databases simultaneously. Google Scholar was rejected as it is not a database and would not allow for a systematic review of the available literature. The use if Google Scholar would require a labour-intensive manual approach that was rejected as the research method due to the time required and lack of repeatability. Web of science was rejected based on the initial number of studies returning 705 studies compared to 1,963 with Scopus. It was determined that Scopus cast a wider net initially therefore offering a larger research body as a basis.

("offsite construction" OR "off-site construction" OR "off site construction" OR "offsite Manufacturing" OR "off-site Manufacturing" OR "off site Manufacturing" OR "offsite Manufacture" OR "off-site Manufacture" OR "off site Manufacture" OR "offsite fabrication" OR "off-site fabrication" OR "off site fabrication" OR "Prefabrication" OR "Pre-fabrication "OR "Modern Methods of Construction" OR "Lean Construction" OR "Industrialized Buildings" OR "Modular Construction" OR "Modular Building") AND ("Barrier" Or "Benefit*"OR "Popular" OR "adoption")

The first stage generated a total of 1,963 potentially relevant studies based on the database search. After limiting the results to those available in English, Journal articles and duplicates a total of 238 studies were reviewed by subject area, title. This process was relatively simple to undertake and weeded out several irrelevant studies. For titles that were not as clear or abstracts that answered part of the research focus a more detailed review of the abstracts was required leaving 141 studies. Following the abstract review, a total of 69 studies were deemed to be potentially relevant and required a full text review including introduction, findings and conclusions.

Upon finalizing the screening process, the remaining research left 28 studies that required a full content analysis. Once confirmation against the research aims and objects were confirmed the list was finalized in SCOPUS to create a bibliography. Further data relating to country of origin, guiding themes contained within the literature for (1) benefits of offsite construction (2) Barriers to adoption.

RESULTS

Literature map on the Emerging Themes of Offsite Construction		
Benefits		**Barriers**
Higher quality		**Lack of knowledge of efficient delivery**

Figure 1: Literature map on the Emerging Themes of Offsite Construction

The benefits and barriers to adoption from the systematic review have been placed to represent the common findings in the Literature Map as shown in Figure 1. There are contrasting views across the study, interestingly the researchers are more aligned on the benefits based on the tighter grouping and more succinct topics when compared with more sporadic points on the barriers to adoption.

RQ1. What is the current knowledge surrounding the barriers to adoption of offsite construction (globally)?

The biggest barriers to adoption are knowledge, higher cost, perception, design, lack of skilled labour and complexities in supply chain.

Knowledge on how to identify the risks of offsite construction and apply the learnings to meet the business objectives is required to increase the rate of adoption (Peltokorpi, 2017). The existing knowledge as it pertains to onsite delivery does not apply in the same way as the entire approach in project execution is different from design, fabrication, transportation, and site installation (Peltokorpi, 2017). Education specifically on the following areas: in first selecting the appropriate delivery methodology based on project goals, design suitable for manufacturing reducing turbulence, robust project execution planning with an understanding on risks mitigation strategies, integration of supply chain earlier in design to reduce the introduction of complexity and lastly procurement strategies to align with project objectives.

Pre-construction requires more upfront skilled labour in design due to the complexities that need to be solved earlier in the process than compared to onsite building (Navaratnam *et al,* 2019). This is partly driven by the requirement to order long led items earlier in the process and in part due to the design needing to be more complete earlier for design freezes to be in place prior to fabrication.

Supply chain integration focuses on the flow of materials from suppliers to the site on time for the work to commence and providing value across the interrelated business (Sooriyamudalige *et al*, 2020). In onsite construction this is a well-established process for mature general contractors. Offsite construction however follows a different network, in most cases, of unfamiliar supply chain suppliers in the form of skilled design practitioners, fabricators and installers (Sooriyamudalige *et al*, 2020). By a conventional site builder to integrate offsite construction it is fair to deduce an entirely new supply chain will be required to deliver the project. First, understanding of the complex supply chain is a barrier to adoption of offsite construction and secondarily the knowledge of how to plan and implement the delivery approach to avoid delays is lacking. Regionality has an impact on the research findings specifically in the complexities in the local supply chain, regulatory processes, and government incentives country to country (Sooriyamudalige *et al*, 2020; Zhang, Skitmore and Peng, 2014).

Tam *et al* (2017) found that inflexibility for change in design scored the highest challenge in their study and happened to be derived from previous project experience whereby the design was not frozen and doing so caused the consultant and client team frustration in unmet goals. Design happens earlier in the process for offsite construction and requires an early integration of stakeholders including manufacturers and suppliers all leading to a long lead into the construction process (Pan, Gibb and Dainty, 2007). Changes in design that happen later in the fabrication process can be more costly than conventional construction which may also be linked. Furthermore, understanding some of the barriers to adoption specifically around complex supply chains and lack of knowledge may also be driving costs up in some projects. Prefabrication is not new and with that comes preconceived ideas of how the building approach will influence the project outcomes based on past experiences and dated connotations from the post war reconstruction (Shahzad, 2015).

RQ2. What is the current understanding of the benefits to offsite construction?

The benefits to offsite construction, that are widely supported, include a reduction in schedule and higher quality. Additionally, a reduction in costs, wastage and improved safety round out the remaining findings.

Pre-fabricated buildings are constructed in controlled environments out of the weather conditions leading to a higher quality of build than compared to onsite construction (Shahzad, Mbachu and Domingo, 2015). Inside fabrication facilities technology can be deployed to increase the accuracy of material processing, reducing waste and improve built quality (Cerro, 2021). Due to the fragmented construction approach with buildings being constructed separately to the site allowing progression of both entities the progress at the same construction times can be reduced if both the manufacturing and the site maintains the as planned schedule (Si *et al,* 2021). Si *et al* (2021) goes on to identify a potential contracting strategy to help financially incentivize on time completion, in reality it would be very hard to integrate a new contracting method that is not normalised in the industry.

Shahzad, Mbachu and Domingo (2015) connotes a reduction in cost and schedule savings with conventional construction taking longer than offsite therefore indicating a lower cost for prefabricated buildings. The softer benefits of health and safety appear to be less relevant as a primary driver for winning work based on how larger contracts are awarded and tendered. Safety is perceived as a baseline opposed to a tangible differentiator like faster completion or lower cost.

DISCUSSION

Pan *et al* (2007) interviewed the top 100 performing home builders in the UK and found the majority of stakeholders are satisfied with traditional construction methods and furthermore the drivers for building methodology are tied to the historic considerations for contractors. When considering if a construction scheme will proceed with traditional onsite or prefabrication methods contractors typically make decisions based on schedule, cost, quality, and productivity. Pan *et al* (2007) study did not differentiate between actual stakeholder experiences or if the responses were based on perception. The drivers for decision making are important in understanding which of the benefits, and barriers are most relevant to the broader industry to determine if the barrier is a result of an actual route cause issue that needs to be solved or based on a preconceived perception because the remedies are different for each outcome.

BENEFITS

Schedule efficiencies are gained due to the fragmented delivery whereby the site progresses in the same sequence as conventional methods and the offsite components are manufactured at a factory simultaneously before being put together at site (Arashpour *et al*, 2014). This can result in schedule efficiency over that of site-built projects due to a reduction in time onsite with up to 34% in time savings (Shahzad, Mbachu and Domingo, 2015). ***Shorter schedule*** is thought to be the largest benefit of prefabrication compared with traditional construction (Tuesta *et al,* 2022), this point is supported by nine of the thirteen contractors surveyed by Goodier and Gibb (2007) in their contribution *The research into the future opportunities for offsite in the UK.* Goodier Gibb (2007) used their previous studies in the literature review, this could have led to bias in towards the findings of this later research being influenced by outdated findings and missing current thinking. The incorporation of prOSP (pre curser to Buildoffsite) would help answer the question as to the future opportunity of prefabrication in the UK construction industry but is unlikely to offer a balanced view due to the pro-offsite nature of the body. The inclusion of a sub section of stakeholders including clients, construction industry, offsite fabricators lend to a triangulation of opinions on the same perceived benefit adding further credibility to the results.

Offsite construction is bound by the same building codes as onsite construction and uses the same certified design professionals in the process. As such assembled buildings are virtually indistinguishable from their on-site counterparts (Chen *et al*, 2019). On site construction by contrast can experience variable environments with inclement weather conditions challenges with quality forcing rework and labour constraints for specialist trades (Arashpour *et al*, 2014). Due to offsite buildings being constructed in a factory setting, where the conditions are controlled and the skilled work force is performing repeatable tasks, a consistent and **higher quality** of fabrication can be produced (Jang, Ahn and Roh, 2022). None of the research challenged the quality of the offsite process therefore it may be surmised the body of knowledge agrees that quality is better when factory produced.

Extensive research has been conducted into the **cost impact** of offsite delivery to project budgets. It is reported to reduce costs derived from shorter schedule and more efficient use of labour. However, there can be an increase in material costs, for example the doubling up of interior walls in volumetric deliveries or shipping walls that are then disposed of once the components reach the site. It is expected that even with the increase in material for building completion the cost is offset against material wastage from onsite building due to inclement weather and mistakes. For the cost benefit to be realized the labour on the project needs to be managed effectively and any impacts of material costs to be reduced (Loizou *et al.* 2021).

It is important to recognize the delivered cost of a project not just the initial price since prefabrication can deliver a higher quality with less wastage and a significant reduction in snags or defects at the close out stage offering a potential lower end cost (Goodier and Gibb, 2006). Modular construction costs in Singapore are reported to be higher than site built concrete construction as much as increase of 8.1% (Jang, Ahn and Roh, 2022), however only one direct comparison was used as a comparison with a steel delivery. If a more robust process was used to evaluate the multiple solutions, there may have been a potentially different outcome for example that case study used would have likely been delivered through wood framing in North America.

Offsite construction, no matter which form, requires a different design approach than compared with traditional methods. The more complex the project and delivery methodology chosen has a direct correlation to the amount of specialized knowledge experts, sub consultants and inextricably the time it takes in predesign **increasing costs** (Navaratnam *et al,* 2019). Largely these costs can be offset by the time savings when moving into production and a shorter duration of occupancy.

The **environmental** benefits of not using wet construction methods in some forms of prefabrication prove beneficial in diverting waste from land fill. (Cerro, 2021). Global construction activities produce approximately 25% of all solid waste, with 40% of material in landfills as a result of construction activities. (Loizou *et al,* 2021). To fully understand the environmental benefits of modular, more recent studies have elected to review the full life cycle assessment (LCA) to better determine the impact (Jang, Ahn and Roh, 2022). Life Cycle assessments when using conventional process do not reduce the margin of error to an acceptable level in part due to the complexity and diversity of the supply chain (Aye *et al*, 2012). This has led to an absence of detailed research in environmental performance to substantiate the environmental benefits as it pertains to prefabrication.

Social sustainability covers the wellbeing people get from the places in which they reside and work. Recent research indicated the offsite construction is a **less hazardous environment** and is more controllable with a reduction in injuries and less onsite noise (Loizou *et al,* 2021). The fabrication process can be louder, but this is often in industrial estates having a lower impact on the community. Li *et al* (2010) argues that due to the size of prefabricated components the risk profile on sites can increase creating a more hazardous environment to work in but does not provide evidence to support or a methodology for the research conducted and does not consider the vertical integration of trades in the precast industry like Steinhardt *et al*. (2019). Due to less time onsite prefabrication reportedly has less safety risks by default. (Blismas, Pasquire and Gibb, 2007; Zhang, Skitmore and Peng, 2014; El-Abidi *et al*, 2019; Goodier *et al*, 2019).

BARRIERS

Tam (2007) found that **inflexibility for change in design** scored the highest challenge and happened to be derived from previous project experience whereby the design was not frozen and doing so caused the consultant and client teams frustration in unmet goals (Tam *et al*, 2007). The research method in this case included a survey based on a literature review to identify the key areas to be graded as benefits and barriers. The author covered a broad base of stakeholders but did not disclose how many of the respondents were represented in the study results making it challenging to assess the validity of the results.

Design happens earlier in the process for offsite construction and requires an early integration of stakeholders including manufacturers and suppliers all leading to a **long lead** into the construction process. (Pan, Gibb, and Dainty, 2007).

A significant choking point in the delivery of offsite construction in China is related to the inefficiency of **Supply chain**. The trades are complex and disjoined in their approach leaving coordination to be challenging. Unlike more developed countries with mature supply chain and standardized construction programs (Zhang, Skitmore and Peng, 2014). Compared to the UK where there is a standardized building system, by comparison, the supply chain limitations inhibit the design community adoption of offsite construction. (Pan, Gibb and Dainty, 2007).

Aside from the benefits associated with offsite construction, the industry is still dogged by some of the same challenges as onsite construction, in terms of inefficient prefabrication methodologies. These inefficiencies are caused by dispersed and often **lack the coordination** to prevent work starvation (Arashpour *et al,* 2014). Most factories are set up in a linear fashion whereby each station is trained to perform one task. When inefficiency is found a bottle neck can be created when oversubscribed tasks take longer to perform than others. The more efficient a building can be constructed in a factory setting the better the flow and less turbulence it generates. Construction by nature contains a high degree of turbulence. The degree to which the prefabrication encounters **turbulence** due to the variation in dimensions, material selections, transportation requirements can degrade the fabrication system (Mossman and Sarhan, 2021).

Offsite construction uses a different supply chain and requires in-depth understanding by **skilled labour** of how the buildings are designed, built, moved and interface with the site. There are a limited number of professionals with this skill set today (Sooriyamudalige *et al*, 2020).

Si *et al* (2021) suggests that the challenges faced with **inefficient communication** caused by a fragmented delivery process whereby work and onsite are controlled differently can be resolved by realigning the contract terms whereby if the factory causes a delay they are penalized and where the General contractor allows a production schedule that favors the factory, they are incentivized. This appears to be a complicated solution that most stakeholders will not be familiar with. Where there is a stakeholder lack of understanding this approach may lead to further complications as it doesn't align with traditional construction procurement practices (Daniel *et al,* 2018).

Perception within the market has a negative impact on the adoption rate whereby past experiences have not been positive or concerns with quality from industry examples in past eras influence decision of today. The lack of flexibility in the design, typically being limited to the builders pre-determined designs (Shahzad, Mbachu and Domingo, 2015) contributes to the decision of conventional builds.

Knowledge Typically Suppliers (30%) believe their customers are not fully educated on the benefits and barriers for offsite construction compared with the designs (73%) and Builders (54%) who believe they are fully aware (Goodier and Gibb, 2007). Traditional construction experience and understanding how the offsite approach of choice works is a knowledge gap that needs to be closed to have a better adoption rate of prefabricated construction (Goodier and Gibb, 2007).

Summary

Global perspectives help to inform the potential benefits and barriers to adoption. The local supply chain, government involvement, knowledge and perceptions all have an impact on the potential outcomes of the project success with an offsite delivery. A gap in the research is: *What knowledge is required effectively to deliver offsite construction in Canada leading to more desirable outcomes?*

CONCLUSION

This research sets out to identify the benefits, and barriers to adoption for offsite construction.

Based on the qualitative analysis of this study it can be concluded that efficiency can be improved when the benefits of higher quality and improved schedule are realized when compared to conventional construction. The barriers are largely around design and understanding of how to work within an offsite delivery process whereby design is frozen earlier. When the design is not efficient for the fabricator it impacts the project line flow and has a knock-on impact to cost and schedule. This research found a lack of knowledge, specifically in design for manufacturing, interfacing between onsite and offsite works, understanding the supply chain and how to mitigate the complexities create further barriers to adoption.

The results of this research provide relevant industry stakeholders with the identification of benefits, and barriers to adoption of offsite construction. By understanding the barriers adoptees can effectively plan mitigation strategies to avoid issues with design freezes and potential cost increases. Recognizing the barriers to adoption will inform potential objections from partners that may need to be overcome to progress with an offsite delivery and help to inform new supply chain strategies.

This study was limited to using Scopus database only, as such the use of more databases could have provided richer evidence.

The findings confirm that there is a gap of knowledge in Canada, to better understand the implication from the results a future study could answer questions of; stakeholder knowledge, how to interface effectively between the fabrication and onsite works and what influence the local supply chain complexities have upon the delivery methodology. Based on this evidence it is recommended that an empirical study be conducted in the specific geographical region of Canada to capture the intricacies of local supply chain based on the limited research into this region specifically to interrogate the findings locally. By using a cross section of the industry including design consultants, fabricators, contractors, and customers would better allow to differentiate between lived experience and perception in the study and focus on the knowledge gaps that exist to better provide specific solutions.

BENEFITS OF ROBOTIC UTILIZATION IN THE PREFABRICATED CONSTRUCTION INDUSTRY

Peter Adekunle[1], Cliton Aigbavboa[2], Osamudiamen Kenneth Otasowie[3], and Samuel Adekunle[4]

ABSTRACT

Electronically automated machines with a longer lifespan than human work make up robotic technology. The aging workforce in the prefabricated building business may be addressed by robots, which explains why there are less young people employed there than in other sectors of the economy. Robotic technology is cost-effective since it reduces the time required to complete building projects and the expense of manpower, which also lessens the possibility of accidents. Therefore, it is crucial to consider the benefits of robotic technology adoption in the context of the South African prefabricated building industry. The study adopted a quantitative survey method to obtain data from architects, civil engineers, quantity surveyors, mechanical and electrical engineers, construction managers, and project managers. The data were examined using SPSS, and the suitable dispersion measure and inferential statistics were used. According to the report, the key benefits of adopting robotic technology in the prefabricated building business in South Africa include faster construction timeframes, improved work quality, and increased productivity, efficiency, and profitability. The results also showed that improving worker health and safety would result from introducing robotic technology to the prefabricated building industry. The study's conclusions suggest that because of the advantages discovered, the prefabricated building industry in South Africa should adopt robots more swiftly.

KEYWORDS

Robotics, Prefabrication, Accuracy, Construction Duration

INTRODUCTION

Mhlanga & Moloi, (2020) claim that South Africa is one of the world's emerging nations. Because building processes have changed and improved through time, the industry is currently experiencing a productivity issue due to a lack of investment in technical development. The South African construction industry must adapt to technological advancements on a worldwide scale since technology is essential to increasing effectiveness. According to Akinradewo et al., (2021) the use of robotic technology in the prefabricated building sector would improve worker health and safety since robots will do laborious activities on the construction site. Also, Maurice et al., (2018) opined that there will be lesser health problems associated with physically demanding construction labor. Its adoption is primarily for employee welfare. Less

accidents and unplanned events will occur because of the use of robot technology in the prefabricated construction sector. Prefabricated materials might endanger the health and safety of manual employees since they are bulky and heavy. In modern businesses like the chemical and educational industries, robots have helped lift the heavy goods (Grau et al., 2020). According to Adekunle et al., (2022), robotic technology will also handle the repetitive jobs, cutting down on task length. Consequently, projects will be finished on time and within the allotted time framse without experiencing any more delays. It is crucial to consider the advantages of robotic technology in the context of the prefabricated building sector.

Robotic technology is the automation of machines using electronics to improve their accuracy (Toma et al., 2022). They outlive human effort in terms of lifespan. Robots are the answer to the labor shortfall caused by the construction industry's needs and an aging labor force (Flandorfer, 2012). Since these robots are trained to carry out certain jobs in detail, their precision minimizes errors brought on by improper handling and underestimation of building processes. Therefore, using robot's technology improves the quality of the job produced. Robotic technology can save money since it cuts down on labor expenses and building time. There seems to be a lack of information in the literature about the advantages of using robotics within the prefabricated construction industry practices being carried out in developing and sub-Saharan countries like South Africa, aside from the issue of the prefabricated construction industry's poor adoption of digitization. It is crucial to keep in mind that South Africa is only now beginning to adapt and use prefabricated construction. This study evaluated the benefits of adopting robotic technology for prefabricated construction processes within the South African construction industry based on this information, with the goal of suggesting potential actions that would lead to an increase in utilization.

LITERATURE REVIEW

Due to a number of well-known obstacles, the adoption of robotic technology within the construction sector has historically been met with great opposition (Carra et al., 2018). Thanks to several recently discovered forces that are driving innovation processes within the construction sector, the situation is now changing quickly. Additionally, these factors gave rise to several easily visible trends that are altering how buildings are designed, constructed, and maintained. Because there is less human labor present when robotic technology is deployed, there are less opportunities for mishaps and strike breakouts (Delgado et al., 2019). As a result, robotic technology is a more dependable alternative to manual labor in terms of efficiency, production, and profitability. It is crucial to understand that prefabricated components are made in a factory with rigorous regulations, in a regulated, and under constant observation environment. This suggests that enhanced work supervision and factory inspections are carried out to guarantee that the components adhere to specification, according to Zhu et al., (2021). Additionally, components are produced in factories and merely transported to the construction site to be built into the required structure, requiring less handling and storage of resources. As building projects are delivered in modules to be built on site, less material storage and handling leads in lower site waste (Mahbub, 2012). The factories are constructed so they may repurpose building materials that were utilized in a prior manufacturing or production process. Due to this phenomena, more recycled materials are being used (Bademosi & Issa, 2022). Prefabricated construction is an ecologically beneficial method of building that will aid the sector in attaining its aims for sustainable growth. Robotic technology can help with material logistics and on-site assembly for reasons of health and safety.

Since the construction sector is dangerous to work in, businesses aim to adopt safer practices. And as a result of human's construct subassemblies in climate-controlled factories, there is a reduced likelihood of issues with dirt, dampness, and other environmental dangers when employing robotics for prefabrication (Malomane & Musonda, 2022). Prefabricated building structures and assemblies are now as sturdy as conventional structures because to advances in engineering and prefabricated material technology. A factory-controlled environment offers greater safety compared to a project job site since employees and potential tenants are more vulnerable to weather-related health concerns on construction sites. Additionally, stricter production protocols and practices shield employees from workplace accidents. Despite the importance placed on worker safety at construction sites, shifting ground conditions, weather-related circumstances, and wind all increase the risk of accident. Another advantage is that the building business will become more productive, efficient, and profitable as a consequence of the implementation of robotic technology in the prefabricated construction sector (Tankova & Da Silva, 2020). Given how few construction companies now use automation, robots hold enormous potential for revolutionizing the sector.

Robotic technology's use in the lifting of large objects will reduce the demand for physical labor because workers won't need to engage in arduous activities there (Kyjanek et al., 2019). For the safety of human workers as well as the financial health of heavy industrial and construction enterprises, a robot is an attractive alternative to a human employee. The world population is aging, and the construction sector will have a difficult time attracting new employees in the future. The use of robotics technology appears to be the industry's panacea. Companies will recruit younger, more technologically knowledgeable employees if they are regarded to be implementing cutting-edge techniques and technology (Oke et al., 2019). Additionally, this will guarantee that businesses can retain productivity when the number of people in the globe who are working-age declines. Prefabricated materials are produced in facilities with extensive quality assurance and control procedures (Yahya et al., 2019). Realizing the harmony and unity of all parts is essential to building quality management. Considering construction quality management in its whole will help to advance the development of construction quality. Robotics adoption not only enhances quality management through the creation of economic advantages, but also fosters the growth of businesses (Adekunle et al., 2022). Less accidents and unplanned events on the job site will come from the application of robotic technology in the building procedures. Since robots are machines and are programmed to do certain tasks, there are fewer opportunities for error than there are with manual labor.

Robotic technology is appropriate for heavy lifting in a construction setting where flexibility and range are crucial (Pan et al., 2018). Robotic technology lowers building expenses and ultimately generates enormous profits for construction companies because it removes the possibility of human mistake and waste while producing results that are extremely exact. The robots have a long-life span because they are machines they merely need to be maintained and updated as frequently as necessary (Pan & Pan, 2019). Literature demonstrates that employees may easily disassemble and move sub-assemblies to other locations (Huang et al., 2022). But since prefabricated building technologies offer flexibility without stifling innovation, general contractors and clients are increasingly turning to alternatives. The use of robots in prefabricated and modular building opens up a world of possibilities by allowing for flexible structural design.

METHODOLOGY

This study used a structured questionnaire that was given to quantity surveyors, architects, engineers, construction managers, and project managers as part of a quantitative methodology. These experts were chosen from the public and private (contractor and consulting) sectors. These experts were chosen from the public and corporate sectors of Gauteng, the country's largest province. The province was chosen due to its strategic position and capacity to handle administrative duties. The province is also the core of high-end service delivery for industries including manufacturing, technical and industrial services, and construction. Those registered with the different professional organisations in South Africa and other countries in the Southern African area were the construction industry's target professions. This precaution was deemed essential for the poll to guarantee that the findings accurately reflected the public's perception of the advantages of adopting robotic technology. 110 professionals were chosen as the sample size using a non-random sampling approach. As in the study conducted by Adekunle et al., (2022), a closed-end questionnaire was created and split into two portions. The purpose of the first portion was to gather demographic data from the respondents, such as their level of education, occupation, and experience. The purpose of the second section was to evaluate the benefits of using robots. In order to evaluate the advantages of robotic use, a 5-point Likert scale was used. 88 of the 110 questionnaires that were distributed received a response, which is an 80% response rate. When analyzing the collected data, percentages were used to evaluate the advantages of using robotic technology in pre-fabricated homes, and Mean Item Score (MIS) was used to rate the data on the respondents' backgrounds. Kruskal-Wallis was also used to compare respondents' perspectives based on their years of experience. The Cronbach's alpha reliability test, which was used to evaluate the data sets' dependability, yielded a result of 0.905, which denotes a high degree of consistency.

FINDINGS AND DISCUSSION

In terms of gender, the statistics showed that men, who made up 73.2% of respondents, received more responses than women, who made up 26.8% of respondents. In terms of profession, 14.2% of respondents were civil engineers, 13.3% were mechanical and electrical engineers, 24.5% were quantity surveyors, 4.5% were project managers for construction, 15% were managers of construction, and 13.2% were project managers. Moreover, 49.4% of respondents worked for contracting firms, while 29.9% were consultants. Also, 20.8% of them worked for the government. In addition, more than 87% of the respondents claimed that they had worked on seven or more projects, while the remaining 13% had only worked on six or less. The responses were trustworthy and credible as, on average, more than 90% of respondents had over five years of working experience in the South African construction business, which is a significantly high proportion.

Table 1 shows the respondents ranking of the benefits of the application of robotic technology in the South African prefabricated construction industry in Gauteng. The results reveal that ‘shortens construction duration’ was ranked first with a mean score of 4.25 and standard deviation of 0.821, ‘Improved quality of work’ ranked second with a mean score of 4.24 and standard deviation of 0.951, ‘productivity, efficiency and profitability’ ranked third with a mean score of 4.22 and standard deviation of 0.856, ‘less material storage and handling’ ranked fourth with the mean score of 4.16 and standard deviation of 0.857, ‘less accidents and unforeseen circumstances’ ranked fifth with the mean score of 4.14 and standard deviation of 0.939. Furthermore ‘suitable for lifting heavy materials’ ranked sixth with the mean score of 4.10 and standard deviation of 0.900, ‘improved work supervision’ ranked seventh with the mean score of 4.04 and standard deviation of 1.095, ‘improved health and safety culture’ ranked eighth with the mean score of 4.02 and a standard deviation of 1.104, ‘Reduced mishandling and miscalculation’ ranked ninth with the mean score of 4.00 and standard deviation of 0.980, ‘reduce health issues for strenuous activities’ ranked tenth with the mean score of 4.00 and a standard deviation of 1.077, ‘reduced site waste’ ranked fourteenth with the mean score of 3.88 and standard deviation of 0.931, ‘long-life span’ ranked eleventh with both having the mean score of 3.88 and standard deviation of 0.952, ‘increased use of recycled materials’ ranked thirteenth with the mean score of 3.86 and standard deviation of 1.020, ‘solves ageing population crisis’ ranked fourteenth with the mean score of 3.71 and standard deviation of 1.119 and ‘cost effective’ ranked fifteenth with the mean score of 3.45 and the standard deviation of 1.006 as the least benefit of the application of robotic technology in the South African prefabricated construction industry.

Table 1: Benefits of Adopting Robotic Technology

Benefits	Rank	Mean	Std. Deviation
Shortens construction duration	1	4.25	0.821
Improved quality of work	2	4.24	0.951
Productivity, efficiency and profitability	3	4.22	0.856
Less material storage and handling	4	4.16	0.857
Less accidents and unforeseen circumstances	5	4.14	0.939
Suitable for lifting heavy materials	6	4.10	0.900
Improved work supervision	7	4.04	1.095
Improved health and safety culture	8	4.02	1.104
Reduced mishandling and miscalculation	9	4.00	0.980
Reduction of strenuous activities	10	4.00	1.077
Reduces site waste	11	3.88	0.931
Long-life span	12	3.88	0.952
Increase use of recycled materials	13	3.86	1.020
Solves ageing population crisis	14	3.71	1.119
Cost effective	15	3.45	1.006

Table 2: Kruskal-Wallis Test Showing P-Values for Measures

Benefits	P-Values
Shortens construction duration	0.003
Improved quality of work	0.000
Productivity, efficiency and profitability	0.000
Less material storage and handling	0.064
Less accidents and unforeseen circumstances	0.827
Suitable for lifting heavy materials	0.000
Improved work supervision	0.000
Improved health and safety culture	0.004
Reduced mishandling and miscalculation	0.013
Reduction of strenuous activities	0.000
Reduces site waste	0.002
Long-life span	0.000
Increase use of recycled materials	0.044
Solves ageing population crisis	0.031
Cost effective	0.022

The results of this study back up Delgado et al., (2019) claim that the South African prefabricated building sector may reduce construction time by using robotic technology. As a consequence, projects will be finished on time and within the allotted time frame without experiencing any more delays. This advantage received the highest ranking, indicating that respondents believe it to be the most significant benefit that will hasten the adoption of robotic technology in the prefabricated building sector. Additionally, the study supported Chea et al., (2020) who claimed that using technology improves the caliber of work produced. Robotic technology is a more dependable alternative to manual labor since it will increase efficiency, production, and profitability in the prefabricated building business. Application of robotic technology leads in less material storage and handling since materials are created at the plant and only delivered to the site to be built to the appropriate structure because they are prefabricated components. This is in line with the findings of a research by (Bademosi & Issa, 2022), which predicted that the use of robot technology will lead to fewer mishaps and unanticipated events. The results of this study further confirm Oke et al., (2019) assertion that robots will be useful for carrying large goods on site, especially prefabricated pieces. Prefabricated parts are created at a plant that adheres to stringent regulations and is closely watched. This will lead to better job supervision because factory checks are done to guarantee that the components meet specifications. According to Akinradewo et al., (2021), the use of robotic technology in the prefabricated building sector would improve worker health and safety since the robots will handle activities that are riskier.

Robots are machines whose accuracy prevents errors caused by carelessness and error in calculation, depending on their capacity and what they are programmed to do (Pan et al., 2018). However, the respondents to this study gave a low rating to this benefit, believing that it does little to encourage the use of robotic technology. Robotic technology will thereby lessen the health problems caused by physically demanding construction labor since its adoption will improve employee wellness. In line with Kumar et al., (2016) study, the outcome also showed that less material handling and storage leads to less waste generated on the site. Prefabricated buildings require no adjustments, so materials are delivered on site and put together to create the desired structure. Despite the fact that robotic technology has a longer lifespan than human labor (Pradhananga et al., 2021), the results of this study do not appear to view this advantage as a key driver for the use of robotic technology in the prefabricated construction sector. According to the study's findings, the fact that factories are built so they may reuse materials from earlier production processes does not significantly influence whether or not robotic technology will be applied there. This also increases the usage of recyclable materials. The findings of this study do not support Aghimien et al., (2020), who claimed that robots are the answer to the construction industry's ageing population, which results in fewer young people than in other industries. Even though this is a benefit, it does little to influence the construction industry's adoption of robotic technology in the prefabricated construction sector.

The cost effectiveness of robotic technology was the benefit that received the lowest ranking in this study for its use in the prefabricated building sector of South Africa. Robotic technology, according to Chen et al., (2022), is cost-effective since it lowers labor expenses and construction time, which has a cost associated with it because construction equipment must be hired; the less time spent on a project, the more money is saved. Because they are not considering the fact that robotic technology shortens the period of building, which would save money, the respondents to this survey do not see the benefit as being crucial to encourage its implementation.

A Kruskal-Walli test was also run, as seen in Fig. 2, to compare the respondents' perspectives depending on their years of experience. Except for "Less accidents and unforeseen circumstances," which revealed that there is a statistically significant difference in the mean values of the respondent category, it was determined that there really is no significant difference in the mean values for any of the benefits.

CONCLUSION

Among the major institutions in the global market is construction. Construction has been slower than other industries to adopt robotics because, as was already mentioned, it is one of the sectors that takes the longest to start down the path of automation and digitalization. A number of things, including the price of labor or the processes’ lack of preparation, causes this. Robotics has several benefits, and it is already used in a number of industries, including architecture, masonry, demolition, and infrastructure. Safety and inspection activities, which employ technology to examine and detect any problems in real time and convey the information to the system so that it can be fixed as soon as possible, are some of the duties that call for succinct use of robots. Robotics will improve the construction sector in a variety of ways, including greater production, decreased mistakes, meeting deadlines, reducing accidents, and lowering prices.

The study suggests that the government step in to fund and provide incentives for construction companies to apply robotic technology in order to make the construction industry appear innovative and efficient rather than outdated and reticent to adopt new technologies. This is because the application of robotic technology is thought to be expensive to implement. If the construction industry is to quickly adopt robotic technology in the South African prefabricated construction industry, big private construction companies must also consider this collaboration and collaborate with the government to educate and train small construction companies, clients, and end-users in this area.

CONTRIBUTION OF LEAN TECHNIQUES TO INDUSTRIALIZED CONSTRUCTION ADOPTION: A BARRIERS MITIGATION APPROACH

Alejandro Vásquez-Hernández[1], Jesús Ortega[2], Luis Fernando Alarcón[3], and Eugenio Pellicer[4]

ABSTRACT

Despite the benefits associated with industrialized construction (IC), it has low overall levels of adoption. IC is an innovation that is not aligned with institutionalized project supply chains; it has implications in process integration that intensify adoption barriers. Several studies have shown the effectiveness of implementing Lean techniques in different stages of the IC process. This paper exposes the analysis of the contribution of implementing Lean techniques to performance, process flow, knowledge management, and value addition. The implementation results are analyzed in terms of their contribution to mitigating the IC adoption barriers identified in the Chilean context. A systematic literature review is carried out to identify the Lean techniques implemented in some of the phases of the IC process. The analysis of the results reported and the contribution of the implementation of Lean techniques to the mitigation of the impacts of some of the existing barriers to the adoption of IC is conducted using thematic content analysis. Thirty Lean techniques are identified whose implementation results are related to the mitigation of conditions associated with 76.5% of the IC adoption barriers considered to be of high and very high impact for the Chilean context.

KEYWORDS

Lean construction, prefabrication, assembly, off-site construction.

INTRODUCTION

Industrialized construction (IC) has been identified as a promising approach to improving project performance. Despite the associated benefits, IC presents an incipient level of adoption and implementation (Jaffar & Lee, 2020), and it still faces immense resistance from the industry and the market (Razkenari et al., 2019). In Chile, the construction industry faces pressures and substantial threats related to the shortage of skilled labor, increased labor costs, the disruption of new competitors, and the postpandemic economic crisis scenario. Due to this, the Chilean

Chamber of Construction has identified the adoption of IC as one of the three levers that encourage leaps in productivity, along with Building Information Modeling (BIM) and digitization (Matrix Consulting, 2020). However, the adoption of IC in Chilean construction maintains low levels (Construye 2025, 2022).

The adoption of IC is an example of the diffusion of innovation. In the construction industry, the diffusion of innovation is extremely slow due to the adoption processes being carried out amid a complex series of barriers (Wuni & Shen, 2020), which directly affects the perception of the offer of improved utility compared to existing technologies. Because of this, IC implies technological adoption and a cultural management process aimed at reducing the uncertainties associated with the perceived benefits of innovation.

IC is a phenomenon oriented toward the integration of processes, which implies long-term relationships between the different actors, advanced supply chain management, a design oriented to better support the manufacturing and installation phase, and the capture of experience and knowledge management aimed at continuous improvement (Lessing, 2015). It is an innovation not aligned with institutionalized project supply chains. These chains, therefore, require a change in the process that implies that multiple companies modify their practice in a coordinated way (Lavikka et al., 2021). This condition intensifies the difficulty of implementing innovations in project networks that consist of numerous parts and present fragmentation.

Many of the emerging problems in IC implementation experiences are related to the forms of adoption, that is, a focus on the incorporation of industrialized construction systems under a context of organizational structure, project development model, and conventional work methods (Andersson & Lessing, 2017); such characteristics include highly fragmented scenarios, poor communication, information exchange, cooperation and coordination between actors, and using conventional acquisition methods. These adoption conditions lead to failed experiences and unsatisfactory/inconsistent performance results.

Numerous papers have illustrated the contribution of Lean techniques in the domain of supply chain management and the rationalization of construction processes. In the field of IC, various studies have shown the effectiveness of different degrees of implementing Lean techniques in different stages of the process (Innella et al., 2019). Given the above, one of the emerging research directions involves a combination of IC and Lean techniques. However, the systematic analyses described in the literature in this field are insufficient, and there needs to be more clarity about the progress of current research. Therefore, reviewing previous research on implementing Lean techniques in the various stages of the IC process is opportune. Similarly, based on the implementation results, we analyze the contribution of these techniques to performance, process flow, innovation management, and value addition and mitigate the impacts of conditions identified as barriers to adopting IC.

RESEARCH METHOD

A systematic literature review (SLR) was carried out to identify the Lean techniques implemented in the different phases of the IC process. Additionally, a thematic content analysis (TCA) was conducted to analyze the results of the reported implementations and the contribution of the implementation of these techniques to the mitigation of the impacts of some of the existing barriers to the adoption of IC.

The search for related research papers published between 2017 and 2023 was conducted in the Scopus and Web of Science (WoS) electronic databases. The criteria for database selection were based on the fact that these databases are the largest in the field of inquiry; Web of Science has a longer time frame, while Scopus has more recent articles (Chadegani et al., 2013). The search equations were built according to the following combination criteria: TITLE-ABS-KEY (("lean construction" OR "lean practice" OR "lean principles" OR "lean tools" OR "lean strategies" OR "lean techniques") AND ("off-site construction" OR " industrialized building system" OR "industrialized construction" OR "modern method of construction" OR "prefabrication" OR “modular construction)) AND (LIMIT-TO (PUBYEAR, 2017-2023). Through the search strategy, 36 articles were selected from the electronic databases. Following the criteria for the exclusion of irrelevant articles, based on the nonexplicit declaration of Lean techniques or a specific phase of the IC process, seventeen were discarded. The resulting nineteen studies were included in the analysis.

The studies on implementing Lean techniques in IC processes were analyzed from a quantitative and qualitative approach. The quantitative analysis integrated the prevalence of the techniques and results found in the literature. The qualitative study was carried out based on the thematic content analysis (TCA) method to identify relationships between outcomes associated with Lean techniques and IC adoption barriers. The barriers identified by Ortega (2022), with high and very high impacts on the context of Chile, were taken as a basis for the analysis of the contribution of Lean techniques to the mitigation of the impacts of the existing barriers to the adoption of IC.

FINDINGS

LEAN TECHNIQUES IMPLEMENTED IN THE IC PROCESS

Nineteen studies were identified from the literature review that address implementing Lean techniques in different stages of the IC process. These studies, their country of origin, and the associated industrialized system examined are presented in Table 1.

Table 1: Studies resulting from the literature review.

Id.	Authors	Country	Industrialized system
1	(Ahmad et al., 2019)	Malaysia	Precast components
2	(Barkokebas et al., 2021)	Canada	Unspecified

18	(Li et al., 2018)	China	Precast components
19	(Xiong et al., 2018)	China	Unspecified

In the studies, thirty implemented Lean techniques were identified. These techniques were grouped according to the purpose of the implementation: identifying and reducing waste, improving flow, adding value, and continuous improvements. Eleven Lean techniques associated with identifying and reducing waste were found, aimed at identifying waste (3), reducing cycle time (1), reducing batch size and work-in-progress (4), increasing transparency (2), and materials management (1). Regarding improving the flow and reducing variability, fourteen techniques were identified aimed at reducing flow variability (1), increasing manufacturing flexibility (2), increasing stakeholder and systems integration (3), improving product and operation flow (2), pull production (2), reducing process variability (2), and leveling production (1). One identified technique was found to be associated with adding value and oriented toward decision-making (1). Finally, regarding striving for perfection and continuous improvements, four techniques were identified (4). Table 2 shows the thirty techniques identified based on the grouping stated, and the ID number of the study (according to Table 1) in which each technique is listed.

Table 2: Lean techniques implemented in the IC process.

	Goal	Techniques	Included by (ID from Table 1)
Identifying and reducing waste	Identifying waste	T1 - Value stream mapping (VSM)	2, 11, 13, 14, 17
		T2 - Genchi Genbutsu (Gemba)	2
		T3-5 Whys technique (RCA)	13
	Red. cycle time	T4 - Total Productive Maintenance (TPM)	12
	Reduction of batch size and work-in-progress	T5 - Takt Time planning	4,14
		T6 - Work-In-Process (CONWIP)	18
		T7 - Location-Based Planning (LBP)	4
		T8 - Line of balance (LOB)	4
	Increasing of transparency	T9 - Visual boards/management	4, 14, 15
		T10-5S	13, 5
	Material mgmt.	T11 - Kanban	1, 10
Improving flow and reducing variability	Flow variability	T12 - Last planner system (LPS)	4, 11, 14
	Flexible manufacturing	T13 - Process modularity (PM)	4
		T14 - Bidirectional workflows (BDW)	16
	Stakeholder and systems integration	T15 - Integrated Project Delivery (IPD)	4
		T16 - Lean Project Delivery (LPD)	14
		T17 - Target Value Design (TVD)	4, 14
	Product and operations flow	T18 - BIM	2, 3, 4, 5, 6, 9
		T19 - Simulation	6, 8
	Pull production	T20 - Just-in-time (JIT)	1, 4, 10, 13, 14
		T21 – On-demand production (ODP)	16
	Process variability	T22 - Mistake proofing (Poka-yoke)	14
		T23 - Cross training (CT)	10
	Leveling the production	T24 - Standardization (Procedure, time,	15
		T25 - Process Specification Language (PSL)	19
Value	Decision-making	T26 - Choosing by advantages (CBA)	7, 14
Continuous improvement	Aiming to perfection	T27 - Kaisen	2
		T28 - First Run study	14
		T29 - Quality Check (QCH)	14, 16
		T30 - Total Quality Management (TQM)	10

Registered implementations are tied to different phases of the production process. A total of 10.5% of the studies report implementations in the design phase, including 6.7% of the identified techniques. The design phase's implementation focuses on adoption decision-making and design for assembly. Off-site production is the phase addressed most frequently; 63.2% of the studies report implementations in this phase, and 63.3% of the identified techniques emerge from them. The implementations reported in the off-site production phase focus on rationalizing the production process. The on-site assembly phase is addressed in 26.4% of the studies, with the implementation of 60.0% of the techniques. The focus of the implementations associated with this phase is to improve the installation process by synchronizing off-site production with on-site production. The most prevalent Lean techniques found in the literature are Building Information Modeling (BIM) (31.6%), Value Stream Mapping (VSM) (26.3%), and Just-in-time (JIT) (21.1%), followed by 5S, the Last Planner System (LPS), and visual boards, which are reported in 15.8% of the studies. Figure 1 presents the prevalence in the literature of the identified Lean techniques.

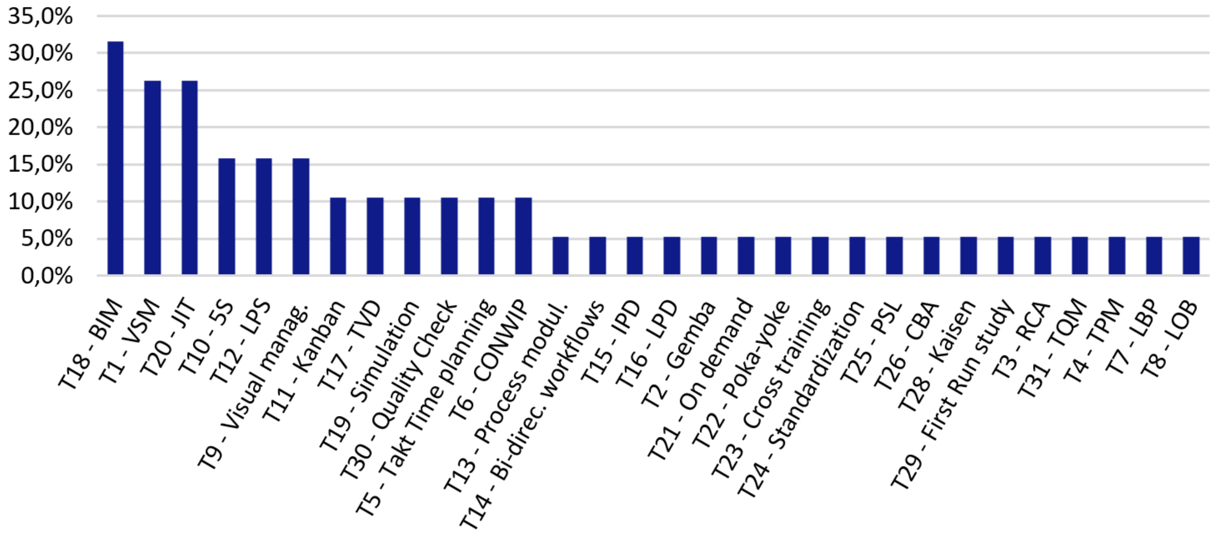

Figure 1: Prevalence of Lean techniques in the literature

RESULTS ASSOCIATED WITH THE LEAN TECHNIQUES IMPLEMENTED

Studies relate specific results to the implementation of Lean techniques. These results can be divided into two categories: diagnostic and interventional. Of the studies, 36.8% report results associated with the possibility of an adequate diagnosis, that is, waste identification from the use of the VSM, Gemba, and RCA techniques.

In terms of the results of the intervention, improvements in the performance process flow, knowledge and labor management, and value addition were identified. A total of 68.4% of the studies report changes in performance indicators. A total of 57.9% of the studies report a reduction in process time. This reduction is associated with lead time reduction (36.8%), cycle time reduction (36.8%), and idle time reduction (47.4%). Likewise, 26.3% of the studies report a decrease in costs; 21.1% mention the reduction of costs related to the off-site production process, 21.1% report total project costs, and 26.3% report labor costs. A total of 21.1% of the studies reported quality improvements linked to the early detection of deviations and eliminating design errors and inappropriate designs. A total of 42.1% of the studies report more significant control over the work in process, 15.8% declare a general improvement in performance, and 31.6% declare an improvement in productivity.

Regarding the improvement of the process flow, studies report results associated with decreased fragmentation among stakeholders and phases of the process. A total of 36.8% of the studies report improvements in terms of early integration and adequate conditions for integration, namely, adequate collaboration among actors from different phases (31.6%) and improvements in communication (31.6%). Linked to these improvements in terms of integration, 26.3% report greater synchronization between design and off-site production, and

15.8% report greater synchronization between off-site production and on-site installation. A total of 5.3% of the studies report a reduction in transport processes.

Some studies report improvements associated with knowledge and labor management. A total of 21.1% of the studies declare a decrease in the complexity of knowledge management linked to the increase in transparency and standardization. Likewise, 15.8% report a reduction in risk at work, and 5.3% report a reduction in training time for the workforce.

Regarding value addition, 15.8% of the studies report that implementing Lean techniques increases the satisfaction level of end users, and 10.5% report that such implementation provides adequate support for decision-making on IC adoption. A total of 22 results were identified, which are presented in Figure 2.

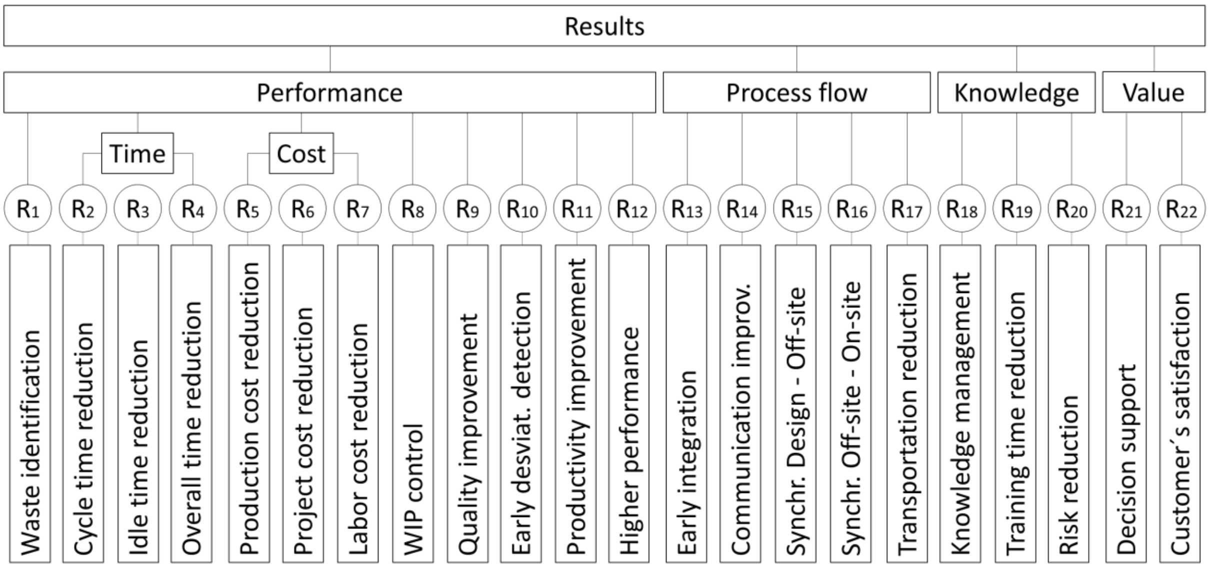

Figure 2: Results of the implementations of Lean techniques reported in the literature.

In 42.1% of the studies, the reported implementation integrates only one Lean technique. In most of these cases (15.8%), the implemented technique is BIM. The CONWIP, VSM, simulation, PSL, and CBA techniques are integrated into the rest of the cases of isolated technique implementations. In 21.1% of the studies, the implementations integrate two Lean techniques; these are simultaneous implementations of JIT and TPM, JIT and Kanban, VSM and LPS, and BIM and simulation. A total of 10.5% of the studies report implementations that integrate three techniques such as bidirectional workflows, on-demand production and quality checks, visual management, 5S, and standardization. A total of 10.5% of the studies simultaneously incorporate four techniques, 5.3% incorporate five techniques, 5.3% incorporate nine techniques, and 5.3% incorporate eleven techniques. It is opportune to point out the form of implementation of the techniques as being either isolated or together since the results reported by the studies result from the specific type of implementation in terms of the confluence of different techniques. Therefore, even though the results attributed to implementing a particular technique can be traced in the studies, there is the incidence of the synergistic effect of implementing multiple techniques to consider. Figure 3 presents the relationship among the identified Lean techniques and the specific results associated with their implementation.

LEAN CONTRIBUTION TO MITIGATION OF IC ADOPTION BARRIERS IMPACTS

Based on the previous relationship between Lean techniques and results, the areas of incidence of these results were analyzed to identify relationships among them and the barriers to IC adoption. That is, we aimed to identify from the results the possible contribution of implementing Lean techniques to modifying the conditions constituted as barriers and, consequently, mitigation of their impact. In previous research (Ortega, 2022), existing IC adoption barriers have been identified, and their level of impact has been evaluated for the Chilean context. The barriers assessed as having high and very high impact have been previously grouped into cultural, quality, market, cost and finance, design and development, innovation and technology, skills, regulations, status, diffusion, and logistics. In the present study, these barriers were analyzed and regrouped based on the possibility of their mitigation from Lean implementations. The authors acknowledge that grouping barriers into typologies is highly subjective and that there may be overlaps between groupings. The proposed grouping seeks to align with the results related to Lean technique implementations.

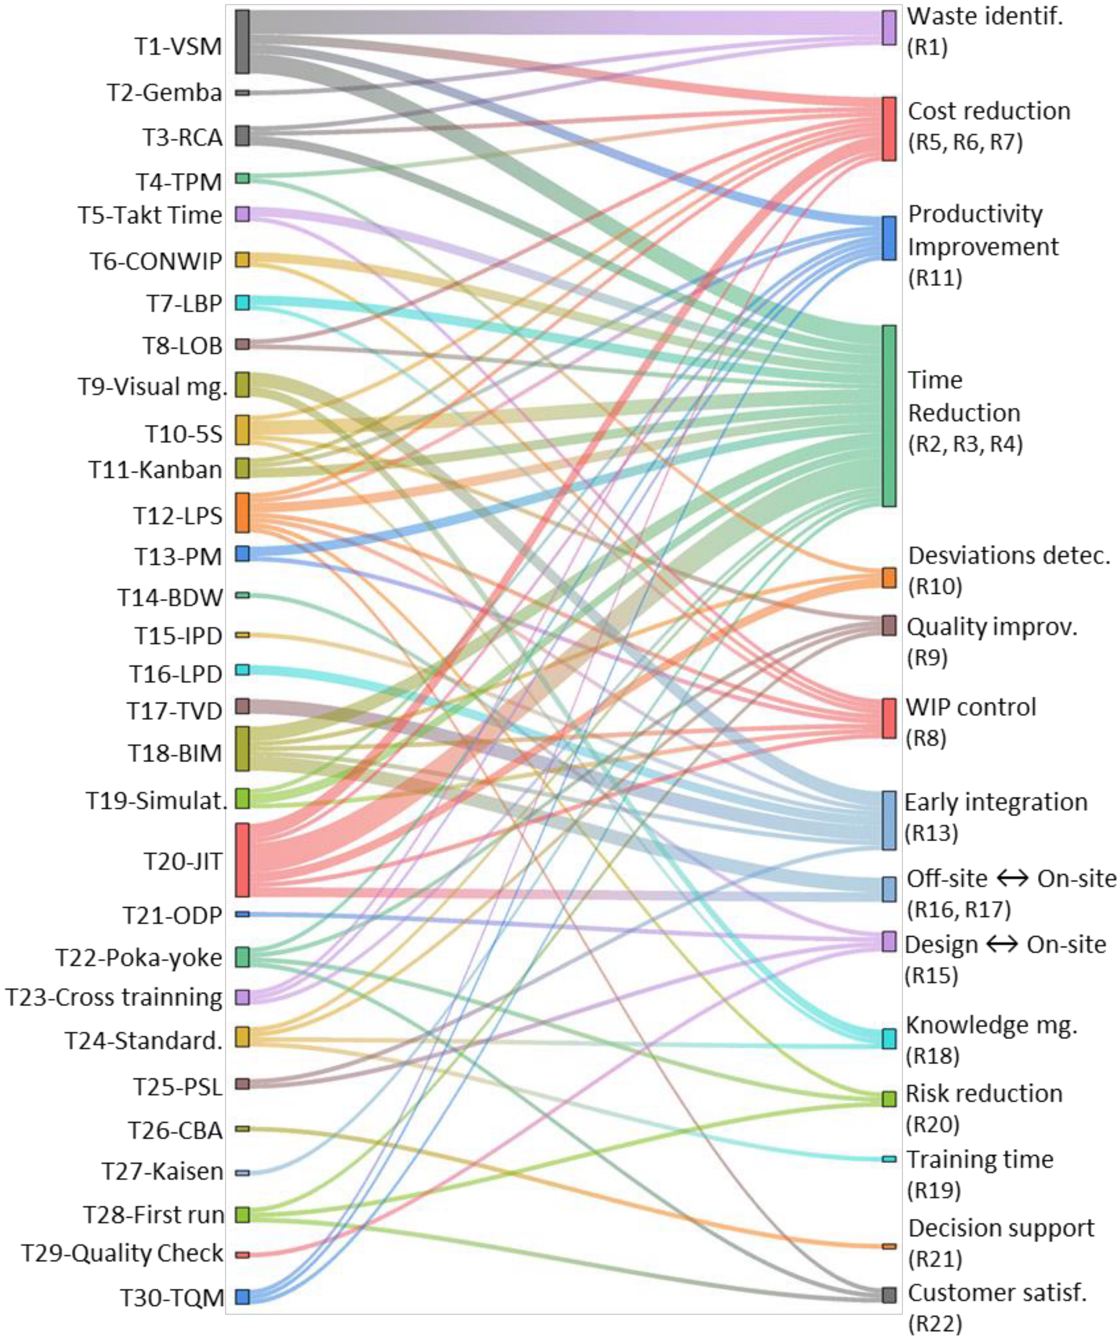

Figure 3: Results associated with Lean techniques.

Initially, the barriers were analyzed based on their dependence on external agents. Sixteen high external dependence barriers were identified, which are related to limitations of offers, demands, regulations, external incentives, financing possibilities, and external actors' IC knowledge. These barriers are as follows: lack of offers from manufacturers, low standardization level of materials/elements, higher and volatile cost of materials, low market demand, low client/consumer/general public acceptance/valuation, unsuitable for small projects, difficulty obtaining financing, lack of regulations, rigid regulations, incompatibility between current and emerging regulations, lack of more demanding quality regulations, lack of quality assessment/accreditation instruments, lack of knowledge on the part of the state, lack of modernization of university curricula, lack of government incentives, and lack of financing for system innovation ventures. These barriers were not included in the relationship analysis with the results related to Lean techniques. However, other barriers with less dependence on external agents were included in the analysis. These barriers were grouped according to their association with performance, process flow, and knowledge management.

Barriers associated with performance.

The barriers associated with performance indicators are as follows: higher overall cost (B1), higher initial costs (B2), higher costs of technology (B3), higher labor costs (B4), difficulty obtaining advances (B5), higher cost of transportation (B6), difficulty in achieving economies of scale (B7), greater economic risk (B8), longer setup times during the planning stage (B9), and longer setup times during the design stage (B10). Eighty percent of these barriers are related to conditions that, according to the results reported, are modified by implementing Lean techniques. Only barriers B3 and B5 are not directly related to any of the results. The result R4, namely, time reduction, is associated with the implementation of VSM, RCA, Takt time planning, COWIP, LBP, LOB, 5S, Kanban, LPS, process modularity, BIM, JIT, standardization, and Kaisen, can help mitigate the impact of barriers B8 and B9. Results R5, R6, and R7, which are linked to cost reduction related to implementing VSM, RCA, TPM, LOB, 5S, Kanban, LPS, JIT, cross training, and TQM, can help mitigate the impact of barriers B1, B2, B4, and B8. The result R7, namely, labor cost reduction, is directly related to barrier B4. The result R15, which is associated with implementing bidirectional workflows, on-demand production, and quality checks, can contribute to mitigating the impact of barrier B7. Result R17, which is related to the implementation of JIT, can contribute to mitigating the impact of barrier B6.

Barriers associated with process flow.

The barriers associated with the process flow are associated with a lack of integration and changes in the process. The barriers linked to the lack of integration are fragmented supply chains (B11), short-term business relationships (B12), inappropriate project delivery models and contracts (B13), poor communication/coordination among stakeholders (B14), and poor collaboration among stakeholders (B15). The results 13 and 14, associated with implementing visual management, LPS, IPD, LPD, TVD, BIM, and PSL, can contribute to mitigating the impact of barriers B11, B13, B14, and B15.

The barriers linked to changes in the process refer to changes in planning and design, off-site production, transportation and storage, and on-site production. The barriers associated with planning and design are as follows: lack of adapted planning and control structure (B16), inadequate approval and quoting processes (B17), incompatibility between traditional and industrialized designs (B18), inability to define/freeze design early (B19), design limitations that affect customization (B20), inflexibility to apply late changes to the design (B21), lack of design standardization (B22), and low investment in the design stage (B23). The result R15, related to implementing bidirectional workflows, on-demand production, and quality checks, can mitigate the impact of barriers B18, B19, B20, B21, and B22. Likewise, the results R21 and R22, associated with the implementation of LPS, Poka-yoke, CBA, and the first-run study, can contribute to mitigating the impact of barrier B20. Despite not being declared as a direct result, the results in performance improvement associated with the implementation of techniques such as LPS, LOB, and LBP, which establish planning and control methods, allow linking these techniques to the mitigation of the B16 barrier.

The barriers associated with off-site production are the inflexibility of production lines to respond to changes (B24), limited productive capacity of suppliers (B25), and poor management and production in the factory (B26). Result R15, which is associated with implementing bidirectional workflows, on-demand production, and quality checks, can contribute to mitigating the impact of barrier B24. Results R11 and R12, which are related to the implementation of VSM, Kanban, LPS, simulation, JIT, Poka-yoke, cross training, and TQM, can contribute to mitigating the impact of barriers B25 and B26.

The barriers associated with transportation and storage are long transport distances (B27), increased transportation restrictions (B28), and the lack of storage and transport quality measures (B29). Result R17, which is associated with implementing JIT, can contribute to mitigating the impact of barriers B27, B28, and B29.

The barriers associated with on-site production are increased site restrictions (B30), low tolerances between precast systems and on-site structures (B31), the predominance of conventional over industrialized processes (B32), and a lack of recognition of indirect construction cost impacts (B33). Result R16, which is associated with implementing BIM, JIT, and PSL, can contribute to mitigating the impacts of barrier B31.

A total of 69.6% of the barriers associated with the process flow are related to conditions that, according to the reported results, are modified by implementing Lean techniques.

Barriers associated with knowledge management.

The barriers associated with knowledge management are related to knowledge, skills and experience, and change and motivation management. The barriers linked to knowledge, skills, and experience are the low documentation of economic benefits (B34), low levels of R&D in the industry (B35), the lack of university-industry joint work (B36), the lack of planning capacities (B37), the lack of technical skills (B38), the lack of skilled labor (B39), the lack of capacities to adopt technology and innovation (B40), the lack of capacity to objectively benefit assessment (B41), inadequate education and training (B42), the lack of capacity to synchronize off-site and on-site activities (B43), the lack of previous design experience (B44), the lack of previous on-site management experience (B45), and the lack of previous construction experience (B46). Results R11 and R12, which are associated with the implementation of VSM, Kanban, LPS, simulation, JIT, Poka-yoke, cross training, and TQM, can contribute to mitigating the impact of the B37 barrier. Results R18 and R19, which are related to implementing visual management, 5S, and standardization (procedures, time, quality), can contribute to mitigating the impact of barriers B38, B39, B40, and B42. Result R10, which is associated with the implementation of TPM, BIM, and JIT, and result R15, which is related to the implementation of bidirectional workflows, on-demand production, and quality checks, can both contribute to mitigating the impact of the B44 barrier. Result R16, which is associated with implementing BIM, JIT, and PSL, can contribute to mitigating the impact of barriers B43, B45, and B46.

The barriers linked to change and motivation management are the lack of support for adoption (B47), negative perception of failed experiences (B48), the lack of IT adoption (B49), the lack of BIM adoption (B50), and resistance to change (B51). Result R21, which is associated with implementing CBA, can contribute to mitigating barrier B47.

A total of 72.2% of the barriers associated with knowledge management are related to conditions that, according to the reported results, are modified by implementing techniques. Some of the barriers not considered in the field of incidence of the reported results, such as low documentation of economic benefits (B34), can find mitigation in the study of the phenomenon of IC adoption and strategies aimed at improving implementations, such as the studies considered in this document.

CONCLUSIONS

This research conducted an SLR of the Lean techniques implemented in the IC process, using the Scopus and Web of Science (WoS) database. The literature review results showed thirty Lean techniques whose implementation modify conditions associated with 76.5% of the IC adoption barriers considered high and very high impact for the Chilean context, and based on this, could contribute to mitigating the impact of the barriers on adoption scenarios.

The contribution of the implementation of Lean techniques in the cases studied is based on several factors: (i) the rationalization of the process associated with the identification and reduction of wastes, which leads to an improvement in performance indicators (cost, time, quality, productivity) and contributes to reducing the negative perception related to failed experiences and unsatisfactory and inconsistent results; (ii) the reduction of fragmentation, which is associated with greater early integration, better communication and collaborative work, and greater synchronization between phases, both between design and off-site production, as well as production or off-site and on-site installation, and (iii) the management of knowledge and change.

Research efforts in the field of IC management, from a Lean approach, are concentrated in the off-site production phase. A total of 63.2% of the studies, from which 63.3% of the implemented Lean techniques emerge, have this phase as a focus of interest. The number of studies focused on IC design management and construction site management, from implementing Lean techniques, is limited.

The approaches based on integration include integration among actors of a phase and among phases of a project, while practices aimed at reducing the level of fragmentation between projects are not identified. The techniques reported as IPD, LPD, and TVD are framed at the project scale. The adoption of IC by construction companies implies establishing a structure to manage continuous processes to develop and manage their production system and the associated subsystems, as well as the execution of construction projects. This approach that integrates continuous processes and discrete projects requires different technical systems, organization, processes, and supply chains than traditional construction companies. The approach to overcoming the B12 barrier, namely, short-term business relationships, implies not only integration at the project level but also the search for solutions to the loss of tacit knowledge, with a focus on how to work together effectively after the dissolution of the teams at the end of the projects. This aspect emerges as a field of potential contribution of Lean techniques not addressed in integrated studies.

The current document contributes to the body of knowledge on IC management by discussing the implementation of Lean techniques and their contribution to mitigating adoption barriers. Likewise, in terms of practical contribution, it identifies specific Lean techniques that can be integrated into different phases of the IC process and links them to results that modify conditions associated with adoption barriers. These findings constitute input based on the proposition of implementations that utilize a Lean approach that, based on performance improvement, process flow, knowledge management, and value addition, contributes to reducing the number of uncertainties associated with the perception of the improved utility of IC versus conventional construction and, consequently, to mitigating barriers to IC adoption.

ACKNOWLEDGMENTS

The authors would like to acknowledge financial support from ANID through project FONDECYT Regular No. 1210769, as well as thank the Production Management Centre GEPUC from Pontificia Universidad Católica de Chile for facilitating this study. Additionally, we would like to thank ANID National Doctorate 2022-21220895 and VRI-UC for funding the postgraduate studies of two authors.

THE IMPACT OF AN OFFSITE PRODUCTION APPROACH ON MECHANICAL AND ELECTRICAL PROJECTS: EVIDENCE FROM THE UK

Tonisha Carys O'Gorman[1], Emmanuel Itodo Daniel[2], and Ezekiel Chinyio[3]

ABSTRACT

Previous studies have reviewed the impact of offsite production on the delivery of construction projects, however, there have been limited studies examining the specific impact of offsite on mechanical and electrical installations (M&E). Therefore, the aim of this study was to determine the impact of offsite production in the delivery of mechanical and electrical installations for construction projects. In this study, a mixed method was adopted, using quantitative data obtained through a questionnaire survey and qualitative data through case study interviews. In total, primary data was collected from 36 questionnaire responses, and 3 case studies that involved 12 in-depth interviews.

This study shows that offsite production has a positive impact on construction project performance indicators for M&E installations regarding factors such as time, quality, health and safety, sustainability, logistics, and collaboration. However, the study showed no general conclusion as to the cost saving impact of offsite construction on the outcomes of projects. Nevertheless, the study established that the offsite approach offers the client more confidence relating to cost certainty.

Recommendations from this study are that offsite production should be selected based on its impact on project performance indicators rather than cost alone. The study argued that the offsite production method should be explored as much as possible when maximal benefits are sought; however, it should not be utilised simply for the sake of it but on a case-by-case basis.

KEYWORDS

Offsite construction, prefabrication, assembly, modular construction, M&E installations.

INTRODUCTION

Offsite production is a modern method of construction (MMC), often referred to as 'prefabrication' 'pre-assembly' or 'modularisation'. It is the process of completing construction elements away from the physical site in a controlled facility; to achieve time, cost, quality, health, and safety efficiencies (Vurren, 2020). In recent years, offsite has increased interest due to increased utilisation of Building Information Modelling (BIM) (Farmer, 2016). According to Sherratt, Dowsett and Sherratt (2020), the current concerns of the Global Construction

[3] Reader in Constr. Mgmt., School of Arch. and Built Envir., Faculty of Sci. and Engrg., Univ. of Wolverhampton, Wolverhampton, UK, E.Chinyio@wlv.ac.uk, orcid.org/0000-0001-8448-5671

Industry are labour shortages and the demand for shorter construction programmes, heightening the need for innovative modern construction methods such as offsite production. Offsite production can achieve material efficiency, reduce waste, reduce timescales on site, improve health and safety and reduce disruption to construction projects (Hough, 2019). The UK Construction industry is being pushed to modernise and innovate, with Farmer (2016) stating the industry-wide issues of low productivity, low margins, an ageing workforce and lack of research and design. Samarasinghe et al. (2019) claim the past decade has seen a growing trend towards the offsite production of M&E systems.

Extant literature shows a range of information about adopting offsite in the construction industry. Smith and Quale (2017) focus on the theory and practicality of offsite concerning the demand for housing. Court, Pasquire and Gibb (2009) observe offsite as a solution for the UK's health, safety, and productivity issues. Marte Gómez et al. (2021) note the effects of implementing offsite construction within the UK housing sector. Sutrisna, Ramnauth and Zaman (2020) highlight the competitive advantages and risks of offsite production on construction projects.

In contrast, there is less information on adopting offsite for M&E installations. Said (2015) discusses best practices for offsite production; however, the paper focuses solely on electrical installations. Korman and Lu (2012) research focuses on the link between M&E but with a specialisation on the improvement in BIM. Although M&E installations contribute 40-60% of the total construction costs (Guo, Wang, and Park, 2020), limited studies have explored the impact of offsite construction in delivering M&E projects. Given this, this study aims to identify the effects of the offsite process on time, quality, safety, and cost in M& E projects in the UK.

The key research question is: **What is the impact of offsite production in the delivery of mechanical and electrical installation aspects in projects?** With the following research objectives:

- To review the current knowledge relating to the use of off-site production on the M&E sector.
- To determine the impact of utilising offsite production, relating to project performance indicators and cost, on M&E projects.
- To draw conclusions from the findings and provide a decision on the suitability of using offsite production in the M&E sector.

Findings from this study are that offsite production should be selected based on its impact on project performance indicators rather than cost alone. With the argument that the offsite production method should be explored as much as possible when benefits are achieved; however, it should not be utilised simply for the sake of it but on a case-by-case basis. This research will help organisations understand the effects of offsite approach construction on delivery and performance indicators in M&E projects.

LITERATURE REVIEW

INDUSTRY VIEW OF OFFSITE CONSTRUCTION

According to Agarwal, Sridhar and Chandrasekaran (2022), the construction industry is subject to change; projects can take up to 20% longer than programmed and cost 80% more than budgeted. Ren, Atout, and Jones (2008) research suggest that main contractors are the root cause of 62% of project delays, consultants 27% and clients 11%. Common issues include poor communication, incomplete drawings, and compressed programmes. Agur, Chipatpo and Thom (2015) describe how offsite construction can impact projects by improving productivity, collaboration, and skills.

The key reports relating to the UK Construction Industry are of Latham (1994), Egan (1998), Wolstenholme (2009) and Farmer (2016). The recommendations offered by these reports are primarily the same: standardisation and offsite. The House of Lords (2016) also suggests that offsite production could be the solution that would help the UK Government achieve its 2025 targets of 33% reduction in construction cost, 50% reduction in programmes and 50% reduction in greenhouse gasses.

CURRENT KNOWLEDGE RELATING TO THE USE OF OFFSITE PRODUCTION IN M&E

Guo, Wang, and Park (2020) discuss how M&E installations contribute 40-60% of the total construction costs. Issues affecting the installation of these systems include interface with the other trades on-site and general issues facing the industry, such as dangerous weather conditions and quality control. Sands and Quale (2019) specify further problems with M&E installation, such as limited space, health and safety and demanding programmes. Guo, Wang, and Park (2020) continue with, for the reasons described above, M&E installations are increasingly taking an offsite approach to delivery. Wilson, Smith, and Deal (1998) summarise that all projects utilising an offsite system to M&E have benefited. However, this must be balanced with the drawbacks. According to Goulding and Pour (2019), low design standardisation reduces the uptake. Farmer (2016) believes reluctancy is due to clients being unwilling to finalise designs at an earlier stage, a crucial requirement of offsite production.

METHOD

The research method adopted for this study was a mixed-method approach including triangulation (Palinkas et al., 2015). A questionnaire was used to gain quantitative data, and a case study analysis was used to gather qualitative data. According to Breach (2009), case study analysis is instrumental in collating ideas and perceptions. This was applied to obtain further in-depth information on how offsite is adopted on live and completed M&E projects.

RESEARCH DESIGN

The study commenced with a literature review, which according to Naoum (2019) is to create a focus for the data collection. The research instrument utilised for the subsequent quantitative phase was an online questionnaire survey administered via ‘Google Forms’., Naoum (2019) suggests that this method increases the number of responses. The questionnaire was designed to be short and engaging, with 13 number close-ended questions relating to findings from the literature review and research objectives. An example of a question was, “Off-site is more cost effective in comparison to traditional on-site delivery of M&E installations". Please indicate your opinion of the above statement by ticking the appropriate response”.

However, an additional 5 number open-ended questions were included to connect to the findings from the interview. An example of one of these questions was “What recommendations would you have for someone considering off-site production for the M&E installations on their next project?”.

Firstly, the questionnaire was piloted with three industry professionals before data collection; according to Fellows and Liu (2015), this ensures the questionnaire is easy to understand and provides the opportunity for amendments. Purposive sampling was applied in this study, given that a limited number of people are available in this research area (Palinkas et al., 2015). According to The UK offsite Hub and Building and Design, the number of offsite construction organisations in the UK is 228 number. Using a confidence level of 90% and a margin of error of 10%, a sample size of 53 was determined. The questionnaire received 36 responses, 68% of the sample size. The questionnaire was live from the 1st until the 31st of March 2021.

CASE STUDY ANALYSIS

Case studies give a complete picture by drawing on multiple sources of evidence. Knight and Ruddock (2008) suggested that case study analysis is relevant for construction-driven research as the industry is project-specific. Following Yin (2018) the decision was made to utilise multiple (3) case studies for this study and adopt the unit analysis of the interview. This was to understand the real-life adoption of offsite M&E and the opinions of those involved in these projects. The M&E organisation utilised for this study is a national sub-contractor with an offsite manufacturing facility in the UK.

A mixture of 12 project participants from roles that included: Quantity Surveyor, Project Manager, Planner and offsite representative were selected to undertake the interview. The participants were selected based on their experience and active involvement in the case study projects. The case studies and project participants interviewed were selected utilising justified sampling, the 3 projects were selected as they used offsite methods, were completed within the past 12 months and were of a M&E value of £1m or over.

Below is a summary of the case studies assessed as part of this research.

- Case Study 1 (CS01) - This project was a £3m M&E installation in an educational building.
- Case Study 2 (CS02) - This project was a £11m M&E install in a leisure facility.
- Case Study 3 (CS03) - This project was a £2m M&E installation in an educational building.

The interviews were kept open, which created the flexibility to ask the interviewee for further details. Each interview was targeted to be 60 minutes long, utilising online video communication tools Microsoft Teams. Examples of questions asked during the interview are as follows: "What in your opinion are the benefits of utilising off-site on this project?", "What in your opinion are the downfalls of off-site on this project?" and "What is your overall opinion of the use of off-site for M&E?". Ethical approval was obtained before the data collection.

To manage the data analysis process, Creswell, and Poth's (2018) five step process was applied throughout the data collection stage. Silverio-Fernandez, Renukapppa and Suresh (2019) suggest that this methodology creates a deeper understanding of the completed interviews and a more straightforward way of extracting themes. Steps 1 to 4 were applied: recording and transcribing each interview, reading, and reviewing each transcript and making notes of any emerging themes, colour coding to organise transcripts into segments and finally, creating a summary of responses related to themes and producing meaningful information. To maintain confidentiality, the approach adopted to code the case study interviews followed that of Daniel et al., (2018). The case studies are referred to as 'CS01: P01' where C is case, S is study P is a participant. Table I lists each participant's job role, experience, and case study involvement.

Table 1: Case Study Participants

Participant Information				**Case study involvement**		
Participant Code	Job Role	Years' Experience	Employment	CS01	CS02	CS03
PC01	Project Manager	10	M&E Sub-Contractor	Y		
PC02	Planner	32	M&E Sub-Contractor		Y	Y
PC03	Quantity Surveyor	20	Offsite Manufacturer		Y	Y
PC04	Factory Manager	13	Offsite Manufacturer	Y	Y	Y
PC05	Commercial Manager	40	Offsite Manufacturer	Y	Y	Y
PC06	Project Manager	40	M&E Sub-Contractor			Y
PC07	Estimator	45	Offsite Manufacturer	Y	Y	Y
PC08	BIM Manager	25	Offsite Manufacturer	Y	Y	Y
PC09	Project Engineer	6	M&E Sub-Contractor			Y
PC010	Project Manager	20	M&E Sub-Contractor		Y	
PC011	Quantity Surveyor	6	M&E Sub-Contractor	Y		
PC012	Quantity Surveyor	4	M&E Sub-Contractor			Y

Miles and Huberman (1994) suggested that interviewing project participants should continue until saturation of answers was achieved. As no new themes or ideas were emerging within interviews 10 to 12, the project interviews concluded at this point.

The results from completed questionnaires and case study interviews are presented and discussed in the next section.

RESULTS AND DISCUSSION

This section presented and discussed the results of the data collected from both the questionnaires and the interviews.

RESPONDENT BACKGROUND

The 36 respondents to the questionnaire consisted of '22.2% Project Managers', '22.2% Engineers', '22.2% Quantity Surveyors', '8.3% Commercial Managers', '5.6% Planners', '2.8% Academics', '2.8% BIM Managers', '2.8% Estimators', '2.8% Factory Managers' and '2.8%

Team Leaders'. The results also showed that the respondents have varied backgrounds, are employed by different organisations, and have experience working in various sectors. 61.2% of the respondents had over ten years of experience, 89% had worked on projects utilising offsite construction for construction elements of the build, and 86% had experience working on projects using offsite for the M&E aspects of the build.

Like the questionnaire, the case study interview participants were of the same roles and level of experience. This shows that the projects and participants had sufficient knowledge, breadth and experience relating to M&E works and offsite construction; therefore, they were qualified in relation to this research.

THE IMPACT OF OFFSITE PRODUCTION ON M&E INSTALLATIONS

To understand the impact of offsite production in M&E installation, questionnaire respondents were asked to respond using the five-point Likert scale. The results of the analysis are presented in Figure 1. In summary, the questionnaire concludes that most respondents believe that offsite production has a positive on the project performance indicators listed concerning M&E installations.

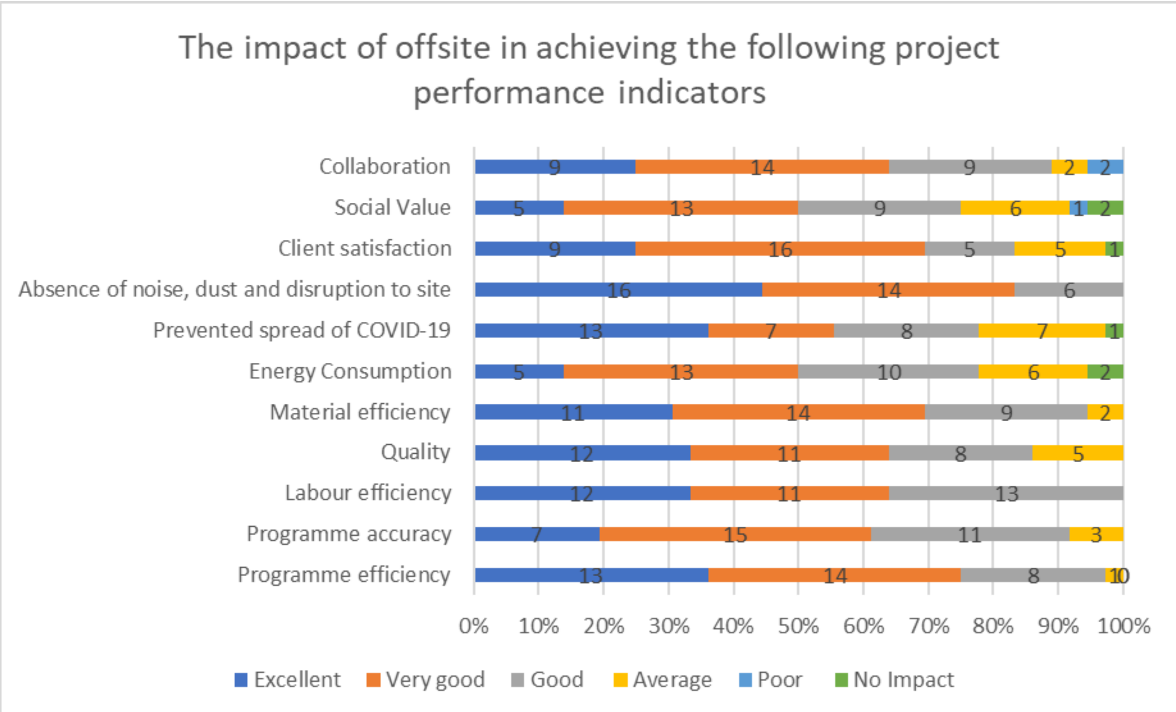

Figure 1: The impact of offsite production in achieving project performance indicators.

The findings from the 12 interviews were grouped into six sections and compared with the questionnaire and literature findings.

TIME

P01 described the impact of offsite on CS01 as saving "6,000-man hours on site and installation of the modules were four times quicker than traditional". The interviews also found that the utilisation of offsite can lead to elements of the installations being completed concurrently with on-site works such as demolition, resulting in M&E installations being able to start on-site later to achieve the same completion date. This creates programme certainty as elements of the programme subject to delay have been removed from the site. Similar findings have been shown in the questionnaire, whereby 97% of respondents believed that offsite has a good or above impact on programme efficiency and 92% respectively relating to programme accuracy. The results found in this investigation are like those of other researchers. Smith and Quale (2017) describe how offsite production can reduce time on site, and Farmer (2016) discusses how offsite can improve labour productivity.

QUALITY

P09 describes how offsite can achieve better levels of quality, "It is easier to build in a factory compared to onsite". The interviews also found that offsite can improve M&E installations' quality through works being completed in a more controlled environment, with quality control checks such as witness, and pressure testing being conducted to the system before delivery to the site. P02 adds, "Offsite production also limits the systems, such as modules and risers, exposure to other trades, reducing damage to the works". The interview findings are comparable to the questionnaire result; 86% of respondents agreed that offsite production positively impacts the quality of M&E installations. This is in line with Sands and Quale (2017) description of how offsite can ensure that the right conditions for tasks are achieved, which leads to an improvement in quality. This is supported further by Farmer (2016) suggestion that offsite production is a more design focussed approach allowing a focus on quality.

HEALTH & SAFETY

The findings from the case study interview were that offsite production positively impacts a project's health and safety. P09 states that "a reduction in the amount of labour on-site reduces the accident frequency", P01 builds on this by saying, "offsite production reduces the spread of transmissible illnesses such as COVID-19". The achievement a higher standard of health and safety could be attributed to offsite works being completed in a controlled facility. This is as offsite enables containment, pipework, and wiring to be completed at a work-bench level compared to ceiling level, eliminating the need for access equipment, and reducing the potential of falls from height. Hot works such as soldering and welding can be completed offsite, reducing risks to other trades. This is supported by Court, Pasquire and Gibb (2008), in which it is detailed how prefabricating M&E modules create the need for mechanical lifting to position these modules, reducing manual handling and the risk of injury. This is additionally supported by Fraser et al. (2015) suggestion that by moving a proportion of the site installation works to a lower risk environment, the project injury rate would reduce.

SUSTAINABILITY

The interviews highlighted that an offsite facility could achieve sustainability better than on-site, P09 details how "the facility has the resources available to implement re-use of materials which may have been over-ordered and create clear segregation of waste promoting recycling". This is supported by Farmer (2016) suggestion that offsite creates standardisation therefore reducing material waste. Additionally, 75.5% of the questionnaire respondents agreed that offsite positively impacts sustainability. Oakley (2017) found that offsite production can reduce CO2 tonnes and reduce material wastage.

LOGISTICS

P02 details how offsite construction was necessary for CS03 as "location of the site was in a built-up area with limited parking; therefore, would not be possible to complete construction of the packaged plantroom". P02 details how offsite construction was also necessary for CS02: "The site was located in a busy residential area, allocating a proportion of the work to an offsite factory reduces congestion in that area". This builds on findings from Farmer (2016), showing that a reduced on-site programme positively impacts noise, air, and traffic pollution, which usually affects the neighboring residents to construction sites.

Collaboration

Surprisingly, collaboration was not discovered in the literature review, this being a sub-theme developed from this research. CS01:P08 described how a "traditional approach to M&E installations lends itself to becoming packaged into sub-contract elements. This is in contrasts to an offsite approach which encourages more collaboration allowing parties to discuss elements of the design which may not have been considered previously until site install. This is in line with the questionnaire findings, where 88% of respondents believed that offsite has a positive impact.

The cost impact of applying offsite production on M&E installations

The questionnaire respondents were asked why offsite production may be more expensive compared to a traditional installation. The four themes developed were design, offsite facility costs, logistics and additional materials.

The responses received have been built on through the interview responses. Like questionnaire findings, P01 details how "BIM and logistics costs are increased compared to a traditional install". P08 adds that material costs increase in an offsite build as "everything offsite is to be enclosed within a steel frame; this adds additional expense". Other findings from the case study interview were that transportation costs increased as materials must be delivered first to the offsite facility and then delivered to the site in their refined form. Additionally, heavy equipment will be required for lifting and positioning on-site. According to Court, Pasquire and Gibb, 2008), lifting and transportation increase offsite costs. The current study identified other costs associated with offsites, such as frame costs, storage, and coordination costs.

The overall impact of offsite on cost

To conclude on the overall impact on cost, the questionnaire respondents were asked to indicate their opinion on the following statement, "Offsite is more cost-effective in comparison to traditional on-site delivery of M&E installations". The majority (47%) of people believe offsite production has a neutral impact on the cost of M&E installations. The second highest response (33%) was that offsite is more cost-effective. This differs slightly from the findings from the case study interview. The overall opinion of the interviewees is that offsite production is either cost neutral or more expensive compared to a traditional approach. This suggests that there is no explicit agreement that offsite creates cost savings. Within the literature review Court, Pasquire and Gibb (2008), Wilson, Smith, and Deal (1998) and Dicks (2002) all suggest that offsite production can offer cost or time-related cost savings. This research suggests slightly different findings, that offsite can be but is not always the most cost-effective approach. This implies that an offsite method is not selected based on cost alone but factors such as labour efficiencies and reduced programme.

The questionnaire respondents were asked about the most essential cost-benefit of offsite production to further understand the reasons for cost savings. 42% of the respondents believed that this benefit was through achieving labour efficiencies and 31% by reducing time-related costs. This mirrors that of Dicks (2002) view that offsite reduced time-related expenses and Court, Pasquire, and Gibb's (2008) suggestion that offsite production reduces labour losses. The remaining 27% of responses were cost certainty, reduced defects, reduced time-related penalties, and reduced life cycle costs.

The case study interview responses show a more detailed understanding of the cost benefits. P08 details how "cost savings can be achieved through an offsite approach by utilising out-of-town low-skilled workforce. This can be compared to a skilled pipefitter from London compared to an out-of-town facility". P02 uses the example of CS03 Packaged Plantroom to describe cost savings. "Modularisation may result in increased costs to the M&E contractor in the case of a plantroom as it includes cladding, concrete base, roof, flooring etc. However, overall savings can be seen on the project cost as a whole”. P05 says that “offsite may be a more expensive approach when the assessment is first completed; however, the process involves considering aspects of the installation that is often not considered until construction, therefore reducing the overall build cost”. Further findings from the interview were that the process of offsite construction includes a much more detailed analysis of costs which considers elements of the construction that may have previously been missed. This implies that offsite construction may improve the level of cost certainty.

CONCLUSIONS

This investigation aimed to explore offsite's impact in delivering M&E installation projects. To achieve the aim of this study, a mixed method was utilised. The study found that offsite production positively impacts the delivery of M&E projects, as demonstrated by the impact on project performance indicators such as time, quality, health and safety sustainability, logistics, and collaboration. However, in terms of cost impact, the respondents have no concession on this. The overall opinion of the interviewees is that offsite production is either cost neutral or more expensive compared to a traditional approach. However, this evidence does not align with a previous study by Pasquire and Gibb (2008). From the evidence gleaned from this study, it can be argued that there is no explicit agreement that offsite creates cost savings. Nevertheless, the study found that the detailed process associated with the offsite approach could give the client the confidence of cost certainty. Additionally, the study found that a more detailed understanding of offsite production's positive and negative implications on M&E installations is essential in costing it.

This study contributes to the future application of offsite production in the construction industry. First, the study has shown that offsite production should be selected based on its impact on project performance indicators rather than cost alone. The study argued that the offsite production method should be explored as much as possible when benefits are achieved; however, it should not be utilised simply for the sake of it but on a case-by-case basis

The limitations of this research were that there was not enough cost information available to compare a traditional and offsite approach based on these findings. Future studies should investigate a detailed cost comparison between offsite production and traditionally installed elements of either M&E or other installations within the build.

OFF-SITE/ON-SITE COMPOSITE CONSTRUCTION METHOD: AN UNCONSCIOUS LEAN CONSTRUCTION PRACTICE

Jeferson Shin-Iti Shigaki[1] and Tomonari Yashiro[2]

ABSTRACT

This paper provides a contemporary outlook on the concept, features, and achievements of the composite construction methods (fukugōka kōhō) developed in Japan between the 1970s and 1990s. The topic has not been widely publicised abroad, contrasting with prefabricated housing and construction robotics research conducted in the same period. However, the "compounding" approach can play a pivotal role in overcoming the present-day challenge of making digital construction technically possible and economically feasible. This research has employed two research methods. The first was a bibliographic survey of historical construction records and academic articles to grasp how fukugōka kōhō helped construction firms to deal with the pressing business and technological needs of that time. The second was focus group interviews with experienced engineers who came across the yielding effects of the compounding strategy and are now developing and implementing new elemental technologies integral to "smart construction systems" as part of R&D initiatives and productivity improvement management policies, which are tacitly lean. The awareness that try-out implementations of digital construction methods reassemble those past experiences put light on the possibility of resurging lean-ish hybrid production models to ensure competitiveness and reliability advantages in the transition period of technological maturation.

KEYWORDS

Fukugōka kōhō, prefabrication, off-site construction, work structuring, lean construction.

INTRODUCTION

The concept and technology of composite construction methods (*fukugōka kōhō*) emerged and flourished in Japan between the 1970s and 1990s. The fundamental idea was to combine conventional construction methods (*zairai kōhō*) and industrialised construction methods (*kōgyōka kōhō*) to improve the productivity of construction sites in the face of a chronic shortage of specialised construction workers (Nishida and Eguchi, 1989). Thus, it resulted from combining diverse construction technologies, promoting off-site production while maintaining the reliability of established on-site techniques in critical construction parts.

Previously existing composite structures (*gōsei kōzō*), by contrast with single-type counterparts, took the best of each material to respond to earthquake resistance requirements and high performance for realising skyscraper construction (AIJ, 1985). In turn, *fukugōka kōhō* combined the "off-site/on-site" production strategies with specific structural material settings.

[1] Research Assistant, Institute of Industrial Science, The University of Tokyo, Tokyo, Japan, (Current Position: Senior Researcher, Takenaka Corporation Research & Development Institute, Inzai, Chiba, Japan), shigaki.jeferson@takenaka.ac.jp, orcid.org/0000-0003-4513-6334

[2] Professor, Institute of Industrial Science, The University of Tokyo, Tokyo, Japan, yashiro@iis.u-tokyo.ac.jp, orcid.org/0000-0003-1675-0212

The *fukugōka kōhō* approach gained track when contractors perceived the technical and logistical difficulties of shifting directly to "purer" prefabrication (Takada, 1999).

Thus, *fukugōka kōhō* set realistic alternatives to tackle issues left unsolved by the desired but not all-rounded prefabrication schemes (Eguchi et al., 1988). For example, precast slabs did not eliminate local operations because the connection components remained as on-site manual work. Also, building pathologies, such as water, air, and sound leakage, compromised performance and durability. Thus, contractors preferred to continue employing conventional (by extension, more reliable) techniques in specific components and critical building interfaces.

Prototypical attempts of *fukugōka kōhō* focused on reinforced concrete (RC), steel frame reinforced concrete (SRC), and steel frame (S) structural systems. They usually strived to adopt as many precast concrete (PCa) elements as possible into the constituent parts of a conventional RC Rahmen structure (Ueno et al., 1989). The reasons for adopting it varied according to the requirements and conditions of each project. They included time shortening, reduction of personnel on-site, the downsizing or eventual elimination of temporary installations, reduction of material waste and energy consumption, quality improvement, and safety assurance (Konishi et al., 1996). The expected effects should fit the management targets of QCDSE (Quality, Cost, Delivery Time, Safety, and Environment).

Such strategy, resulting from selecting different construction methods in the same project, conveyed direct implications to structural design (type, properties, and composition of structural parts) and construction planning (construction zone division, erection sequence, assembly techniques, and temporary equipment allocation). The tentative plans employed high-variety low-volume parts to respond to design-construction conditions flexibly, simplifying work composition, nurturing multi-skilled workers, and enabling JIT (Kato et al., 1995).

Composite construction method plans resulted from disassembling, re-aligning, and integrating technologies concerned with construction work division, temporary equipment allocation, and labour assignment (Yashiro et al., 1993). The task of picking up features of existing methods considered the building use, construction site environmental conditions, gemba management policies, and the contract's ability to design technology interfaces between subsystems conceived independently (Takada, 1997). Contractors believed that accumulating improvements would lead to more robust and reliable structures in future projects.

The fact that *fukugōka kōhō* is not discussed under these terms today does not mean it has failed as a technology strategy or management concept. R&D projects were discontinued when the Japanese national economy stagnated after the "bubble economy" burst (Konishi et al., 1996). Then, many construction firms have resumed adopting conventional methods by default, while some suppliers have specialised in prefabrication for specific situations.

However, new technologies pledging to improve on-site operations have transformed the supply chain. Therefore, a revival of *fukugōka kōhō* is arguably an opportunity to promote innovative construction with productivity and personalisation advantages, satisfying both the customer and the production organisation. Digital platforms have significantly evolved, providing a comprehensive set of manufacturing, assembly, and inspection technologies unavailable by that time. The R&D initiatives, like those linked to the Construction RX Consortium, are a case in point (Construction RX Consortium, 2023). On the other hand, Lean Construction principles have been consolidated and can now offer an improved ground to establish better processes for both prefabrication and on-site digital construction schemes. Still, it seems that Japanese firms have handled them unconsciously or tacitly.

This research aimed to introduce the concept of *fukugōka kōhō* to the "outside world" with a refreshed outlook that helps identify drivers and potential barriers to future construction systems seeking to balance technical possibility and economic feasibility, taking advantage of the Japanese experience in developing and deploying composite construction methods.

RESEARCH SIGNIFICANCE

Japanese building construction is acknowledged for its quality and production efficiency. However, most studies disclosed outside Japan have focused on the housing sector, associated with the keywords “prefabrication”, “unit construction method”, and “modular construction”. The seminal papers of Groàk (1993) and Gann (1996) diffused their impressions of missions to Japan to assess the development of prefabricated housing technologies in the 1990s. They did it from an “outsider perspective” through site visits, document analysis, and interviews.

The works of Yashiro (2014) and Matsumura et al. (2019), who interacted with those groups, are some of the few reports published in English conveying a “domestic view”. The ZEMCH network, led by Noguchi (2016), has spread and popularised information about Japanese prefabrication, but they often recall the specific examples of the modular housing niche.

By contrast, the practices of Japanese General Contractors remain somewhat “mysterious” to the international community, given the limited number of sources about them. Foreigner researchers are aware of their technological strengths but know little about them. Bennett (1993) also visited Japan on technical missions and explored this niche. He emphasised the efficient production systems of the leading firms known as the “Big Five” (Kajima, Obayashi, Shimizu, Taisei, and Takenaka), praised for their massive research and development programs. Another notable yet rare case was the work of Bock (1989), who collected, organised, and diffused information in English about prefabrication and construction automation from housemakers to general contractors in rich detail due to the long-term nature of his stay in Japan.

Nevertheless, almost no research about composite construction methods has been published outside Japan. Evidence could be found in domestic papers and magazine reportages of that time. Although the peak of project implementation dates to the second half of the 1980s, the most relevant articles appeared in the early 1990s, based on the accumulated trial and error experience. The case of *fukugōka kōhō* was not limited to the Big Five. Semi-large and mid-sized firms also developed their authored versions and achieved positive results.

Current R&D programs promoting digital construction have set visions of not shifting directly to “purer robotisation” but establishing human-machine partnerships to reduce human labour. Arguably, lessons from the achievements and hardships of *fukugōka kōhō* could be used to set evidence-based R&D programs and support early-stage decision-making. Thus, there are reasons to revisit the *fukugōka kōhō* experience from a contemporary outlook.

RESEARCH PROCESS AND SOURCES OF EVIDENCE

The first part of this investigation identified the characteristics of *fukugōka kōhō* through a historical review to generate insights that could be revived today.

The bibliographic survey employed a triangulation strategy, uniting the academia and industry standpoints. The first source was the “*Sekō: kenchiku no gijutsu = Architectural product-engineering*” magazine series by *Shokokusha Publishing Co*. The second was the annual proceedings of the *Kenchiku Seisan Symposium* (Symposium on Building Construction and Management of Projects) sponsored by the Architectural Institute of Japan (AIJ). The third was a selection of miscellaneous papers from the AIJ database.

Table 1: Sources of the bibliographic survey

Source	Emphasis	Articles (no.)
Sekō: Kenchiku no Gijutsu (1966-2001)	Industry-centred	35
Kenchiku Seisan Symposium (1985-2021)	Industry-academia	10
AIJ miscellaneous papers (1989-1995)	Academia-centred	15

The second part attempted to understand the evolution of the characteristics of composite construction methods over time and the reason for their modifications through focus group interviews with veteran engineers. The target of this study was five prominent Japanese construction firms that developed and employed composite construction methods in the past. Three belong to the so-called "Big 5" group, and the other two are semi-large firms well-acknowledged for their technological achievements. The interactions were conducted entirely in Japanese between May and June 2022 and freely translated into this paper. The interviews were part of a broader study in which some questions focused on the *fukugōka kōhō* theme.

The participants belonged to various departments, including construction management, production technology, research and development, and design strategy. Their position varied from chief engineers to department managers and general managers. The average professional experience of the 14 participants was 30.75 years, with an average of 13.25 years on the gemba.

Table 2: Profile of the interviewees

Focus group	Interviewees: Position (Department)
Company A 2022.05.10	A1: Head manager (Building construction)
	A2: Head manager (Technical research institute)
	A3: Deputy manager (Operations support division)
Company B 2022.05.11	B1: Deputy director general (Building construction headquarters)
	B2: Manager, structure field (Production technology)
	B2: Manager, construction field (Production technology)
Company C 2022.05.12	C1: Head manager (Building construction)
	C2: Manager in charge (Building construction)
Company D 2022.05.27	D1: Head manager (Building technology)

FINDINGS OF THE HISTORICAL REVIEW

THE RISE OF FUKUGŌKA KŌHŌ

The Japanese construction sector has long faced a chronic labour shortage and declining productivity associated with an ageing workforce. Construction firms had struggled to find skilled tradespeople, mainly formwork carpenters and rod busters. At the same time, a plethora of new industrialised technologies was under development to meet ever-challenging project requirements, making construction methods more diverse and complex (Eguchi et al., 1988).

Despite the success of prefabrication among housemakers, production conditions were significantly different for order-made projects commissioned in mainstream construction. Traditional builders faced adversities associated with the uncertainty of the site environment and temporary supply organisations, making the production task more challenging. Still, general contractors were optimistic about off-site construction and positively invested in prefabrication technology development as part of rationalisation efforts (Takada, 1997).

However, precast concrete technology could not eliminate on-site operations because the joints still required local manual work (Konishi et al., 1996). Also, quality issues caused by flawed engineered interfaces disturbed users and urged hard-to-solve responses. Hence, *zairai kōhō*, considered more reliable, had to share the stage with prefabricated parts.

Ultimately, *fukugōka kōhō* served as an alternative to "pure prefabrication". It tackled issues left unsolved by the latter regarding productivity, quality, and its associated building performance, which were hard to perfect due to their production specificities. It enabled the realisation of superior structural performance and gemba productivity improvement by combining construction methods according to specific site conditions (Furusaka, 2009).

Figure 1 illustrates two examples of *fukugōka kōhō*. They shared the idea of utilising prefabricated components wherever possible and half-prefabricated parts wherever judged necessary to bind structural sections. However, the design details of those components and joints considered the specific production strategy of each firm and were often patented.

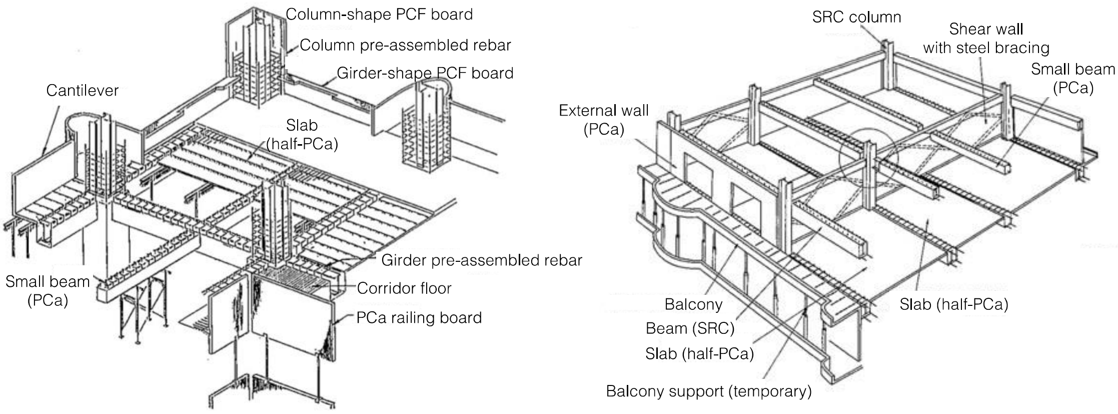

Figure 1: Examples of fukugōka kōhō (Adapted from: Sekō magazine, Aug 1986; Oct 1988)

The compounding approach enabled "leaner" sites to deliver buildings with similar outlooks, reducing wasteful local work subject to variability by systematically prefabricating components within reasonable boundaries, not pushing too much. Inspiration from the naval sector (i.e., Block Production System) and automotive sector (i.e., Just-in-Time) helped eliminate waste, overburden, and unevenness, the so-called *muda*, *muri*, and *mura* (Umehara et al., 1995).

By outsourcing tasks in the critical path, the project team could shorten the delivery time, reduce on-site personnel, and flexibly tighten connectors due to the modular design and the well-coordinated delivery of semi-finished parts, which were usually large and, in some cases, self-supporting. Consequently, the site necessitated fewer temporary construction equipment that obstructed the flow of people and hindered the execution of concurrent services.

DEFINITION AND TERMINOLOGY

Despite the absence of a resolute definition of *fukugōka kōhō*, the quote below hints on the concept development.

> "Fukugōka kōhō is a construction method that incorporates as many precast concrete (PCa) elements as possible into the skeleton constituent parts of a conventional structure (viz., generic cast-in-place concrete) aiming to improve the production efficiency on-site (Ueno et al., 1989)."

The terminology has changed as the management implications became clear. Records in the *Sekō* magazine revealed that the technology was first referred to as "*fukugōka kōhō*" in which the "*kō*" of "*kōhō*" was written with the ideogram "*takumi*" conveying a nuance of "engineering process (how to make it)". Afterwards, practitioners substituted that ideogram for "*kamai*", which is also read "*kō*" but suggests "structural composition (what is it made of)". Then, both ideograms were combined in a single word (*kōkōhō*) which implied that technologies were stacked together like a mosaic, integrating materials, equipment, workforce, and operations with the construction zone division and temporary work plans (Yashiro et al., 1993).

Regarding the specific names, it was common to attach a prefix (usually an acronym) that identified the core technology involved in each building system. Most companies labelled each variation by describing the specific material in use, functional cross-sections, connection types, and the target building typology to which it was conceived. Other companies would collectively address their inventions under an umbrella title, such as "*x-company-style fukugōka kōhō*".

PIONEERING SOLUTIONS

The planning of *fukugōka kōhō* resulted from the iteration of construction method selection and combination for rationalisation purposes. Construction firms first prioritised structural systems over other disciplines, considering it would bring impact benefits to urgent issues, such as cost. Despite the technical challenges, contractors believed that accumulating improvements over time would make these composite structures more robust and reliable (Eguchi et al., 1988).

Figure 2 illustrates the construction cycle of a project employing *fukugōka kōhō*, which directly impacted work structuring. The mix of precast and conventional work set specific takt times that were usually in between those estimated to *zairai kōhō* and full prefabrication.

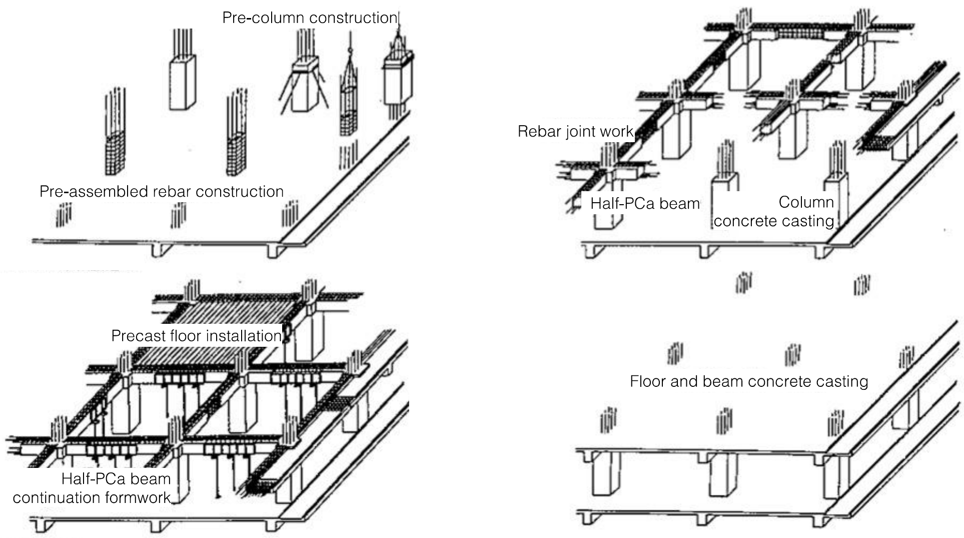

Figure 2: Construction cycle with fukugōka kōhō (Adapted from: Sekō magazine, Jan 1991)

A survey by Konishi et al. (1996) with several companies identified the most recurrent merits among 51 composite construction method variations. A breakdown of these factors revealed that the leading one was time shortening (43), followed by labour-saving (*shōryokuka*) (38), quality improvement (29), personnel reduction (*shōjinka*) (28), proficiency effect (*shūjuku kōka*) (27), cost reduction (26), and material-saving (24). Other benefits reported included the independence of weather conditions, the possibility of constructing higher buildings, larger spans, lighter structures, and improved earthquake resistance, to name a few.

A major consequence of *fukugōka kōhō* was the simplification of temporary construction (*kasetsu kōji*). The reduction of storage, transport, and safety installations implied cost savings and clear space for the remaining work on-site. For instance, precast horizontal boards avoided vertical supports and allowed the quick start of subsequent tasks. Parallel work optimised equipment utilisation (*kadōritsu*) and promoted site tidiness (viz., 5S workplace organisation).

A study by Ueno et al. (1989) compared two projects of similar scope and scale (3-story residential building) in which one employed *zairai kōhō* and the other *fukugōka kōhō*. Regarding resource utilisation, the project with *fukugōka kōhō* saved about 30% of man/hour in the structural frame construction and about 30~50% in the formwork, rebar, and concrete casting operations. The cycle process was shortened from 12 to 8 days, and the total construction time was compressed from 15 to 12 months.

INTERVIEW RESPONSE-BASED CONSIDERATIONS

DRIVERS AND BARRIERS IN ADOPTING FUKUGŌKA KŌHŌ

The historical survey revealed that the **main drivers** for adopting composite construction methods in the so-called first-generation *fukugōka kōhō* (1970-1990) were:

- Productivity (or QCDSE in the broadest sense).
- Structural performance (or overall building performance).
- Flexibility of construction process and operations.
- Product individualisation and customisation capabilities.
- Enhanced component supply and on-site logistics.

The interviewees were asked about the main reasons for adopting composite construction methods today in light of the current industry situation. The motivation has not significantly changed, as the most frequent responses were pursuing "*cost reduction*" through the willingness to increase productivity compared to conventional construction methods.

> "It is [mostly] about money. The selection of construction methods considers the customer's requirements. Roughly speaking, decision-making strives to balance cost and construction time. [That is because] there are cases where they are willing to pay a bit more for faster construction (Mr A1)".

The secondary factor was the "*flexibility*" of the construction process and operations. The argument was supplying the advantages that an element technology is good in a composite structural system that better fits the project overall. The other factors were pointed out as "manageable". Although not necessarily easy to solve, the engineers "don't overthink them". Regarding *structural performance*, the interviewees reported that improved material properties (viz., high-strength concrete) have made combining too many different materials unnecessary to extract their advantages (e.g., employing RC where SRC used to be required), making the construction process simpler and more efficient. By all means, the application was contingent on compliance with technology evaluations and obtaining permission from the local authorities.

> "I think structure performance was not a reason to adopt *fukugōka kōhō* because the selection of a construction method must ensure '*dōyūi tanpo*', that is, the new candidate must ensure equal advantage or performance superiority compared to established methods (Mr B2)".

In the past, the construction method combinations were necessary for erecting a building with particular architectural features (i.e., high-rise, large spans, earthquake resistance). Now, many venturous designs are possible with fewer structural type combinations which means a trend toward simplification. Structures of either "single-type method" or "composite method" must satisfy the design's performance specifications and adhere to technical requirements.

Construction records of the historical survey revealed that the **main barriers** to deploying the first-generation *fukugōka kōhō* (1970-1990) were:

- The need for adaptation and rework due to the complexity of the design.
- Lack of skilled labour.
- Technology interface issues.
- Regulatory permissions (i.e., technical standards, town planning etc.).
- Reliability of parts and component supply.

The discussion about the barriers called out the kernel of the composite construction method idea. Some interviewees highlighted that *fukugōka kōhō* variations were devised to overcome the pitfalls of previous construction methods, so it was hard to point out their barriers.

> "Generally speaking, *zairai kōhō* is the reference construction method to be employed. Occasionally, we face a problem such as 'the construction period is too short' so the adoption of *fukugōka kōhō* is worthwhile. Regarding the barriers, I would say that solving the decomposition and continuity between construction methods is challenging (i.e., *technology interface issues*) (Mr A1)".

Furthermore, *fukugōka kōhō* can simultaneously raise advantages and disadvantages on the same factor. For instance, 'cost-saving' was considered the main reason for adopting. However, the extra cost of adapting the technology to peculiar project conditions (rework of designing a piece devised for a different construction method) can be a barrier at the same time.

> "In principle, *fukugōka kōhō* takes only the good parts of each element method, so adding a few PCa in *zairai kōhō* structures would be good. However, off-site production implies the need for transportation, which implies extra costs (Mr C2)".

Some of the obstacles of *fukugōka kōhō* are similar to those of *kōgyōka kōhō* (prefabrication) since the latter is integral to it. The external and internal logistics are a case in point.

> "A significant factor is the yard condition. Whether there is a yard or not, whether a crane can be placed or not, whether the trucks can come in or not (Mr B3)".

Because *fukugōka kōhō* was new to most players, project teams struggled to understand the underlying process and streamline actions leading to tangible gains. The information flow and decision-making chain could fall short of clarity when adopting novel arrangements.

> "If we adopt a generic (default) construction method, there is a generic flow to proceed. However, *fukugōka kōhō* does not follow the generic flow. So, we must imagine and elaborate it (from scratch) by ourselves (Mr A3)".

Moreover, the new combination must meet the quality and performance threshold; otherwise, it will be rejected as a candidate system for that project.

> "If it clears the quality threshold, we will check the cost merit. After that, we assess the impact in construction time. […] We want to select a combination that takes this balance. We often ask ourselves: 'How far should we prefabricate?' (Mr D1)".

The need for adaptations in the construction plan and the rework of interface design undermined a more extensive application. Thus, design-bid-build projects in which the design comes from an external office were also more challenging to deal with than design and build commissions for a single firm (large Japanese general contractors hold full-scale design teams).

TECHNOLOGY ADVANCEMENT AND CHANGES IN ITS IMPORTANCE PERCEPTION

Regarding the **conceptual and physical changes** over the decades, it was unanimous that progress in building materials promoted significant transformations in structural design. These changes modified the strategies for the appointment of corresponding construction methods.

> "In the 1980s, PCa was widely discussed. However, at that time, there was no high-strength concrete as we have today, so it would have been impossible to build high-rise buildings only with PCa (Mr A1)".

An example was the substitution of SRC by PCa frames for high-rise building structures, thanks to the evolution of concrete technologies, reducing gemba operation complexity.

> "About 40 years ago, SRC was the only choice for high-rise residential buildings because of its superior performance. However, SRC is expensive and makes the construction period longer. From the 1980s, [high strength] PCa became an option. Nowadays, there are almost no new buildings with SRC (Mr B1)".

Fukugōka kōhō aggregated PCa parts into conventional RC skeletons for rationalising the erection process. It also combined RC columns and S beams to extract their superior structural properties, creating many design variation possibilities to satisfy customer needs.

> "In the 2000s, we often used a construction method of RC columns and S beams. It was a way of having the best of each material. The older mentality was 'If I use an S beam, then I should use an S (or SRC) column too'. However, the development of joints has made it possible to use this (alternative) combination (Mr B2)".

Because the number of prefabricated parts increased, construction equipment had to become more efficient. Consequently, scheduling and stock management adapted to the new erection pace. However, the productivity of people-operated tasks has not changed much since then.

> "The capacity of tower cranes has increased. In the past, they lifted no more than 20t. Also, the provisional service elevators have become faster (Mr C1)".

It is worth noting that the term *fukugōka kōhō* became unused over time. There is an awareness that undertaking 100% *kōgyōka kōhō* (prefabrication), although not impossible, is complicated and not necessarily worthy depending on the project conditions.

> "I think the so-called *fukugōka kōhō* that flourished in the 1990s has provided good combinations of element construction methods. However, the technology was still in its infancy at that time. […] In our company, we have developed a comprehensive construction method called '*x-construction method*' (pseudonym). Since then, we probably have not called it *fukugōka kōhō* anymore (Mr A1)".

Similarly, in the idea, but without a standardised solution pattern, some companies referred to their subsequent *fukugōka kōhō*-ish arrangements as a "hybrid construction method" or merely a "rationalised construction method".

> "PCa (prefabrication) is the choice with the highest merit. However, the cost factor recurrently leads to hybrid options with *zairai kōhō*. The construction time might enlarge a little (compared to pure PCa). The so-called 'hybrid method' or 'rationalised method' takes the balance of cost and time (Mr E2)".

The theoretical concept of *fukugōka kōhō* was not uncontroversial and is hardly mentioned today. Young architects and contractors face the term as a simple description of an engineering strategy rather than an actual concept. The interviewees reacted with surprise when asked about their memories and reflected on how they could be helpful today. Besides, they demonstrated a certain nostalgia and conjectured that "almost everything today is a sort of *fukugōka kōhō*". They would not spend much energy on it because "it just sounds natural" to pursue prefabrication without "doing *muri*" and relying on *zairai kōhō* when inevitable.

DISCUSSION: DIRECTIONS FOR NEW BUILDING SYSTEMS

The compounding approach had taken part in construction rationalisation policies (*gōrika hōshin*) initially emphasising productivity and quality (Takada, 1999). Despite not using the word "lean" explicitly, many "*gōrika"* efforts resembled what the West would call lean-ish endeavours, pursuing eliminating waste and improving flow. *Fukugōka kōhō*, within that macro-concept, could be considered an unconscious and partial "lean construction" example.

Regarding the lessons to devise future construction systems, there was no consensus on whether the proportion of prefabrication shall increase, decrease, or continue at about the same level as today. It would depend on whether construction robotics will make local operations more advantageous than bringing on semi-ready parts. Ultimately, "new hybrid" construction systems could result from sophisticated prefabrication and on-site automation coordination. For the automation element, the *Construction RX Consortium* (2023) is an example of technology cooperation aiming at labour saving and worksite efficiency through site robots introduction in gradual steps. The initiative does not claim to be lean but features some lean-ish characteristics.

The interviewees suggested that a new *fukugōka kōhō* employing on-site robotics could be developed shortly, but probably without using the "composite construction method" name.

> "The changes are from hereon. Digital technologies have evolved a lot. However, the fundamental aspects of the production systems have not changed yet. There is progress in elemental technologies. Now, we are investigating 'how to link these element technologies to our productivity improvement actions' (Mr B2)".

The development of *fukugōka kōhō* had been partially *cumulative* on a succession of routine improvements (*kaizen*) and *disruptive* as part of innovation programs to anticipate response to social and market change. Compared to the robotics wave of 30-40 years ago, there is an increased willingness to employ assist robots. They are not meant to replace humans but aid the fewer (multi-skilled) of them who remain on-site to perform as much as many workers traditionally, reducing redundancy (waste). Still, systematic robotic utilisation shall satisfy certain conditions, including finding the necessary input to start operating. However, these robots still do not hold enough autonomy to handle "improvisations" and deal with their risks. The word "making-do", as defined by Koskela (2004), is not heard in Japanese gemba, but a similar "drive" or "impulse" to control them tacitly exists in *dandori* arrangements.

CONCLUSION

The labour shortage issue has been further aggravated in Japan and other countries. In response, construction firms have proactively set internal policies to promote off-site production. Nevertheless, they have been conservative about the time robots developed in the R&D laboratories will run in the real gemba. The lessons of the past showed that the hurdles of "full prefabrication" and "full automation" are exceedingly high. Thus, it has been more realistic to face automation as performing an "assist" function, and prefabrication as a spotted strategy.

Former versions of *fukugōka kōhō* brought out the best of "off-site and on-site" for optimal efficiency with a touch of parsimony. Future building systems are likely to follow the compounding rationale. However, the "on-site" part might be modified due to recent technologies. The "*new fukugōka kōhō*" will likely be a mix of "off-site/on-site" in which the on-site work will be more digitalised, contingent on technology robustness issues.

Since new combinations are subject to falling short in performance-quality trustworthiness (trial-and-error experimental nature), the transition will take time. The deployment of "*new fukugōka kōhō*" depends on the construction method technology in itself but also the ability of design teams to devise coherent and robust combinations in response to the project requirements. Procurement models integrating design and construction control (*sekkei-sekō*) provide a favourable ground to maximise the available machine's capabilities and realise frontloading.

Lastly, stakeholders must beware of the advantages and limitations of each elemental technology and communicate with construction planners and component suppliers to streamline the comprehensive production system. Therefore, the realisation of such building system design is the product of sophisticated internal and external teamwork pursuing the balance between optimal and feasible. It is, ultimately, a tacit expression of lean-like efforts. It may be a peculiarity of the Japanese construction industry and business environment and not necessarily applicable to projects where the underlying conditions are significantly different.

EXPLORING A PLATFORM APPROACH TO IMPROVE THE UPTAKE OF OFFSITE CONSTRUCTION IN HOUSEBUILDING: EVIDENCE FROM THE UNITED KINGDOM

Zoe A. Kennedy[1], Emmanuel I. Daniel[2], Matthew Egan[3], Trudi Sully[4], and Gaynor Tennant[5]

ABSTRACT
The purpose of this this research is to create guidance and direction for industry especially developers and / or housebuilders who can directly influence the decision-making process to create buildings and land developments that are considered more valuable. The UK has a massive housing shortage and with the added pressure of climate change and a very fragmented construction industry the need to look at smarter building methods is critical. The benefits of offsite construction are well documented but still thought of as expensive and high risk, therefore other solutions such as platforms could lower the barrier of entry and increase uptake. This study aims to investigate the current understanding of platform construction and the challenges that are contributing to its slow uptake. Qualitative research method was used and only construction professionals who have experience in offsite construction were interviewed to ensure the richest information. The study found that cost and supply are the core issues limiting uptake of product platforms. Through the continuation of government and industry collaboration, both supply and demand can be aggregated to solve these issues. However, the bar for improving knowledge and understanding across industry needs to be raised and points of recommendation are provided.

KEYWORDS
Offsite construction, product platforms, manufactured construction, standardisation, collaboration

INTRODUCTION
To date, the UK construction industry has been built on inefficient processes and often described as a broken business model with issues relating to construction costs, supply, labour availability, productivity, and fragmentation in the market (Egan, 1998; Farmer, 2016). Many countries are facing a housing shortage and the UK is no different with projections of the

number of households in England rising from 23.2 million in 2018 to 26.9 million in 2043 (House of Commons, 2021), which means the sector desperately needs to create more high quality and sustainable housing. With the construction industry contributing to 39% of global carbon emissions (WBCSD, 2021) it means the sector must also change the way it designs and builds to mitigate the acceleration of global warming. Looking at smarter ways to build, through manufactured construction, will not only help both the UK's housing shortage but also help decarbonise the sector.

Offsite construction has a critical role to play in moving the industry forward, however, to date the uptake of offsite manufacturing approaches remains low within UK housebuilding (MGCLG, 2019; Marte Gomez et. al., 2021). Offsite construction techniques where entire modules are constructed in a factory need extremely high capital costs for investment and funding. For one, there is a huge investment for the factory setup alone, plus with factory production there are very high upfront costs for production and delivery to site (Goulding and Rahimian, 2019; Barbour ABU, 2020; Tuesta et. al., 2022). As per, House of Lords, 2018, this means a lot of working capital is tied up, especially if the manufacturer is not paid until work is delivered to site, and that can be very challenging in terms of cash flow for the manufacturer to stay afloat. In fact, that can be the difference between an offsite manufacturer being successful or not as the case maybe. Platform construction, as per Mosca et. al., 2020; CIH, 2022, comprise of standardised interoperable components and assemblies which can be used at scale as well as standardising processes and programmes which ultimately will reduce project cost, delivery time and carbon emissions. A platform approach also creates a lower barrier of entry around investment and risk that come with offsite modular construction (Barbour ABI, 2020).

In an interview conducted by Bryden Wood, a manufacturing design and engineering practice, it highlighted there is a mindset shift is needed to really progress the uptake of manufactured construction by making better choices early in the process. This means that smaller housebuilders and developers have a pivotal role to play to ensure a better delivery of housing stock (Bryden Wood, 2021). This research tests the viability of manufactured construction, such as offsite and platform approaches, amongst UK housebuilders and developers by encouraging "manufacturing thinking" right at the very start of a project to drive design, client and supply chain engagement (Goulding and Rahimian, 2019; Tuesta et. al., 2022). To improve uptake of offsite construction and increase the housing supply in the UK this study seeks to achieve these two objectives:

1. Investigate the current level of knowledge amongst UK developers and / or builders, concerning platform construction;
2. Identify the challenges that prevent UK developers and / or builders from adopting such building methods thus contributing to the slow uptake of offsite construction.

LITERATURE REVIEW

OFFSITE AND PLATFORM CONSTRUCTION

Offsite construction typically has become to be known as an approach to a project whereby a proportion of construction activities are carried out under factory conditions and then later transported to the site usually in the form of complete modules (Goulding and Rahimian, 2019; CITA, 2022). It has been recommended as part of the solution to solving some of the inefficiencies in the construction sector for decades now from the UK's government report Re-thinking Construction (Egan, 1998) to the government's review of the construction labour model in Mark Farmer's Modernise or Die report (Farmer, 2016). Subsequently this has evolved thinking and best practices by taking the learnings from other manufacturing industries, like automotive, and applying them to the delivery of buildings. The construction sector is now using terms such as 'standardisation', 'lean manufacturing', 'pre-assembly', 'economies of scale' which has given rise to various categorisations of offsite construction designed to help improve understanding and confidence in the use of smarter building techniques (MHCLG, 2019).

Figure 1 was developed for a report for Construction Research & Innovation Strategy Panel (CRISP) and focuses on the term 'pre-assembly' by subdividing into four categories based on increasing amounts of pre-assembly (Gibb and Isack, 2003). More recently, in Figure 2, construction was further defined by incorporating innovative construction techniques known as the Modern Methods of Construction (MMC) Definition Framework (MHCLG, 2019). This divided the innovative construction techniques or MMC into seven categories by encompassing a range of offsite manufacturing and onsite techniques and measuring how much pre-manufacture is used on a construction project. Measuring pre-manufacture or Pre-manufactured Value (PMV %) enables organisations to adapt design, supply chain and construction choices to aggregate and standardise demand (Pan and et. al., 2008; MHCLG, 2019).

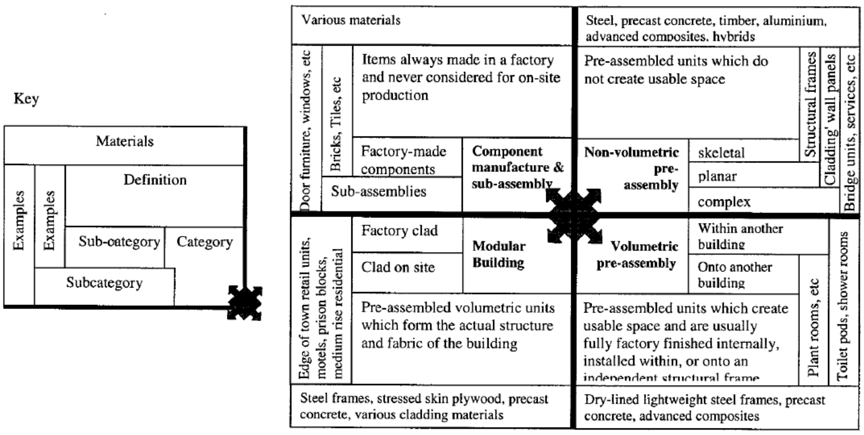

Figure 1: Four categories of pre-assembly, definitions, subcategories, examples and main materials (Gibb and Isack, 2003)

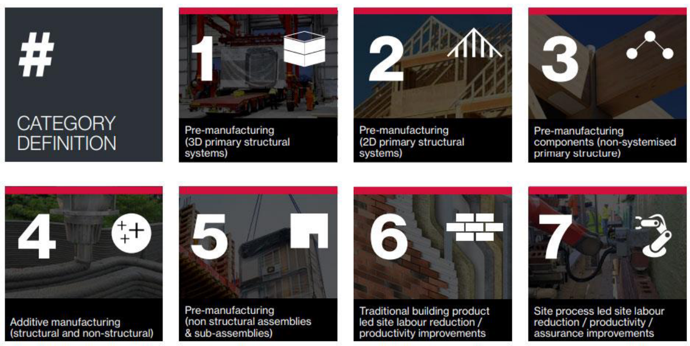

Figure 2: The MMC Definition Framework: Categorisation (MHCLG, 2019)

Platform construction, however looks at the project holistically by identifying commonalities and creating components that offer a higher level of standardisation and repetition (Barbour ABI, 2020; CIH, 2022). This negates the need for a large costly factory because platforms can leverage on existing processes through value engineering and continual improvements (Bryden Wood, 2021c; Bryden Wood, 2018; Barbour ABI, 2020). As per Mosca et. al., 2019, there are many kinds of product platforms but they all have three characteristics. Firstly, a group of fundamental components, such as a car's chassis, that don't vary too much. Second, a group of auxiliary parts which may be paired with the chassis to produce lots of repetition of the same vehicle. And lastly, a reliable interface that enables the components to connect (Mosca et. al., 2020; CIH, 2022). So whichever framework is used to categorise offsite manufacture, whether it be Figure 1 or Figure 2 or another, they illustrate examples of pre-assembly or pre-manufacture in construction, which really aligns to the thinking of a product platform approach by providing a stable core which is configured and combined with complementary components (via defined interfaces) to suit a particular project (CIH, 2022).

MANUFACTURED CONSTRUCTION PRINCIPLES

In understanding offsite and platform construction techniques and securing the benefits of these manufacturing led processes in housebuilding, there is a real need to recognise the importance that "manufacturing thinking" is different to "construction thinking". As per Bryden Wood, 2021c; Bryden Wood, 2018; Goulding and Rahimian, 2019; Tuesta et. al., 2022, a key manufacturing principle is to strip out anything that is non-value adding and work out what is the leanest possible way to deliver it to the end user. Design for Manufacturing & Assembly (DfMA) describes the process of manufacturing and assembling a product and the need to design a product towards the process (Bryden Wood, 2021).

One of the major problems in the construction industry is that far too often people do a traditional design process and then shoehorn DfMA into a project such as modular or panelised. This compromises the design by making it fit the system and thus designing an inefficient system. This is where architectural and consultancy practices specialising in offsite construction would be able to add significant value in the process by being system-agnostic and designing the best solution for that project also advocating the role of the MMC Adviser at RIBA Stage 0 (Modularize, 2021; RIBA 2021). In manufacturing there is a different set of constraints to traditional construction such as manufacture and assembly (and dis-assembly), transport, safety, cost, environment etc. which all need to be carefully planned and considered right at the very start of a project (Modularize, 2021; Laovisutthichai et. al., 2022; CITA, 2022).

According to Zhang and et. al., 2009, DfMA is more familiar in offsite construction such as building fully completed volumetric and modular buildings where there is controlled environments and optimised processes. Platform construction, takes components and assemblies that can be put together in lots of different ways to make lots of different products and has been termed a 'kit of parts' (Bryden Wood, 2021c; Bryden Wood, 2018).

Identifying commonalities to work from a common kit of parts and applying manufacturing techniques and processes can really drive productivity, innovation and cost efficiencies (Zhang and et. al., 2009; Barbour ABI, 2020). As mentioned, product platforms are used extensively in the automotive industry where there is a lot of customisation but use the same components and standard manufacturing processes, for example BMW and VW use the same chassis on a lot of their models and it's the engine, the wheels, the trim etc. that make the car different even though technically it is the same model allowing a degree of customisation (Bryden Wood, 2021).

PLATFORM CONSTRUCTION DRIVERS AND ENABLERS

The UK's government for procuring construction has changed significantly and has seen them championing MMC and committing to migrating from traditional construction techniques to smarter building methods. The creation of the Product Platform Rulebook was created to support the implementation of the government's strategies outlined in the Construction Playbook [December, 2020] to improve the uptake of MMC and increase adoption of platform approaches also described in TIP (Transforming Infrastructure Performance): Roadmap 2030 [September 2021] which builds on the Industrial Strategy of 2017 about delivering greater value in buildings (HM Gov, 2017; HM Gov, 2020; IPA, 2021; CIH, 2022). The Rulebook, therefore, not only sets out 'The Rules' that should be followed to develop a successful product platform but also details a common framework of approaches that can be used to implement a platform approach to delivery (CIH, 2022; Bryden Wood, 2021c).

The Platform programme therefore incorporates an end-to-end solution by re-evaluating the whole construction process, not just by considering the kit of parts approach and associated manufacturing processes but the knowledge, people and relationships required to deliver a project from inception to completion and beyond. It therefore focuses on 1) utilising manufacturing approaches to improve efficiencies by shifting focus to quality, performance and whole-life value; and 2) changing behaviours of clients and supply chain by enabling all-encompassing outcomes. This is really important as the industry moves towards a focus on performance outcomes and building a net zero carbon future (CN, 2021; Bryden Wood, 2021b).

RESEARCH METHOD

In order to look at a project more holistically so it can drive improvements by focusing on outcome-based specifications it needs to be pushed by industry. This puts emphasis on the housebuilding community to ensure a better delivery of housing stock by making decisions earlier on in the process (Bryden Wood, 2021). However, because the understanding of platforms is a relatively a new subject, a qualitative approach was used for this research to allow a more thorough discovery into this subject area (Nauom, 2013; Fellows and Liu, 2015). To date the current information available on platform construction is based on offsite manufacturing philosophies and lean manufacturing practices to improve efficiency and eliminate waste (Laovisutthichai et. al., 2022; Goulding and Rahimian, 2019; Tuesta et. al., 2022). At scale these methodologies have successfully been adopted in other industries such as automotive but have not yet translated to the construction industry.

This means the numerical data is not readily obtainable for manufactured housing because it has not yet “stood the test of time” compared to traditional methods of construction. A lot of the information to date, therefore, remains idealistic and even though there has been some great work between government and industry showing the potential of manufactured and platform construction, it doesn’t show the scale it needs to become mainstream (CIH, 2022; Bryden Wood, 2021c). This new concept of platform construction means a purposive sampling technique was best suited for this research allowing people with the most knowledge to participate in order to ensure the richest information was obtained (Braun and Clarke, 2013). Because of the newness of ‘platform construction’ more recognised terms such as ‘volumetric’, ‘modular’, ‘panelised’ etc. were used to identify those that have used manufacturing techniques in their building practices. This was essential to ascertain if a platform approach could be adopted more widely to build more quality houses faster.

Structured interview questions allow more accurate answers to be obtained compared to unstructured ones, as well as helping the interviewer to remain impartial (Naoum, 2013). For this research a semi-structured approach was taken by using both open and closed questions to 1) help prevent predeterminism but 2) allow respondents to give their views and opinions where necessary (Naoum, 2013). During data analysis common language was identified, in the form of themes and sub-themes, to rationalise the results. Thematic analysis is an approach that determines a level of prevalence by using code-frequency counts to identify common patterns in the data (Braun and Clarke, 2006; Braun and Clarke, 2013). Therefore, a middle-ground was achieved through the inclusion and exclusion of code-frequency counts.

RESULTS AND DISCUSSION

RESPONDENTS BACKGROUND

Although some additional dialogue with industry experts was undertaken to allow a deeper examination of this subject area, the focus of this research methodology is the UK housebuilding community. Therefore, twenty developers and / or housebuilders and key personnel were identified and contacted based on their knowledge and experience in this field of study, with ten confirming their participation. Before any data collection was undertaken respondents were asked to confirm their business category e.g., builder, developer or developer-builder and the type of housing projects they are involved in e.g., build-to-sell, detached, low-rise, affordable etc. etc and confirm their understanding of platform construction.

RESPONDENTS UNDERSTANDING OF PLATFORM CONSTRUCTION

The research showed that most of the respondents, 90% in fact, had heard of the term platform construction shown in Table 1. But to evaluate the true understanding amongst respondents they were also asked to describe platform construction which as in seen in Table 2 comprises of three initial codes. What this shows was most respondents mentioned the Use of a manufactured construction process to create efficiencies in the build by standardising components like they do in the car industry; using the same components & standard manufacturing processes to build, offering different finishes & ways to assemble to create variation, in the words of one respondent, "Constructing buildings in a manufacturing way – not just efficiencies in the design & build of the product but also in the process."

Table 1: Data analysis of respondents re. What is platform construction?

S. No	Description	Frequency	Percentage
1	Yes	9	90%
2	No	1	10%
Grand Total		**10**	**100%**

Table 2: Detailed data analysis of respondents re. Understanding about platform construction

Themes	Initial Codes	Frequency	Quotes from Transcripts
Understanding about platform construction	Building with a manufacturing mindset	1	Building with a manufacturing mindset by limiting choice to leverage greater economies of scale.
	Standardising	2	The ability to standardise the main asset like a chassis of a car and then a continuous reuse of manufactured components to produce variations in the supply chain. For example, VW Beetle and VW Golf are the same chassis! Kit of parts approach creating standardised components, with standardised processes to create efficiencies whilst having customisation.

Use of manufactured construction process	5	Using manufactured construction processes to create efficiencies in the build by standardising components like they do in the car industry. Using the same components & standard manufacturing processes to build, offering different finishes & ways to assemble to create variation - car industry!! Constructing under the limitations of manufacturing techniques to produce very efficient buildings. Using a manufacturing environment to create a fixed set of parts that can be put together in different ways to create variety & throughput. Constructing buildings in a manufacturing way - not just efficiencies in the design & build of the product but also in the process.

During the launch of the new DfMA Overlay to the RIBA Plan of Work, one of the major challenges that has contributed to the slow uptake of MMC and DfMA is a fundamental lack of understanding within the construction industry about manufacturing processes (RIBA, 2021; SCSS, 2021). Because there are currently so many variations and interpretations around terminology, whether it be modular, offsite or platforms, it makes it a very confusing and complicated landscape to work in (RIBA, 2021). Most of the respondents interviewed used these terms interchangeably to mean the same thing including modular, DfMA, MMC, offsite, prefabrication. Certainly, some respondent's understanding was more comprehensive than others, but most could relate platforms to manufacturing processes such as the automotive industry and understood the need to standardise to create efficiencies in the construction process.

But this confusion around terminology therefore limits the respondents understanding about how to get the best out of manufactured construction. As per Modularize, 2021; SCSS,2021, it was discussed that offsite architects that work across all MMC systems can identify the best solution for that project, therefore not limiting the design to a particular system. This coupled with the role of the MMC Adviser to be assembled as part of the project team at RIBA Stage 0 will ensure that offsite is not an afterthought, so all the benefits of MMC can be consumed and it does not impinge on design choices and customisation (RIBA, 2021). Although standardisation creates less design and layout choice compared to traditional, there are still lots of opportunity to create customisation by offering a variety of sizes, materials and finishes to suit different tastes, styles, and types. As per Mosca et. al., 2020, platforms need a holistic approach to be successfully adopted therefore moving the conversation away from cost and focusing on performance outcomes.

THE CHALLENGES SLOWING MMC UPTAKE AS PER THE RESPONDENTS

To identify the challenges that prevent UK developers and / or builders from adopting manufacturing techniques, respondents were asked to give their key reasons for the slow uptake of MMC allowing four initial codes to be formed as highlighted in Table 3.

Table 3: Detailed data analysis of respondents re. Key reasons for the slow uptake of MMC

Themes	Initial Codes	Frequency	Quotes from Transcripts
Key reasons for the slow uptake of offsite construction	Cost related issues	6	No cost benefits. For most projects we undertake it's not cost-effective compared to traditional. We are a developer / builder that sell our houses, so cost is a major driver. Ultimately we can talk about other value drivers such as innovation and sustainability but if you can't make the project viable it becomes irrelevant. The build size cost is too high for offsite, of course if you can build in volume and benefit from economies of scale it is cost comparable. But most brown field sites don't offer the opportunity to build 100 homes at a time. We've looked at modular several times on larger projects & still unable to get the numbers to stack up in terms of viability.
	Other	1	Planning is inadequate – lots of challenges here but main issue is that current planning policy does not consider zero carbon. MMC houses surpass building regulations but there is no recognition of that in current planning policies – you still only need to meet building regs.
	Lack of Understanding	2	Lack of understanding in how to deliver MMC therefore no cost benefits. Too late post-planning
	Supply Chain Issues	5	No cost certainty from supply chain. Not enough supply-chain availability and no interoperability. Not enough supply chain capability on the market. Manufacturers not interested in small projects – need volume. We build high-end luxury homes – at the moment there isn't enough design flexibility in the current supply-chain without incurring huge cost.

Cost was definitely a bone of contention throughout the interviews, in the words of one respondent "Ultimately, we can talk about other value drivers such as innovation and sustainability but if you can't make the project viable it becomes irrelevant"." A lot of this can be attributed to the lack of understanding in the level of detail required at the early design stages of a project as discussed in the above section (Modularize, 2021; CITA, 2022). In manufacturing there are a different set of constraints to be considered right at the very start of a project compared to traditional construction and it is knowing these intricacies that will give housebuilders and developers the edge to maximise project value and deliver a viable and cost-effective solution (Modularize, 2021; CITA,2022). Also, it brings into focus about not looking at a project in isolation and designing bespoke every time like traditional construction. Of course, a platform approach makes sense when delivered at large scale but even for small housebuilders there's no reason why some elements and processes cannot be standardised and used across multiple sites to reduce costs (Bryden Wood, 2021a; (CIH, 2022).

An interesting finding in the research contributing to the slow uptake is the planning inadequacy with one respondent making the point "Planning is inadequate – lots of challenges here but main issue is that current planning policy does not consider zero carbon. MMC houses surpass building regulations but there is no recognition of that in current planning policies – you still only need to meet building regs." If industry were able to get to a point where it was evaluating on other aspects such as social, economic, or environmental outcomes, it could then start to bridge the gap between on-site, offsite and everything in between. This might even remove the confusing industry terminologies and rather than differentiating between offsite and traditional, it could be referred to as just 'construction'. The use of materials are the same whether you build on-site or offsite, it's just the location that changes to whether it is built in a factory or on-site. As per CITA, 2022; Daniel et. al., 2020, most house designs surpass building regulations as standard in terms of airtightness and thermal performance, but if there is no recognition of this in current planning policy these extra costs a 'green' developer incurs naturally make offsite construction more expensive compared to traditional.

One of the other recognised challenges amongst the respondents was the insufficient supply-chain with one respondent saying there is "Not enough supply-chain availability and no interoperability". The result of this is the developers and / or builders interviewed felt the current supply-chain is monopolising the marketplace making a manufacturing option unviable in terms of price competitiveness (compared to traditional). And because every manufacturer is doing something slightly different, there is no interoperability, so each time a project must be redesigned as per the manufacturers system (Modularize, 2021; Bryden Wood, 2021a). As mentioned, where platform construction starts to be viable is delivering on large scale to drive the benefits of applying the standardisation of process and approach (CIH, 2022). But if there was interoperability and willingness to collaborate in the industry, it would allow manufacturers to come together and deliver a much larger programme (Daniel et. al., 2020). For example, by having different manufacturers using common elements, and potentially being able to procure together, not only is it a much more exciting environment in terms of materials, appearances, and styles, it becomes a much stronger commercial case for them to be involved. But as one respondent went onto describe so much of this is chicken and egg because for the supply chain to work together and invest, they need to have confidence in demand. That's the problem to date that so many of the platform projects highlight the opportunity but not the scale (Bryden Wood, 2021a; Bryden Wood, 2021b; Bryden Wood, 2021c; CIH, 2022).

CONCLUSIONS AND RECOMMENDATIONS

The aim of this study is to improve adoption of offsite construction, by investigating if a product platform approach can lower the barrier of entry and scale housing production in the UK. The study found that lack of knowledge of the platform approach, lack of supply chain capability and cost are among the barriers to the adoption of the platform approach. The study also found that the current planning policy that do not fully incorporate NetZero carbon limit the level of adoption of the MMC by house builders. For sure, there are a lot of challenges to overcome, but it is this joined up approach with government and industry working together that will move the industry away from procuring on just cost. This enable higher quality and sustainable houses to be built faster. As seen the Platform Rulebook has been instrumental in setting out key processes and approaches to enable the market to develop product platforms and learn how to deliver platform projects at scale.

Although the industry may not be quite there yet, as this research was conducted, the elements are coming together, and this makes the industry a very exciting place to be right now. As the industry moves away from cost to performance outcomes it will start to create an equal playing field for construction. Digitalisation of course will support this transformation and expanding interoperability to technology will allow the design process to be sped up to facilitate true digital design and operation. However, it cannot be stressed enough the industry needs to collaborate to innovate and make the industry less complex and more efficient to work in. Those three words from the Construction Playbook 'harmonising', 'digitising' and 'rationalising' demand will enable standardised and repeatable components and interfaces to be designed and drive the adoption of offsite manufacturing technologies.

RECOMMENDATIONS FOR INDUSTRY

This study helps anyone working in the UK residential sector by improving industry knowledge and understanding. It is joining up the design, client, and supply chain relationships to work in collaboration, that will assist UK developers and / or housebuilders in making manufactured and platform construction their first choice. The main points of recommendation are:-

- Manufactured construction is not an afterthought, it is a conscience business decision that is made at the start of a project with buy-in from all the project stakeholders;
- Understand that a manufacturing approach has a different set of constraints to traditional construction and therefore cannot be procured in the same way;
- Look at the project more holistically and move away from cost by focusing on performance outcomes and building a net zero carbon future;
- Standardising, components, assemblies and processes, as much as possible and taking the concepts and learnings across multiple projects will reduce costs in the long run as well as strengthening supply and demand;
- To unlock the true benefits of DfMA engage early with a MMC Adviser / Specialist Offsite Architect (ideally RIBA Stage 0).

This study is limited to ten interviews which may not adequately present the state of the art of application of the Platform approach in the UK. Future study should conduct an industry wide survey to present a more broader picture of the issue. Case study approach should also be used.

APPLICATION OF FUZZY LOGIC FOR SELECTION OF OFF-SITE CONSTRUCTION APPROACH

Amirhossein Mehdipoor[1], Ivanka Iordanova[2], and Mohamed Al-Hussein[3]

ABSTRACT

Compared to other industries, the construction sector has poor productivity performance. Many megaprojects in this industry incur cost overruns, and this is largely due to inefficiencies. Although there are several reasons for these inefficiencies, the most significant factor is the lack of efficiency. One effective solution to improve productivity in construction projects is to adopt Off-site construction (OSC) methodology, which enhances efficiency. The construction method selection is an important exercise toward the productivity and success of a building project. This exercise is particularly critical during the early stages of a building project, as it is important for decision makers to consider all criteria and make a prompt decision.

The use of off-site construction (OSC) is gaining popularity in building projects. Therefore, assessing the most relevant and key success factors in this context is necessary. Multiple Criteria Decision Making (MCDM) techniques have been widely used in the construction management domain. These are being applied as a medium for decision-making purposes in the construction sector. One of the most frequent methods is Fuzzy Logic to select an option among different alternatives based on a ranking system. In this paper, Fuzzy logic was applied to evaluate and rank the performance of two alternatives i.e. conventional method of on-site construction cast in situ works and Off-site construction steel structure fully modular approach. This project forms part of a Ph.D. research program which aims to develop a Two-Stage BIM-Lean Decision Support System (DSS) for the selection of a suitable Industrial Building System (IBS).

The proposed DSS development consists of two main steps: 1) Identification and evaluation of Key Decision Support Factors (KDSF) for the selection of the OSC approach and 2) Choosing an appropriate IBS for a building project. This paper focuses on the second step where fuzzy logic is applied to rank and select the appropriate alternative. A decision maker was provided with a list of Key Decision Support Factors (KDSF), which had been validated by industry experts, to input data and measure the importance and performance of each alternative. Crisp scores calculated using a fuzzy model indicated the rank of each alternative**.** The highest score of alternatives indicates the best approach. The result shows that alternative B – Off-site construction Steel Structure Modular approach, is the better option.

KEYWORDS

Off-site construction, Fuzzy Logic, Decision Making.

INTRODUCTION

The construction industry is known for its subpar productivity when compared to other industries. It is common for large-scale construction projects to go over budget. The primary cause of these inefficiencies is a lack of productivity. While there are various reasons for this, adopting Off-site construction (OSC) methodology has proven to be an effective solution to improve efficiency in construction projects (Abdul Nabi & El-adaway, 2020). Using decision-making models in the Off-site construction (OSC) domain has improved project productivity and sustainability in building projects. Therefore, it is necessary to promote the OSC approach by proposing a comprehensive decision-making model from the perspective of the Canadian construction industry. While various forms of OSC systems are available in the market, there is a need for a comprehensive decision-making tool that can effectively aid decision-makers in swiftly and confidently selecting the appropriate method during the preliminary design phase (Daget & Zhang, 2019).

The process of selecting an appropriate construction method can be complex due to the many options available. Those responsible for making these decisions must take into account various factors and considerations to determine the most appropriate construction method. As a result, the process of selecting a suitable construction methodology is complex and involves multiple attributes and objectives (Attouri et al., 2022). Moreover, the selection of the construction approach method includes multiple factors and criteria which can turn it into a complex process. This paper is part of a more comprehensive project to develop a decision support system (DSS). The main focus of this project is to demonstrate and present the proposed methodology to assist a decision maker in the construction management domain. The authors employed a mixed method of qualitative and quantitative expert review in addition to a systematic literature review (SLR) to identify and validate the Key Decision Support Factors (KDSF) utilized for data collection and implementation.

RESEARCH BACKGROUND

Considering Off-site construction approach at the early design stage of the project would assist all the team members to “think offsite” which is very important for the success of the project (Attouri et al., 2022). In the construction industry, decision-making is an important and relevant task which can be supported by the use of computer technology to improve quality and efficiency in building projects (Marcher et al., 2020). Due to the complexity of the construction process and the variety of different techniques and methods in planning, manufacturing and constructing a building project, the significance of decision-making becomes prominent.

Earlier scholars have examined decision-making elements associated with Off-site construction. Wuni (2019) discerned the primary five factors involved in the selection of modular integrated construction (MiC) including the availability of skilled labour and management, project timelines, transportation, limitations in size, and equipment availability. The process of decision-making in the construction management domain based on Multi-criteria decision-making (MCDM) techniques has been reviewed by pioneer researchers such as Aboelmagd (2018), Alhumaidi (2015), An et al. (2020), Daget & Zhang (2019), and Ordoobadi (2009). Aboelmadg (2018) used Analytical Hierarchy Process (AHP) as a tool in MCDM to select the best constriction bid price. In that research, the benefits of MCDM techniques were demonstrated. Specifically, in the OSC domain, Daget & Zhang (2019) developed a decision-making model for the assessment of Industrialised Building System (IBS) using MCDM techniques. However, that research is limited to housing projects in Ethiopia.

There are different techniques in the MCDM approach. Ordoobadi (2009) applied fuzzy logic for the selection of a proper supplier capable of meeting the client’s requirements and demands. Daget et al. (2019) preferred to use the analytical hierarchy process (AHP) to develop a decision-making model in the OSC domain. Wuni (2020) developed a decision-making framework by determining fuzzy modelling to evaluate the critical failure factors for OSC projects. Poor design and lack of proper supervision and management were considered the main key failure factors for modular projects (Wuni & Shen, 2020). Ishuzaka (2014), compared the most widely used techniques in MCDM i.e. fuzzy logic, AHP, Fuzzy AHP (FAHP) and hybrid fuzzy AHP. Integration of Fuzzy logic with AHP is a new trend to overcome the challenges of uncertainties in the MCDM approach (Ishizaka, 2014).

This research is focused on applying fuzzy logic in the MCDM approach to evaluate and rank alternatives in a case study based on relevant factors that influence the decision making process in OSC building projects. The alternatives taken into consideration are Alternative A- Conventional method of onsite construction using cast in situ concrete works and Alternative B- Off-site construction steel structure fully modular approach.

RESEARCH METHODOLOGY

This section explains the methodology that will be applied in the case study, followed by an elaboration of the procedure for using Fuzzy Logic to rank each alternative. The data analysis calculation and results will be discussed in the next section. The selection of the proper construction method in this paper is part of a larger project that aims to develop a two-stage computerized decision support system (DSS) for selecting an appropriate Industrial Building System (IBS) in OSC projects.

The process of developing the proposed Decision Support System (DSS) consists of two main aspects: 1) identification and evaluation of Key Decision Support Factors (KDSF) for the selection of the OSC approach, and 2) choosing an appropriate approach based on a ranking system for a building project. This study mainly focuses on the second part, where fuzzy modeling is chosen to analyze and rank the alternatives. The list of KDSF validated in the first stage of the research project was used to collect data from a decision-maker to rank alternatives. The expert was asked to give a value to the importance and performance of each factor. A mixed method of quantitative and qualitative techniques was implemented to identify, validate, and assess Key Decision Support Factors (KDSF) for the selection of the OSC concept. The assessment of KDSF importance and relevancy resulted in generating a list of the system's suggestions of weighting based on the mean score ranking.

The list of the system's suggestions assists the decision-maker in proceeding with the application of the Multi-criteria decision-making (MCDM) model using Fuzzy logic. The expert can refer to the values suggested by the system and adjust them according to the nature of a specific project to determine the best judgment in this process. Fuzzy logic evaluation and modeling determine the ranking of the alternatives. Figure 1 shows the overall fuzzy modeling methodological framework applied in this project. However, this project is only focusing on Fuzzy logic analysis and system recommendations on the selection of the proper alternative.

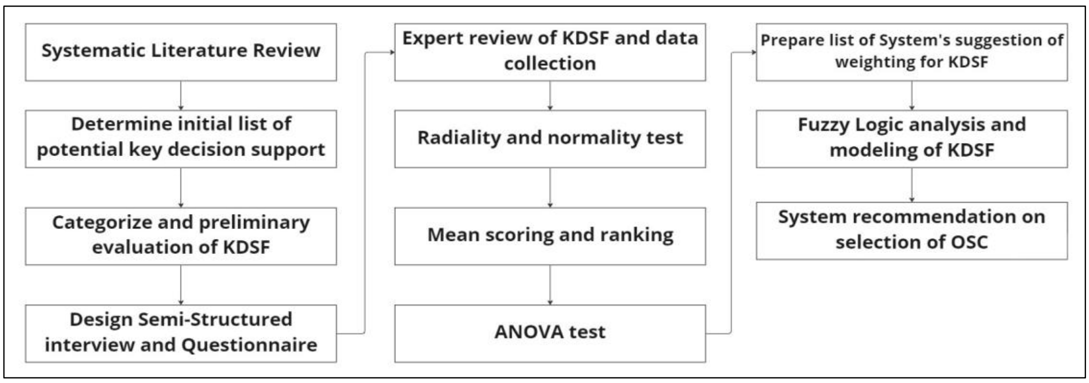

Figure 1: Fuzzy modelling methodological framework

The initial list of potential key decision support factors consisted of 32 factors that were categorized into seven dimensions. These were validated by 12 experts through semi-instructed interviews. A total number of 21 KDSFs were used to implement Fuzzy logic as per Table 1. A real case study was selected to assess the functionality of the proposed method. The selection process was based on the list of KDSF validated during the first stage and the expert's (decision maker's) weighting for each factor's importance and performance in stage two.

Table 1: Key Decision Support Factor (Main and sub-criteria)

Main Criteria	Key Decision Support Factor (KDSF)	Weights
Project characteristics (D1)	Project Location (F1)	w_1
	Project Design (Size, complexity and flexibility) (F2)	w_2
Supply chain (D2)	Financing (F3)	w_3
	Available Manufacturer (F4)	w_4
	Available Infrastructure (Hardware & Software) (F5)	w_5
	Available experts and skilled workers (F6)	w_6
Time (D3)	Design period (F7)	w_7
	Production time (F8)	w_8
	Mobilization & transfer time (F9)	w_9
	Assembly & construction period (F10)	w_{10}
Cost (D4)	Design (F11)	w_{11}
	Production & Manufacturing (F12)	w_{12}
	Logistics (F13)	w_{13}
	Assembly & Construction (F14)	w_{14}
	Maintenance (F15)	w_{15}
Quality (D5)	DfMA + Disassembly (F16)	w_{16}
	Standards and protocols (F17)	w_{17}
	Sustainability (Carbon emission, Energy consumption, waste) (F18)	w_{18}
Procurement (D6)	Type of procurement & delivery method (F19)	w_{19}
Socio-Cultural (D7)	Cultural resistance (F20)	w_{20}
	Local authority regulation (Workers Union-Syndicate) (F21)	w_{21}

The alternative weight given to each factor is based on the importance and performance scale given verbally by the decision-maker. For this case study, the value is assigned by an expert user with more than 10 years in OSC. Fuzzy logic is used to convert the 'linguistic' assessment into a numeric scale (Zadeh, 1965). The perception of the expert (decision maker) is based on 2 aspects, i.e. 1) the importance of each dimension (D_i) and 2) performance rating of DKSF (F_i). Ordoobadi (2009) applied membership functions consisting of two axes. The vertical axis represents the degree of membership and the horizontal axis represents the importance and performance scale (Ordoobadi, 2009). Table 2 and Table 3 respectively show the importance and performance of linguistic scale to fuzzy importance/performance. The importance of each dimension for each alternative is assessed by assigning a linguistic importance set of "Low", "Medium", "High" and "Very High" which correspond to their relevant fuzzy value on a scale of 0-1 as per Table 2. The membership functions of the linguistic importance weight and performance rate are based on the linguistic importance and performance scale presented by Ordoobadi (2009). The performance of an alternative with respect to each factor is evaluated on the linguistic scale of "Poor", "Good", "Very Good" and "Excellent" which correspond to a fuzzy value of 0-10 as per Table 3.

Table 2

Linguistic Importance	Fuzzy importance value
Low (L)	(0.0, 0.0, 0.2, 0.4)
Medium (M)	(0.2, 0.4, 0.4, 0.6)
High (H)	(0.4, 0.6, 0.6, 0.8)
Very High (VH)	(0.6, 0.8, 1.0, 1.0)

Table 3

Linguistic Performance	Fuzzy Performance value
Poor (P)	(0, 0, 2, 4)
Good (G)	(2, 4, 4, 6)
Very Good (VG)	(4, 6, 6, 8)
Excellent (EX)	(6, 8, 10, 10)

Equation 1 shows the calculation of the Fuzzy weight of a KDSF, where I_{Di} is an importance fuzzy value of a dimension and I_{Fi} is an importance fuzzy value of a factor. For example, the Fuzzy weight w_1 is calculated by multiplying the importance of project characteristics D_1 by the importance of size F_1 as per Equation 1.

Equation 1: $w_i = I_{Di} \times I_{Fi}$

The next step is to construct the fuzzy performance rate for each KDSF and to calculate the fuzzy score for each alternative. The fuzzy score of an alternative is calculated by multiplying the fuzzy performances by the fuzzy importance weights in a weighted sum according to equation 2, where fs_i is a fuzzy score, fp_i is a fuzzy performance and w_i is a fuzzy importance weight:

Equation 2: $fs_i = \sum_{i=1}^{n} fp_i \times \ w_i$; where *n = number of KSDF*

The final step is to rank the alternatives based on crisp scores. Fuzzy scores are defuzzified using the centroid method according to equation 3 where *(l,* m_l*,* m_u*, u)* construct fuzzy score. The alternative with the higher crisp score ranks first:

Equation 3: Crisp score $x = \frac{l+m_l+m_u+u}{4}$; where *l= first member,* m_l*= second member,* m_u*= third member, u= fourth member*

The following shows an example calculation of fuzzy weight w_i, fuzzy score fs_i and fuzzy performance fp_i:

Importance input by the expert for D1 (Project characteristics): High (H)

Importance fuzzy value for D1: (0.4, 0.6, 0.6, 0.8) = I_{D1}

Importance input by the expert for F1 (Project Location): High (H)

Importance fuzzy value for F1: (0.4, 0.6, 0.6, 0.8) = I_{F1}

$w_1 = I_{D1} \times I_{F1}$= (0.16, 0.36, 0.36, 0.64)

Performance input by the expert for F1 in Alternative A: Poor (P)

Performance fuzzy value for F1 in Alternative A: (0, 0, 2, 4) = fp_1

Fuzzy score for F1 in Alternative A: $fs_1 = fp_1 \times w_1$ = (0, 0, 2, 4) × (0.16, 0.36, 0.36, 0.64) = (0, 0, 0.72, 2.56)

As discussed earlier, among various techniques in MCDM, Fuzzy logic was selected for this project since it was necessary to show the importance of decision making in the early design stage of a building project while the amount of information and data might be very limited. By using Fuzzy logic compare to other methods such as AHP or FAHP, the decision making process is faster (Ishizaka, 2014).

RESULTS AND DISCUSSION

CASE STUDY

A real case study is presented to evaluate the application of the proposed method. The case study is a building project located in Canada that had a unique characteristic in terms of location, accessibility, and delivery time. The weather condition of the case study is characterized by extremely cold winter and short summer duration. Accessibility is very difficult, and the client's priority is to have an efficient building that can overcome challenges in that area such as proper thermal insulation, fast delivery and minimum building energy consumption. The decision maker was asked to provide input based on the list of KDSF to be considered for the selection of an appropriate construction method. The decision maker in this case was an expert with more than 40 years of professional experience in the construction industry. The list of KDSF criteria as per Table 1, consisting of 7 Main criteria and 21 sub-criteria, was used to develop the fuzzy model. The first input set was the importance values for the main and sub-criteria. Table 4 shows the importance rating for Project characteristics (D1), Project Location (F1) and Project Design - size, complexity and flexibility (F2) as an example.

Table 4: Importance rating for Project Characteristics (D1)

Main Criteria rate	Sub-Criteria rate	Weight
Project Characteristics (H)	Project Location (H)	w_1 = (0.16, 0.36, 0.36, 0.64)
	Project Design (VH)	w_2 = (0.24, 0.48, 0.60, 0.80)

The other weights are calculated in the same manner:

w_1 = (0.16, 0.36, 0.36, 0.64), w_2 = (0.24, 0.48, 0.60, 0.80), w_3 = (0.24, 0.48, 0.60, 0.80), w_4 = (0.16, 0.36, 0.36, 0.64), w_5 = (0.08, 0.24, 0.24, 0.48), w_6 = (0.24, 0.48, 0.60, 0.80), w_7 = (0.36, 0.64, 1.00, 1.00), w_8 = (0.24, 0.48, 0.60, 0.80), w_9 = (0.36, 0.64, 1.00, 1.00), w_{10} = (0.36, 0.64, 1.00, 1.00), w_{11} = (0.04, 0.16, 0.16, 0.36), w_{12} = (0.04, 0.16, 0.16, 0.36), w_{13} = (0.08, 0.24, 0.24, 0.48), w_{14} = (0.08, 0.24, 0.24, 0.48), w_{15} = (0.04, 0.16, 0.16, 0.36), w_{16} = (0.36, 0.64, 1.00, 1.00), w_{17} = (0.24, 0.48, 0.60, 0.80), w_{18} = (0.36, 0.64, 1.00, 1.00), w_{19} = (0.16, 0.36, 0.36, 0.64), w_{20} = (0.24, 0.48, 0.60, 0.80), w_{21} = (0.16, 0.36, 0.36, 0.64).

Table 5 shows alternative A - Traditional method and alternative B – Off-site construction (Modular) performance rating in the case study.

Table 5: Performance rating with respect to KDSF

Criteria	Rating of Alternative A	Rating of Alternative B
Project characteristics(D1)		
Project Location (F1)	P	EX
Project Design (Size, Complexity and Flexibility) (F2)	VG	G
Supply chain (D2)		
Financing (F3)	VG	VG
Available Manufacturer (F4)	P	VG
Available Infrastructure (Hardware & Software) (F5)	G	EX
Available experts and skilled workers (F6)	P	VG
Time (D3)		
Design period (F7)	VG	VG
Production time (F8)	P	EX
Mobilization & transfer time (F9)	VG	G
Assembly & construction period (F10)	P	EX
Cost (D4)		
Design (F11)	VG	VG
Production & Manufacturing (F12)	VG	VG
Logistic (F13)	VG	G
Assembly & construction (F14)	VG	EX
Maintenance (F15)	G	VG
Quality (D5)		
DfMA + Disassembly (F16)	P	EX
Standards and protocols (F17)	VG	VG
Sustainability (Carbon emission, Energy, waste) (F18)	G	EX
Procurement (D6)		
Type of procurement & delivery method (F19)	VG	VG
Socio-Cultural (D7)		
Cultural resistance (F20)	VG	G
Local authority regulation (Workers Union-Syndicat) (F21)	G	EX

Fuzzy score was constructed by using performance rating for each alternative with respect to the sub-criteria. Fuzzy scores of the alternatives were calculated by applying Equation 2 with respect to the expert's rating. The fuzzy scores were defuzzified by the centroid method determined in Equation 3. Finally, Alternatives were ranked according to their crisp score. The highest ranking was considered the most appropriate construction method for this project's specific case study. Table 6 summarizes the result. Alternative B- Off-site steel structure fully modular building, has a higher crisp score compared to alternative A- conventional method cast in situ concrete building. Therefore, the proposed fuzzy model ranked alternative A first. It is also supporting the critical success factors for this particular case study.

As mentioned earlier, due to the case study's location, weather conditions, accessibility, and specific client's quality requirement the factors of project location (F1), available infrastructure (F5), Production time (F8), assembly and production period (F10), assembly and construction cost (F14), DfMA + Disassembly (F16) and local authority regulation (F21) are major factors with higher performance value.

Table 6: Fuzzy score, crisp scores and ranking

Alternatives	Fuzzy Score	Crisp scores	Rank
Alternative A	(9.60, 31.76, 48.24, 94.56)	46.04	2
Alternative B	(18.72, 55.84, 81.76,124.96)	70.32	1

The finding of this research is also in line with discussions by previous scholars in this domain such as the study by Wuni (2019) on the five primary factors involved in the selection of modular methodology since skilled labour, project timeline, transportation, limitation in size and equipment availability have a similar perception to this study's factors with higher performance value. The significance of this study is the validation of the suggested alternative for the specific case study which is an ongoing project. The real scenario shows the reliability of the proposed system as well as its adaptability to other cases with different characteristics.

CONCLUSION

The decision-making process for selecting a suitable construction method is complex and influenced by many factors. It is an important process since a rapid and proper decision needs to be made at the early stages of a project. The initial selection of the most suitable approach will assist all stakeholders, such as engineers and architects, to develop their detailed designs in compliance with the specificities of the selected method (in the case study, the Off-site concept).

This project studied the application of fuzzy logic in the MCDM concept to select an appropriate offsite construction approach. The decision maker was asked to rank their preferences in a linguistic manner using a given scale to address subjectivity during data collection. These data were used to measure the importance and performance of Key Decision Support Factors. For the specific case study used in this project, Alternative A is the conventional method of cast-in-situ concrete works on site, while Alternative B is the Off-site steel structure fully modular building. The results show that Alternative B, with a crisp score of 70.32, ranks first, while Alternative A scored 46.04 and ranked second. Since the case study of this project was an ongoing modular project, the decision maker could validate the suggestion of the proposed Decision Support System (DSS) and its functionality.

The outcome of this research provides a useful and applicable framework to support the management process to reduce failure risk and improve the decision-making process. The proposed framework can be relevant and applied to any similar context, such as the comparison between various types of Industrial Building Systems (IBS). The importance and performance of relevant KDSF may differ in other countries and different types of construction projects, such as infrastructure, which are excluded from this study. Therefore, a future comparative study is suggested to investigate these differences. This project is limited to the use of data input by one expert. Furthermore, future research aims to collect more data to cover a larger context.

IMPROVING PREMANUFACTURING PHASES IN OFF-SITE CONSTRUCTION THROUGH A DIGITALIZATION APPROACH

Beda Barkokebas[1], Felipe Ost[2], Claudio Mourgues[3], and Lissa Saruhashi[4]

ABSTRACT

The integration of digitalization and building information modelling (BIM) has been lauded as a cornerstone to improve processes and enhance communication across the construction industry. Nevertheless, the implementation of digitalization approaches has suffered due to the lack of methods and processes uncertainties, particularly in the case of off-site construction (OSC) companies where its premanufacturing phases (design, planning, and procurement) differ significantly from traditional construction. This research presents a case study of a digitalization-based workflow to reduce the duration and increase accuracy of premanufacturing phases. To that end, a digitalization plan is developed using value stream maps, supported by Monte Carlo simulation, to identify the waste of current practices and propose suitable improvement measures. Afterwards, a digitalization-based workflow is developed and implemented to exchange data between BIM models and other systems. After one year and a half of implementation, the proposed workflow reduced the duration of tasks in 92.31% while providing an average of 12.24% more accurate bill of materials compared to the previous approach. As such, the contribution of this study is twofold: first, a lean-based method to implement digitalization in OSC companies considering its particularities and inherited process uncertainties; and second, an improved process for OSC premanufacturing phases.

KEYWORDS

Off-site construction, digitization, BIM, simulation, value stream.

INTRODUCTION

Off-site construction (OSC) is characterized by its fast approach in construction where building components are manufactured in a shop floor meanwhile civil and foundation works are performed onsite. Although known for its performance onsite, Barkokebas et al. (2019) attributes the success of OSC to its integrated project delivery approach where premanufacturing (e.g., design, planning and procurement) phases are performed by the OSC contractor to design, procure materials, and develop shop drawings for production and final installation onsite. By adopting this approach, the OSC contractor transfers a significant risk

from the client to themselves as they become responsible for all activities from the provision of engineering services up to the partial or full execution of the project.

To that end, OSC requires expedited procurement processes to account for variances in product and short lead times thus demanding digitized processes to aid in transparent coordination and accurate pricing (Oti-Sarpong, 2019). Additionally, Zheng et al. (2021) suggest the use of digitalization strategies to exchange data between stakeholders and automate processes to streamline premanufacturing phases given the complexity and risks involved in this approach. In this context, building information modelling (BIM) appears as an emerging trend of digitalization as it provides a representation of the intended project while exchanging accurate data (Wen et al., 2021). Indeed, Singh (2019) argues that, despite lagging behind other sectors, digitalization efforts are revamped in the construction industry due to the increased level of maturity in areas such as BIM, analytics and industrialization. Therefore, the development of BIM-based methods is a cornerstone for the advancement of digitalization strategies in OSC given its complexity and intrinsic integration in design and procurement phases.

The objective of this paper is to propose a case study involving the digitization of premanufacturing phases in the largest OSC wood-frame contractor in Brazil. By identifying wastes in current practices, this paper proposes a digitized workflow assisted by a BIM-centric add-on to automate customized quantity takeoffs as means to exchange data to streamline premanufacturing phases and assist in the accurate pricing considering different types of projects. To that end, the following hypothesis is tested: *a BIM-lean digitalization of premanufacturing phases will lead to lower development times and more accurate estimates of OSC projects*. To test this hypothesis, this paper provides methods for the digitalization of premanufacturing phases in OSC companies through a case study that can be later adapted and applied by other researchers and practitioners.

LITERATURE REVIEW

BIM has been heavily studied in the context of OSC in different areas such as constructability, exchange of data, and automation of design and procurement processes. Gbadamosi et al. (2019) propose a BIM-based system to evaluate optimal solutions for the design of elements and materials considering different factors such as the ease of assembly of handling parts, production rate, and waste in OSC projects. Additionally, Rausch et al. (2019) apply Monte Carlo simulation for tolerance analysis in the manufacturing of steel frame module while indicating if rework is required or not. To bridge the gap between design and manufacturing teams, An et al. (2020) propose the use of an ontology to establish a formal link between BIM models and knowledge from manufacturing experts to detect what operations can or need to be performed to manufacture wall panels.

Despite relevant BIM efforts and digitalization, Mukkavaara et al. (2018) argue information is segregated between different stakeholders in OSC projects and requires manual operations to ensure an information flow between systems. Additionally, they point out the importance of automation of contributory activities such as the development of bill of materials (BOM) from BIM models as a key feature for more interactive and digitized processes in OSC. With that in mind, Hussamadin et al. (2020) propose a conceptual model for the conversion of BOM extracted from BIM models to assist different stakeholders from off-site and onsite operations.

To address the issue of manual interpretations from estimators to perform takeoffs, Tang et al. (2022) propose rule-based algorithms to automatically detect takeoffs specific to OSC manufacturing operations. Besides comprehensive applications involving the automation of takeoffs in OSC, there is a lack of studies considering different types of project whereas the addressed papers refer to single case studies only. Despite significant studies to digitize OSC premanufacturing phases applying BIM, Oti-Sarpong (2019) points out the scepticism of practitioners to adopt these approaches due to a natural resistance to innovation from the industry and its inherited uncertainties. Schimanski et al. (2019) voice similar concerns pointing out the need for structured approaches to implement and maintain digitalization approaches in OSC. They also suggest lean thinking as a guiding principle for the implementation of digitalization approaches through the combination of construction-related data generated through premanufacturing phases of OSC projects and BIM models. Moreover, more implementations are needed to assist practitioners and propose methods to digitize OSC premanufacturing phases considering a holistic approach between different stakeholders and the exchange of data between them. To that end, Barkokebas et al. (2021) developed a framework for addressing the impact of digitalization in OSC by adopting a BIM-lean approach. Within the proposed framework, BIM models are used to improve processes and exchange data between teams (e.g., architectural, structural, etc.) while lean-based metrics are applied to evaluate the impact of digitalization in OSC premanufacturing phases.

RESEARCH METHODS

This study applies a case study approach to demonstrate the implementation of a digitalization-based workflow and test the proposed hypothesis. For this purpose, the unit of analysis to test the proposed hypothesis is a comparison between the development times and accuracy of the affected tasks before and after the implementation of the proposed workflow. A case study approach is applied due to its capacity to describe and offer insights on the object of interest (i.e., the effect of digitalization in OSC) (Yin, 2013). Figure 1 shows the research steps followed in this study where the first three steps are achieved by applying a framework developed by Barkokebas et al. (2021) to acquire a digitalization plan containing improvement measures in the case company based on the inherited uncertainties of its premanufacturing tasks. This framework applies value stream mapping (VSM), leveraged by Monte Carlo simulation, to identify waste in the current workflow while suggesting digitalization-based improvement measures that are applicable to the case company. Monte Carlo simulation is applied in this framework to quantify the inherited uncertainties of tasks identified during the development of VSM maps. During the development of VSM maps, durations are often provided by company experts in ranges (e.g., worst-case scenario, best-case scenario, and normal duration) instead of fixed durations to better understand the variability of their tasks.

Indeed, the applied framework asserts the duration of tasks as triangular distributions based on scenarios (pessimistic, realistic, and optimistic durations) provided by experts at the case company. Moreover, tasks are categorized in the VSM as value-added (i.e., productive), contributory (i.e., task necessary to perform the work that do not add value), and waste (i.e., non-contributory work) according to Pérez and Costa (2018). At the end of the framework's implementation, a digitalization plan is provided containing different improvement measures tailored to the context of the case company. Based on the digitalization plan, the case company decides which measure to implement whereas a digitalization-based workflow is designed and implemented. Different interactions between authors and company experts are performed during the implementation of the improvement measure so feedback is incorporated, and better results are achieved during evaluation. After implementation, the proposed workflow is evaluated by comparing the waste and other metrics identified during the development of VSM maps. After the comparison step, the hypothesis is addressed and the results of the proposed workflow are published. In total, the mapping process (i.e., first step of the digitalization plan) was developed in one month followed by another two months of implementation of the approved improvement measure. Finally, a comparison of results between the previously mapped and modified processes is presented after one a half year of its implementation.

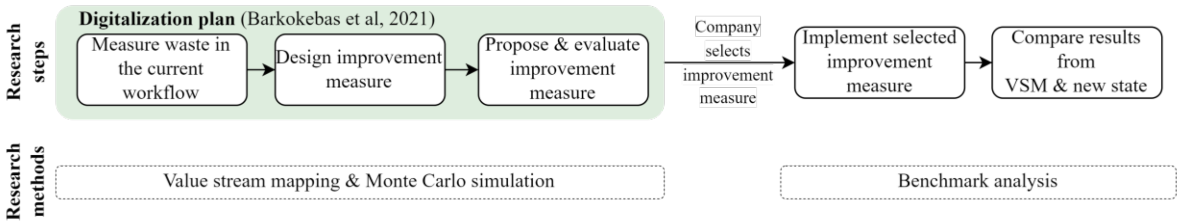

Figure 1: Research steps and methods according to DSR

CASE STUDY

As previously mentioned, the case study involves the work developed with the largest wood frame OSC company in Brazil specialized in the residential sector. The case company must adapt drawings provided by the client often designed to be built in masonry onsite (Brazil's most common construction method) to wood frame panels (walls, floors and roofs). Wall and floor panels will be manufactured on a semi-automated shop floor and later installed onsite while the roof is built onsite. Five premanufacturing teams are identified in the company: (1) project management office (PMO), responsible for estimating, preparing commercial proposals, and bidding for new projects; (2) architecture, responsible for preparing all architectural drawings and documentation for manufacturing and construction; (3) the design for manufacturing and assembly (DFMA) team, responsible for elaborating drawings and plans for the manufacturing and assembly of the manufactured panels; (4) plumbing, responsible for all plumbing drawings and documentation; and (5) electrical, who is responsible for all electrical drawings and documentation. All teams must upload its drawings, models and other documentation (BOM, estimates, schedules, etc.) in an enterprise resource planning (ERP) system. The following section will show the results of the digitalization plan according to the framework developed by Barkokebas et. al. (2021). Afterward, the results of the implementation of the proposed digitalization plan, the digitalization-based workflow, is presented followed by a discussion of similar studies.

RESULTS & DISCUSSION

DIGITALIZATION PLAN

Measure waste in the current workflow

Initially, the overall workflow is mapped to identify the exchange of information between teams on each project. This process is performed through semi-structured interviews performed online with each team's manager followed by other meetings to validate the information provided previously. Figure 2 shows the overall workflow and exchange of information between different teams followed by the main software used at the time. PMO receives the drawings in computer aided design (CAD) format from clients where manual takeoffs are performed to estimate the project's cost and the commercial proposal is delivered for bidding. Changes in the initial design by the client are common, thus the takeoffs must be updated so the commercial proposal reflects the latest project version, and the case company is competitive during the bid. A BIM model is not developed at this point due to the significant effort to develop the model where takeoffs are the only information needed. Moreover, the PMO argues that the significant effort is not justified since the project is still in the bidding stage whereas the case company still does not know if it will win the bid or not. Hence, quantity takeoffs are performed on AutoCAD and manually transposed to MS Excel for cost estimation.

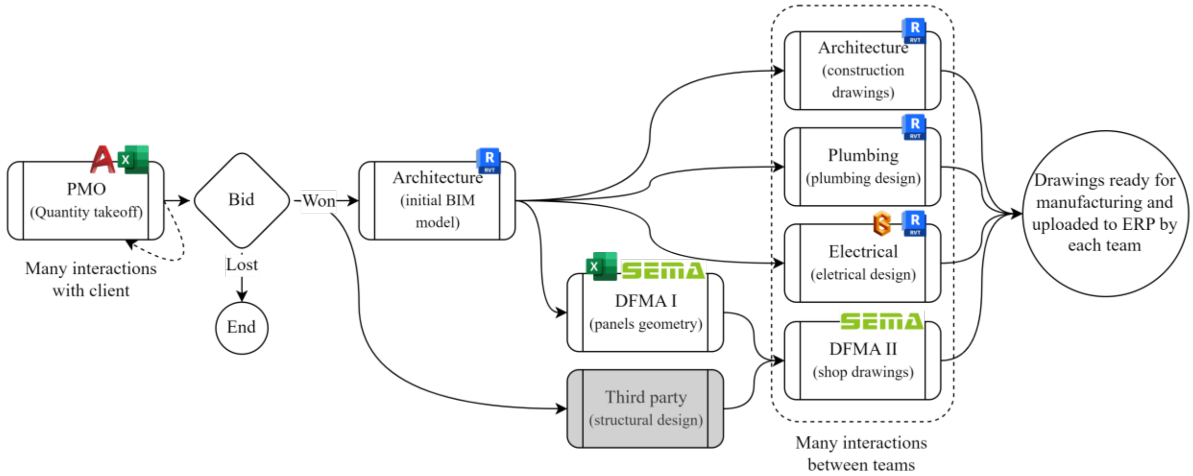

Figure 2: Overall workflow between teams

If the bid is won, the latest version of the project is sent to a third-party structural consultant and the architectural team starts developing the initial BIM model so the remaining teams (electrical, plumbing and DFMA) can start their work using BIM authoring software. At this point, Autodesk Revit is used as the main BIM authoring software by most teams. The initial BIM model includes all panels (floors, walls, and roofs) with its openings, thus delimitating the spaces and overall geometry of building elements in the project. Architectural and construction specifications are defined by the architectural team during the design process whereas decisions are made and coordinated with the remaining teams. The electrical and plumbing teams develop the drawings and specifications of their respective disciplines using Autodesk Revit whereas the electrical team also utilizes a specialized software (AltoQi Builder) to perform calculations. Meanwhile, the DFMA team is responsible for adjusting building elements according to the case company's manufacturing and construction methods. At the beginning of the project (i.e., DFMA I in Figure 2), the DFMA team defines the exact geometry of panels according to previous projects. After structural design is finished by a third-part consultant, the DFMA team revises the geometry of panels and generates shop drawings for manufacturing in the shop floor leveraged by semi-automated machines (i.e., DFMA II in Figure 2). Hence, the DFMA team utilizes SEMA, a specialized software in wood construction, to generate the shop drawings and computerized numerical control (CNC) codes to be use in the semi-automated machines. Due to different software used, data between the DFMA and electrical teams is exchanged using industry foundation class (IFC) format. Since the remaining teams use the same software (Autodesk Revit), data between them is exchanged through native files.

Some of the identified challenges are the loss of data and productivity when using heavy IFC models (DFMA and electrical teams) and the lack of documented design solutions and material consumptions used in previous projects (PMO and DFMA teams). All teams, except for PMO, also pointed out the extensive time required to develop the project documentation while maintaining all information updated during project revisions. Nevertheless, the most common challenges, identified by all teams, are associated with the exchange of data related to takeoffs where schedules created automatically in Revit and other software need to be transposed to spreadsheets or ERP following manual procedures. Indeed, every team needs to perform quantity takeoffs and provide schedules such as BOM to account for the cost of each discipline. Specialized software used by the DFMA and electrical teams provide automated BOM for each discipline. However, automated schedules developed by the remaining teams using Autodesk Revit needs to be transposed and modified manually in Excel to include all materials required without the need of extra modelling in the BIM model. Furthermore, teams indicate that takeoffs are often outdated after several project revisions due to the error-prone and extensive time spent on revising updated takeoffs due to changes in the models. After all teams are finished, this information is uploaded by each team to the case company's ERP system so material can be ordered and the project is scheduled for manufacturing by other departments.

The architectural team was selected for the application of the proposed framework and to evaluate whether it would benefit from a digitalization-based workflow. This team was selected because it provides the base BIM model to the remaining teams and is responsible to determine the actual quantities related to the architectural discipline. Hence, a VSM is developed to map current waste in the architectural team considering the inherited uncertainty of design processes applying a Monte Carlo simulation using Simphony.NET software.

Table 1 shows the tasks identified during interviews with the architectural team manager to develop the VSM supported by the Monte Carlo simulation. Tasks are performed in the order described in the table and are categorized as per value-added, contributory work or waste according to lean philosophy (Pérez & Costa, 2018). The initial three tasks in Table 1 correspond to the first process from the architectural team (i.e., initial BIM model) in Figure 2 whereas the remaining tasks in the table correspond to the second process (i.e., construction drawings) demonstrated in the same figure. As previously mentioned, task durations are given by experts in the form of scenarios (pessimistic, realistic, and optimistic) which, in turn, are modelled as triangular or uniform distributions depending on how the information is gathered by experts. Table 1 shows only one task categorized as waste which entails developing the initial BIM model from the latest CAD drawings while the most impactful contributory work is related to the takeoff and exchange of data process once this design phase is finished. Therefore, the observations made during the interview process with all premanufacturing teams confirms the significant effort in exchanging data as supported by the data displayed in Table 1 where the takeoff and exchange of data task amounts over 30% of the total average duration. The results of simulation are presented in the Propose & Evaluate section together with the proposed scenarios.

Table 1: Input for simulation model

Task description	Task type	Duration (days)		
		P	R	O
Develop initial BIM model	WT	2	1	0,5
Determine location of electric outlets	VA	1		0,5
Send initial BIM model to other disciplines	VA		0	
Review project scope	CW	0,3		0,2
Architectural detailing	VA	3–4	2	1
Roof detailing	VA		1,5	
Construction detailing	VA	5	4	3
Waterproofing detailing	VA	2	1	0,5
Develop views for federated model	CW		0,5	
Quantity takeoff and exchange of data	CW	4,5	4	3

Note(s): VA: Value-added, CW: Contributory work, WT: Waste, P: Pessimistic scenario, R: Realistic scenario, O: Optimistic scenario.

Design

In light of what was mapped and considering the current waste in the architectural team, two improvement measures are suggested by the authors: (1) the development of an add-on to generate BIM elements (walls, floors, and openings) from the latest CAD drawings approved during bid by the client , and (2) the development of a workflow to automate the exchange of data between BIM models and other systems (e.g., ERP) leveraged by an add-on and coupled with the adaptation of currently used MS Excel formulas to increase the speed and accuracy of takeoffs during the design process.

The first suggested measure (i.e., add-on in Autodesk Revit to generate BIM models from CAD files) aims to minimize the only task categorized as waste while ensuring the remaining teams start working as soon as possible. The nature of this task also involves time-consuming and repetitive work without requiring specialized expertise thus becoming an ideal candidate for automation. Moreover, the proposed add-on is also applicable to PMO during the cost estimation phase where a BIM model can provide accurate data without the expense of extensive development time. The second suggested measure aims to automate the takeoff process exchange of data between the BIM model and other systems in the case company. This data is used to provide information related to the quantity of materials, cost and production schedules required during the procurement and manufacturing phases which are uploaded to the ERP system. The development of an add-on for Autodesk Revit is suggested to generate CSV files containing the required data for the entire project that will be uploaded in the existing MS Excel spreadsheets used by the case company. The main difference between the current process and the proposed workflow involves the automated exchange of data from the entire project whereas manually updating information from BIM-based schedules results in mistakes and extensive time to make sure all information is updated and correct. Furthermore, this workflow is also applicable to other teams using Autodesk Revit (Plumbing and Electrical) in case the proposed workflow is accepted by the architectural team. It is important to note that both improvement measures are developed based on previous studies and the experience of authors in similar OSC companies. Therefore, other suggestions may be applicable depending on different experiences if other participants were involved.

Propose & Evaluate

This section provides an evaluation of the impact that the proposed suggestions will have in case they are implemented. To do so, the duration of affected tasks by the improvement measures are adjusted in the validated Monte Carlo simulation to predict changes in the average project duration. The modified tasks durations are estimated according to the author's

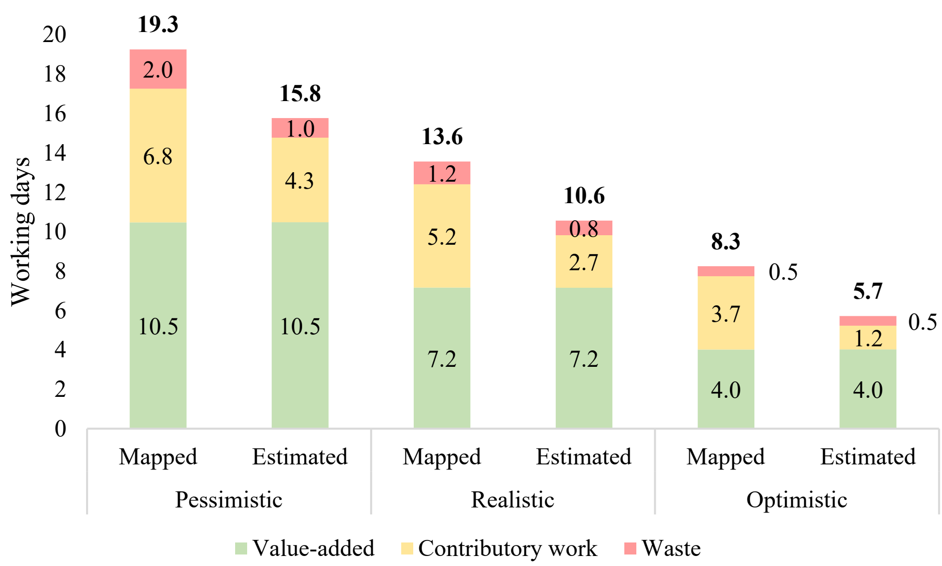

Figure 3: Comparison between the mapped and estimated durations according to different scenarios and task types

experience and in discussion with the case company's experts. The first and second suggested measures will reduce the duration of each task significantly. In the case of the proposed add-on to generate BIM models from the latest CAD drawings (i.e., first suggested measure), authors estimate the task "Develop initial BIM model" will take between half to one working day (e.g., pessimistic and optimistic scenarios, respectively) in case this measure is implemented. Moreover, on the second suggested measure, authors propose an add-on to automate the takeoff and exchange of data process between Autodesk Revit and Excel to reduce the task "Quantity takeoff and exchange of data" between half to two working days (e.g., pessimistic to optimistic scenarios, respectively) considering the size of projects and team's productivity. Hence, the validated Monte Carlo simulation is updated with uniform distributions (i.e., 0,5 to 1 working days in the case of the first modified task) according to what was estimated by authors and compared to the mapped state of durations. Figure 3 shows a comparison between the mapped durations and estimated durations according to what was gathered with the architectural team and author's experience, respectively. Also, the figure shows the total average project duration (in bold) while highlighting the contribution of each task type according to different scenarios. According to Figure 3, the total project's duration can be reduced 23,84% on average in case both measures are implemented. After this assessment, the digitalization plan was completed, and the case company experts could decide to implement the proposed measures or not.

PROPOSED DIGITALIZATION-BASED WORKFLOW

Implementation of selected improvement measures

Based on the digitalization plan developed in the previous subsection, the architectural team decided to not move forward with the first suggested improvement measure and prototype the workflow leveraged by an add-on to automate the exchange of data between BIM models and other systems (i.e., second improvement measure). Therefore, an add-on to automate exchange of data between Autodesk Revit and Excel was developed since these software are currently used by the architectural team. Moreover, the developed addon is applicable to other design teams using Autodesk Revit to design their models while using Excel to import data to the ERP system. Since the ERP system requires specific access to develop applications in it, importing data via Excel was suggested as this is a common default feature in most ERP systems. Hence, in case it is approved by the architectural team, the proposed workflow is applicable for all design teams with the exception of PMO and DFMA. Figure 4 shows changes suggested in the architectural team according to the proposed workflow and leveraged by the developed add-on. The add-on, named BTO provides an automated connection between data embedded in the BIM model and takeoffs required by the design team using Excel as an interface. Once the required takeoffs are entered in an Excel spreadsheet, the spreadsheet is uploaded to BTO which collects the data from Autodesk Revit and returns it in a structured format in Excel. The takeoffs are then processed through formulas in Excel to account for material waste, and labor or materials that are not modelled directly in the BIM model (e.g., ceramic tile placed up to a certain height in wet areas are calculated from the wall length at a specified height).

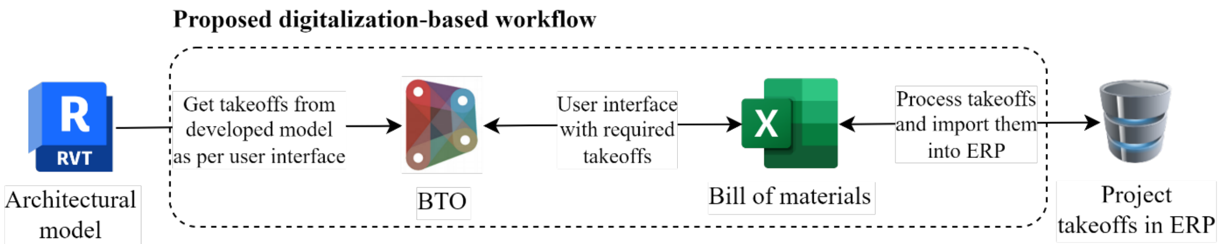

Figure 4: Changes in the current workflow

Comparison between mapped and proposed workflows

To address the hypothesis, this section shows a comparison of results between the previously mapped workflow and actual results gathered through interviews and data provided by the architectural team after implementation. Table 2 shows a comparison between the previously mapped and current durations and coefficients of variation, calculated using the program evaluation and review technique (PERT), in the affected task by the proposed workflow. The actual durations for quantity takeoff were gathered during interviews with the architectural team's manager after one year and a half of implementing the proposed workflow and add-on. Following the same procedure when developing the VSM maps, the actual durations of the affected task were gathered considering the inherited uncertainties (i.e., pessimistic (P), realistic (R), and optimistic (O) scenarios) of design processes as determined by Barkokebas et al., (2021). Table 2 shows that the proposed automated process, leveraged by the addon BTO, reduced the task in 92.31% % where the actual task duration varies between 0,2 to 0,5 working days. This result exceeded the expectation from authors where they forecasted 0,5 to 2 working days in the Propose & Evaluate section of this paper. This discrepancy is explainable with two reasons: (1) authors wanted to be conservative in their forecast while developing the digitalization plan, and (2) company experts modified formulas in their bill of materials so takeoffs could be performed more easily. Nevertheless, this result is aligned with previous studies comparing the application of BIM versus traditional approaches where takeoffs are consistently reduced by 70% of duration (Bečvarovská & Matějka, 2014; Wahab & Wang, 2022). The coefficient of variation increased significantly in the proposed workflow compared with the previously mapped workflow. Nevertheless, the manager of the architectural team indicated that, even when accounting for a more variable process, the duration in the takeoff process is greatly reduced by the proposed digitalization workflow.

Table 2: Task duration comparison between the mapped and proposed workflow

Task description	Scenarios			Expected duration (days)	Coefficient of variation
	P	R	O		
Takeoff and exchange of data (mapped)	4,50	3,80	3,00	3,90	6,38%
Takeoff and exchange of data (proposed)	0,50	0,30	0,20	0,34	14,43%
Difference between takeoff processes				**-92.31%**	**111,71%**

To assess the effect of the proposed workflow in the accuracy of estimates, the architectural team gathered data from three projects and compared their takeoffs performed by BTO with the BOM developed manually by the PMO team during the bidding phase. Table 3 shows the deviation between the manual and automated takeoffs on the main items surveyed by the architectural team. Deviations as significant as 80,3% confirm the high potential for error of manual takeoffs in the construction industry. Furthermore, an average 12,24% deviation between manual and automated takeoffs are observed between the three projects thus indicating that the automated takeoffs are significantly more accurate than the manual approach. Once again, this result is aligned with previous studies such as Pratoom & Tangwiboonpanich (2016) that indicate a deviation of 17,76% in the quantity of items considering manual and BIM-based takeoff practices. The results of improvements in both metrics established to test the proposed hypothesis (tasks durations and takeoff accuracy) are aligned with findings in previous literature as described in this section. Therefore, based on the results provided, the architectural team accepted the proposed workflow and decided to implement it in the entire team.

Table 3: Takeoff deviation between manual and digitalized processes

Material	Unit	Deviation from original takeoff (%)		
		Project 1	Project 2	Project 3
Ceramic tile	m^2	5,19%	12,44%	12,22%
Cementitious board	m^2	9,12%	16,78%	16,02%
Gypcrete	m^3	-15,15%	20,00%	7,03%
Ceiling	m^2	6,75%	7,21%	22,89%
Plaster board	m^2	8,71%	16,16%	4,04%
Water proofing	kg	-0,31%	61,82%	13,86%
Batt insulation	m^2	5,09%	45,39%	8,95%
Windows	un	0,00%	0,00%	0,00%
Painting	m^2	80,30%	6,76%	11,16%
Doors	un	0,00%	0,00%	0,00%
Roofing	m^2	9,10%	14,79%	7,75%
Exterior finishes	m^2	9,35%	7,45%	9,83%
	Average	**9,85%**	**17,40%**	**9,48%**

CONCLUSION

Despite relevant studies in the area, digitalization strategies and the use of BIM are still not fully implemented in OSC due to its inherited uncertainties and specific aspects compared to traditional construction. Aligned to that, the present study provides a practical implementation of a digitalization-based workflow in an OSC company aiming to reduce the current waste in its premanufacturing phases. Through the application of a framework developed by Barkokebas et al. (2021), the authors developed a digitalization plan supported by VSM maps and Monte Carlo simulations to identify current waste and propose improvement measures considering its potential impact to the case company. The digitalization plan identified two improvement measures to automate the generation of BIM models and the exchange of data between BIM models and other information systems, respectively. By selecting and implementing the second improvement measure, an add-on (i.e., BTO) was developed to automate the takeoff and exchange of data process and rendered a reduction of 92,31% in duration while providing more accurate BOM when compared to the previously mapped workflow. The achieved results performed better than expected in comparison to the estimated reduction presented in the digitalization plan. Yet, results were validated by the case company experts throughout interviews and based on the implemented digitalization-based workflow after one year and a half of its implementation. Given the positive results, the proposed workflow is incorporated in the case company. Despite its results, this study still presents limitations regarding the case study approach, as it becomes biased to the specific context of the case company and ultimately, cannot be generalized. Therefore, more case studies are needed to increase the number of methods to digitalize premanufacturing phases in OSC. Nevertheless, the hypothesis of this study is approved within this context since the case study demonstrates that the implementation of a BIM-lean digitalization approach results in lower development times and more accurate estimates when working with OSC companies. Finally, this study contributes with a lean-based method to implement digitalization practices in OSC companies considering its particular context and inherited process uncertainties to improve processes in OSC premanufacturing phases.

INVESTIGATION OF THE SUPPLY CHAIN OF MASS TIMBER SYSTEMS

Rafael V. Coelho[1], Aaron K. Anderson[2], and Iris D. Tommelein[3]

ABSTRACT

How well production systems and their supply chains are designed, configured, and managed affects the delivery of construction projects. Industrialized Construction (IC) and mass timber present a shift from traditional project delivery: they are reshaping existing supply chains and creating new ones within the construction industry. The rapidly increasing number of mass timber projects in North America and the emergence of mass timber supply chains bring the need to study and seek ways to design and improve the production systems that deliver customer value by means of such projects. Accordingly, this paper presents an exploratory case study that describes the characteristics of the mass timber supply chain in North America and the major steps in the process of designing and delivering a mass timber structural system for a multi-story residential building. In addition, we present a list of recommendations for designing and delivering mass timber systems.

KEYWORDS

Mass timber, supply chain management, industrialized construction, off-site construction, production system design.

INTRODUCTION

The performance of construction projects—including mass timber projects—is tied to how well production systems and their supply chains are designed, configured, and managed. Being efficient on the jobsite is not enough. An integrated network of individuals and companies is key to ensuring that trade-offs are collaboratively evaluated, and optimal decisions are made during the design of products and processes. These in turn increase the likelihood of successfully delivering a project (i.e., providing the value that the customer expected). As O'Brien et al. (2008) point out, "it is difficult to address supply chain production improvements without also considering arrangements between organizations."

In the case of mass timber products and systems, due to the novelty of the material and the building codes that bring new design (not only product design but also process design) and use opportunities, the supply chains to deliver these products are still emerging and worthy of research. New businesses are emerging in many places, each one aiming to provide value for a part of the supply chain. Additionally, automated manufacturing equipment is becoming less expensive and increasingly versatile, which is encouraging companies to contemplate entering the Industrialized Construction (IC) and off-site fabrication world (ABB 2021) as they identify opportunities to deliver projects more economically, efficiently, and effectively.

The opportunity for this study comes from three directions: (1) the rapidly increasing number of mass timber projects in North America (WoodWorks 2023), (2) the emergence of mass timber supply chains, and (3) the use of automated manufacturing equipment becoming more widespread in construction. Furthermore, given the lack of publications on how to design and manage the production systems to deliver projects (including mass timber projects) using IC, we see the need to study and seek ways to design and improve the production systems that will deliver customer value by means of such projects. These systems will be enabled by companies that use manufacturing principles, methods, and tools and strive to lower costs, shorten lead times, and increase quality.

Exploring the current state of the mass timber supply chain and the process of designing and delivering a mass timber structural system for a multi-story building is essential for formulating recommendations that will improve the efficiency and effectiveness of the mass timber industry. As part of ongoing research, this paper aims to answer the following questions: (1) What are the characteristics of the mass timber supply chain? and (2) What is the process of designing and delivering a mass timber structural system for a multi-story building? In response, we (1) introduce mass timber as a family of engineered wood products and as a structural building system, (2) present the reasons for its increase in use in the North American building industry, (3) describe some mass timber products used in building construction, (4) report on the emergence of the mass timber supply chain in North America, (5) explore the association of mass timber with IC, (6) describe the delivery process of a mass timber structural system for a multi-story building, and (7) provide a list of recommendations for designing and delivering mass timber structural systems.

SUPPLY CHAIN MANAGEMENT IN CONSTRUCTION

A supply chain is a network of entities involved in the design, production, and delivery of products to customers. Supply chain management (SCM) is "the practice of a group of companies working collaboratively in a linked chain of interrelated processes designed to best satisfy end-customer needs while rewarding all members of the chain" (Tommelein et al. 2003). Companies need to decide, for example, either individually or collectively, what products to make, where to make them, and how to make them, and what products to purchase, where to purchase them, and from whom to purchase them.

The importance of managing supply chains comes from the potential that developing relationships, integrating processes, increasing transparency and alignment, and focusing on customer needs can enable organizations to gain an economic advantage over their competitors. SCM—a term used more widely since the 1980s (Ashcroft 2021)—originated in the manufacturing industry (Vrijhoef and Koskela 2000) and evolved significantly in the 20th century. A substantial advancement in SCM came from Just-in-Time (JIT) production, one of the pillars of the Toyota Production System (TPS) (Liker and Meier 2006). JIT production is concerned with providing only the necessary quantity of items to each process in an assembly sequence, only when needed. The principles of the Lean production philosophy that constitute the TPS inspired the conceptualization of Lean Construction in the 1990s. The study of construction supply chains, which is a more recent phenomenon than the study of manufacturing supply chains, is closely related to the emergence of Lean Construction. Both adopt a systemic view of production systems.

Construction supply chains have been studied by several authors including Vrijhoef and Koskela (2000), who presented four roles for SCM, Arbulu and Tommelein (2002), who studied the supply of pipe supports used in power plants, Akel et al. (2001), who studied practices of parametric product design, vertical integration, and Lean construction in a pre-engineered metal building company, and Souza and Koskela (2013), who proposed a set of contextualized practices for improving construction SCM. Construction supply chains are arguably among the most complex supply chains to study and manage due to several factors, including (1) the temporary nature of projects, (2) the large number of stakeholders, (3) the wide variety of products and services, (4) the need for customization of products (e.g., Engineered-to-Order or ETO products) (5) long lead times, (6) disruptions caused by the existence of global supply chains, (7) regulations, codes, and standards, and (8) market volatility. Additionally, built assets—the finished products of these construction supply chains—are not only unique products (or prototypes) but they also require capital-intensive investment. These factors all have contributed to the existing fragmentation of construction supply chains. This fragmented nature has culminated in a business with low-profit margins, high risk, and a huge amount of waste—not only material (physical) waste but also waste from inefficient processes. Although a focus of construction management research has been on improving on-site processes, the uptake of off-site construction and IC means that a broader view of the design and aspects of supply chains is needed. Accordingly, and given the growing number of mass timber projects, this paper focuses on studying the supply chain of mass timber.

STRUCTURAL WOOD BUILDING SYSTEMS

In North America, wood structural materials have been used mainly in the construction of single-family homes and low-rise residential, commercial, and industrial buildings. Light-frame wood construction is the predominant structural wood building system in North America. It has dominated the North American housing market (both single- and multi-family) since the latter part of the 20th century and is also widely used in low-rise commercial and light industrial applications (Ross 2021). The vast number of builders with experience in light-frame wood construction and the relatively low cost and off-the-shelf availability of the materials (e.g., lumber, plywood, and fasteners) and tools used in this type of construction have contributed to its predominance in North America.

Other types of structural wood building systems such as post-frame, log, and heavy timber construction have also been used for decades in North America. In the early 1990s, cross-laminated timber (CLT) was invented in Europe and began to define a new family of engineered wood products known as mass timber. The use of CLT increased significantly in Europe in the early 2000s, driven by the green building movement and the increased efficiencies achieved with the fabrication and installation of CLT (Karacabeyli and Douglas 2013, p. 1). Other mass timber products include products that have existed for decades such as glued-laminated timber (glulam or GLT), nail-laminated timber (NLT), and others developed more recently, such as dowel-laminated timber (DLT), mass plywood panel (MPP), and mass plywood lam (MPL).

MASS TIMBER CONSTRUCTION

The term “mass timber” (with “mass” referring to “massive”) refers to a family of engineered wood products (or structural building systems) that are made of multiple compressed solid layers of wood joined together with glue, dowels, or nails, forming large solid wood elements such as CLT, glulam, NLT, DLT, MPP, or MPL. These products are manufactured (additive manufacturing) to various sizes and later processed or fabricated (subtractive manufacturing), usually off-site and according to a set of fabrication shop drawings. In the fabrication process, mass timber elements are cut to size, hollowed to make openings for penetrations to allow for the passage of Mechanical, Electrical, Plumbing, and Fire Protection (MEPF) elements, receive fire protection and connections, and are sealed. This turns mass timber elements into custom (ETO) building components. These components are then delivered to a jobsite as a kit of parts to be assembled. They are generally used for load-bearing purposes (e.g., columns, beams, floors, walls, stairs, and roofs) but can also function as an interior finish material (e.g., walls).

Although timber framing is not a new concept, it was the invention of CLT that now enables the construction of taller wood structures. Successful fire tests supported the inclusion of mass timber as a structural material into the 2015 IBC (ICC 2015), allowing mass timber buildings up to 6 stories (commercial projects) or 5 stories (residential projects) and about 26 m (85 ft.) in height. This spearheaded the development and construction of hundreds of mass timber projects in the United States (US). The most recent IBC (ICC 2021) went even further, introducing three new construction types that allow mass timber buildings of even taller heights, more stories above grade (up to 18 stories), and greater allowable areas.

Sustainability has been a major driver for the use of mass timber. Compared to alternative materials such as steel or concrete, the benefits of mass timber construction are significant, both in embodied carbon reduction because it requires much less energy to produce and in the long-term storing of carbon in the wood (carbon sequestration). That being said, mass timber products are only as sustainable as the process used to harvest, transport, and manufacture them, which explains why embodied carbon data can vary between different mass timber manufacturers. Nevertheless, mass timber construction also offers other benefits such as aesthetics and efficiency gained through off-site fabrication, which can accelerate construction (resulting in schedule savings) and reduce on-site labor.

The mass timber movement in North America has been fueled by more manufacturers entering the market, architects, engineers, and builders acquiring expertise in the design and construction of mass timber, and the advancement of digital processes, workflows, tools, and equipment. This has given rise to mass timber being now considered one of the most suitable building materials or systems for IC and off-site prefabrication. Mass timber systems are also included in the Modern Methods of Construction (MMC) framework (MHCLG 2019).

Because mass timber is a relatively new system, oftentimes owners and designers will compare it to alternative structural systems to decide on the most appropriate one. Therefore, we suggest using a sound decision-making system like Choosing by Advantages (CBA). CBA is a system that considers value expressed by means of advantages of alternatives relative to one another, and makes comparisons based on those advantages, without considering money (cost or price) until after attributes of alternatives have been evaluated based on factors and criteria (Suhr 1999). Examples of CBA applications in the AEC industry were presented by Parrish and Tommelein (2009) and Arroyo et al. (2012, 2013). Factors that can be used with the CBA system to compare mass timber construction to other types of construction include but are not limited to (1) building type, (2) building height, (3) building and floor areas, (4) fire resistance, (5) structural strength, (6) sustainability, (7) aesthetics, (8) material availability and lead time, (9) site logistics, (10) on-site work and schedule, (11) off-site work and schedule, (12) material sizes, (13) tolerance management, (14) industry knowledge, (15) insurance availability (e.g., builder's risk and property), (16) integration with other building systems, (17) transportation and logistics, (18) use of technology during design and fabrication, and (19) material durability.

Next, we provide a categorization of some of the most used mass timber products in North America with their usual applications and dimensions. Knowing what products are offered and what they can be used for is fundamental when studying SCM and designing production systems because different products may require different processes and resources.

GLUED-LAMINATED TIMBER (Glulam)

Glulam is a wood element composed of lumber boards that are joined end-to-end and bonded by means of structural adhesive. The grain of the laminations runs parallel with the length of a glulam. Glulam elements are commonly used as beams and columns. They can be straight or curved and are stress-rated. They are available in four appearance classifications: (1) framing, (2) industrial, (3) architectural or commercial, and (4) premium. Glulam elements fabricated in North America are typically between 7.5 cm (3 in.) to more than 50 cm (20 in.) wide, 10 cm (4 in.) to more than 150 cm (60 in.) deep, and up to 18 m (60 ft.) long.

CROSS-LAMINATED TIMBER (CLT)

CLT is a large-scale solid, straight, and rectangular wood panel that consists of an odd number (usually three, five, seven, or nine) of layered lumber boards stacked in alternating directions, bonded by means of structural adhesive, and pressed. CLT panels can be used as load-bearing elements and applications include floors, walls, and roofs. Panels fabricated in North America are typically up to 3.6 m (12 ft.) wide, up to 18 m (60 ft.) long, and up to 32 cm (12.5 in.) thick.

MASS PLYWOOD PANEL (MPP) AND MASS PLYWOOD LAM (MPL)

MPP and MPL consist of multiple layers of 2.5 cm (1 in.) thick lamellas joined together, with each lamella constructed of multiple layers of thin veneer that are glued and pressed together (Freres Engineered Wood 2023). Lamellas are stacked in alternating directions in an MPP (like CLT) while they are stacked end to end in an MPL (like glulam). MPP is certified as a CLT panel and can be used in identical applications. MPL elements can be used as beams and columns, like glulam elements. MPP fabricated in North America are typically up to 3.6 m (12 ft.) wide, up to 14.6 m (48 ft.) long, and up to 30.5 cm (12 in.) thick. MPL are typically up to 61 cm (24 in.) wide, up to 121 cm (47.5 in.) deep, and up to 14.6 m (48 ft.) long.

MASS TIMBER SUPPLY CHAIN IN NORTH AMERICA

CLT panels combined with glulam beams and columns were used in 2012 as a structural system for the first time in North America (Structurlam 2019). The high-volume manufacturing of mass timber products requires the use of specialized equipment to, for example, apply adhesive between lumber boards and press the lumber boards together. For this reason, even though the US and Canada have a long-established lumber industry, the mass timber supply chain is still young and relatively small but is rapidly growing.

The Pacific Northwest region of the US and the Canadian province of British Columbia are home to forests that provide softwood of good quality (e.g., spruce, pine, fir, and Douglas fir) to manufacture mass timber products. Not surprisingly, this region houses not only the largest number of mass timber suppliers but also the largest number of mass timber projects in North America. Some of these suppliers focus on the manufacturing of Fabricated-to-Order (FTO) mass timber products. FTO products are those "put together from parts that are already designed, but as-of-yet have to be made, so as to meet the specifics of a customer request" (P2SL 2023). In the case of FTO products, a customer provides a list of mass timber products with their exact quantities and sizes, and the supplier (manufacturer) manufactures them to size, without having to redesign or engineer these parts. Other suppliers focus on the fabrication of ETO mass timber products. ETO products are those for which design and engineering are done in response to a specific order from a customer, and the product is then made according to those design specifications (P2SL 2023). In the case of ETO products, a customer provides, e.g., structural- or architectural drawings and the supplier (fabricator) needs to create fabrication shop drawings so that all openings and connections can be included according to those drawings.

Some mass timber products have been manufactured and used for decades in North America. For example, the first glulam structures were erected in the US in the 1930s, although the first American manufacturing standard was published only in 1963 (APA 2023). Significant advances have been achieved during this time, particularly with respect to the adhesives used to join lumber boards during the manufacturing of glulam.

Other products, such as CLT, MPP, and MPL have come onto the market much more recently. The first manufacturer of CLT based in the US was SmartLam in 2012 (SmartLam 2012); this was followed by other manufacturers that opened factories and began producing CLT panels a few years later. Among this group, arguably the most notable one was Katerra, the now infamous vertically integrated off-site construction company founded in 2015 and shut down in 2021 after filing for bankruptcy. Katerra opened a state-of-the-art CLT and glulam factory in 2019 in Spokane Valley, WA, with the largest capacity at the time and still today to produce CLT in North America (Wohlfeil 2021). This factory has since been purchased by another company and is now back in operation (Dalheim 2021).

MPP and MPL are newcomers to the family of mass timber products. They were developed and launched in 2018 and 2020, respectively, by Freres Lumber and are alternatives to CLT and glulam, respectively. Instead of using lumber boards as with CLT and glulam, MPP and MPL are produced by combining thin layers of veneer, which allows more wood to be used out of a log compared to sawn lumber. However, the manufacturing process for MPP and MPL is more energy intensive than that of CLT and glulam (Atkins 2018). At this time, MPP and MPL commercialized in the North American market—not considering the subtractive manufacturing process that turns them into custom (ETO) building components—are offered at a slightly lower price than CLT and glulam.

INDUSTRIALIZED CONSTRUCTION (IC) AND MASS TIMBER

The industrialization of manufacturing—the evolution from creating goods by hand to using machines to produce them faster, cheaper, with better quality, and in larger quantities—took place in the 1760s with the Industrial Revolution. Manufacturing has continued to evolve ever since. Ford introduced the moving assembly line to mass produce automobiles in 1913 and Toyota developed the TPS decades later, focusing on eliminating waste in its production processes and improving customer satisfaction. The construction industry, however, has lagged behind most other sectors in the adoption of technology and mechanization, which has consequently stalled productivity growth (Barbosa et al. 2017).

Various often-mentioned reasons explain why the construction industry has been traditionally slow at developing and using new technologies, and thus has not progressed at the same pace as other industries. Some of these reasons are (1) the uniqueness of every project, (2) the nature of production moving from one location to another, (3) the divided authority (owner, designer, contractor, etc.) over the process of development and construction, and (4) market volatility (Warszawski and Sangrey 1985). In recent years, however, the construction industry has increased its appetite for innovation, technology, and consequently industrialization. This is a result of owners, developers, contractors, and other players striving to become more competitive, deliver complex projects in less time, and overcome challenges such as the current construction labor shortage (Hovnanian et al. 2022).

In this context, IC has emerged as a means to leverage high-volume manufacturing principles and tools (both software and hardware) for optimizing the delivery of construction projects. Building systems and their components are designed using, for example, Design for Manufacturing and Assembly (DfMA) principles and employing digital tools, such as 3D modeling software. The fabrication of building components takes place at a location other than a project site ("off-site"), in a controlled environment (i.e., a manufacturing or factory setting). It can use Lean production principles (e.g., from the TPS) and employ mechanization or automation. The systems and components are then delivered to a jobsite, where they are assembled—i.e., connected to other parts that were either built on-site or also fabricated off-site—to create a built asset (building), which is the final product of the construction process.

Arguably the best-known IC framework at this time is the MMC definition framework, created in 2019 by the UK Government's Ministry of Housing, Communities & Local Government (MHCLG 2019). This framework presents seven MMC categories in total, of which five are off-site. Mass timber as a structural building system is part of category 3 (pre-manufacturing of non-systemized structural components), standing out as one of the most promising MMC today because of its (1) environmental benefits over alternative materials such as concrete and steel, (2) suitability for off-site automated prefabrication, and (3) easy and rapid on-site assembly.

IC and mass timber present a shift from traditional project delivery and are reshaping existing supply chains and creating new ones within the construction industry. Since large elements are fabricated off-site months or weeks before they are installed on a jobsite, intensive design efforts are required upfront. These efforts are to coordinate, integrate, and optimize structural, MEPF, and other building systems to guarantee that all key design decisions are locked in early on, before the fabrication of mass timber components begins. This ensures off-site fabrication and on-site assembly can proceed seamlessly, reducing or eliminating downstream rework.

CASE STUDY: DELIVERING A MASS TIMBER SYSTEM FOR A MULTI-STORY RESIDENTIAL BUILDING

The exploratory case study presented in this section describes the delivery process from design to installation of an ETO mass timber structural system for a multi-story affordable housing project in the US. The data for this study was collected through various unstructured and semi-structured interviews and from project documents such as construction and shop drawings and project schedules. This paper presents the initial findings of this ongoing research.

Project X herein studied is currently being delivered under a design-build contract, in which the owner signs a single contract with a general contractor who is also responsible for the design of the project. The general contractor on this project worked together with a design firm and an engineering firm to develop the architectural and structural design of the project. They also hired multiple specialty contractors to deliver the project, including Company A which was responsible for the entire mass timber scope. Company A is a vertically integrated mass timber contractor based in the US, providing design, engineering, off-site fabrication, and on-site installation services. Company A has an in-house design and engineering team and owns a fabrication facility with Computer Numerical Control (CNC) machines that are used to process FTO mass timber products (manufactured by third-party suppliers) into custom ETO mass timber components such as beams, columns, floor panels, and stairs.

For Project X, Company A's design team started to work with the architect from the beginning of the design phase. Their early involvement was crucial in the decision-making of several design, procurement, fabrication, transportation, and installation aspects of Project X's mass timber system. Designing a mass timber building requires early coordination between designers, builders, fabricators, and suppliers because mass timber components are not only long-lead items but are also fabricated off-site weeks or months before they are installed on-site. A benefit of mass timber construction is the speed at which the structure can be erected, which can shorten the project schedule, but for that to be realized it is critical that little to no rework on the mass timber components is needed after they are delivered to a jobsite.

Project X uses a post and beam structural system consisting of glulam columns and beams creating structural grids and CLT panels spanning horizontally across these grids. Most of the glulam and CLT elements in the building are exposed. Exposed MPP stairs complement the mass timber system. Steel-braced frames are used as the system to resist lateral forces, while the mass timber structure sits on top of a concrete foundation. Company A provided design and on-site installation services for the following ETO components of the mass timber system: (1) CLT floor panels, (2) glulam columns, (3) glulam beams, and (4) MPP stairs. Additionally, Company A procured FTO glulam and MPP, custom-fabricated (2), (3), and (4) at their own fabrication facility, and then delivered these elements to the jobsite, located around 170 miles from the fabrication facility. (1) were both manufactured and custom-fabricated by a third-party supplier, stored by Company A at their facility, and later delivered to the jobsite. Figure 1 depicts the major steps of delivering Project X's mass timber system, with emphasis on the design, engineering, and procurement phase.

Figure 1: Delivery Process of Project X's Mass Timber System

The design process is iterative and non-linear. Over the years, Company A has developed relationships with several architects who design mass timber structures. For Project X, Company A got involved with both the project owner and the project architect early on. Collaboratively they were able to evaluate and make design trade-offs to develop an optimal mass timber system that achieved the project goals and kept it within budget. Initial considerations included design and constructability constraints, occupancy and construction type, and project goals. After these initial considerations were understood, a conceptual design was developed, defining key project characteristics such as the number of floors, building height, building and floor areas, fire resistance ratings, and allowable exposure of mass timber. Next, Company A began to seek out potential mass timber suppliers located in North America. All suppliers for Project X were located within a 400-mile radius of the project site.

For Project X—as is the case with any multi-story mass timber building—one of the most important design decisions concerned the size of the CLT floor panels, in particular their widths.

Overall, manufacturers offer panels with the same typical thicknesses (3-, 5-, 7-, or 9-ply), but varied widths and lengths. Different manufacturers also produce CLT from different wood species, which affects the appearance of the panels (this aspect is particularly relevant when the panels are left exposed on at least one side in buildings), and have different lead times, which can severely limit the number of companies that can supply CLT panels to a project. Choosing a CLT panel supplier early in the design phase is critical because it determines what panel sizes can be used, which in turn defines the building's structural grid layout. Determining the size of CLT panels is particularly crucial because it involves three trade-offs: (1) the transportation of panels from the factory to the jobsite, (2) the number and type of surface spline joints (that are used to connect CLT panels together), and (3) the number of crane picks on the jobsite (less is better). The maximum legal load width in the US is 2.6 m (8.5 ft.), although some manufacturers can provide panels up to 3.6 m (12 ft.) wide, which could potentially reduce (2) and (3). Although most of the CLT panels used on Project X are 2.6 m (8.5 ft.) wide or narrower, some are wider than 2.6 m. The transport of oversize loads usually requires permits and can be done only during certain hours of the day (depending on local rules), which increases the cost of transportation. Determining the size of glulam columns and beams, although also important, is not so much of a constraint as it is with CLT panels. It mostly revolves around finding the most economical solution, i.e., the minimum depths and widths (lengths are determined based on CLT panel sizes) that satisfy all structural requirements, and working with suppliers that can provide those glulam elements.

One design goal of Project X, an affordable housing project that was to benefit from both a reduced project cost and accelerated installation of the mass timber system on-site, was to eliminate or reduce the number of steel connections (e.g., to connect beams to columns). Company A worked with the design team to develop a wood-to-wood mortise and tenon connection to that end. Another design goal was to have as much exposed mass timber as possible inside the residential units. To achieve that, most of the overhead MEPF systems are routed above the hallway ceilings and then distributed to each unit, so that the units could have, for the most part, fully exposed CLT ceilings.

Although Company A has an in-house engineering team that designed and engineered the entire Project X's mass timber system, Project X still had an outside structural engineer of record responsible for the engineering of the project. This engineer of record was also tasked with designing some of the structural non-mass timber components of Project X, including the concrete foundation. After the mass timber system and other related systems (e.g., lateral-load resisting, MEPF, framing) were designed and integrated, the engineer of record reviewed and signed the structural drawings. These drawings were then used to create fabrication shop drawings, where each mass timber component is individually modeled in Building Information Modeling (BIM) software. Then, files were generated to feed the CNC machines. These files describe paths for CNC machines, instructing them on how to perform the tasks required to fabricate the custom mass timber components.

Finally, after fabrication, the mass timber components were stored at Company A's fabrication facility and later delivered to the Project X jobsite when it was ready for installation. Due to space constraints on the Project X jobsite, the deliveries were JIT with all pieces being erected and put in place the same day they were delivered. Installation of all the pieces took around 8 weeks.

DISCUSSION

As new materials and products are developed and come to the market, new supply chains are formed, or existing ones are reshaped. In the case of mass timber, the supply chains to deliver these products are still emerging and worthy of research due to the growing demand for this product. Consequently, new theory and knowledge ought to be developed so that these supply chains can evolve and mature, and people can think about how to design production systems for the efficient and effective delivery of mass timber buildings.

Delivering such buildings poses new challenges when compared to delivering, for example, concrete or steel buildings. Wood requires more careful handling, storing, and transporting—for example, if a piece of mass timber is not properly stored and its moisture content is higher than ideal, it may not meet the specified tolerance requirements. Upfront design coordination is a must to ensure that all components and systems fabricated off-site not only fit together when they are brought to the jobsite but also fit with what is built on-site. Company A identified an opportunity to integrate multiple phases (design, fabrication, and installation) of the delivery process of mass timber systems and, as a result, provide their clients—owners, architects, and general contractors—with a "one-stop shop." A challenge for Company A comes from having to keep capacity across all their teams (design, fabrication, and installation) balanced (i.e., to keep all teams busy), although this has not yet been a significant issue. Demand for mass timber projects is high and increasing in the US construction market. Not many companies operate in this market space or offer the same level of vertically integrated services as Company A does, but this may change in the future as competitors seek to enter this growing market. Another challenge is that because the number of CLT suppliers in North America is still small and the current demand for the product is high, Company A does not have much bargaining power over its upstream suppliers.

From the exploratory case study presented in this paper, we present several general recommendations for teams designing or delivering mass timber systems: (1) communicate with the project owner to understand the project timeline so that it can be aligned with mass timber lead times, as they can vary from 4-6 weeks (if sourced nationally) to 3-6 months (if sourced internationally), (2) integrate design, fabrication, and installation by having the design team coordinating with the fabrication and installation teams so that all fabrication and installation constraints can be understood early enough to reduce design iterations and facilitate fabrication and installation, (3) before locking in the grid layout and consequently the panel layout of a building, find out what products and sizes mass timber manufacturers offer and then design accordingly to optimize the use of CLT panels since it accounts for most of the volume (70 to 85%) of mass timber in a multi-story building, (4) standardize by reducing the number of unique mass timber connections to speed up and reduce complexity in design (less detailing), fabrication, and installation, (5) evaluate ways to reduce the number of MEPF penetrations through floors and beams by, for example, strategically using corridors (with soffits) and shafts to distribute MEPF systems, and (6) verify and reconcile the tolerance of mass timber components with other off-site and on-site building components during design of the mass timber system.

CONCLUSION

The aim of this paper was twofold: (1) to describe the characteristics of the mass timber supply chain and (2) to describe the process of designing and delivering a mass timber structural system for a multi-story building. To achieve (1), we presented mass timber construction as an MMC, a number of mass timber products and their respective applications, and how the mass timber supply chain has developed in North America. To achieve (2), we presented an exploratory case study, described the major steps in designing and delivering a mass timber structural system for a multi-story residential building, and presented a list of recommendations for designing and delivering mass timber systems.

Some future research ideas stem from the limitations of this exploratory case study. This paper provides only a general view of the delivery process of a mass timber system. Additional research is needed to develop more detailed process maps (e.g., value stream maps), focusing, for example, on other phases (e.g., fabrication) of the mass timber delivery process to identify additional opportunities for improvement. Furthermore, research is needed to study other types of mass timber projects (e.g., commercial- or educational projects) and compare their characteristics with the (residential) case study presented in this paper. In addition, future research could also investigate opportunities to use other IC building systems that in conjunction with mass timber can accelerate the delivery of construction projects.

LEAN AND IOT INTEGRATION TO IMPROVE FLOW IN CONSTRUCTION PREFABRICATION: A PROPOSED FRAMEWORK

Wassim AlBalkhy[1], Sara Rankohi[2], Zoubeir Lafhaj[3], Ivanka Iordanova[4], Jorge Mauricio Ramirez Velasquez[5], Mario Bourgault[6], and Robert Pellerin[7]

ABSTRACT

Creating a stable and smooth flow is an essential principle of lean thinking. Failure to create a stable flow in the production system degrades performance and impacts value creation. In construction prefabricated systems, variability in flow between the construction site and manufacturing plant can cause an increase in time and cost of the projects. This paper aims to deal with the problem of lack of synchronization between the onsite and offsite fabrication. To achieve this aim, a framework that is based on the integration between lean and the Internet of Things (IoT) is proposed. The proposed framework integrates the planning and control work from the Last Planner System® (LPS) with IoT to improve the planning, tracking, and delivery of prefabricated components. The study sheds the light on some of the expected challenges that may face the use of the proposed framework and covers the preliminary observations after putting it in use to improve flow in the delivery of prefabricated steel components.

KEYWORDS

Lean construction, Last Planner System® (LPS), Internet of things (IoT), lean construction 4.0, construction prefabrication, flow.

INTRODUCTION

Construction prefabrication is the term that describes the practice of producing a certain quantity of building components partially or fully in a factory to further assembly on the construction site (Qi et al., 2021). As one of the most important examples of industrialization of construction (Cheng et al., 2023), construction prefabrication has attracted attention and is considered an effective way to improve performance in the Architecture, Engineering, and

Construction (AEC) industry. This is due to the various improvements it could improve when it is compared with conventional on-site construction practices (Cheng et al., 2023; Xu et al., 2018). Examples of possible improvements include time and cost savings, reduction in greenhouse gas emissions (GHGs), safety improvement, reduction in materials consumption, and productivity gain (Arashpour et al., 2015; Mossman & Sarhan, 2021; Qi et al., 2021; Xu et al., 2018). Prefabrication is also an effective way to reduce more than half of the physical waste (Jaillon et al., 2009). While comparing fully on-site construction with prefabrication, Horman et al (2006) presented a list of economic, social, and environmental benefits of prefabrication. Some of these benefits were the establishment of long-term supply chain planning, less maintenance work and reworks due to the improved quality, fewer defects, variety in materials choices, improved de-constructability, and improved working conditions.

Nevertheless, prefabrication in projects faces various challenges that may hinder the smooth flow of processes. According to Mossman and Sarhan (2021), synchronizing flow between offsite prefabrication and onsite construction is essential to ensure success when depending on prefabricated components. This synchronization has to cover all flow phases starting from the arrival of the raw materials at the factory and ending with the onsite assembly. Failure to achieve such synchronization can prohibit the delivery of materials or components and cause an increase in time and cost of the project (Kanai et al., 2021). The heavy dependence on the critical path method (CPM), delivery of materials based on pushing strategies, and lack of focus on optimizing the overall production system in the factory and site are among the most affecting factors that limit the flow synchronization (Mossman & Sarhan, 2021). The use of lean principles and tools such as the Last Planner System® (LPS), Jus-In-Time (JIT), and Kanban or pull signals can help mitigate the impact of these problems by focusing on the end-to-end process flow, collaboratively working and planning based-on what can be done rather than what should be done, and produce and deliver only what is needed and when it is needed (Kanai et al., 2021; Mossman & Sarhan, 2021).

The Internet of things (IoT) has shown effectiveness in managing the flow of information and materials in many sectors but has still not been adopted on a large scale in the construction industry. IoT can help in reducing the time between data capture and decision-making, which allows for coping with real-time changes in the production system (Ben-Daya et al., 2019). It also helps improve coordination and facilitates monitoring based on accurate information. Furthermore, it helps to identify the locations and track employees, trucks, and materials, which result in higher productivity and safer site (Gamil et al., 2020; Kumar & Shoghli, 2018; Matteo Giovanardi et al., 2021). Its interaction with lean comes from its ability to improve the visualization of processes and share it with different stakeholders to improve flow, collaboration, problem-solving, error-proofing, and achieving continuous improvement (Dave et al., 2016; Tezel et al., 2022). Therefore, there have been, recently, various efforts to support lean-IoT integration. These efforts have resulted in some lean-IoT applications and software such as Visilean®, KanBIM™, and others (Dave et al., 2016; Kanai et al., 2021; Sacks et al., 2011). Nevertheless, the focus on synchronizing flow between offsite and onsite operations and integrating LPS planning results in this synchronization is still not widely implemented. The current study proposes a lean-IoT framework to integrate LPS planning levels in the synchronization between the construction site and the prefabrication factory.

LITERATURE REVIEW

PROCESS DEFINITION AND TECHNOLOGY USE IN PREFABRICATED CONSTRUCTION

The literature has several definitions for the prefabrication process. For instance, Cheng et al (2023) considered that the process can be depicted in three main stages such as design, manufacturing, and onsite assembly. According to Liu et al (2020), the process comprises ordering, manufacturing, transportation, and assembly. In turn, Qi et al (2021) stated that the prefabrication process includes design and planning, production and manufacturing, delivery and store, and the assembly stages. In their study, Qi et al (2021) affirmed that challenges along all these phases can appear. The traditional approaches, which consider mainly architectural and performance requirements in the design stage can lead to a decrease the efficiency; therefore, manufacturing, delivery, and assembly aspects have to be considered. In the production stage, the lack of real-time information to monitor quality, location, and performance aspects can hinder optimal productivity. In the delivery process, errors in logistic management can affect the performance of the whole project.

Cheng et al (2023) classified technologies in offsite construction (OSC) based on data perspective technologies into data acquisition, data integration, data analysis, and decision-making technologies. For the acquisition, their study listed paper-based monitor and sensor techniques. They highlighted the use of long-range radio communication techniques (LoRA), radio frequency identification (RFID), the global positioning system (GPS), laser scanning, and photogrammetry techniques. The integration technologies connect data with web platforms. In the making decision field, most of the decisions are taken by human actors and some are taken by artificial artifacts. Liu et al (2020) found in their review, advances in the management and implementation levels for OSC. In the management process, strategic research, overall design, and supply chain integration and management are key. At the technological level, supply chain process design and optimization and application of advanced technology.

TECHNOLOGICAL GAPS AND CHALLENGES IN PREFABRICATED CONSTRUCTION

According to Xu et al (2018), despite the numerous expected benefits when presenting technological solutions to construction prefabrication companies, these companies face various challenges. Among these challenges, is the reliance on traditional methods and the resistance to adopting new technologies, which results in inaccurate and inefficient practices. The second problem is the low level of coordination and collaboration, which prohibits the dissemination and sharing of information with the prefabricated companies; as a result, causes late and misplaced delivery. The third problem is related to the nature of the prefabricated companies as most of these companies are small and medium-sized companies (SMEs). It is widely conceived that this type of company faces several challenges when trying to adopt technology such as the lack of financial capabilities, lack of managerial flexibility, resistance to change, lack of skilled employees, and lack of knowledge (Agostini & Nosella, 2020; Albalkhy et al., 2021; Albalkhy & Sweis, 2021; Elhusseiny & Crispim, 2022; Kolla et al., 2019). The fourth problem is that most of the provided technology-based practices do not fully address the nature of the prefabricated construction and the link between the onsite and offsite production in construction. As a result, these solutions cannot be directly applied in prefabricated companies (Xu et al., 2018). Additionally, in their review, Qi et al (2021) classified the technologies that are currently applied in prefabricated construction into business digitalization, computer-integrated design, data acquisition, optimization, predictive analytics, and robotics and automation. According to their analysis, most technological applications to improve prefabrication processes have been done in a research context.

Based on the above-mentioned challenges, more practical and scalable technologically supported solutions should be proposed and put into use. However, these technologies should fit with the nature of work in the prefabricated construction sector. They also should ensure high levels of collaboration between different stakeholders in the project and synchronization of practices and flow on the site and at the factory. This means that the proposed frameworks should be based on linking the three pillars of production systems, which are technology, process, and people. Linking these pillars is essential in lean thinking (Sacks et al., 2010).

THE PROPOSED FRAMEWORK

The current study is based on linking planning and control deliverables of the construction processes with the manufacturing processes in the prefabricated companies to ensure the synchronization of flow processes between the two production systems. To do so, the proposed framework tries to cover deliverables from the planning and control tool (LPS), application of JIT and pull signals, and development of IoT architecture to continuously track, monitor, and localize prefabricated components. The proposed framework was based on studying different cases in offsite and onsite construction (Chen et al., 2020; Dave et al., 2016; Kanai et al., 2021; Li et al., 2018; Von Heyl & Teizer, 2017; Xu et al., 2018) and based on studying a process map in a prefabrication company in Canada.

LAST PLANNER SYSTEM® (LPS)

LPS is one of the most important tools that support the adoption of lean theory in the construction sector (Albalkhy & Sweis, 2022). LPS can be understood as a short-term planning tool that is based on integrating collaborative planning with all possible stakeholders especially the last planner (people who do the work) (Ballard, 2000; Mossman & Sarhan, 2021). As shown in Figure 1, LPS has generally different levels of planning and control and incorporates the pull concept and plan based on what "CAN" be done instead of the push mechanism that is based only on what "SHOULD" be done. This planning structure identifies constraints to be removed, develops performance measures such as Planned-Percent-Completed (PPC), and integrates the learning process based on the principles of continuous improvement and non-compliance to plan analysis (Porwal et al., 2010). The main planning and control levels in LPS are (LCI Congress, 2016):

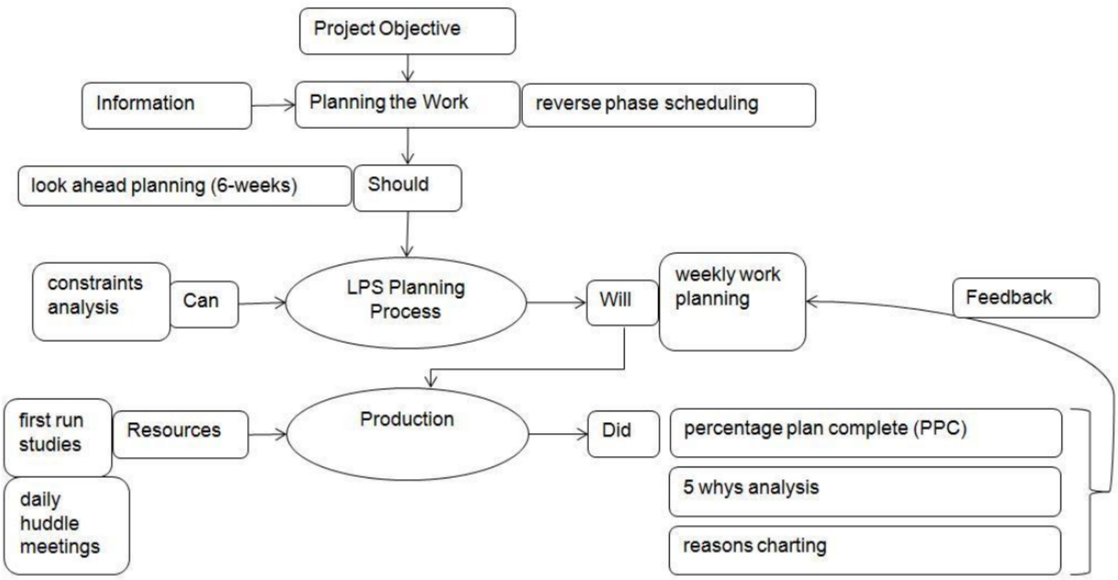

Figure 1: LPS planning process (Porwal et al., 2010).

1- Master planning or milestone planning: which defines the overall road and the main milestones of the projects (identifying what should be done).
2- Phase planning or pull planning: collaborative planning of phases to achieve the milestones (identifying what should be done).
3- Lookahead planning: uses phase planning to make work ready. In this phase, the focus is on identifying constraints-free tasks (identifying what can be done).
4- Weekly work plan (WWP): a detailed weekly plan that includes commitments and promises to deliver the tasks (identifying what will be done).

5- Daily huddle meetings and learning: to identify what will be completed and what was completed, what needs to be re-planned, and how to prevent deviations from the plan (identifying what will be done and what was done).

According to Mossman and Sarhan (2021), the short-term collaborative planning approach in LPS facilitates the synchronization of flow between onsite and offsite fabrication and creates the conditions for JIT delivery, which aims to reduce the volume in inventory and ensure the delivery of materials to the right place at the right time. With a technological application such as Building Information Modeling (BIM) and IoT, LPS planning can integrate real-time information that can create reliable flow, improve visibility, and reduce variability (Dave et al., 2016; Mossman & Sarhan, 2021; Sacks et al., 2010).

IOT-BASED ARCHITECTURE FOR THE PROPOSED FRAMEWORK

According to the International Organization for Standardization (ISO) and the International Electrotechnical Commission (IEC) (ISO/IEC, 2014), IoT is "an infrastructure of interconnected entities, people, systems and information resources together with services which process and react to information from the physical world and from the virtual world".

Figure 2 shows the various layers of the IoT architecture in the proposed framework inspired from (Karmaoui et al., 2022; Rankohi et al., 2023). The developed architecture is based on using barcode tags, RFID antennas, and readers for collecting data. The data transmission is done by WiFi to databases that are accessible to the plant operators and project managers to conduct analysis and make decisions. As shown, the proposed architecture consists of three main layers: perception, network, and application layers.

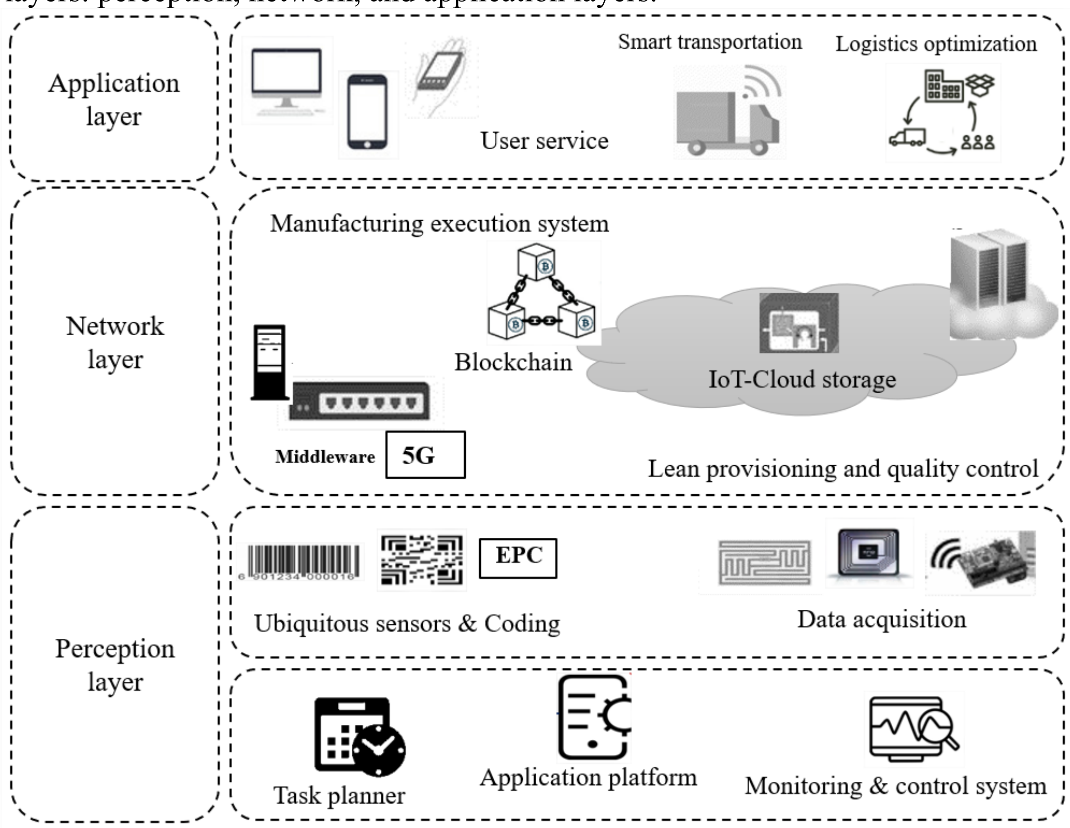

Figure 2: IoT-based architecture for the proposed framework.

The perception layer represents platforms for planning the tasks, using the application, and monitoring and controlling systems. It also represents units that are responsible for coding, information extracting, data processing, controlling, and monitoring. In the coding phase, an ID number is assigned to each prefabricated component. The component can be recognized in the whole cycle of the IoT. Then, the obtained information will be transmitted from the collection phase in the perception layer to the lean analyzing phase in the network layer. The network layer is a network platform based on IPV6. It consists of an intelligent network, which connects all the resources in the network. In this layer, data is collected and objects are identified via RFID tags. Then the information is integrated into the cloud, to manage and control the collected data in real-time. In this layer, the data is reorganized, filtered, shared, and transformed into the content service in the Service-oriented architecture (SOA).

Finally, the application layer integrates the service capabilities and provides the application service to the clients. Users can use different applications to access their required information, such as smart transportation, smart material tracking, and logistics optimization. For instance, barcodes are installed on prefabricated components. The users can use a smart material tracking application to scan these barcodes with their smartphones, which directs them to any used storage (e.g. company's database or website). This application can be equipped with mobile tag reader technologies, which are used by the clients to make sure they have collected all received steel bars in returning racks. In addition, clients can use this application to send automated alerts to project managers to inform them that prefabricated components or pallets are ready for pick-up.

PROCESS

Figure 3 shows the process in the proposed framework. The proposed framework covers the different phases of the prefabrication process and the onsite and offsite fabrication. It also integrates different LPS levels with the IoT tracking system for the delivery and installation of prefabricated components. The framework is integrating the pull concept, buffering, and JIT during the production and manufacturing and delivery, and storage phases. It is also linked with nD BIM models to improve the tracking of the process flow.

More specifically, the process starts with the development of the master planning, which is the first level of LPS planning. At this level, the main milestones of the project are identified and the development of the BIM models starts. The next phase is the phase or pull planning, in which the supplier of the prefabricated elements should participate and define the estimated lead times to deliver the orders. Using the results from the pull planning, the requirements and orders can be estimated and the look-ahead plans can be developed.

Estimates of the orders and requirements are useful to identify the production schedule and initiate the production process of the elements to be stored in warehouses. Simultaneously, the work on site focuses on the identification and removal of all possible constraints that may hinder the installation of the prefabricated elements onsite using logs from the look-ahead plans. Following the identification and removal of constraints, onsite demands and transportation plans are created to deliver the elements on time to the site. Based on the transportation plan, elements can be pulled from warehouses to be tagged and identified in the IoT system. The trucks can be tagged and linked to the IoT system as well.

The IoT system is responsible for delivering real-time updates about the delivery process including tracking, localizing, and counting the delivered elements and reporting any problem that may happen. Once the elements arrive at the site, they can be directly integrated with the weekly work plans, then installed, and then integrated into the daily huddle meetings and learning sessions.

Despite the potentials of the proposed framework, it is worth mentioning that there are different points to consider when integrating lean construction and IoT. Examples of these points include the security of data, availability of skills and knowledge when implementing the proposed framework, availability of policies and guidelines for implementation, connectivity, in addition to acceptability and readiness to make a change in the traditional practices (Albalkhy & Sweis, 2021; Khurshid et al., 2023).

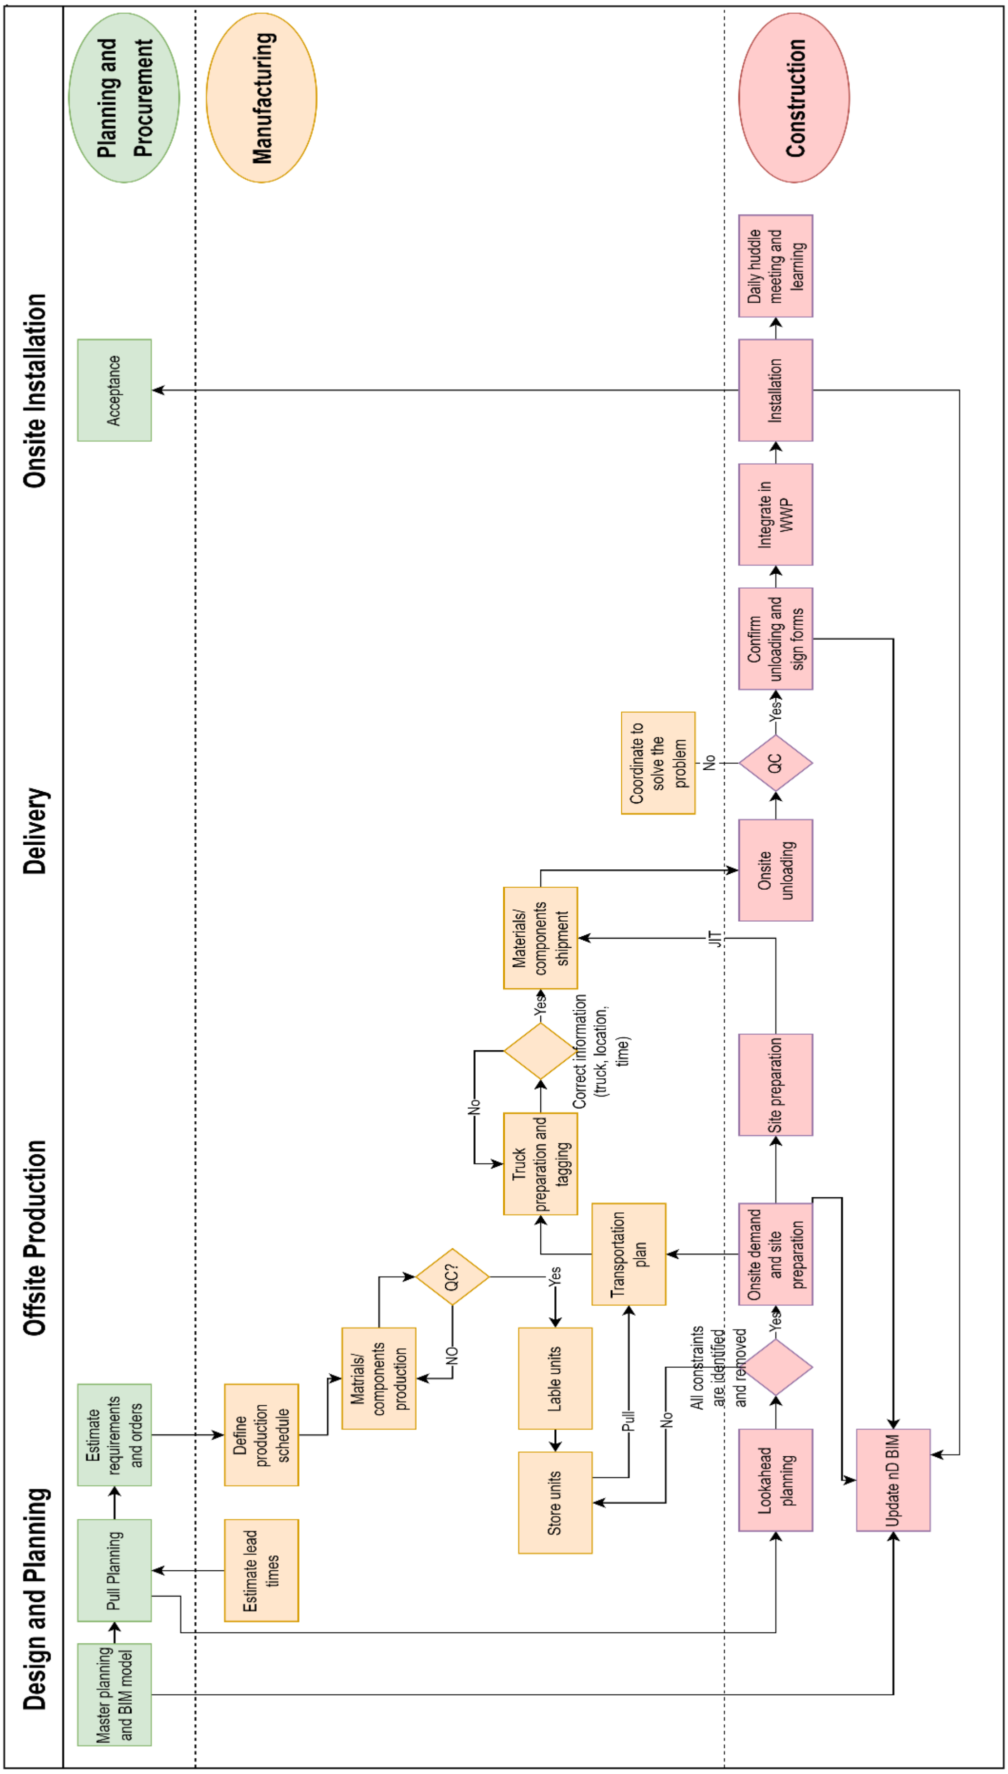

Figure 3: The proposed framework.

CONCLUSIONS AND FUTURE DIRECTIONS

The proposed framework was presented to improve the flow of prefabricated components and avoid the problems of lack of synchronization between the onsite and offsite fabrication. Integrating the plans from LPS and IoT in the proposed framework can help to improve the efficiency of prefabricated delivery. This is due to improving the traceability, localization, and identification of these components, enhancing the communication between the plant and the site, and avoiding errors resulting from the low levels of coordination. The proposed framework can be effective in linking the supplier schedule and the production plan of the project, which is very helpful to achieve improvement along the whole process rather than achieving fragmented changes that might not result in time reduction, cost saving, or quality improvement. Moreover, the proposed framework aims to reduce flow variability, cope with complexity, increase flexibility, and improve the decision-making process in prefabricated construction.

The proposed framework is to be tested to deliver construction prefabricated steel components in a Canadian company. The preliminary experiments utilizing the proposed IoT-based platform show initial promising results concerning the ability to track the delivery and installation of steel components. Nevertheless, despite starting the implementation of the framework, its results are not yet evaluated and validated. Therefore, further extensive experimental studies on-site and in manufacturing plant environments are required to validate the proposed framework. In addition to conducting more cases, future work can be conducted to identify possibilities of framework improvement using, for instance, digital twin technology to improve on-time tracking and monitoring and artificial intelligence (AI) to predict delivery dates. Further research can also focus on studying different performance indicators for the proposed framework or different barriers to adopting it.

The current study aims to contribute to the existing efforts to link lean construction and construction 4.0 practices (known as lean construction 4.0). It also serves as a good example to integrate both concepts to improve the performance in offsite and modular construction.

MATURITY MODELS IN OFF-SITE CONSTRUCTION AND ANALYSIS OF LEAN INCORPORATION: REVIEW

Jesús Ortega[1], Alejandro Vásquez-Hernández[2], Harrison A. Mesa[3], and Luis Fernando Alarcón[4]

ABSTRACT

The adoption of off-site construction (OSC) is still uncertain although many contributions to its promotion have been made. In many studies, lean construction (LC) has been declared to be the most suitable approach to support managing OSC, but there are challenges regarding its incorporation into OSC. A maturity model (MM) has been proposed to evaluate and guide OSC adoption. However, the literature shows misunderstandings about the MM structure and how these models incorporate LC. This article aims to review maturity models (MMs) developed in the OSC field to identify benefits and deliver deep insight into their structure and the incorporation of LC. The methodology involved three steps: *(i)* systematic literature review (SLR) of OSC-MMs, *(ii)* thematic analysis to identify associations among MM benefits, OSC barriers, and LC challenges, and *(iii)* analysis and interpretation of results. The findings suggest that MMs developed in OSC are incipient, many of them suffer bias and have weaknesses in their structure, and LC incorporation is poor and not explicit in most OSC-MMs.

KEYWORDS

Off-site construction, prefabrication, lean construction, maturity models, barriers.

INTRODUCTION

Off-site construction (OSC) is an innovative type of construction that has been demonstrated to be more effective in overcoming the inefficiencies associated with traditional construction (Suliman & Rankin, 2021). OSC is also known as off-site production, industrialized construction, concrete prefabricated housing, and modern method of construction (Blismas et al., 2010; Dang et al., 2020; Liu et al., 2018; Wang et al., 2020). All these terms refer to innovative engineering systems in which significant portions of operations and construction elements are produced off-site in a factory environment before the final assembly on-site (Suliman & Rankin, 2021). The benefits of OSC adoption are related to improving quality, productivity, and safety, reducing labor intensiveness and construction time, and ensuring better

sustainable performance (Dang et al., 2020; Suliman & Rankin, 2021; Wang et al., 2020). Despite all these advantages, the adoption of OSC still faces significant resistance (Nadim & Goulding, 2011), particularly in developing countries where adoption remains low (Dang et al., 2020). Previous studies have identified several OSC barriers that inhibit its adoption. In the current research, OSC barriers identified in the context of the Chilean architecture, engineering, and construction (AEC) industry are used as the main reference. According to Ortega (2022), low OSC adoption, to some extent, is attributed to the inability to objectively evaluate the benefits offered by OSC due to a lack of knowledge, technical skills, and experience related to this type of construction. In addition, all these challenges are enhanced in an AEC industry that is characterized by conservative behavior, in which innovative systems such as OSC seem to be a risk that many organizations do not need to assume.

In sum, OSC suffers from the ineffectiveness of successful measures to improve its project performance for organizations and a lack of adequate understanding of the system to understand the current level of adoption of the organization and how to improve it (Dang et al., 2020).

LEAN IN OFF-SITE CONSTRUCTION

The OSC approach differs from conventional construction methods (Bendi et al., 2021) in many aspects, such as the complexity of the buildings, manufacturing process, application of technologies, logistics system, planning, coordination, and control. This can be explained by the similarities between OSC and the manufacturing approach (Höök & Stehn, 2008). Therefore, the AEC industry must be prepared to adopt suitable manufacturing practices and be prepared to change old practices to enable this to happen (Mawdesley & Long, 2002). To this end, lean construction (LC) is a philosophy conceptualized at the beginning of the 1990s that came from the Toyota production system and aimed to meet the client's requirements (deliver value to customers). Comparable to OSC, lean construction is also an innovation in the AEC industry (Singh & Kumar, 2020) and is based on adapting manufacturing practices to construction. For this reason, LC has been mentioned in many studies as the most suitable approach to support the adoption of OSC.

The effectiveness of LC principles in OSC projects has been proven. Mawdesley & Long (2002) researched two case studies. All the projects involved the provision of multistory office blocks, and a different procurement system was adopted for each case. In the first case, a traditional procurement method and conventional practices were employed in the construction phase. In the second case, a lean approach, which consists mainly of the early incorporation of all stakeholders before the start of the design phase, was used. The results showed up to 98.3% improvement in factory productivity, a 50% reduction in on-site operations, and a 180% increase in on-site efficiency against the traditional procurement method (case Study I). Other studies have made positive alterations to the OSC production system to make improvements and implement lean tools. For example, Yu et al. (2013) implemented 5s, standardized work, takt time planning, variation management, and value stream mapping in a shelter production line. In only 6 months of implementation, significant improvements were achieved, including a 34% increase in labor productivity, a reduction in overtime of 15% of total man-hours, and a reduction of 15% to 2% in average staff and personnel absenteeism.

Notably, benefits for the AEC industry can be obtained in a short time by using OSC and LC together. However, empirical evidence highlights that it is not enough to just move to a factory environment to institute lean culture because OSC exhibits a project-based culture and the production setup, construction site, and temporary organization are similar to traditional construction (Stehn & Höök, 2008). Therefore, most implementations within LC in OSC are fragmented. Furthermore, there are still challenges that inhibit the adoption of LC, including complexities in understanding it, lack of strategies for implementing LC at the micro level (downstream players), and lack of guidelines for gradually introducing LC to the construction industry (Aslam et al., 2020). Addressing these issues might support a successful start to incorporating LC into OSC and the effective adoption of OSC in the AEC industry.

MATURITY MODELS AND OPPORTUNITIES

Maturity models (MMs) seem to be an ideal methodological tool for addressing the aforementioned concerns. MMs may facilitate OSC adoption and alleviate the challenges of clarifying LC incorporation into OSC. Since the introduction of MMs in the software manufacturing industry (Wang et al., 2020), MMs have been used in different fields (e.g., medical service, science, technology, and the manufacturing sector). MMs are used to assess the maturity of elements in the process to determine the maturity level reached by the system (Cano et al., 2020). In addition, this tool provides benchmarks (the current organization level), highlights paths to reach excellence (maturity gaps), and identifies goals or target levels (Suliman & Rankin, 2021). Consequently, several studies have employed MMs to assess the maturity of new technology implementations or strategies in the AEC industry (Razkenari & Kibert, 2022).

In sum, MMs deliver several benefits for organizations. For example, they enable organizations to know their ecosystem in terms of performance status, current capabilities, and what they need to achieve organizational goals by supporting the development of better management practices. Furthermore, this application makes it possible to reduce the competitiveness gap among construction firms and to deliver a differentiated, sustainable, and innovative value offer (Cano et al., 2020). All these arguments support the idea that configuring an MM based on LC as a suitable approach to achieve the requirements of OSC may mitigate the key barriers that inhibit OSC adoption and the challenges for the incorporation of LC.

This article aims to review the existing MMs in OSC to identify the potential benefits and determine the current structural gaps, the thematic areas they address, and the incorporation of the LC approach. In doing so, the paper has three specific objectives: *(i)* identify the benefits of MMs and their relationship to address the challenges that inhibit OSC adoption and the incorporation of LC into OSC; *(ii)* assess of the MMs that have been developed in the OSC field; and *(iii)* explore the potential research opportunities of OSC-MMs development through the systematic incorporation of LC into OSC.

METHODOLOGY

The primary method used in the current research is a systematic literature review (SLR). The methodological framework involved three principal stages: *(i)* systematic literature review of MMs in OSC, *(ii)* thematic analysis of MM benefits, OSC barriers and challenges to incorporating LC into the OSC field, and *(iii)* analysis and interpretation of the selected OSC-MMs. Figure 1 presents the entire research process.

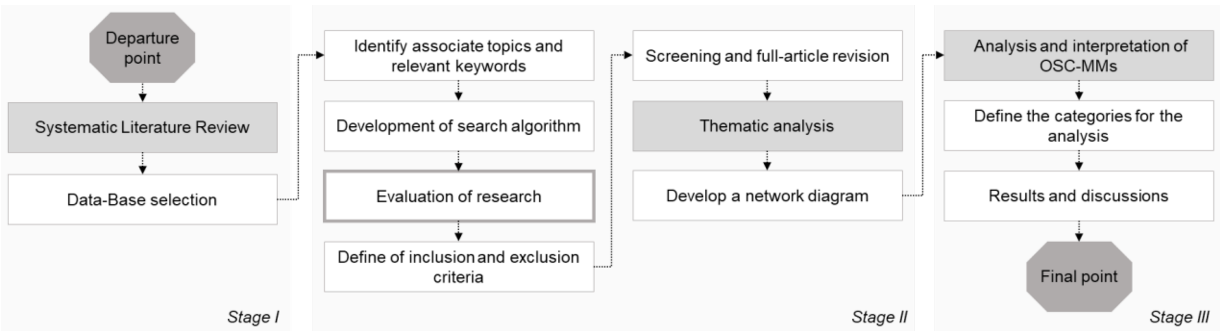

Figure 1: Research frameworks

STAGE I · SYSTEMATIC LITERATURE REVIEW

The SLR methodology is an objective, replicable and transparent tool that is used to examine the existing studies on a subject (Levy & Ellis, 2006). Furthermore, SLR has been used in the AEC industry to *(i)* establish the boundaries of existing research, *(ii)* identify potential future research considerations, and *(iii)* keep up-to-date with developments on a subject (Ibrahim Y. Wuni, Shen, & Osei-Kyei, 2019). Therefore, the authors adopted SLR because it helps organize and compile suitable studies to obtain information of interest and determine the main coinciding characteristics among them. The SLR approach comprised selecting the database, identifying the associated topics and relevant keywords, developing the search algorithm, defining inclusion and exclusion criteria, and evaluating the research.

Database, topics and keywords, and algorithm development

Once the research objective(s) was established, database selection was the next step in the SLR. According to Donthu et al. (2021), settling on one appropriate database is recommended to mitigate the need to consolidate information into a single format and minimize potential human errors. Therefore, the SLR was performed in Scopus, given the recommendations by other studies in the field of OSC construction management (Ibrahim Y. Wuni, Shen, & Mahmud, 2019). Moreover, Scopus has been mentioned as the research engine that covers more journals and recent publications than any other database (Aghaei Chadegani et al., 2013; Ibrahim Yahaya Wuni & Shen, 2020).

Next, a list of keywords was identified in the extant literature. This list comprised synonyms of “Off-site construction” and “maturity model”. Then, to ensure coverage and to develop the search algorithm, the ‘title/abstract/keyword’ functionality of Scopus and the Boolean concatenator ‘OR & AND’ were used. The search algorithm contained the following: (“off site construction” OR “off-site construction” OR “offsite construction” OR “modular construction” OR “modular integrated construction” OR “prefabricated prefinished volumetric construction” OR “modern method of construction” OR “prefabrication” OR “prefabricated building” OR “industrialized building system” OR “industrialized building” OR “industrialized housing” OR “industrialization” OR “industrialised construction” OR “industrialised housing” OR “industrialisation”) AND (“construction”) AND (“maturity Model” OR “maturity” OR “model capability” OR “maturity grid”). The search was restricted to papers published between 2010 and 2022 and articles in the English language because it is the most widely used scientific language (Ibrahim Yahaya Wuni & Shen, 2020). In the end, 49 studies were retrieved.

Evaluation research: Inclusion and exclusion criteria

Inclusion and exclusion criteria were established to ensure that the retrieved research studies met the quality requirements (Ibrahim Yahaya Wuni & Shen, 2020). According to Tranfield et al. (2003), this step is relatively subjective and, to avoid any bias should be performed by more than one reviewer. Thus, two researchers with experience in OSC and MMs participated in this step. The main inclusion criteria involved *(i)* articles that develop a type of maturity model under the topic of OSC and *(ii)* articles that are published in a peer-reviewed journal or rated conference proceeding.

Screening and full-article revision

Based on the algorithm developed and inclusion/exclusion criteria, the authors screened the titles and abstracts of the 49 articles, which resulted in the inclusion of 10 articles. A duplicate check of the 10 items was performed, and no duplicates were found. Then, a full-text evaluation was employed, and a final list of 8 articles was included for further analysis and interpretation. The search was repeated before submission to ensure that important recently published articles were included in the study. No articles were added to the final sample. Figure 2 depicts the screening process through a flowchart.

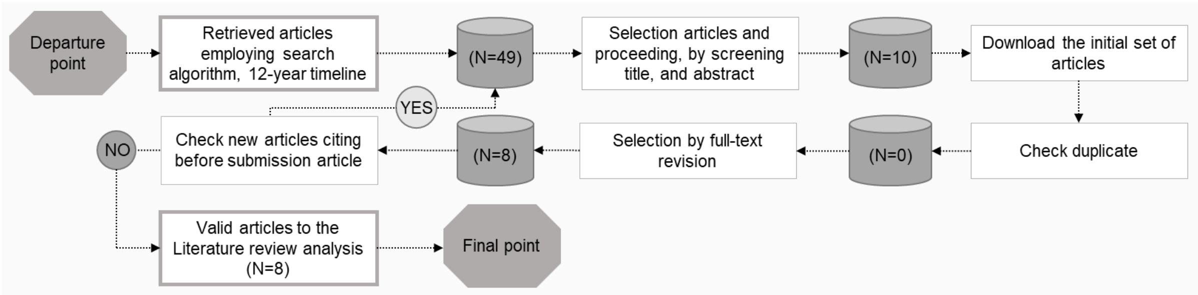

Figure 2: Article protocol selection

This stage was concluded with a complementary literature review to identify other benefits of MMs beyond those of the previously reported OSC-MMs and challenges prevailing in incorporating LC into OSC. The topics in Scopus included "LC challenge in OSC," "barriers to implementing LC," and "maturity model in construction." The OSC barriers were mainly taken from those identified in the Chilean AEC industry context by Ortega (2022) and from the articles chosen in the SLR.

STAGE II · THEMATIC ANALYSIS

A thematic analysis was employed to identify in the literature the aspects regarding how the benefits of MMs can contribute to overcoming the barriers that inhibit OSC adoption and the incorporation of LC. Thematic analysis is a method that is used to identify, analyze, and report patterns (themes) within records (Braun & Clarke, 2006). To this end, the authors summarized and codified the most relevant benefits of MMs reported in the literature, mainly in the OSC field, and listed the fundamental OSC barriers and challenges that must be addressed to facilitate OSC adoption and the incorporation of LC into OSC. Then, a network diagram was built, wherein the nodes at the bottom represent the MMs benefits, and the nodes at the top represent the OSC barriers and LC challenges. Finally, the patterns among those variables were represented with arrows. This input supports the author's idea that MMs are a powerful tool that must be developed in the OSC field to help and facilitate its adoption.

STAGE III · ANALYSIS AND INTERPRETATION

Stage III aimed to extract the relevant evidence from the final list of articles to support the analysis and interpretation of each OSC-MM. According to Broome (1993), to analyze and interpret information, each study that forms part of the literature review needs to be categorized, ordered, and summarized. Therefore, the authors established 6 categories for the analysis. If any article did not contain information in a category or subcategory, the label "no information" was employed. Table 1 shows the name and description of each category.

Table 1: Categories employed in the analysis and interpretation of OSC-MMs

Category	Subcategories	Description
Geospatial contribution	Article's location	Region or country in which the paper was developed.
	Publication's year	Year in which the article is available to the readers.
Maturity measure	Maturity levels	The scale is employed to measure the maturity level.
	Descriptors	Name of each maturity level.
Application areas	-	It is related to the dimensions targeted by the maturity model.
Analysis method	Qualitative (Qlt)	No weighting mathematical or statistical method is applied.
	Quantitative (Qnt)	A mathematical or statistical method is applied.

Weighting method	-	Approach to assigning value for dimensions or indicators that comprises the maturity model.
Lean construction adoption	Low level = "**0**"	LC adoption is low or imperceptible. Not explicitly stated by the author.
	Medium level = "**+**"	LC adoption is palpable. It does not necessarily have to be made explicit by the author.
	High-level = "**++**"	LC adoption is remarkable. The author explicitly states it.

RESULTS

Table 2 shows MMs' main benefits as a methodological tool. The review was conducted in the construction field, and special attention was given to the OSC area. The outcome was the identification of 11 benefits of MMs. Regarding OSC barriers and LC challenges, the authors detected six key (6) OSC barriers and four (4) LC challenges that can be effectively addressed by applying an MM base to incorporate lean construction into OSC.

Table 2: MMs benefits, OSC barriers, and challenges for the incorporation of LC within OSC

Item	ID	Description	Reference
MMs Benefits	MMb1	Allows identifying weak areas or gaps	[1] [2] [3]
	MMb2	Serves as a prescriptive tool for improving performance	[1] [2] [5] [13]
	MMb3	It is a tool to assess an organization's maturity (e.g., process maturity, product maturity, the skill of people, social system) and to assist in increased maturity level	[1] [2] [3] [4] [5] [6] [9] [13]
	MMb4	Assists in continuing improvement	[2] [3] [6] [7]
	MMb5	Helps managers to reach organizational or project goals	[1] [2] [6] [10] [13]
	MMb6	Helps to set prioritized goals	[1] [6]
	MMb7	Serves to assess the maturity of new technologies in the AEC industry	[6]
	MMb8	Helps to reduce the competitiveness gap among organizations	[10]
	MMb9	Promotes the creation of value	[10]
	MMb10	Serves as a comparative tool (e.g., benchmarks tool)	[1]
	MMb11	Establishes a common and shared language	[8]
OSC barriers	OSC1	Lack of understanding of manufacturing principles to be applied in OSC	[5] Cf. [9]
	OSC2	Lack of market maturity	[1] [3] Cf. [9]
	OSC3	Failures in the management of OSC projects	Cf. [9]
	OSC4	Insufficient project management skills	[9]
	OSC5	Poor project performance	[5]
	OSC6	Inability to assess the benefits offered by OSC	[9]
LC Challenges	LC1	Complexities in understanding LC	[11]
	LC2	Lack of appropriate lean technology or tools	[12]
	LC3	Lack of strategies to implement LC	[11]
	LC4	Lack of guidelines for introducing LC gradually into the industry	[11]

Note: **[1]** Suliman & Rankin (2021) **[2]** Wang et al. (2020) **[3]** Liu et al. (2018) **[4]** Wei et al. (2022) **[5]** Dang et al. (2020) **[6]** Razkenari & Kibert (2022) **[7]** Bendi et al. (2021) **[8]** Blismas et al. (2010) **[9]** Ortega (2022) **[10]** Cano et al. (2020) **[11]** Aslam et al. (2020) **[12]** Yuan et al. (2020) **[13]** Correia et al. (2017)

Following Table 2, through a network diagram, Figure 3 indicates the direct relationship between MM benefits and key OSC barriers and LC challenges. Almost five positive MM benefits would have an impact of mitigating one OSC barrier and one LC challenge at the same time. The benefits of MMs have addressed the overall key OSC barriers and LC challenges. This result suggested that MMs are a powerful tool for facilitating the adoption of OSC, especially in mitigating key OSC barriers that have been reported recently in developing countries.

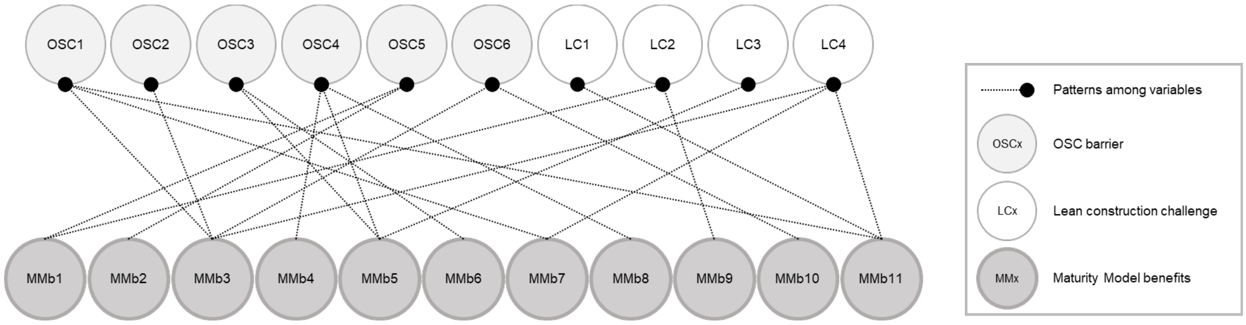

Figure 3: Benefits of MMs to overcome OSC barriers and challenges of LC incorporation.

ANALYSIS AND INTERPRETATION OF OSC-MMS

This section summarizes the SLR findings of the OSC-MMs identified. The results respond to the analysis and interpretation based on the categories established in stage III.

Geospatial contribution of MMs in the OSC field

Despite the potential positive impact of MMs on overcoming OSC barriers and LC challenges, as suggested in Figure 3, the geospatial contribution in the domain of MMs (Table 3) indicated a low level of development of this methodological tool in the field of OSC. Just only 8 OSC-MMs have been developed in the last twelve years. Moreover, every country and region has its realities, and many dimensions in the OSC field require doc treatment. Furthermore, it is not possible to establish a statistical trend in the development of MMs in the field of OSC over time. However, in the last 3 years, the authors observed an incipient development of this methodological tool of 2 MMs per year worldwide.

Table 3: Number of papers per year and geospatial contribution.

Location of development	Year												
	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022
International													1
Canada												1	1
India												1	
China									1		2		
Australia	1												

Structural key categories of OSC-MMs

The authors ordered the key categories that comprised OSC-MMs in Table 4. These categories support the inference that there is no unique way to build up MMs in OSC. For example, regarding maturity measures, some OSC-MMs comprise 3, 4, or 5 maturity levels. Additionally, most of them used different terminologies to describe each maturity level. Even one "MM" in the sample did not employ a descriptor for the maturity levels. The relevant contribution of maturity levels is clearly describing the path to reaching higher maturity levels. However, the findings suggested that not all authors gave a full explanation. These outcomes correspond to those of reviews carried out in other construction areas, e.g., sustainability (Correia et al., 2017).

Table 4: Key categories that constituted OSC-MMs

ID	Levels	Descriptors	Application areas	Analysis Method		Weighting Method	LC adoption
				Qlt	Qnt

LC adoption: Low level = "0," Medium level = "+," High-level = "++".

Regarding "application areas," the scope of MMs is variable. Researchers focused on a particular area of interest, which can be at the level of process or product, e.g., technological capabilities, operation management, procurement process, construction sustainability, or the product's design-production-logistic-maintenance. Most MMs for the analysis method included both quantitative and qualitative approaches. This approach helps to provide mathematical measurements of the maturity assessment and an in-depth understanding of each level. However, no consensus or standard concerning the weighting method applied in MMs exists. Therefore, even most MMs did not include this approach. The weighting method refers to the criteria for assigning a value to each dimension and indicator that was used to build each MM. This helps determine the preponderance of one application area over another (cf. Wang et al., 2020), and the intention is to eliminate the difficulty in obtaining practical data and the subjective nature of expert evaluation (Dang et al., 2020). A few studies have employed the analytic hierarchy process (AHP) or fuzzy analytic hierarchy process (FAHP) to evaluate MMs.

The evaluation outcomes related to LC adoption are aligned with expectations due to similarities between OSC and LC. All studies, to some extent, present management practices or tools belonging to LC. For instance, various studies have established the adoption of BIM, virtual design, or simulation as a minimum standard for incorporating OSC. Additionally, the early integration of the value chain to develop an integrated design and construction is also considered an initial maturity level in OSC adoption. More than half of MMs (e.g., [2], [3], [5], [6], [8]) include explicit mentions of LC to make a comparison with some of their own concepts or just to encourage its use. For example, training the workforce based on lean concepts is recommended to facilitate the improvement in production and construction in situ (Razkenari & Kibert, 2022). However, what should be learned, how, and when is not explicit. In other words, there is no clear explanation of how to implement LC in those MMs that promote its use.

DISCUSSION

MMs have certain limitations. For some MMs, a scale of maturity level or maturity level descriptors was not developed. Instead, applying qualitative analysis methods was the only focus, making it difficult to generate numerical indicators to assess maturity. For a few, a weighting method for the framework's dimensions and indicators was adopted. This suggests that most of the MMs had a significant degree of subjectivity and bias.

In most studies, the incorporation of LC in the dimensions/indicators of the OSC-MMs must be inferred. Consequently, determining the objectives and functionalities of LC practices and tools in the MMs frameworks is not provided. Therefore, the challenges of “complexities in understanding LC” (LC1) and “lack of appropriate lean technology or tools” (LC2) are not resolved. In contrast, this lack reinforces these challenges since it sets off a critical ambiguity space due to the variety of terms that are often used to explain the same concept and assumptions that must be made to select the appropriate LC practice/tool. For example, the transportation component is conceptualized regarding the assurance and efficiency of component transportation, considering distances, storage, and availability. This is associated with LC's “just in time” (JIT) management practice, which could have been standardized under this term. Such a divergence of terms contributes to a “lack of understanding of manufacturing principles to be applied in OSC” (OSC1). This scenario in a sector that is characterized by being conservative and volatile promotes the entrenchment of the known (e.g., traditional construction practices). It, therefore, transfers old vices to the OSC field.

Creation value-oriented management is an essential characteristic of the LC approach (Koskela, 1992). An important finding is that none of the OSC-MMs presented performs a *value analysis* regarding the dimensions that comprise each MM framework. Most of the proposed dimensions are taken from the literature, interviews, or workshops but do not have a *value analysis* to guarantee that the proposed dimensions meet internal (organization) and external (customers) requirements. Therefore, a vital principle of LC is not considered in the confection of MMs.

CONCLUSIONS

In this research, an SLR of the MMs developed in the OSC field using the Scopus database was conducted, and the level of LC incorporation in those OSC-MMs was evaluated. The literature review results showed poor development of this approach in the OSC field. Only 8 OSC-MMs have been developed in the last 12 years in a few countries. Furthermore, the incorporation of

LC showed weaknesses in terms of establishing a common language, providing clarity in the applications of LC practices and tools, and conducting an explicit and integrated framework for the adoption of LC. The authors identified that the OSC-MMs comprise transversal dimensions across the AEC industry at the global and local levels since each region has different "financial and market conditions" and "policies and regulations." This scenario confirms the idea of the poor availability of OSC-MMs. Moreover, the network diagram highlights how MM benefits can positively impact overcoming key barriers that inhibit OSC adoption. Therefore, the use of a powerful tool to facilitate OSC assessment, measurement, and adoption is lacking.

The analysis showed that application areas addressed by MMs are diverse and not directly associated with OSC phases in most cases. Based on this, the authors found the need to promote the development of OSC-MMs from two perspectives: *(i)* considering the project life cycle and *(ii)* using LC as a main approach to avoid any room for ambiguity. In addition, the authors suggest that in future developments of OSC-MMs, a *value analysis* of their dimensions/indicators should be performed as a complementary method of validating the model.

Despite its contribution, the study has certain limitations. The review includes research articles or proceedings. Other types of documents in which a kind of MM could have been developed to measure OSC maturity were not considered. Although some researchers recommend using one database, the authors suggest that a more extensive review, including other recognized databases in the scientific field, must be employed. Additionally, this paper mainly focused on exposing the weaknesses regarding incorporating LC into OSC-MMs. Therefore, future research should develop a comprehensive review of the LC critical coincident factors that have been included in the current MMs. This will be a baseline for further OSC-MMs development and facilitate incorporating LC practices or tools. Nevertheless, future revisions can take the current revision as a starting point to address the stated limitations.

ACKNOWLEDGEMENT

The authors would like to acknowledge financial support from ANID through project FONDECYT Regular N°1210769 as well as thanking the Production Management Centre GEPUC from Pontificia Universidad Católica de Chile for facilitating this study. Also, to ANID National Doctorate 2022-21220895 and VRI-UC, for funding the postgraduate studies of two authors.

DEVELOPING A FRAMEWORK FOR ASSESSING TEAM ALIGNMENT IN CONSTRUCTION USING TVD

Nazanin Najafizadeh[1] and Farook Hamzeh[2]

ABSTRACT

Customers’ value is crucial to the success of a construction project, and team alignment is required to steer projects toward their intended value. Alignment is when the right people work together on a project to generate and achieve values that are consistently communicated and accepted. In the architecture, engineering, and building industry, teamwork challenges are inevitable. The existence of a team does not guarantee the success of the project, and a dysfunctional team might result in project failure, wasting resources such as time, money, and energy. Target value design (TVD) is a lean approach that leads the design and construction phases to meet project objectives while adhering to team and project limits. Based on their values, each project has different conditions, facts, or impacts that help strengthen team alignment (factors). Additionally, a team that is aligned has particular qualities that are recognized as attributes. Measuring and assessing team performance based on TVD using factors is complex. This research fills the gap in the literature review concerning the measurement and assessment of team alignment. The process and its results could help construction project leaders regularly assess and identify team strengths and weaknesses to improve team alignment. A case study is also presented to apply the proposed framework to measure team alignment on a construction project, to improve team performance.

KEYWORDS

Lean construction, target value design, collaboration, and team alignment.

INTRODUCTION

The architectural engineering and construction (AEC) sectors require a cooperative effort that has become more multi-disciplinary, complex, and interconnected (Ashcraft, 2016). There are various challenges in setting up a virtual organization for building projects. The AEC industry's long history of individualism and hostility is the first obstacle. Instead of working in teams, people have worked together on projects in groups. Furthermore, due to the casual usage of the term "team" many individuals mistakenly assume they have participated in teamwork (Ashcraft, 2011). In order to transform groups into teams, there must be a substantial shift in how people collaborate and in how work and hierarchy are organized. In a software environment, it is said that "successful deployment of multifunctional teams involves a radical rethink of the whole firm" (Larman, 2008). The lack of collaboration between designers, subcontractors, and other specialized groups as well as the unpredictability of costs, timelines, and quality standards

during the design phase reports that typically come after those from the construction phase are the causes of disappointments. The result is costly rework, change orders, and repricing, which is off-target for clients (De Melo et al., 2016).

Target value design (TVD), a lean approach technique for creating value in projects with favorable features, has also been acknowledged by Miron et al. (2015). The cornerstones of effective TVD implementation are team alignment (TA) and value alignment (VA) (Ashcraft, 2016). By leveraging the client's perceived value as a design engineer and attempting to minimize waste, or at least surpassing the client's expectations, TVD is also used to improve cooperation (Kim & Lee, 2010). When TVD is not used, poor team alignment (TA) creates several obstacles and problems that ultimately cause projects to fail (Griffith, 2001). According to the literature study, little to no research has been done on utilizing TVD to measure and evaluate TA.

Based on the ideas from TVD, this study aims to propose a framework to measure team alignment in construction projects. The measuring technique used to assess the framework through relationships and correlations between team alignment attributes and factors is a quantifiable variable that is influenced by these interactions. This study's industrial contributions include showing how to employ a team alignment measurement tool to assess team performance in AEC projects and offering analyses with a roadmap for identifying team weaknesses and improvement possibilities. Pearson’s correlation coefficient test and the Fuzzy Inference System (FIS) are two approaches used in the experiment to simulate correlation and measurement. Participants completed the prepared survey, and data analysis techniques were then applied to the survey findings. Based on the findings, suggestions are made for improving team alignment.

PREVIOUS RESEARCH

Lean project delivery system is a form of integrated project delivery (Mossman et al., 2013). Lean construction or lean project delivery is the process of applying lean thinking to the conception and execution of capital projects, or the delivery of projects in general (de Melo et al., 2016). Lean projects are arbitrary production processes that offer products with the highest possible value and the least amount of waste. The main differences between standard and lean project delivery are the stages, interactions between phases, and participation in each phase (Ballard & Howell, 2003).

The goal of target value design (TVD), a Lean management practice and design methodology, is to provide customer value while adhering to a project's restrictions (Kaushik & Koskela, 2015; de Melo et al., 2016). TVD was developed based on the principles of target costing used in the manufacturing industry, but with modifications to its ideas, methods, and implementations. This approach is an upgraded version of target costing that emphasizes the creation of stakeholder value as a driver for design and construction. While target pricing concentrates on setting "cost" goals, target value design extends this concept to include targets for time, quality, and value, among other factors. Since its inception in 2002, TVD has gained popularity and acceptance among construction firms in the United States, according to Do et al. (2014). TVD successfully minimizes cost overruns and maintains predictable project costs, delivering projects for up to 20% less than market value without compromising quality or schedule; ensures early participation of key stakeholders; and promotes collaboration (Do et al., 2014).

Team alignment and value alignment are prerequisites of TVD. “Organizations develop alliances, often termed networks or constellations, to match their own goals with stakeholders' interests and to decrease environmental uncertainty,” according to Barringer and Harrison (2000). The condition in which team members collaborate within acceptable bounds to create and realize consistently specified and accepted project values can be characterized as the alignment between appropriate project participants (Griffith, 2001). Even if groups operate differently, they can still align if they share the same objective. The project's outcomes are directly impacted by the project team's alignment. These direct ties also looked into the possibility that alignment mediates the connections between the project's antecedents and outcomes (Griffith, 2001). According to Frey et al., 2006, three primary categories for partnerships categorized based on the level of alignment, which ranges from low to elevated are misaligned (networking and cooperation), poorly aligned (coordination and coalition), and aligned (collaboration and alignment).

The fragmentation of the company's specialized teams causes a lack of alignment between team members and project stakeholders, as noted by Ashcraft (2011). This misalignment can result in leaders wasting time pursuing productive ideas that are not the most important goals at the time, according to Kochhar (2013). Moreover, if the company's culture is unclear to operational employees, they may lose trust in its vision, objectives, and value proposition, which can impede their willingness to give their best to the project, leading to a negative impact on the company's culture and bottom line. In contrast, strategically linked firms are more effective and deliver better results because team members work together to achieve common goals and objectives (Ashcraft, 2011). When people are not strategically linked, they may become confused about their priorities, make fewer effective decisions, and engage in conflicts, which can lead to a lack of excitement and motivation to do their best work. Therefore, people want to be part of something meaningful.

The current study aims to evaluate team alignment and its impact on project success by examining several factors such as the level of commitment to the team and project value, morale among team members, ability to overcome challenges, and providing timely and creative knowledge and information. Table 1 presents the research studies focusing on implementing TVD, team alignment, and influential factors for promoting team alignment. However, none of them have proposed a method and framework to measure team alignment based on TVD.

Table 1: Implementing TVD to Evaluate Team Collaboration

METHODOLOGY

Design science research (DSR) is the approach followed in this study. According to Hevner et al. (2007), DSR strives to learn about and comprehend a problem area by developing and deploying a designed artifact. The basis for adopting design science as a research method is the purpose of DSR, which has been stated as creating trustworthy information to be utilized in designing solutions to problems and significantly advancing the practice and theory of the subject in which it is employed (De Melo, 2015).

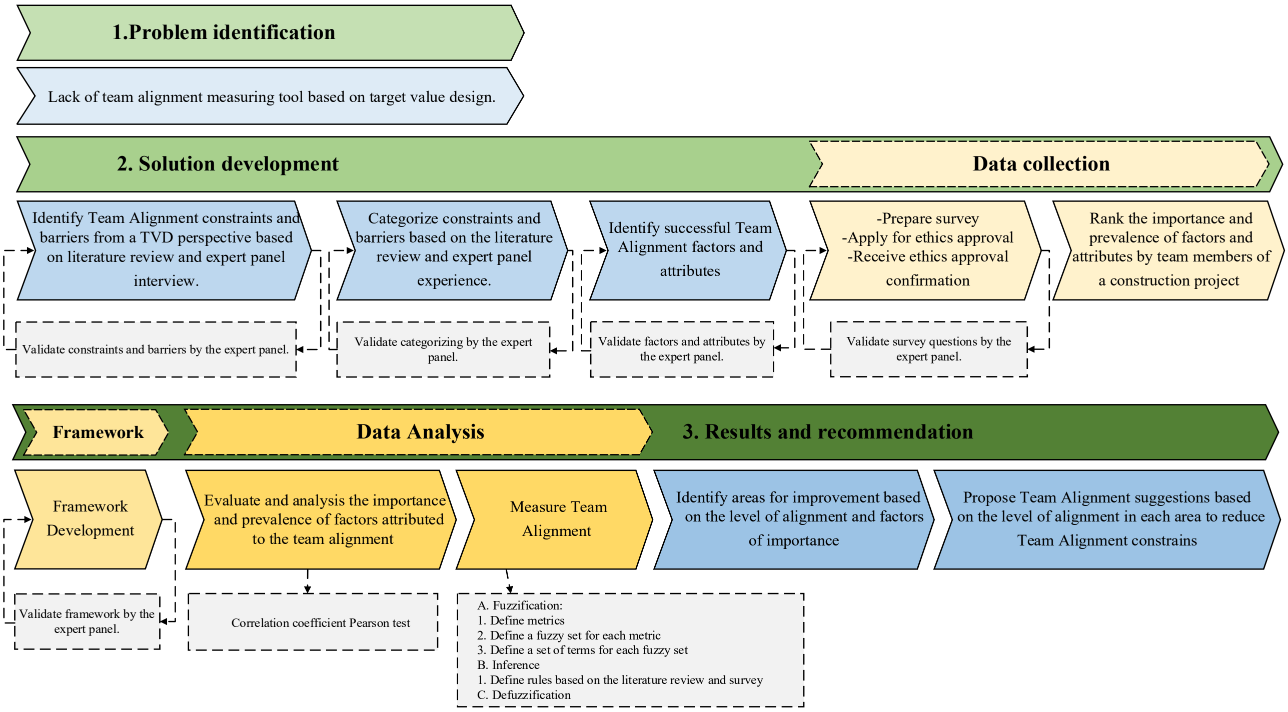

Figure 1: Research Methodology

The three major phases of this research are problem identification, solution development, results, and recommendation. Figure 1 illustrates the approach employed in the study.

Problem Identification

Project failures will result from any issues or deficiencies in the catching value during project phases. Consequently, delivering value will be aided by a regular review of the team's TVD performance. Understanding team alignment drivers and impediments can help project leaders improve and prepare for new challenges. According to the literature study, a team alignment tool built on the target value design principles is required. Leaders can discover the team's strengths and shortcomings by continuously analyzing and measuring team alignment.

Solution Development

The three stages of solution development are as follows. Starting with the TVD principles, it identifies team alignment limitations, impediments, factors, and attributes. The creation of a framework is the second step. Data gathering is the next stage of the solution creation process. The following sections provide explanations of the steps listed.

Team alignment challenges from a TVD perspective

The first step in bridging a gap is to thoroughly understand it from all angles. TA difficulties are known in the solution development phase based on the literature study and are confirmed by the expert panel. This research was developed based on the TA challenges in the literature review. The fishbone diagram (Figure 2) presents a root cause analysis and five main categories of challenges that hinder team alignment in TVD implementation. The major groups include personal characteristics, training, management, culture, and environment.

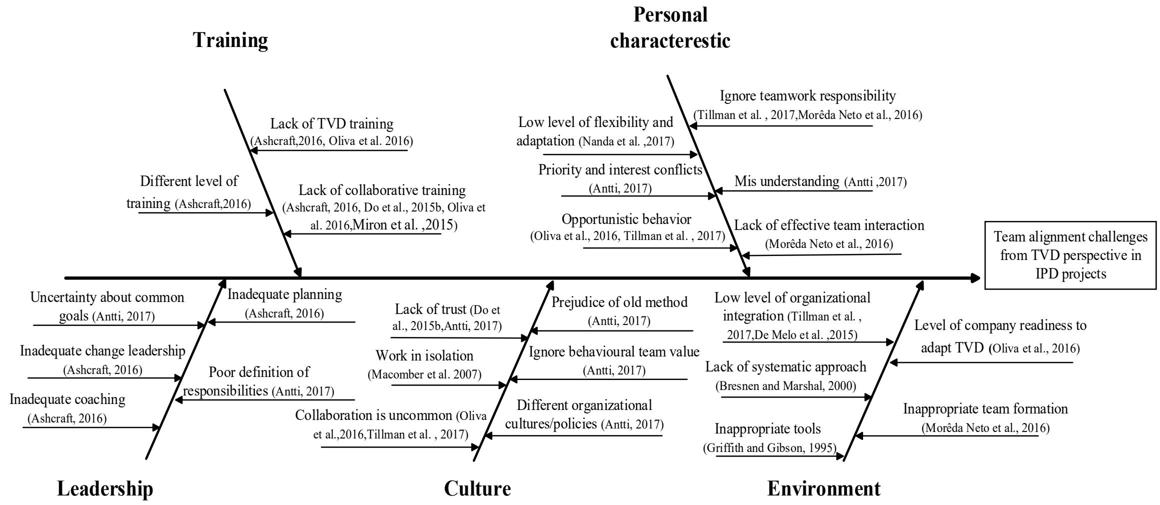

Figure 2: Team Alignment Challenges from TVD Perspective in Construction Projects

IDENTIFY SUCCESSFUL TEAM ALIGNMENT FACTORS AND ATTRIBUTES IN TVD

Being a qualitatively abstract concept, alignment means different things to different teams and projects. The attributes of an aligned team will be what distinguish it. Team leaders and members determine these traits based on the values of the team and the project. To meet the demands of the available cross-functional and multidisciplinary construction teams, these features are multifaceted in the building project. Based on the TVD principles from the literature, this research has compiled a list of factors and attributes for effective team alignment which 24 factors and 5 attributes were verified by the case study team lead. The values, knowledge, or circumstances that support team alignment are contained in factors. The most influential factors may be improved by construction team leaders by being aware of them, assessing them, and investing time and resources into improving them (Table 2).

Table 2: Research Successful Team Alignment Proposed Factors

No.	Factors descriptions	No.	Factors description
F1	Team members have good problem-solving and decision-making skills.	**F13**	Leaders assign tasks that fit team members' strengths and capabilities.
F2	Team members listen effectively and empathize with each other. They share constructive feedback transparently.	**F14**	The team members' strengths and weaknesses are regularly assessed by management.
F3	Team members trust each other to speak up-phycological safety.	**F15**	The project scope and value are clearly defined by team leaders and communicated visually.
F4	The team learns about each other's past professional project collaboration experience.	**F16**	Leaders and team members know and understand the risks and rewards of the project on which they are working.
F5	Team members are encouraged to work on the project.	**F17**	A collaborative culture exists among team members.
F6	The team focuses on the project's goals and objectives.	**F18**	Members respect the teams' diversity; accept and treat each other fairly and equally. Diversity, Equity, and Inclusion (DEI).
F7	Team members are knowledgeable and are constantly trained to work on IPD projects and use Lean techniques and TVD.	**F19**	Leaders and team members express and apply innovative ideas to projects.
F8	Team members benefit from training approaches and methods.	**F20**	Team members attend face-to-face meetings in the big room.
F9	Team members are trained in effective and frequent communication.	**F21**	Members come from different educational and professional backgrounds.
F10	Team leaders ensure that members have equal access to information, equipment, and technology.	**F22**	Leaders size their teams properly according to the project's workload, size, and nature.
F11	Lean mentors are available to guide and train team leaders.	**F23**	Leaders and team members are satisfied with their collaboration and hope to continue it.
F12	Team leaders collaborate with other cross-functional teams and provide cross-disciplinary expertise for successful communication.	**F24**	Key participants are involved early in the project.

Team alignment attributes are qualities or characteristics that are thought to be a component of the alignment (Table 3). Factors are the causes and conditions that enable team alignment, while attributes are the characteristics of an aligned team. Therefore, team alignment factors and attributes are distinct concepts.

Table 3: Successful Team Alignment Attributes

Attribute no.	Attribute description
AT1	Level of commitment to the team and project value
AT2	Level of morale among team members
AT3	Ability to overcome challenges
AT4	Provide the right knowledge and information at the right time
AT5	Level of creativity

DATA COLLECTION

The purpose of the survey is to assess the validity of team alignment factors and attributes as well as their importance and prevalence. Prevalence is the present degree of evaluation of factors and qualities in the team project, whereas importance indicates the priority of factors and attributes as well as the predicted value for the team. Prevalence might fluctuate often with each update or new evaluation, although importance can have a more or less constant value in this context. The Likert scale, a non-comparative, one-dimensional scaling method consisting of 5 points, was utilized in this study, with 1 representing the least prevalent or important factor and 5 representing the most prevalent and significant factor. The expert panel employed the Likert scale in this study's validation phase to rate various factors and attributes.

RESULTS AND RECOMMENDATIONS

The last phase is results and recommendations that start with the framework (Figure 3) development, continue with data analysis, and end with the team performance improvement proposal.

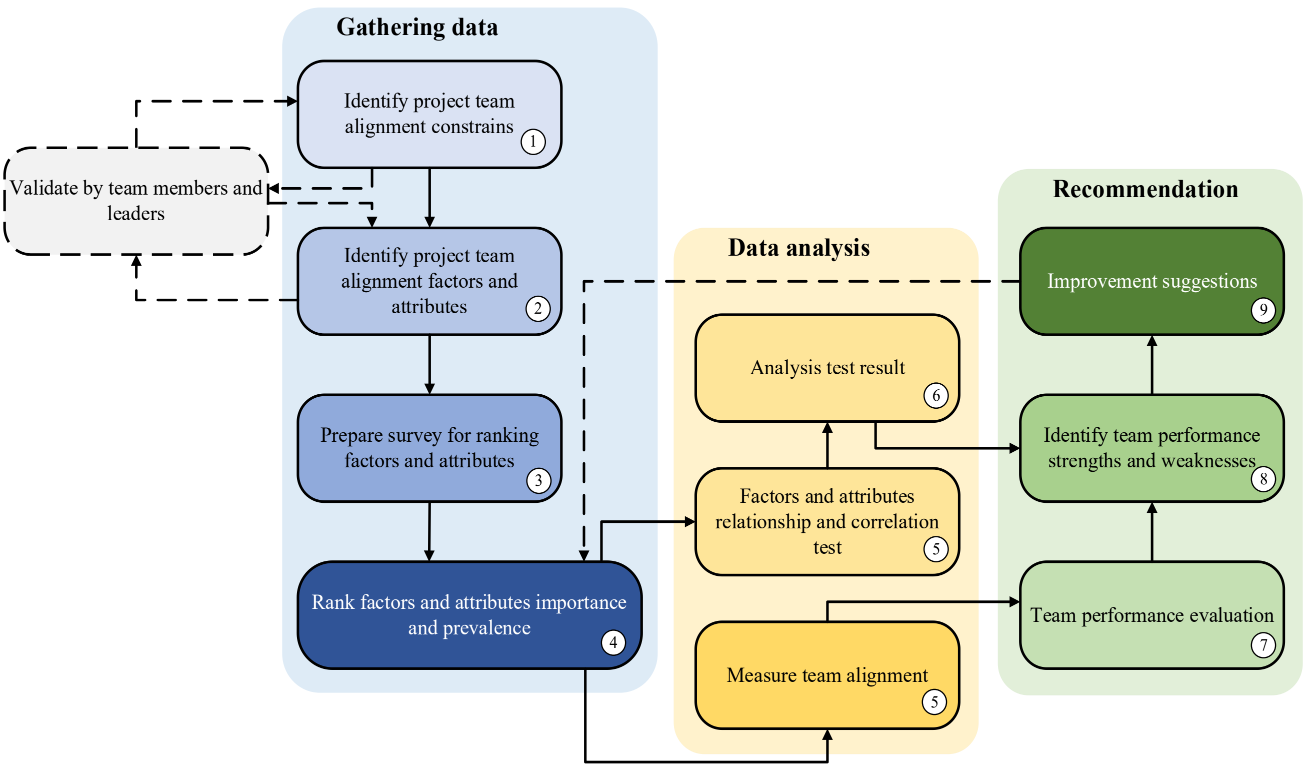

Figure 3: Team Alignment Measuring Framework

The method of developing the framework is innovative and is based on current scientific understanding and real-world experience with construction projects. The proposed framework consists of three phases which are gathering data, data analysis, and recommendation. The concept is built on the connection and correlation between team alignment, factors, and attributes (Figure 4). The Correlation coefficient Pearson's test is used to identify the correlations and coefficients between factors and attributes.

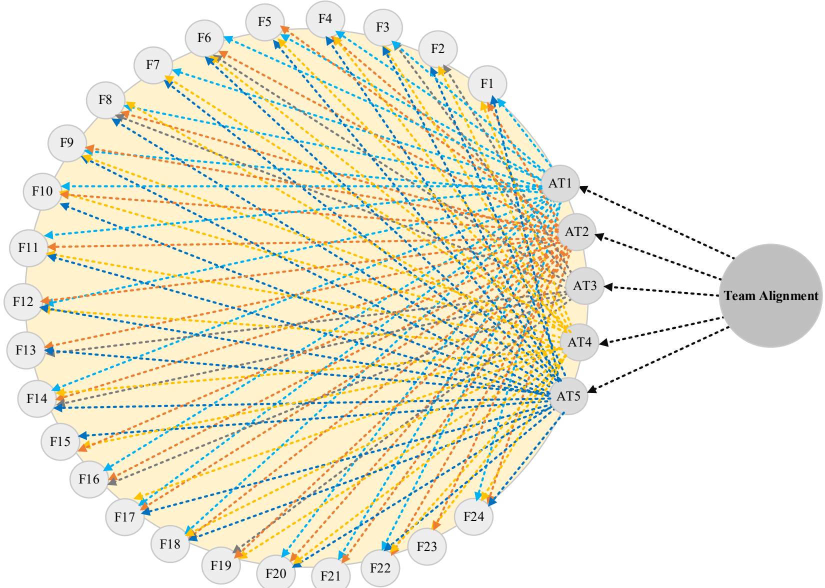

Figure 4: Research Assumptions

Team alignment is a qualitative quality that is subjective and cannot be quantified using quantitative techniques. To address this, our study models the interactions between factors and attributes using fuzzy inference systems (FIS). As mentioned in the data collection section, we ranked the team alignment attributes prevalence in the team project, and the ranking results were used in the FIS to convert a qualitative ranking to a quantitative measure. After measuring each attribute in the FIS, we identified the related factors based on the Pearson correlation coefficient test results. The comparison between attribute prevalence and importance measures helps team leaders identify critical attributes that need improvement. The value of attribute importance represents attribute vitality, and the gap between attribute importance and prevalence indicates the attribute's critical situation. Reaching the level of attribute importance should be the team's feature goal. The correlation test results identify the factors related to these critical attributes for improvement so that team members can focus on them. The recommendation section will provide guidelines based on the effective factors related to critical attributes.

RESULTS AND DISCUSSION

This research offers a method for assessing team performance and keeping track of team alignment on construction projects. This framework attempts to monitor team members' advancement and performance in accordance with the team, project, and corporate values. The method may be used for construction projects, and depending on the project value, influential elements, and aligned team qualities can be identified for each project. It will help team leaders pinpoint the group's strengths and weaknesses and establish monthly and yearly objectives to boost output. A case study of an IPD project at a construction business is used in this study to evaluate the framework.

The survey questions were created, validated with the project manager for the case study, and approved by the University of Alberta's ethics committee before being sent to the project team. The case study is a New Mechanical Wastewater Treatment Plant that is located in Lloydminster, Alberta, Canada. The research required data collected from case study project team members. Out of the 20 members of the project team, 18 participated in the survey to rate the prevalence and relevance of various elements and traits using a Likert scale.

According to FIS's analysis of the attribute's prevalence rating, the case study's team alignment measurement will be 81.2 percent. Although the team is cohesive, there is still potential for development. When team members set the target value too low, they will not be able to increase team performance and will not benefit from this framework. This number fluctuates from project to project depending on the relevance of the characteristic that team members specify by their rating. Team members likely require additional training on lean principles, target value delivery, and team alignment if they give the team alignment traits a low-priority ranking.

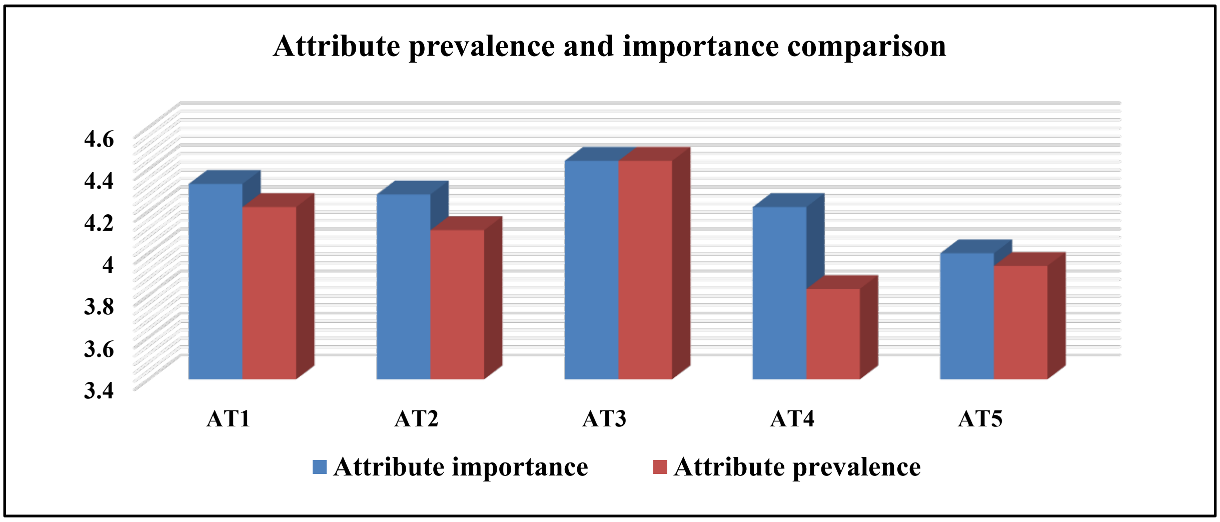

Figure 5: Factors Correlate Values Based on Attributes for Survey Result

Figure 5 compares the mean importance and prevalence of the qualities. Except for attribute four (providing the appropriate knowledge and information at the appropriate time), the mean difference between the importance and prevalence of each attribute is less than 0.2. A larger disparity between importance and prevalence indicates a critical situation for the attribute.

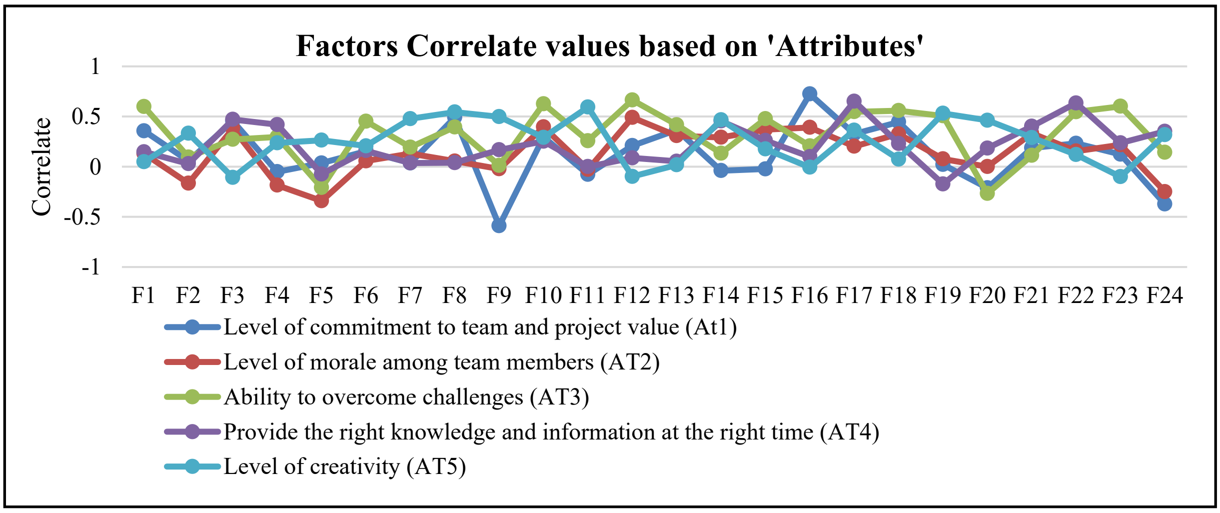

Figure 6: Factors Correlate Values Based on Attributes for Survey Result

Figure 6 presents the results of Pearson's test, which shows the correlations between factors and attributes based on their mean prevalence values. This helps to identify the factors that have a negative impact on team alignment. Positive factors are those that can enhance an attribute by improving the related factors. If the negative factors are improved, there can be a considerable change in the attribute. For example, in attribute four, which is the most critical attribute, the influential factors are F19 and F5. In attribute two, the most influential factors are F5 and F24. In other words, improving these four factors will significantly affect the level of team alignment.

This research presents a method for assessing team performance and maintaining team alignment throughout construction projects, based on the team, project, and corporate values. The framework allows for monitoring team members' progress and performance in relation to these values, identifying influential factors and aligned team traits for each project depending on its value. This will help team leaders identify strengths and weaknesses and set monthly and yearly objectives to improve output. The framework is evaluated through a case study of an IPD project at a construction business.

To create a quantitative approach for a qualitative characteristic, the developed instrument and methodology may benefit both academics and industry, especially in assessing team performance using the TVD. The main contributions of this study are:

Emphasizing the importance of team alignment for the successful use of TVD and establishing a correlation between factors, attributes, and the degree of team alignment.

Providing a system for assessing team performance, establishing a framework for evaluating multiple correlation types, and creating a connection map to assess the degree of team alignment.

The results of Pearson's test show that the degree of correlation between factors and attributes is important to the value of team alignment, and the connection is dynamic, and changes based on the expert panel's rating.

Outlining how a team alignment tool can be used to assess a team's performance in the AEC industry or any other team-based context, such as in the medical and commercial industries.

Addressing team alignment issues in construction projects can result in project failure due to collaboration restrictions and impediments at every stage of the building process.

CONCLUSION

This paper aims to address the challenges of team alignment in construction projects, which are often plagued by teamwork constraints and barriers that can lead to project failures. By drawing lessons from these constraints, team leaders can establish appropriate factors and attributes to monitor and evaluate team performance using the proposed methodology and framework. The case study presented in this paper demonstrates how project leaders can identify and improve team weaknesses and leverage team strengths to improve project productivity. In team-based industries, the team alignment framework can be used to evaluate team performance, outcomes, and risks, as well as to identify process improvements. To enhance the efficiency of this framework, future research should explore ways to automate it and develop a simulation tool.

BUILDING A LEAN HOUSE WITH THE THEORY OF CONSTRAINTS FOR CONSTRUCTION OPERATIONS IN ZIMBABWE: A CONCEPTUAL FRAMEWORK

Cynthia Moyo[1] and Fidelis Emuze[2]

ABSTRACT

The poor performance of construction projects in Zimbabwe, evidenced by cost overruns, extensive delays, reworks, defects, and accidents, has resulted in the need for cost-effective strategies such as the theory of constraints and lean construction (LC). This is because Lean drives out waste, and the theory of constraints (TOC) identifies constraints on which to act to improve performance. By focusing Lean initiatives on construction projects, TOC will lead to better improvements in performance. Although similar studies have been undertaken in other countries, they need to be more contextually relevant due to the myriad of economic challenges synonymous with the Zimbabwean construction industry. A critical review of relevant literature was conducted to observe how TOC allows for identifying constraints hindering progress on construction projects while LC tools would provide solutions. In effect, LC and TOC could reverse poor outcomes of construction operations in Zimbabwe. This conceptual paper thus proposes a framework that identifies constraints using TOC, followed by an evaluation of Lean tools suitable to deal with the identified constraints. The foundation of the lean house will engender effective problem-solving to remove bottlenecks in the design and construction processes.

Construction operations, Lean, theory of constraints, performance, Zimbabwe

INTRODUCTION

Construction projects involve various actors whose activities greatly influence project success, such as the client or project owner, the consultant (architects, engineers, and quantity surveyors), and the contractors (Jin et al., 2017). Even though these parties have one goal: to make a profit, the multi-party working situation involved in construction projects results in conflicts and disputes, which bring direct and indirect cost consequences to clients and contractors (Yates and Hardcastle 2002). According to Goldratt (1991), every company's goal is to make money at present and in the future. The term constraint is defined as any element hindering the company's achievement of that goal. Theory of Constraints (TOC) is an approach that identifies the constraint and offers a solution for its mitigation (Pacheco et al., 2019). The TOC recognizes that constraints on any system restrict maximum performance concerning the goal (Siha, 1999).

[1] PhD Candidate, Department of Construction Management, Nelson Mandela University, Gqeberha, South Africa, cynthiamhungu@gmail.com, orcid.org/0009-0004-5539-9298

[2] Professor, Department of Built Environment, Central University of Technology, Free State, Bloemfontein, South Africa, femuze@cut.ac.za, ORCID.org/0000-0001-7714-4457

In the construction industry, that goal is to profit through increased productivity and minimized waste.

Waste minimization can also be achieved through lean construction (LC). LC involves converting waste into value by reducing waste, improving communication, and promoting teamwork integration through common tools and techniques (Emuze et al., 2014; Srinivas, 2020). Furthermore, LC creates a culture where the occurrence of problems is minimal due to benefits such as a reduction of waste, a decrease in inventory, advanced quality, better system flexibility, reduced variability, and amplified problem visibility (Abdullah et al., 2009). In addition, it ensures conventional flow and an improved capability to deal with uncertainty and difficulty in construction project delivery (Ruin et al., 2016). Maske and Valunjkar (2020) postulated that the LC method had been extensively articulated in developed countries; however, it has yet to attain limited and contextual applications. Lean production is a technique that Toyota Motor Company first implemented in the 1950s (Aziz and Hafez, 2013). Lean Thinking was first introduced in construction by Koskela to tackle certain features of building projects (Salvatierra-Garrido et al., 2010). Koskela et al. (2002: 212) define LC as "a way to design production systems to minimize waste of materials, time and effort to generate the maximum possible value". Koskela (1992) highlights that construction could significantly improve by identifying and eliminating non-value-adding activities.

The profitability of most construction projects depends on construction productivity; if this is not fully addressed, projects will incur cost and time overruns (Besklubova and Zhang, 2019). According to Aziz and Hafez (2013), construction productivity has declined worldwide over the past 40 years, hence the need to implement approaches such as TOC and LC to improve performance. In Zimbabwe, cost, time and quality concerns remain prevalent in infrastructural construction projects (Moyo et al., 2019; Bhebhe, 2022). To add to this, Chazireni and Chagonda (2018) highlight health and safety inadequacies that also affect the performance of construction projects. Hence, cost, time, quality, and safety constraints hamper the success of construction operations in Zimbabwe. By combining LC and TOC, performance improvement can be achieved as waste will be eliminated from construction operations.

Although studies have been conducted on LC and TOC by Ju et al. (2000) in Singapore, Cameiro et al. (2009) and Santos et al. (2012) in Brazil, the implications of those results do not necessarily apply to Zimbabwe. This is because the construction industry in Zimbabwe is resource-restrained due to the foreign currency shortages, prolonged power outages, and ever-increasing inflation estimated at more than 400% experienced over the past five years (Kuwaza, 2019). Therefore, it is essential to identify cost-effective performance improvement strategies applicable to the unique situation currently experienced in Zimbabwe. Hence this paper is the first step of a doctoral study that aims to develop guidelines for using the theory of constraints (TOC) and lean to improve construction operations in Zimbabwe.

THE STATEMENT OF THE PROBLEM

Challenges of time and cost overruns, quality issues, health and safety inadequacies, productivity, performance, and sustainability have been dominant in the construction industry in Zimbabwe (Chazireni and Chagonda, 2018; Mhlanga, 2019; Moyo and Chigara, 2021). Oke et al. (2019) also explained that waste, such as materials, resources, time, movement, production, and creativity, affect the construction industry's performance. Therefore, waste-laden construction operations in the Zimbabwean construction industry promote performance concerns related to cost, time, quality, and safety. Implementing lean tools, coupled with the fact that contractors do not know how to identify, understand, and remove constraints in construction operations, is yet to be operationalized as a resolution in the study area.

Therefore, this study seeks to provide a framework for TOC and LC to improve construction operations in Zimbabwe. The overall benefit is the achievement of key targets within the sustainable development goal of ensuring sustainable production and consumption patterns from the construction industry perspective (United Nations Department of Global Communications, 2020).

Primary research question and secondary research questions

The primary research question elicits responses to what can be done using the theory of constraints (TOC) and Lean to improve construction operations in Zimbabwe. The secondary research questions require responses on the following: what needs to change in construction operations, what can be done for construction operations to change, what can project actors do to cause the change in construction operations, what lean tools will improve construction operations, and what can be done through combining lean and TOC to improve construction operations in Zimbabwe based on literature.

These questions will be answered by first interrogating the causes of cost, time, quality, and safety challenges, thereby indicating what needs to change in construction operations in Zimbabwe. The mitigating strategies for these challenges are identified, highlighting how construction operations can change. Next, implementing the principles of the Toyota Production System (TPS) and Fukuda Production System (FPS) will be examined to show how they can cause the change required in construction operations. Also, lean tools that can improve construction operations regarding cost, time, quality, and safety performance will be assessed. Lastly, recommendations on what construction operation improvements can be achieved through combining the TOC and Lean.

PERFORMANCE OF CONSTRUCTION PROJECTS

The performance of construction projects has been topical over the past two decades, as alluded to by various authors hereafter.

COST PERFORMANCE OF CONSTRUCTION PROJECTS

Moyo et al. (2019) highlight the prevalence of cost overruns in construction projects and suggest the need for sufficient awareness and regulation on decent work conditions for construction workers as it has a bearing on their productivity. Nyoni (2019) indicates how rare it is in Zimbabwe for construction projects to be completed within the estimated budget, thus the importance of finding solutions to these cost performance challenges. According to Moyo and Chigara (2022), the performance of infrastructural projects has been challenging, thus leading to the interrogation of the causes of cost overruns in Zimbabwe. It is essential to identify the causes of cost overruns to cause the change required in the performance of construction projects in Zimbabwe.

TIME PERFORMANCE OF CONSTRUCTION PROJECTS

According to Nyoni and Bonga (2017a), the issue of delays is one of the severest performance challenges in construction projects, and their effect has a bearing on the overall economy of such developing nations. Nyoni (2018) also expresses concern over prevalent delays in most construction projects in Zimbabwe; he explains how these delays culminate in cost overruns and quality defects. Ngendakumana and Kakono (2020) studied the causes of construction project delays in Zimbabwe's public service and identified lack of adequate funds, project variations and inadequacy of resources as the major causes. Nyoni and Bonga (2017b), in their study of critical success factors in the construction sector, highlight the challenge of incomplete projects and postulate critical success factors to significantly improve project effectiveness and efficiency hence providing solutions to time performance and cost performance challenges.

QUALITY PERFORMANCE OF PROJECTS

In Zimbabwe, there has been great concern over poor workmanship on certain high-impact infrastructural projects countrywide (Bhebhe, 2022). This is evidenced by the recently opened registry building in Harare, which is already developing cracks, water leakages, and non-functioning elevators (Chibamu, 2022). This brings out the need for these performance improvement strategies, hence the importance of this study.

SAFETY PERFORMANCE OF CONSTRUCTION PROJECTS

Chigara and Moyo (2014), postulate that there is a high injury frequency rate in the construction sector of Zimbabwe which is estimated at around 2.34%, therefore higher than the ILO-prescribed rate of less than 1%. Further, Chigara and Smallwood (2017) state that the Zimbabwean construction industry is still experiencing injuries at an increasing rate. Charizeni and Chigonda (2018) concur that safety challenges are prevalent on construction sites, hence the importance of continuous performance improvement.

This shows that cost, time, quality, and safety constraints hamper the success of construction operations in Zimbabwe. Additionally, diverse challenges affecting the construction industry's performance in Zimbabwe led Moyo and Chigara (2021a) to interrogate the barriers to implementing LC. These barriers included management-related, design management-related, technical issues, change management-related, quality management-related, and human capital management-related. These findings were supported by other researchers in developing countries (Khaba & Bhar, 2017; Sarhan, et al., 2018; Albalkhy & Sweis, 2020), as they also identified similar barriers. By combining LC and TOC, performance improvement will be achieved as waste will be eliminated in the parts of the system that are the most significant constraints.

THEORETICAL FOUNDATION

The study's theoretical foundation consists of the theory of constraints and lean theory, which are supported henceforth.

THEORY OF CONSTRAINTS (TOC)

The TOC is a theory developed by Dr. Eliyahu Goldratt in 1984 (Goldratt and Cox, 2004). This theory suggests that every organization's goal is to make a profit. However, organizations' constraints hinder the achievement of this goal to make a profit. TOC identifies critical constraints and suggests improvement of activities that would elevate the constraints and inherently prioritize them (Upreti et al., 2020). Hence, TOC is a continuous improvement process because no matter how successful an organization is in achieving its goals, constraints will always exist; hence, TOC focuses on identifying and managing these constraints within organizations (Pegels and Watrous, 2005). Goldratt (1991) identified five steps of the focus process of managing these constraints within organizations, including identifying the constraints, deciding how to exploit the needs of the constraint, subordinating and synchronizing the constraints, elevating the constraints, and, lastly, repeating the process. These steps form the foundation of this study. Therefore, TOC is expected to play a significant part in improving performance.

LEAN APPROACH FOR CONSTRUCTION

Lean principles aim at eliminating or reducing non-value-adding activities (e.g. waste, variation, waiting, low standard) and promoting value-adding activities (e.g. ensuring quality and safety, sustainability, environmentally friendly, customer satisfaction) (Ahmed et al., 2021). Although each organization must develop its way of doing business, The Toyota Production System (TPS) has achieved success for Toyota in terms of waste minimization and value addition. This success makes it a solid foundation for implementing lean principles. The TPS's 14 principles are critical for achieving and responding to constraints as they are supported by pillars of continuous improvement and respect for people (Liker, 2004). In Japan, the TPS was adapted for construction projects by the FPS to improve the efficiency of construction work and lower construction costs (Nakagawa and Shimizi 2004). The FPS flow was suggested as follows:

1. Setting the goal
2. Establishment of indices to achieve the goal (this involves the establishment of Just In Time, and Standard Operating Procedure Documents (SOPD)
3. Setting of target figures for the indices (this includes continuous revisions to the SOPD and target figures)
4. Implementation to attain the goal (this involves checks and confirmations on whether the goal is being achieved.
5. Checking and confirming that target figures have been achieved (If the goal is not achieved, then the cause is examined, and if the goal is achieved, then the procedural steps are standardized
6. Continuous Improvement

The FPS is a more feasible foundation for implementing LC guidelines in the Zimbabwean construction industry. The FPS has the potential to respond to the constraints in the 'setting of the goals' stage and accommodates LC tools within its flow. Above all, it caters to continuous improvement, allowing for the constant generation of constraints and appropriate responses.

METHODOLOGY

The conceptual paper is based on the critical literature review of the theory of constraints and LC theory. The conceptual framework developed is the preliminary stage of a doctoral study expected to solve the challenges of performance experienced in construction operations in Zimbabwe. The study is based on the review of literature on TOC, LC tools, and performance challenges in the Zimbabwean construction industry. The keywords for the search included "Theory of constraints", "Lean construction with the theory of constraints", "lean tools", lean construction", lean construction tools", "lean house", and "Zimbabwean construction constraints". The search was dominated by, but not limited to, Emerald, Science Direct, relevant textbooks on TOC, and publications in the International Group of Lean Construction (IGLC) repository. Articles relating to developing countries were preferred as the study context aligned more with them. An attempt was made to consider the latest articles where it was possible. Content analysis was employed to extract relevant information for developing the conceptual framework, as shown in Figure 1.

CONCEPTUAL FRAMEWORK

Figure 1 shows the proposed framework for providing TOC and Lean guidelines for improving construction operations. The foundation of the lean house is built on ensuring standardization and stability in responding to constraints within construction operations. Achieving this culminates in guidelines that can be utilized for construction operations. The TOC is also foundational as a continuous process for identifying new constraints as and when they become significant. The identification of constraints using the TOC requires two main pillars. The first pillar is the Lean tools that can be implemented to resolve and continuously improve the constraints.

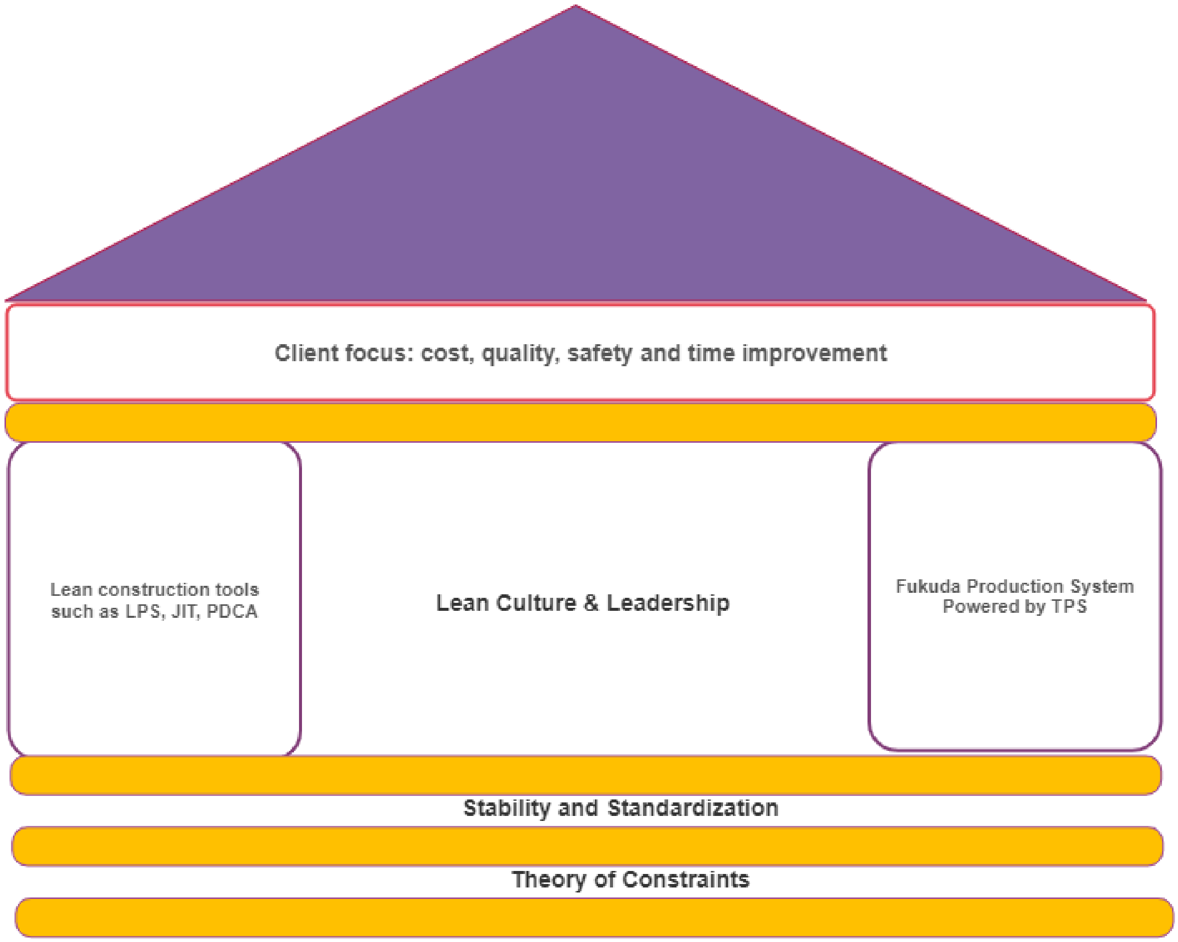

Figure 1: Conceptual Framework- Lean house with the theory of constraints

The lean tools are expected to be implemented in accordance with the TOC steps of identification, exploit, subordinate, elevate and repeat. These lean tools include the Last Planner System, Total Quality Management, Just-in-time and PDCA. The selection of lean tools should be based on context, usability in developing countries and the ability of the tools to contribute to the continuous improvement of construction operations. The other pillar encourages the adoption of the TPS principles as adopted within the construction industry as the FPS. The requirements of the two pillars can only be achieved through adopting lean leadership and organizational culture. All project actors must inculcate lean leadership and organizational culture for the guidelines to be successful. Using lean tools, the FPS principles must lead to cost, time, quality and safety improvements in construction operations. This is envisaged to be a continuous improvement process. The constituents of the proposed framework are briefly reviewed henceforth.

CONSTRUCTION OPERATIONS CONSTRAINTS

To improve construction operations in Zimbabwe, several changes are required in the aspects of cost, time, quality, and safety. Cost aspects require changes in respect of low productivity of the workforce, idle plant and machinery, material wastage on construction sites as well as plant and machinery inefficiency as these have caused poor performance of construction operations. Moreso, changes in time aspects are necessary, including low productivity of the workforce resulting in delays, ineffective coordination, and poor communication among stakeholders. There are also quality changes required to improve the quality performance of operations, and these are the occurrence of defects, reworks, use of poor quality materials, and poor workmanship. Finally, the safety aspects that require change are the number of accidents on construction sites, the frequency of absenteeism of workers from sites, high employee turnover, and low workforce morale.

The abovementioned changes are required to create simple and practical solutions to construction operations' cost, time, quality, and safety challenges. Therefore, effecting the changes suggested will result in increased productivity, less waste paying for idle plant and machinery, efficient use of materials and efficiency of plant and machinery hence improving cost performance of construction operations. Achieving the changes required for time aspects will result in enhanced productivity of the workforce, effective coordination of work, and effective communication amongst stakeholders, thus solving the challenge of delays. Moreso, changes in quality challenges will result in the minimization of reworks, reduced defects, improved quality of end products, and achievement of client satisfaction. Lastly, safety changes will lead to reduced accidents and incidents, reduced absenteeism, and employee turnover, thus increasing productivity and improvement in the morale of workers.

To build a secure and stable improvement environment for the changes required, the research proposes using the FPS, which was developed specifically for construction projects from the TPS. The FPS has principles that allow for performance improvement of construction operations by setting goals for the whole organization, individuals, and construction projects. The principles enable setting safety and quality standards on construction projects required for individuals, construction projects and the organization. Furthermore, these principles provide an improved environment for cost and time challenges. It allows for the identification and continuous reduction of waste, which is the main cause of cost and time overruns. Moreover, the principles allow for continuous improvement through its people-centred approach, realizing that performance can only be achieved if employees are trained, offered incentives for waste reduction, and involved at every stage.

LEAN CONSTRUCTION TOOLS

A plethora of Lean tools exists in the manufacturing and construction sectors. However, the nature of the manufacturing and construction industries varies with the relevant Lean tools (Moghadam and Al-Hussein, 2014). Therefore, selected lean tools relevant to the construction industry are reviewed in Table 1.

Also, the major findings and the constraints addressed in those studies are presented and analyzed for inclusion in the study's conceptual framework. It is practically impossible to operationalize all the suggested LC tools in this study. From the findings in Table 1, the LC tools most effectively responding to cost, time, quality, and safety include the Last Planner System (LPS) and Total Quality Management (TQM). LPS has been the most common LC tool utilized by many researchers, while TQM had a significantly high impact on individual performance, as reported by Li et al. (2019). In addition, the FPS suggests using the Just-in-time (JIT) and Plan, Do, Check and Act cycle (PDCA) on construction sites (Nakagawa and Shimizu, 2004). Therefore, this study has incorporated the LPS, TQM, JIT and PDCA tools for contextualization and standardization within the Zimbabwean construction industry to resolve the constraints of cost, time, quality, and safety. The LPS shapes workflow and responds to project variability in construction (Ballard, 2000). TQM ensures quality management of every stage of construction operations and continually invests in improvement opportunities (Radnor, 2000). The JIT tool reduces waste by ensuring the delivery of materials when required, while the PDCA periodically emphasizes safety, schedule, and quality improvements (Nakagawa and Shimizi, 2004).

Table 1: Lean construction tools from previous studies

Lean construction tools	Findings	Source	Constraints targeted
Last planner system	The proposed Last planner system could significantly improve productivity in developing countries.	Ahiakwo et al (2012)	Cost and Time
Last planner system, Increased visualization, The Five S's Process, Fail Safe for Quality and safety, First, run studies.	Although respondents agreed on their importance, their implementation could be improved by a lack of awareness.	Enshassi and Abu Zaiter (2014)	Safety
Last planner system	Success was achieved on sites where total management commitment was made towards lean tool implementation.	Raghavan et al (2014)	Time
5S, Quality control and Last planner system	The last planner system enabled the monitoring of improvement actions	Berrior et al. (2015)	Cost, Time and Quality
Last planner system	Existing gaps in planning and scheduling vs last planner systems	Dave et al. (2015)	Time
Planning and controlling the production, Kanban, Autonomation, Flows, Production, Transparency, Cleanness, organization and safety.	Lean audit checklist for the various sites' implementation of a standardized manual on lean tools revealed a positive contribution to project performance goals.	Fernandes et al (2016)	Cost, Time, Quality and Safety
Last planner system	The lean tool successfully contributed to the successful completion of four case study projects concerning cost, time and safety.	Karanjawala and Baretto (2018)	Cost, Time, Safety
Last planner system	Work involvement by the last planner improved the performance of the project.	Sundararajan and Madhavi (2018)	Time
Last planner system, a Visualization tool, Six step plan (6S), Just-in-time (JIT), Total quality management (TQM)	TQM had the highest impact on individual performance, while the Last planner system had the least.	Li et al. (2019)	Cost, Time, Quality and Safety
Last planner system	Implementation of the tool led to a positive impact during the COVID- 19 pandemic	Veran-Leigh and Brioso (2019)	Cost, Time, Quality and Safety

PERFORMANCE IMPROVEMENT

The competition in the construction industry has become intense, as evidenced by the large numbers of contractor companies in various countries, which has pressured contractors to minimize costs as much as possible (Bayram, 2017). For the success of construction projects, the ability to deliver a quality product safely is vital (Loushine et al., 2006). According to Buniya et al. (2021), poor safety performance has been a severe challenge in the construction industry. Construction projects are increasingly becoming more complex, competitive and collaborative. Hence timely delivery is critical nowadays (Kerzner, 2022). Delays in construction projects often affect the overall performance of projects in areas such as profitability, efficiency and safety (Gunduz and Al-Naimi, 2022). By addressing the root causes of cost and time overruns and quality and safety challenges, performance will be improved, leading to the success of construction projects.

CONCLUSION

The performance of construction projects in Zimbabwe has been an issue, with most of them failing due to cost overruns, time overruns, quality concerns and safety challenges. This was conceptualized to solve the mentioned problems, which perpetrate waste (non-value adding activities) in Zimbabwe through LC. By applying TOC to construction projects, contractors can identify, understand, and remove constraints in operations to aid work progress. Therefore, this study presents the preliminary step of a doctoral study, which should culminate in guidelines that inform how TOC and LC will become change agents in construction in Zimbabwe. The research will further elicit responses from industry participants to answer the research questions and draw up recommendations for the main study.

PERCEPTION OF PROJECT MANAGEMENT AMONG CONSTRUCTION WORKERS: A SURVEY IN DENMARK

Stephanie T. Salling[1], Cristina T. Pérez[2], and Søren Wandahl[3]

ABSTRACT

According to the Lean philosophy, continuous improvement relies on an investment in people, and Lean methods and tools cannot be sustained without labor. Hence, knowledge about workers' job satisfaction is highly valuable for improving the efficiency of the construction industry. For that reason, a survey was created and applied to understand the level of job satisfaction among construction workers in Denmark within three areas: (1) Project Management; (2) Work Environment; and (3) Health and Safety. The descriptive survey method was adopted as the primary research approach. The study comprised five steps: (1) link to the theoretical level; (2) survey design; (3) pilot test; (4) data collection; and (5) data analysis. This paper presents a part of the survey results concerning project management. The results reveal the most significant issues to be unrealistic commitment plans and poor communication with management and other stakeholders. Respondents generally feel encouraged to suggest improvements to the current practice, however, their knowledge about Lean concepts is very limited. The paper presents two contributions: (1) the identification of the perception of project management among construction workers in Denmark and (2) a survey template that can be applied by others to understand construction workers' job satisfaction levels.

KEYWORDS

Job satisfaction, survey, lean construction, collaboration, culture of respect.

INTRODUCTION

At the core of the lean philosophy lies the concept of increasing production efficiency by continuously eliminating waste, together with the equally important concept of "respect for people" (sometimes called "respect for humanity") (Howell et al., 2017; Liker & Meier, 2006; Ohno, 1988). According to the lean philosophy, continuous improvement relies on an investment in people, not equipment or systems (Hakes, 1991), and lean methods and tools cannot be sustained without labor (Emiliani, 2005). In other words, the "respect for people" principle enables continuous improvement (Emiliani, 2006). This concept does not mean creating a stress-free environment with lots of amenities for employees, rather it implies creating challenging environments in which people can learn and grow and are encouraged to raise problems to the surface (Liker & Meier, 2006). Employees are entrusted with more responsibility and authority, which makes them feel empowered (Marksberry, 2011).

[2] Assistant Professor, Department of Civil & Architectural Engineering, Aarhus University, Denmark, cristina.toca.perez@cae.au.dk, https://orcid.org/0000-0002-4182-1492

[3] Professor, Department of Civil & Architectural Engineering, Aarhus University, Denmark, swa@cae.au.dk, https://orcid.org/0000-0001-8708-6035

According to Howell et al. (2017), behaving in accordance with the "respect for people" principle promotes psychological safety. Psychological safety is a crucial motivating factor for engaging in learning behaviors in project teams, which leads to improved team performance (Bossche et al., 2006). Thus, implementing "respect for people" in the organizational culture can positively impact team effectiveness. The principle is also strongly correlated with job satisfaction (McKinnon et al., 2003).

Despite the emphasis in lean philosophy on the importance of respect for people, the principle is often misunderstood or left out in the implementation process (Coetzee et al., 2019; Emiliani, 2006). Considering the aforementioned dependencies, this could affect project performance and job satisfaction.

In a construction context, job satisfaction has also been identified as one of the most influential motivators for improved labor productivity (Kazaz & Ulubeyli, 2007). Hence, knowledge about workers' job satisfaction is highly valuable.

In 2016, the Danish trade union 3F conducted a survey among construction workers in Denmark to disclose the issues that the workers found to be most dissatisfying about their jobs (Dalsgaard et al., 2016). The answers showed that the most significant issues were: (1) many heavy lifts on site (reported by 59% of respondents) and (2) too much wasted time due to poor planning of the project (reported by 55%) (Dalsgaard et al., 2016).

Since the 3F national survey in 2016, no other studies have been conducted on a national scale concerning job satisfaction in the Danish construction industry. Moreover, to the authors' knowledge, no study has been made regarding the general perception of project management, health and safety, and the overall work environment among construction workers in Denmark. The present paper, therefore, presents a comprehensive survey designed to investigate these three themes.

The survey results are too comprehensive to present in full in this paper. Thus, the goal of this paper is understanding the level of knowledge and the subjective perception among construction workers on Danish construction sites of only one of the three themes, namely project management, including knowledge about Lean concepts. Moreover, this paper presents the contribution of a tool in the form of a survey template (available upon request) that other researchers and practitioners can apply to gain knowledge about job satisfaction in other countries. Of course, minor adjustments should be made to ensure relevance in the context where it is applied, e.g., regarding economy and ethnicities. Applying the same survey in other countries would make it possible to compare results and raise the general knowledge level in this important area.

LITERATURE REVIEW

Questionnaires have been widely applied in research to investigate various topics that affect job satisfaction and the mental and physical well-being of employees. Though the phrasing of topics and questions differ among studies, the overall themes are, in many cases, comparable. Table 1 summarizes the main themes treated in the identified previous literature on surveys of workers, mainly within the construction industry, but also including healthcare and social services.

As shown in Table 1, nine themes have been identified among the studies, namely (1) Workers' contractual characteristics, (2) Rewards, (3) Health and safety, (4) Relations with management, (5) Relations with coworkers, (6) Communication, (7) Worker engagement, (8) Work environment and culture, and (9) Project management. Some studies have included many different themes (Ahmad et al., 2020; Kazaz & Ulubeyli, 2007; Spector, 1985) while others focus on few themes (Dainty, 2007; Han et al., 2019).

Table 1: Themes Evaluated in Worker Surveys

Reference	(1) Workers' contractual characteristics	(2) Rewards	(3) Health & Safety	(4) Relations with management	(5) Relations with co-workers	(6) Communication	(7) Worker engagement	(8) Work environment and culture	(9) Project management

Gomez et al. (2019)			X	X	X	X		X	
Dalsgaard et al. (2016)			X			X	X	X	
Hosseini et al. (2014)		X	X	X	X		X	X	
Marzuki et al. (2012)	X	X		X	X			X	
Chileshe and Haupt (2010)		X	X	X	X		X	X	
Dainty (2007)						X		X	
Kazaz and Ulubeyli (2007)	X	X	X	X	X	X	X	X	
Che Hassan et al. (2007)			X	X	X	X	X		X
Spector (1985)	X	X		X	X	X		X	X

The first theme concerning workers' contractual characteristics is included in four of the identified studies under different topics, such as Salary package (Rani et al., 2022), Fulfilment of higher order needs (Marzuki et al., 2012), Timeliness of remuneration and Social insurance (Kazaz & Ulubeyli, 2007), and Satisfaction with pay (Spector, 1985). This theme is closely connected with theme 2, rewards, which was mentioned in six studies, whereof three were also mentioning theme 1. Besides the word Rewards (Marzuki et al., 2012), this theme has also been addressed with e.g., Recognition (Ahmad et al., 2020), Incentive payments (Kazaz & Ulubeyli, 2007), and Contingent rewards (appreciation and recognition) (Spector, 1985).

Health and safety, theme 3, is one of the most widely applied themes in the literature, included in ten of the 13 studies presented. The topics within the health and safety questions vary, some examples are Safety supervision and management (Asilian-Mahabadi et al., 2020), Psychological safety (Gomez et al., 2019), and Risk behavior (Che Hassan et al., 2007), besides the general Health and safety monitoring (Han et al., 2019; Kazaz & Ulubeyli, 2007; Rani et al., 2022).

Themes 4 and 5, relations with management and coworkers, respectively, are also closely connected. All studies that have included one have also included the other, except for Rani et al. (2022), where only the theme relations with management is included, referred to in multiple topics, e.g., Collaboration between top management and employees and Project leadership. Other studies phrase the relations with management theme in topics such as Leadership (Ahmad et al., 2020) and Supervision (Spector, 1985), to name a few. Topics regarding relations with coworkers (Chileshe & Haupt, 2010; Hosseini et al., 2014; Kazaz & Ulubeyli, 2007; Marzuki et al., 2012; Spector, 1985) are also called Teamwork (Ahmad et al., 2020) and Social activity opportunities (Kazaz & Ulubeyli, 2007). Theme 6, communication, is mostly referred to with the word communication, except in Kazaz and Ulubeyli (2007), where the topic is called Sharing problems and their results.

The topics that fall under theme 7, worker engagement, have more diverse wordings, such as Empowerment and participation (Ahmad et al., 2020) and Personal role (Che Hassan et al., 2007). Theme 8, work environment and culture, is represented through topics in ten of the 13 studies. Some examples of these topics are Migrant issues and Racism (Dainty, 2007), Caring about each other (Gomez et al., 2019), and Work discipline (Kazaz & Ulubeyli, 2007).

Theme 9, project management, is only being treated in a few studies. In the ones that include this theme, it is also being called Project progress (Rani et al., 2022), Contract management (Asilian-Mahabadi et al., 2020), and Operational procedures (Spector, 1985). Table 2 presents additional information on the 13 studies.

Table 2: Approaches Adopted in Worker Surveys

C=Construction; H=Healthcare; SS=Social Services; Q=Questionnaire; I=Interview; C=Checklist

It can be seen from Table 2 that the application of the questionnaires and interviews has been limited to a single country in all of the studies except Asilian-Mahabadi et al. (2020), which included both Iran, Oman, and Syria in their study. Moreover, only half of the surveys have more than 100 respondents. Consequently, the results cannot be used to draw valid conclusions in a broader perspective, such as nationwide or industry wide. Furthermore, some papers (Che Hassan et al., 2007; Dainty, 2007; Kazaz & Ulubeyli, 2007; Marzuki et al., 2012) do not include the applied questionnaire or another representation of the questions asked, which hinders further data collection.

Among the 13 studies, there is only one example of the same questionnaire being applied in a different setting to compare the results, namely the study by Hosseini et al. (2014) which reuses the survey developed by Chileshe and Haupt (2010). Even though there are many similarities between the studies, the different formulations and definitions of topics makes it difficult to directly compare the results, not least because different scales and indexes have been used to evaluate the survey responses. An alignment of surveys across countries would expand the possible learnings and uses of the results.

As mentioned above, only four of the 13 studies include the project management theme explicitly. However, almost all the other themes can be said to arise from project management, be it communication, relations, or contractual characteristics, as these are all results of decisions made within the project management team. Project management is a key element when it comes to understanding job satisfaction and is, therefore, chosen as the focus area for this paper.

RESEARCH METHODOLOGY

The study adopted the survey method as the main research approach. The present survey can be classified as descriptive (Babbie, 1990). Descriptive survey research aims to understand the relevance of a specific phenomenon and describe the distribution of the phenomenon in a population (Forza, 2002). The phenomenon of the present study consists of the job satisfaction of construction workers, and the survey population is construction workers on Danish job sites. The present survey comprised the following five steps (Figure 1): (1) link to the theoretical level; (2) survey design; (3) pilot test; (4) data collection; and (5) data analysis.

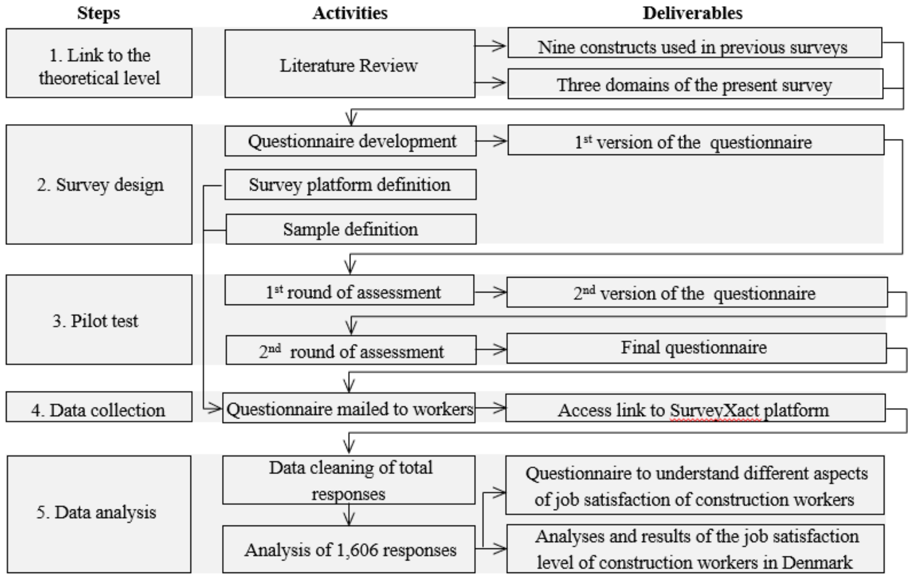

Figure 1: Research Methodology

STEP 1: LINK TO THE THEORETICAL LEVEL

In this step, the authors conducted a literature review to find questions and the constructs (i.e., theoretical concepts) that have already been used in similar studies. As presented in the Literature review section, the authors identified nine constructs generally used in job satisfaction surveys. Lastly, in this step, the authors selected the three main domains that the present survey focuses on: (1) Project Management (PM); (2) Work environment (WE); and (3) Health and Safety (HS).

STEP 2: SURVEY DESIGN

Survey design includes all of the activities that precede data collection. This includes developing the questionnaire and defining the sample. Firstly, the authors identified a comprehensive number of questions and statements from previous studies through the literature review. Then, the questions identified were grouped into the three domains (PM, WE, and HS). Moreover, the authors conducted a reduction of the questions considering their relevance to the construction sector and questions that were too similar.

Secondly, the study population was limited to all construction workers of Danish job sites who are members of a union, including foreign workers. The union membership prerequisite was chosen because it is very common to be part of a union in Denmark, and thus cooperating with the unions for the distribution of the survey provided an opportunity for a large number of potential respondents. Moreover, the survey used non-probabilistic sampling to obtain as much data as possible.

The first version of the questionnaire comprised 48 questions grouped into four sections of 12 questions: (1) demographics (Section 1, S1 for short); (2) project management (S2); (3) work environment (S3); (4) health and safety (S4).

STEP 3: PILOT TEST

The questionnaire was evaluated in two rounds of assessment. The first evaluation consisted of a two-hour online meeting. During this meeting, the group of researchers evaluated the questionnaire together with two industry experts from a professional cooperation organization for Danish unions in the construction industry, called BAT (Danish: *Bygge- Anlægs- og Trækartellet*). Following the experts' suggestions, some questions were added (e.g., S1.10 - Kind of contractual involvement of your company in the current project) and others were removed (e.g., I am satisfied with my involvement in decisions that affect my work).

Then, the questionnaire was reviewed and sent to the experts by e-mail for a second round of evaluation. Moreover, during this round, the access link to the survey platform was sent to the experts to test the viability of the administration of the survey. After making some minor modifications, the questionnaire was finalized. The final questionnaire comprised 39 questions distributed as follows: S1 included 12 questions; S2 included 12 questions; S3 included 8 questions; and S4 included 7 questions.

The questionnaire was initially developed in English and then translated into four other predominant languages spoken on Danish job sites, those being: Danish, Polish, Romanian, and Italian.

STEP 4: DATA COLLECTION

The questionnaire was distributed as a hyperlink included in an e-mail to the respondents. The hyperlink led to SurveyXact; the institutional survey platform used by the university of the researchers. The survey was open for answers from January 4th to 20th, 2023. To increase the probability of success of the data collection, the researchers included the opportunity for respondents to win a reward. This consisted of a draw among all the respondents of 10 giftcards.

STEP 5: DATA ANALYSIS

A total of 2,406 survey responses were collected. To ensure consistency through the presentation of the results, the responses where not all the 39 questions were answered were excluded, which left 1,606 responses for analyzing. The data analysis was conducted with Microsoft Excel. Due to space constraints, the data analyses presented in this paper are mainly descriptive. However, the questionnaire results can also be used for conducting diagnostic and prescriptive analysis.

The demographic profile of the respondents is shown in Figure 2 and Table 3. Most respondents are males (91%) and Danish (95%). About one third (32%) are carpenters, and 58% of the respondents work as skilled workers. The distribution of age and experience is well balanced and similar to the known characteristics of the construction industry.

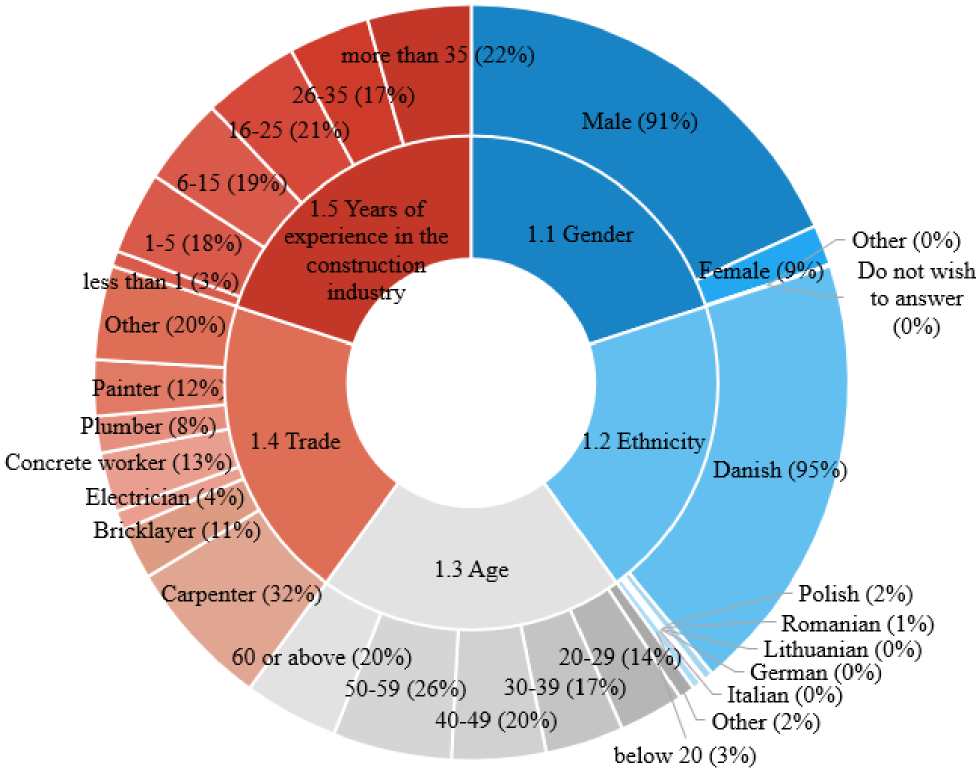

Figure 2: Demographic Profile of Respondents, Part 1

Table 3: Demographic Profile of Respondents, Part 2

Questions S1.6-S1.8		Frequency	Questions S1.9-S1.12		Frequency
6. Your position in the company you currently work in	Unskilled	15%	**9.Origin of the company you currently work in**	Danish	97%
	Apprentice	11%		Foreign	2%
	Skilled worker	58%		I don't know	1%
	Foreman	8%	**10.Kind of contractual in-volvement of your company in the current project**	Contractor	44%
	Other	8%		Subcontractor	34%
7.Years of experience you have in your current company	Less than 1	19%		Temp agency	1%
	1-5	40%		Other	10%
	6-10	15%		I don't know	11%
	11-15	8%	**11.Size of the current project**	Less than 1 mio DKK	23%
	More than 15	18%		1-10 mio DKK	24%
8.No. of employees in the company you currently work in	1	1%		11-100 mio DKK	14%
	2-9	18%		101-500 mio DKK	5%
	10-49	34%		More than 500 mio DKK	4%
	50-99	13%		I don't know	30%
	100-249	13%	**12.The kind of project you are currently working**	Civil works	15%
	250 or more	17%		New buildings	36%
	I don't know	4%		Building renovation	49%

RESULTS AND DISCUSSION

At the beginning of the Project Management section, the respondents were given a list of factors, which they were asked to rank using a 5-point Likert scale concerning the frequency of occurrence (Figure 3a). They were also asked to choose which two out of six communication issues that causes the most dissatisfaction for them (Figure 3b). Figure 3c shows the results of questions related to worker involvement.

The result of S2.1 (Figure 3a) shows that the factors that affect the flow of the project or cause delays the most according to the respondents are the commitment plan (M1 in Figure 3a) and space and communication issues (M6 and M10 in Figure 3a, respectively). The two factors with which workers are most dissatisfied are Factor 1 – Not getting enough information from their employers and Factor 6 – poor communication with other stakeholders. The results shown in Figure 3c reveal that more than 50% of the respondents never or rarely participate in planning meetings (S2.3). However, there is a widespread feeling that the management is committed to quality (S2.6), and only a minority of respondents feel like they are not encouraged to suggest possible improvements (S2.7).

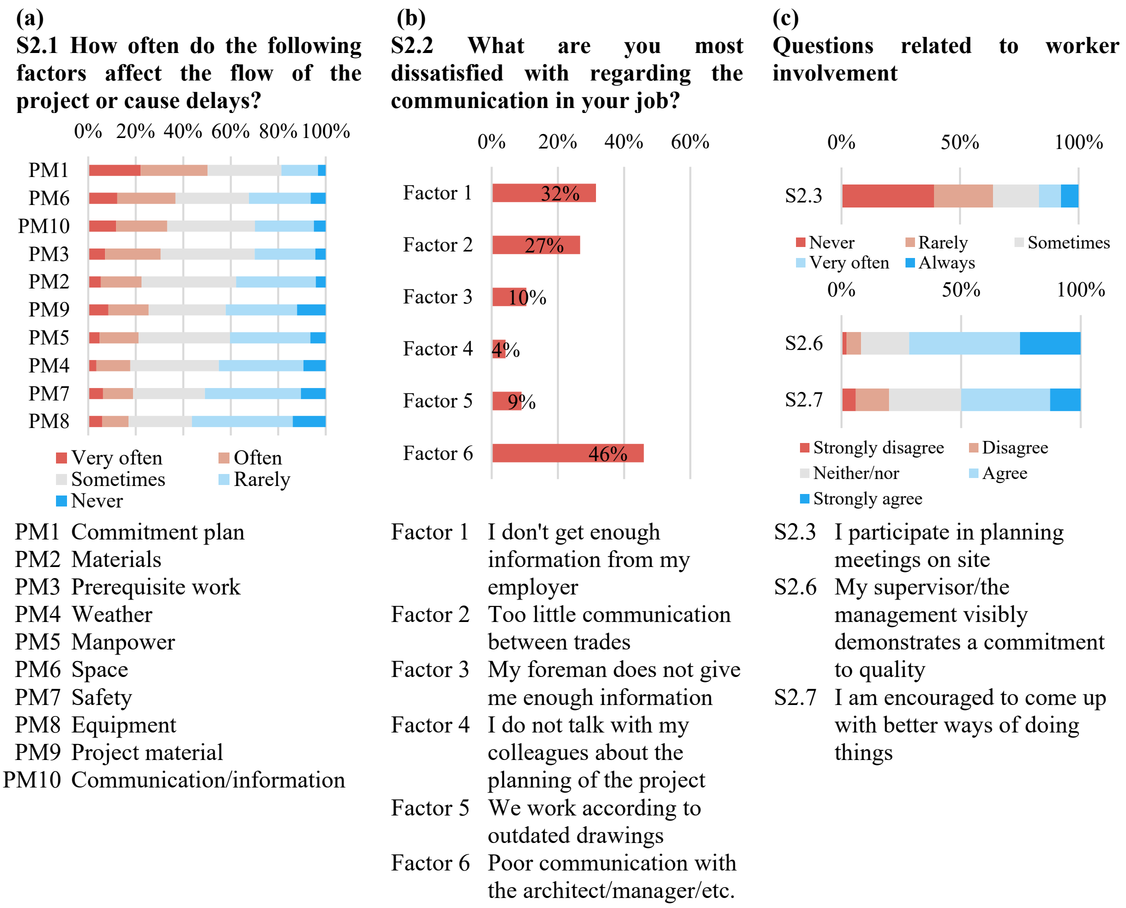

Figure 3: Results for Questions: (a) S2.1, (b) S2.2, and (c) S2.3, S2.6, and S2.7

The respondents were also asked about their knowledge of the project schedule and their own work tasks in the coming week and month. The answers are shown in Figure 4.

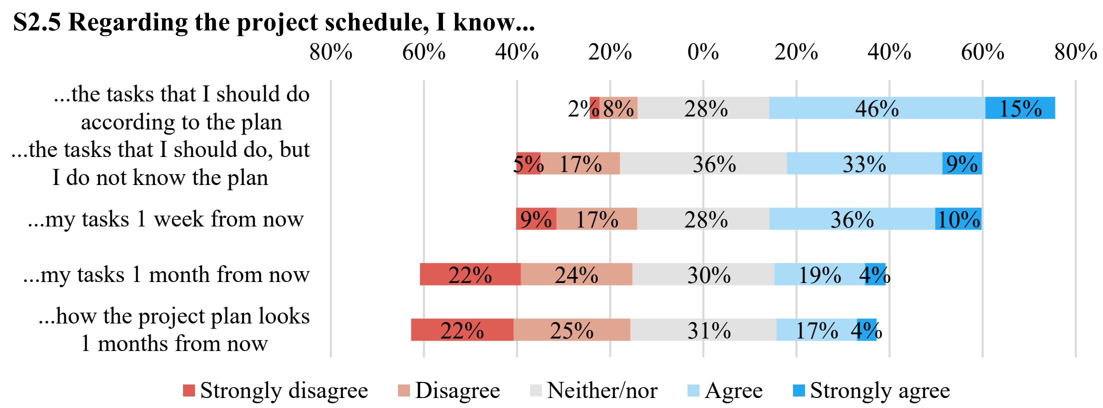

Figure 4: Results for Question S2.5

There is a significant difference in the respondents' knowledge about their imminent tasks compared to their tasks or the project plan in one month. While 46% agree or strongly agree to knowing about their tasks in the upcoming week, only 23% know what they will be doing in one month.

Figure 5 includes the results of questions related to the workers' perception of their time use. Almost half of the respondents (44%) feel they could use their time more efficiently (Figure 5a), and 57% feel that they waste 1 or 2 hours of their workday on unnecessary tasks (Figure 5b). This corresponds well with the result of S2.10B (Figure 5b) that shows 74% feel they spend at least half of their workday concentrating on their planned tasks.

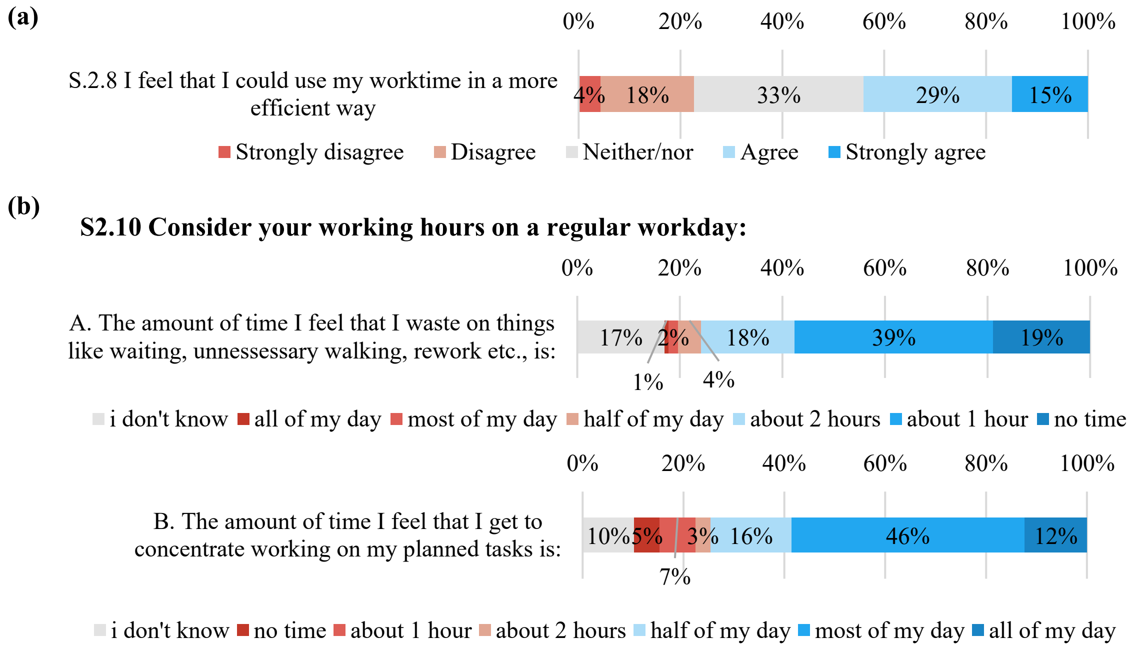

Figure 5: Results for Questions: (a) S2.8 and (b) S2.10 Concerning the Workers' Perception of their Work Time

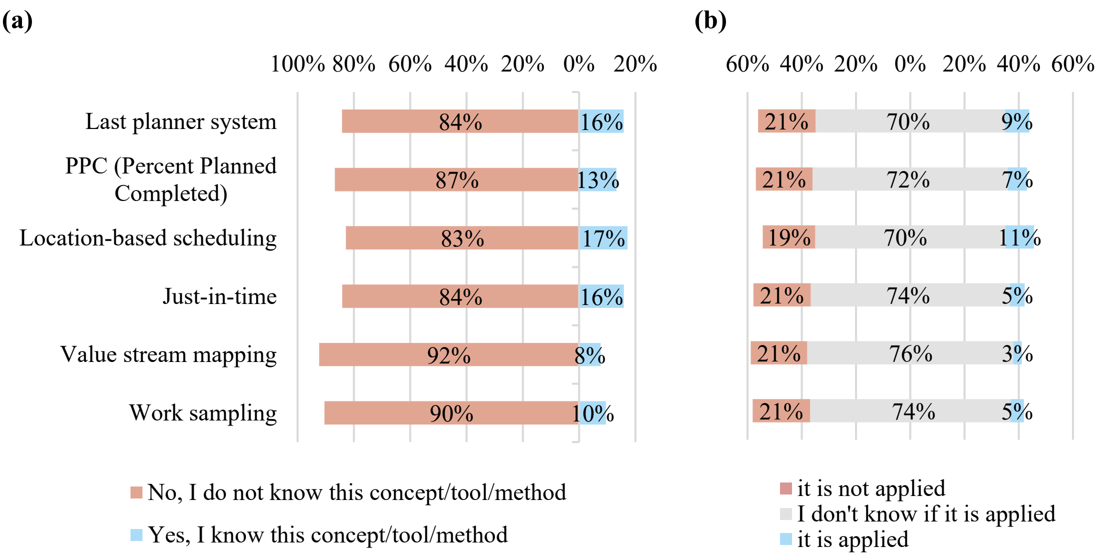

Figure 6: Results for Question: (a) S2.11 Regarding Knowledge, and (b) S2.12 Regarding Application of Lean Concepts/Tools/Methods

The PM section of the questionnaire was concluded with two questions assessing the respondents' knowledge of different Lean concepts/tools/methods (Figure 6). The answers are very clear; only between 8% and 16% of respondents know the six listed Lean concepts.

Consequently, the vast majority, between 70% and 76%, do not know if the concepts are applied in the project they are working on.

CONCLUSION

A high level of job satisfaction promotes psychological safety, which is crucial for workers to engage in learning behaviors and thus be able to improve their performance on construction sites. Psychological safety can be stimulated by acting in accordance with the lean principle of "respect for people".

This study presented a comprehensive job satisfaction survey, comprising aspects of project management, work environment, and health and safety. The survey was developed based on a literature review which included previous studies concerning surveys among workers. The review revealed nine recurring constructs. These formed the basis of the three aspects included in the present survey.

The survey was applied among construction workers on Danish construction sites. The results included in this paper focus on the project management part of the survey and are mainly descriptive. The most significant issues regarding project management are found to be unrealistic commitment plans and space and communication issues. The most dissatisfying factors among the respondents regarding communication are lack of information from their employer and poor communication with management. Most respondents never or almost never participate in planning meetings. However, they feel encouraged by the management to come up with better ways of doing things, which indicates that many employers are successfully creating challenging environments where employees are entrusted with authority, as suggested by Liker and Meier (2006) and Marksberry (2011). Another finding is that the workers' level of knowledge about the project plan and their own upcoming tasks is generally low when looking further ahead than one week. The results also clearly show that the knowledge of Lean concepts among construction workers in Denmark is very limited.

There is a large potential in connecting the survey results with the implementation of Lean on Danish construction sites (e.g., Percent Planned Completed), which did not fit within the length limit of this paper. This will be discussed in future publications.

Only a small part of the survey results is presented in this paper. Future publications will include more in-depth analyses of the results of all parts of the survey, including correlations of answers for different questions. Moreover, aggregated analysis based on demographic variables will be conducted, taking into consideration the impact of the demographic pattern of respondents.

The questionnaire developed for this study represents a tool that can be applied by other researchers and practitioners in other countries (template available upon request). This will provide opportunities to compare and learn from the differences and similarities in job satisfaction among construction workers in different parts of the world.

ACKNOWLEDGMENTS

The authors would like to thank the BAT organization for the collaboration and for providing access to their members. The authors are especially grateful for the help from Sidse Buch and Gunde Odgaard, and for the respondents who contributed to the study.

FRAMEWORK OF INTERACTION BETWEEN ICT, PROCESS, AND PEOPLE IN CONSTRUCTION: A CASE STUDY

Vijayashree TM[1], Paramjit Singh Lota[2], and Bhargav Dave[3]

ABSTRACT

The construction industry is often criticised for lacking a holistic view on applying Information and Communication Technology (ICT) to improve project efficiency. Integration of the three core organisational aspects of people, process, and Information Technology (IT) must be realised to bring true benefits in construction project delivery. However, the industry has not yet reached significant maturity in achieving this synchronisation.

The research follows a case study-based approach where the authors were involved in the implementation of an ICT solution that helped streamline project planning and execution through effective collaboration on a Data Centre retrofitting project in USA.

The research demonstrates the importance of effective communication through efficient information management by deploying ICT which helped overcome inherent process inefficiencies and challenges on the case study project. Based on the observations, the authors have proposed a framework that highlights the interaction of ICT, people, and process, and mapped the results achieved on this project through their integration.

Keywords – Construction Management, Information & Communication Technology, Process Management

INTRODUCTION

It is a significantly evidenced fact that construction projects are still struggling to deploy well-structured processes and automated workflows and tend to resist adoption of technology (Dave et. al., 2008). While ICT has proven to enhance collaboration and integration amongst stakeholders, rigid conventional processes and latent information continue to prove incompetent in addressing the rapid changes in design and environment leading to catch-up planning (Martinez et. al., 2017).

While there is evidence that ICT adoption has enabled project performance by changing the processes, successful implementation of any tool or process requires acceptance and involvement by the people involved in the project (Dave & Koskela, 2009). Research has highlighted the importance of reviewing Business Processes with a need to focus on integrating people with change management for the successful implementation of IT in construction (Dave, 2017). However, there is not enough evidence on the nuances of team culture and process change that have helped in effective deployment of ICT to improve project delivery.

Past studies primarily comprise of individual cases where the success and/or challenges of adoption of ICT towards improving project efficiency have been documenting, while highlighting the importance of integrating the essential aspects of people, process, and technology. However, these studies are often limited to case-specific observations and conclude

[1] Implementation Consultant, VisiLean, vijayashree@visilean.com, orcid.org/0000-0002-4552-0873
[2] Manager – Customer Success, VisiLean, paramjit.lota@visilean.com, orcid.org/0000-0003-4187-337X
[3] CEO, VisiLean, bhargav@visilean.com, orcid.org/0000-0003-4228-506X

with the importance of integrations of the three verticals without any specific clarity or structuring on the "how". These studies provide limited exposure to readers in terms of extrapolating these learnings into a broader methodology or framework that can widen the spectrum of the observations while also providing clarity on the integration and interaction of these critical aspects. The paper here addresses this gap by utilising the observations from this case study towards developing a structured framework that can guide fellow practitioners to take the first steps towards integrating people, process, and technology effectively.

While ICT has played a crucial role in streamlining construction project delivery, the research here dives deep into understanding where the improvement stems from, i.e., the tools adopted, processes that structure and enable participation, and the project culture that drives interaction of people in the teams. The authors believe that a framework will not only guide the industry towards more effective deployment of ICT but will also help them better understand the nuances of their own observations through this structured approach as they deploy this on further projects.

LITERATURE REVIEW

Construction continues to remain a fragmented industry with each participating team bringing in their unique experience and technical expertise. Dave et. al. (2008) highlight the negative impact of this structuring on the project culture which tends to create friction between teams and isolation of information.

Information Management Systems (IMS) have proven to play a critical role in enhancing collaboration within projects (Craig & Sommerville, 2006). Nigel and James (2006) have highlighted the role of IMS in efficient collaboration between the Architect, main Contractor, and sub-contractor leading to successful delivery of an office refurbishment project. A cultural shift towards information sharing was developed through this integrated approach using IMS. Effective collaboration has helped drive efficient decision making for project planning and control (Dave et. al., 2014; Cheng et al., 2013).

ICT continues to help drive improvement and efficiency in construction project delivery. Ambuja et. al. (2013) discuss the use of ICT in providing historical information of previous jobs that helped balance the supply and demand for accurate daily and weekly planning for a mechanical contractor. Mobile tools have a direct impact on decision making efficiency through instant access to accurate and timely information (Harstad et. al., 2015).

Martinez et. al. (2017) have evidenced the benefits of visualisation from ICT in reducing lead time through improved communication from effective information sharing for a large-scale affordable housing project. Visualisation offered by 3D & 4D CAD technology has enabled teams to take effective engineering and design decisions (Khanzode et al., 2005; Rischmoller and Alarcon, 2005).

The characteristics of ICT play an important role in driving project culture in the right direction. Tools that enable participation through simplicity and ease-of-use enable information sharing (Dave and Koskela, 2009) which allows for better integration between project teams (McHugh et. al., 2019).

ICT also has the potential to provide completely disparate versions of the same truth when disconnected sources of information are left open to interpretation by teams in isolation. Effective deployment of ICT must ensure a cross-disciplinary capture and reflection of data across all project teams to develop a shared understanding of product-organisation-and process design (Fischer and Kunz, 2004). The interface between people, process, and IT are the critical points to ensure successful implementation of ICT in construction (Rischmoller and Alarcon, 2005).

The literature reviewed highlights the importance of accurate information exchange and efficient communication in the construction industry, and the role that technology plays in making the process more streamlined and effective. Inefficiencies are common across projects in the industry with a false expectation from technology to deliver instant benefits on projects. The fact is that cultural change and process alignment are the foundations for adopting any new technology (Harstad et al., 2015; Ahuja et al., 2009).

RESEARCH METHODOLOGY

The research is built on a case study approach where the authors were involved in the implementation of ICT (*VisiLean* tool for project planning, execution and monitoring) in the project. The authors helped deploy the ICT tool by working closely with the project management consultants appointed by the client for this project. The authors' participation on the project was in direct capacity through involvement in planning and review meetings while ensuring the tool is used effectively based on the project team feedback and discussions during these meetings.

The case study focuses on the critical factors of ICT for enabling efficient information exchange and effective communication with a keen focus on the accurate alignment of project culture and processes.

Based on their observations, the authors have developed a framework of ICT, people, and processes, to map the interactions and results documented on this. The intent of the proposed framework is to provide a matrix of reference for project teams exploring benefits from ICT, as well as allowing researchers and industry to further contribute to the framework by adding their observations and results from other ICT implementation.

CASE STUDY

The case study is of a retrofitting project at a major data centre in central San Francisco. The project involved the replacement of 10 Power Protection UPS (Uninterruptible Power Supply) units, that provide emergency power backup in the event of a sudden blackout (complete loss of power) or a brownout (temporary dip in voltage). These units are critical to ensure reliable 24x7 operation and protection of the hardware and file systems housed in these data centres.

The project client onboarded a project management and consultancy business in USA, with extensive experience of working on time-constrained, technically complex Data-Centre projects, cloud providers, and their supply chains, to help drive performance improvement through efficient project management methodologies that help streamline construction project delivery.

Various ICT solutions were adopted in this project, amongst which a tool called *VisiLean* was onboarded by the project management consultant for enabling collaborative planning and production control. The authors participated on this project by providing active support for the implementation of this ICT tool, *VisiLean,* by facilitating various collaborative planning and review sessions and working with the project team to ensure the implementation of ICT is aligned with their requirements.

PROBLEM DISCUSSION

The onboarding of an expert consultant along with the ICT solutions was a gradual approach towards overcoming the challenges specific to the project. The major challenges have been documented below to give context to the inclusion of ICT and the benefits achieved therein.

Installation of a new Product

The supporting contractors had no prior experience or background to install this type of equipment. With completely new configuration and operational procedures, without any guidance from the supplier, the team had to carefully understand and develop a strategy to transport, install, and test this equipment. This is also why the Client introduced an expert consultant with prior experience in working on mission-critical data centre projects.

Environmental Factors

The Data Centre was housed in the top-floors of a space constrained building in a congested street with limited access. Further, the Data Centre had to continue operations throughout the replacement of the units, maintaining uninterrupted service to customers across the globe customers. COVID -19 added further restrictions in terms of reduced manoeuvrability inside the building and additional cleaning of spaces and equipment, with stringent protocols to abide by. Simple operation of getting people in and out of the facility had to now follow specific paths and hallways, proving to be quite challenging.

Management of a diverse Team

The team deployed on the project had no past interaction or experience of working together. Everyone came with their unique culture with varying perspectives on technology. The different levels of exposure to ICT ran across a very wide spectrum – while some people were familiar with advanced 3D and CAD technologies, the others were still used to a paper-and-pencil approach. Further, while some teams believe in a data-centric project delivery approach, this team was more used to a people-centric approach, i.e., driven and lead by a key person who takes charge and defines the processes.

Information Management Challenges

With the onset of COVID and the limitations to physical interaction, the dependency on sharing information remotely increased significantly. Conventionally, the reliability of information the project team was presented with was also highly questionable. Further, the scope of information was also very limited, because of which a lot of assumptions would have to be made.

Due to a lack of common understanding between project teams, information was usually misinterpreted. Understanding of the problem statement varied across the project team, since there was no single source of truth, or common understanding of the data available. A combination of limited communication, lack of common understanding, and poor or inaccurate information led to ill-will and a culture of blame game. This created a toxic environment of negativity and uncomfortable conversations, which leads to people hoarding information.

It was difficult to collect everyone together physically in the same place at the same time. This led to limited interaction between project teams, leading to high social and trust barriers, limiting the scope for deeper, rich, conversations.

Problem Resolution with an Integrated Approach

Given the nature of the project and problems identified, the project team was pushed to evaluate ways to overcome these challenges to deliver the project within time and budget. Building on these challenges, the team was able to clearly define a set of requirements for which various ICT solutions were onboarded. Supporting this deployment was the expertise provided by the consultant that was able to curate the adoption of ICT with the right changes in processes by working closely with the teams at the ground-level to help build a culture of participation and good-will towards the project.

With the onset of COVID, the now dispersed project team shifted to connecting remotely by having their project meetings online. The teams could no longer be always present physically at the site for logistics planning as well. Online platforms were chosen to stay connected with the people as well as the site. Laser scans of the facility were used by the teams to virtually manoeuvre through the project site for accurate logistics planning by gaining a clear understanding of the environment challenges. The team was able to visualise the product and process design to develop an installation strategy with accurate information about the facility from these scans, and detailed specifications of the units to be installed. The project team had technical experts from Netherlands, Texas, Washington State, etc. who could join these meetings effortlessly. This helped the team accelerate the process of problem resolution and decision making.

To ensure effective information management even through remote connectivity, the teams deployed a Common Data Environment (CDE) where all project data was stored, barring financial information. Every project member was provided access to the CDE platform - Autodesk® BIM360™ a cloud-based platform which hosted design specs, facility layouts, etc. The intent was to democratise the information, ensuring everyone has access and visibility to all the project related data. The teams would mark-up 2D drawings, design documents, etc, for planning discussions and further information to develop a common understanding of the execution strategy. This was then discussed during the online meetings, so that the entire team was aware of the changes and the comments.

VisiLean, a cloud-based platform was deployed replacing Microsoft Excel® and sticky-note planning to collaborate with teams for accurate production planning, live monitoring of execution, and project control. With real-time updates from site on VisiLean providing clarity on work status, the team could take ownership of the tasks to be executed, and make any adjustments live with the entire team.

The visualisation of the production plan and the environment information gathered through the laser scans and live updates helped in understand the status of the job there. With synchronised information for everyone, the team was able to develop a common understanding of how the work can be executed in the best possible manner. Having this visualisation of information from ICT helped choreograph the sequence of event in sync between all trades with the right timing.

The team was able to drive efficiency in their use of project assets by understanding each phase and optimising the work and resources in sync to mitigate any risks. This approach helped provide evident savings in labour spend and direct cost to the facility owner.

Results Achieved

It is essential to evaluate the post implementation of such tools for continuous improvement. Hence, the implementation of these ICT solutions and process changes within the project team was evaluated to come up with the attained results discussed below.

- **Mistake proofing:** The team was able to limit human error and variability to ensure the project are developed as intended/designed. With ICT, the team moved away from a very paper and people driven approach which removed the heavy dependency on limited human resources for information. By reviewing the data live and together on a common platform, the team could come to consensus democratically. This proved to be transformational for the project by ensuring minimum surprises on-site and completely removing a blame-culture.
- **Information Transparency:** The project team utilised the CDE as the collection point for all project documentation – drawings, schematics, laser scans, etc. This helped develop the idea of one-team amongst the people. Once the team unravelled how one’s work impacted the other down the line, it made a huge difference in their approach to planning. This was done through transparency achieved from using VisiLean, which made these relationships clear and evident to the project team.
- **Visualisation:** Laser scans of the facility were added to the CDE to overcome the environmental constraints mentioned earlier. Project teams could access the entire facility though the scans remotely, visually survey and navigate through the spaces, to figure out the best way to approach the job. They could work out the ingress and egress accurately to work out the exact path for manoeuvring the equipment.

- **Single Source of Truth:** Having access to all this project information without gate keepers made it the single source of truth. In fact, the more people used it and contributed to it, the more information flew into it, thereby creating an approach of sharing, rather than hoarding information. The more one contributes to this information, the more valuable they become to the team, creating rich participation and collaboration.
- **Integration:** The teams would connect remotely using Zoom and other video conferencing tools that enabled them to work from their home offices. This way, even more data came flowing, with technical experts joining from Netherlands, Texas, Washington State, etc. The teams could leverage these tools for clear, valuable conversations, by looking at the same information – the single source of truth. This way, the team could develop a common understanding of the project, common reality, by clearly visualising what the challenges would be, mark them up on drawings, scans, and layouts using ICT, and do all of this remotely, saving the cost of bringing these experts on site. All this information would be transcribed back to the CDE as a captured log of discussed information, following which the tool would automate the process of disseminating this information to the relevant actors for further action.
- **Performance Improvement:** With the installation of each unit, the team was able to review their workflows for its successes and failures, from real-time updates captured on VisiLean from the project site. With this information, the team could review the scope for improvement and then discuss this analysis collaboratively to optimise the sequencing of activities for the next unit.
- **Collaboration:** The team was most successful in realising the importance of adjusting their processes according to the technology deployed. Their primary view was data, and to harness it most effectively, the team focused on revising their processes towards how the data was received, processed, and analysed. The teams started to overcome barriers to technological maturity by getting everyone together and developing a sense of comfort by discussing experiences and backgrounds. Once a level of trust was established, the introduction and absorption of the tools deployed on the project became less resistive.

PROPOSED FRAMEWORK & INTERACTION MATRIX

The results achieved on this project were a direct outcome of process and cultural changes adopted by the project team complimenting the deployment of the ICT solutions. To elaborate on these findings, the authors have proposed a framework that is built on the interaction between people, process, and technology towards streamlining construction project delivery through improved processes, better project culture, and ICT enabling these results.

From the case study, the value propositions attained from the people and process aspects, along with the various ICT solutions used on the project have been highlighted as a matrix of interaction in the proposed framework (Table 2). The interaction matrix acts as a frame of reference for the industry to apply on their projects towards overcoming specific challenges with the help of ICT, while coupling it with the right value proposition from the process changes and project culture.

The value propositions have been derived from the case study observations and results achieved. These have been then categorised by the authors between the aspects of people and process, based on their respective characteristics and alignment. For example, *clear communication* is an aspect of a *process* where information is structurally shared, while the *ownership of that information* cannot be guaranteed by the process; it is an aspect of *people* and their sense of responsibility towards that work and information.

Similarly, while a production management tool can prove to be very effective, it cannot guarantee *clear communication* till the *people* utilises the tool through an online meeting platform to discuss through *rich participation*. However, with *clear ownership*, the tool can guarantee a *sense of appreciation* for the *people* since their progress, work, and contribution is now clearly documented and visible to all.

It is through these various lens that the authors have layered this intricate framework of interaction together to map out a structured approach towards arriving at attainable project outcomes. While neither of the three components are exhaustive and all-encompassing, they are true to this project and a step towards their further applicability on projects across the industry.

Specific to the case study, the interactions have been mapped to highlight the benefits attained from the ICT adoption and the interaction of people and process therein. As an example, drawing on the adoption of a CDE platform, the project team was able to establish clear communication, democratise information and decision making, and understand the impact of work between trades. This helped develop a sense of appreciation, trust, and enable the contribution and ownership of information, which in turn created a positive work environment. This enabled complete information transparency between the project teams, thereby making CDE the single source of truth for the project.

Similarly, to overcome remote connectivity and limited access to the project site, the team used laser scans to develop a common understanding of the facility to help prepare for the logistic challenges by visualising the sequence of work better. This work clarity helped in reducing assumptions, thereby allowing the team to make effective decisions despite barriers to physical interaction.

The proposed framework is open to addition by the industry from their experience of value attained in processes and cultural aspects on their projects based on ICT solutions implemented. The goal of this framework is to offer flexibility and scope for further development in future research, by both industry practitioners, as well as fellow researchers.

Table 2: Framework & Interaction Matrix of ICT, Process, and People

ICT	VALUE PROPOSITION	Common Data Environment (CDE)	Markups on 2D layouts	Laser Scans	Online Meeting Platforms	Production Management Tool
PROCESS	Clear Communication	X			X	
	Democratising information & decision making	X	X			
	Understanding impact of work between teams	X			X	
	Shared view to problem solving		X			X
	Remote access to project site			X		
	Better work preparation			X	X	X
	Remote collaboration with teams				X	
	Accurate visualisation of flow of work			X	X	X
	Better assessment and review of performance					X
	Reducing variability		X			X
PEOPLE	Ownership of information	X				X
	Rich participation	X			X	
	Sense of appreciation	X				X
	Common understanding of project			X	X	X
	Builds more trust, Reduces blame culture	X	X			
	Selfless sharing of information	X	X		X	
	Reduces Assumptions, Clear decision making		X	X		X
	Overcoming barriers of physical interaction	X		X	X	X
	Willingness to improve		X			X
RESULTS ACHIEVED ON THIS PROJECT		Single source of truth Information Transparency	Mistake Proofing	Visualisation	Integration	Collaboration Performance Improvement

DISCUSSION

It is evident from the case study that the team deployed ICT towards streamlining construction project delivery by taking ownership of work, resolving clashes between work packages, and taking control over the risks posed by the project environment. However, it is important to note that the success is evidently credited to the adoption of the new processes offered by the technology, thereby marking a cultural shift. Some of the key points of discussion from the case study are listed below.

- **ICT enables trust and collaboration in the team:** A common platform enriched by information removes the barriers to communication and helps build an environment of trust and support. This is essential for teams to come together towards problem solving, rather than pushing the problem across one-another. While tools promise collaboration, it is important to understand that while technology does enable collaboration, it does so through the provision of accurate information that helps build the collaborative environment.
- **Renewing Processes is Key**: Adding technology on existing processes that haven't proven beneficial will just bring the processes to failure point a lot faster. ICT cannot do improvement on its own unless we allow the new technology to create new processes. With the right alignment of new tools with new processes, the team can enable an environment of least resistance to focus on driving efficiency in project delivery, rather than focusing on overcoming cultural resistance towards the new technology.
- **Technology is not a direct Solution:** Adoption of any new technology does not guarantee success unless the people are ready to make a cultural shift in their work processes. The key to enabling efficiency through ICT is the richness and accuracy of the information provided, the simplicity of its dissemination across the project team, and the ease of contributing to it. All these factors collectively contribute to define processes that support the technology adopted towards its full utilisation that finally helps to improve project delivery workflows.

While all three aspects are interconnected, interdependent, and equally important, the industry has struggled to integrate these effectively since decades. While it might not be a one-size-fits-all, a framework of this manner has the capability to offer the first steps towards understanding the nuances of these three aspects to then build on further.

CONCLUSION

The construction industry continues to be plagued by major challenges stemming from inefficiencies in its core processes. A significant credit for scope of improvement is given to the implementation of ICT in the industry. However, the notion of plugging in a tool and expecting improvement in overall productivity and benefits to the project and the team has proven to be a narrow perception in the industry. Previous research reinforces the drawbacks of this perception and necessitates the implementation of a holistic approach to streamlining construction project delivery.

This research addresses the misalignment of the three core organizational aspects of construction - ICT, process, and people, by proposing a framework of their interaction. Building on their observations and experience on the case study project, the authors map the interaction between the tools deployed and the value impact on the processes and team culture to highlight their complex interdependency.

The interaction matrix can be applied and referenced on other projects to further explore the value proposition from project processes and culture with the adoption of new tools and technology. The interaction matrix depicts how the three aspects function in sync with each other to achieve specific results that can help drive project performance.

LIMITATIONS

The authors acknowledge that the framework is built from a specific case study where limited tools under the ICT umbrella have been deployed with select participants and a set of value propositions have been studied. However, the authors would like to reiterate that this framework is built as a starting point for fellow researchers from the scientific community as well as industry practitioners to further contribute their observations and learnings to. This will help build the framework with more tools, more value propositions, and feedback from their teams to make it more effective and useful for the wider community in the construction industry.

WORKER INVOLVEMENT STRATEGIES IN CONSTRUCTION: INSIGHTS FROM THE LEAN LITERATURE

Hugo Sefrian Peinado[1] and Dayana Bastos Costa[2]

ABSTRACT

The Human-centric approach concept establishes that human needs must be at the center of the production process. Human needs models propose a sense of belonging among these necessities since people require appreciation, collaboration, and involvement. In this work, the Employee Involvement (EI) concept relies on developing the workers’ sense of belonging to the organization and allowing these workers to change the work environment. Despite the potential contributions, papers systematizing EI strategies in the construction industry were not found in the literature. Therefore, this paper aims to identify worker involvement strategies in construction based on the EI concept in the Lean Construction literature. The research method adopted was a Systematic Literature Review (SLR). A total of 12 papers were considered eligible for this review. 12 EI strategies were identified and analyzed based on three constructs: upskilling workers, communication, and autonomy for decision-making. The results reveal that there are still few empirical studies. Furthermore, the strategies are based on the managers’ and researchers’ points of view, not considering the workers’ points of view. However, the presented strategies and discussion might be considered in elaborating and implementing the HC approach for construction. A set of questions was elaborated to support future research.

KEYWORDS

Employee empowerment, Employee participation, Industry 5.0, Lean construction 4.0.

INTRODUCTION

The human-centric (HC) approach is defined as placing the main human needs and interests at the center of the production process (Breque et al., 2021). Lu et al. (2022) bring a similar understanding, pointing out that manufacturing should be HC by positioning the well-being of the industry workers at the production process center. This concept is referred to as one of the cores of Industry 5.0 (Breque et al., 2021; Lu et al., 2022) and Lean Construction 4.0 (Hamzeh et al., 2021; González et al., 2023).

Lu et al. (2022) summarize the needs of workers in manufacturing based on the hierarchy of basic needs presented by Abraham Maslow in 1943. Wahba and Bridwell (1976) and Ward and Lasen (2009) also present other models that discuss human needs. However, the hierarchy proposed by Maslow (1943, 2017) is widely disseminated and used worldwide (e.g., Zhao et al., 2015). Furthermore, it refers to humans (Maslow, 2017), not specifically those who integrate an industrial sector. Thus, these aspects will also be considered necessities of construction workers.

[1] PhD Student, Structural and Construction Engineering Department, Federal University of Bahia, Salvador, BR, hugospeinado@gmail.com, orcid.org/0000-0001-7868-0219

[2] Associate Professor, Structural and Construction Engineering Department, Federal University of Bahia, Salvador, BR, dayanabcosta@ufba.br, orcid.org/0000-0002-1457-6401

The five levels of human needs specified by Maslow (2017) are physiological (bottom), safety, love/belonging, esteem, and self-actualization (up). Based on this and in discussion with specialists, Lu et al. (2022) proposed the “Industrial Human Needs Pyramid”, also integrated into five levels, from bottom to up: safety, health, belonging, esteem, and self-actualization. Although this model needs to be analyzed to determine if it can be fully applied to construction workers’ context, this paper focuses on the third level, related to the need for belonging, presented in both models (Maslow, 2017; Lu et al., 2022). Lu et al. (2022) define the sense of belonging as human emotional needs for interpersonal relationships, affiliation, connection, and being part of a group. Some aspects of this need rely on appreciation, collaboration, and involvement.

Employee involvement (EI) is an important concept regarding this topic. Traditionally, employee involvement has two goals. The first consists of developing a sense of belonging to the organization through high commitment. The second refers to allowing the worker to change the work environment by giving suggestions that improve the organization's performance (Tortorella et al., 2021; Welikala & Sohal, 2008).

Employee involvement in the pursuit of continuous improvement has been widely discussed in the literature on operations management, industrial relations, work process, and human resource management (Hernandez-Matias et al., 2020). According to the authors, EI is a fundamental feature of continuous improvement programs.

EI has also been described as employee empowerment (EE) for decision-making and problem-solving at his/her organizational level (Tortorella et al., 2021; Welikala & Sohal, 2008). According to Sun et al. (2000), this understanding is based on the premise that the worker directly involved with a set of specific tasks is in the best position to decide and improve the process related to these activities. Another conceptualization proposed by Dimitmades (2001) highlights that empowerment refers to allowing and supporting the organization’s human resources to make efficient, effective, and high-quality decisions, leading to continuous improvement. Thus, Vidal (2007) emphasizes the need to increase the responsibility of frontline workers and improve their skills to perform these new demands.

Different terms can be found in the literature to which similar meanings were attributed, which are: involvement (Koskela, 1992; Hasle et al., 2012; Hernandez-Matias et al., 2020; Sun et al., 2000; Tortorella et al., 2021; Welikala & Sohal, 2008), empowerment (Koskela, 1992; Dimitmades, 2001; Vidal, 2007; Welikala & Sohal, 2008), participation (Sun et al., 2000; Tortorella et al., 2021; Welikala & Sohal, 2008), engagement (Liker, 2004; Hernandez-Matias et al., 2020; Tortorella et al., 2021) and commitment (Hernandez-Matias et al., 2020; Welikala & Sohal, 2008). This paper focuses on the first three terms presented since the last two terms also incorporate other meanings. Furthermore, employee, worker, and frontline worker are considered synonyms in this research.

The workers’ involvement has been a study subject by researchers in Lean Production/Lean Management (Beraldin et al., 2022; Hasle et al., 2012; Hernandez-Matias et al., 2020). Hernandez-Matias et al. (2020) named ‘soft-lean practices’ the ones aimed at workers' and managers' involvement and commitment to promoting the system's human aspects. The authors also emphasized that EI/EE are lean practices related to workers, using the terms employee's HRLP (human-related lean practices) to designate these practices. In the context of the Toyota Production System (TPS), Liker (2004) points out that the non-use of workers' creativity is a type of waste (a practice that does not add value). According to this author, this waste occurs when there is no use of time, ideas, skills, or opportunities for learning and improvement by not engaging or listening to workers. Among the 14 principles of the “Toyota Way” presented by Liker (2004), the sixth principle associates the empowerment of workers with continuous improvement.

Aligned with the lean literature, Hernandez-Matias et al. (2020) highlight that the involvement of workers for continuous improvement refers to organizational practices that, when implemented consistently, promote a constant increase in worker motivation and opportunities for improving products and processes.

Within the scope of Lean Construction, Koskela (1992) points out that the concept of employee involvement emerged from efforts aimed at Just-in-Time (JIT) and Total Quality Control (TQC). According to the author, there are several reasons for the empowerment of construction workers, including the need for quick responses to problems. Koskela (1992) also points out that continuous improvement depends on workers' daily observation and motivation.

Despite the potential contributions, papers systematizing strategies for employee involvement in the construction industry were not found in the literature. Besides, Noueihed and Hamzeh (2022) and González et al. (2023) raised important questions to be addressed by future research related to the social impacts of Construction 4.0, which are strongly related to the HC approach concept. One question regarding this review's topic is how to include/involve workers in the design and implementation of new construction processes.

Therefore, this paper aims to identify worker involvement strategies in construction based on the EI concept in the Lean Construction literature. Understanding the existing employee involvement strategies in the LC approach is essential for pondering possible paths to implement the HC approach in construction processes.

LITERATURE REVIEW

Involvement is not a technique but a philosophy that demands a transformation in how organizations are designed and managed (Dimitmades, 2001). As argued by Sun et al. (2000) and Welikala and Sohal (2008), for effective worker participation, it is necessary that responsibility in decision-making and the power and autonomy to act at their organizational level be delegated to these workers. Participation without attribution of power will result in unaccepted suggestions, leading to frustration and potential demobilization of workers in contributing to the organization's performance (Sun et al., 2000).

Welikala and Sohal (2008) and Dimitmades (2001) highlight two workers' empowerment tools available for application by managers: participatory management and self-management. In participatory management, workers receive partial authority and responsibility in decision-making and are encouraged to present their ideas for the organization's continuous improvement in all its aspects. In the case mentioned, implementing the ideas is up to the managers. In self-management, workers are given full authority and responsibility and held accountable for their actions. This autonomy and responsibility refer to presenting new ideas and implementing these proposals. The authors point out that the choice between these two tools will depend on the scope of responsibility and authority to be attributed to workers. Dimitmades (2001) highlights that total empowerment may not be appropriate for all organizations or workers. Thus, it recommends that managers conduct a comprehensive assessment to determine the empowerment strategy that best fulfills the organization's demands.

Despite the implementation of EI strategies being significantly frequent in manufacturing (Hernandez-Matias et al., 2020; Tortorella et al., 2021), the literature indicates a gap regarding applying EI strategies in construction and the systematization of the existing strategies (Lehtovaara et al., 2022).

RESEARCH METHOD

The research strategy adopted is the Systematic Literature Review (SLR). According to Dresh et al. (2016), SLRs are studies to map, find, critically evaluate, consolidate, and aggregate the results of relevant primary studies on a specific research topic. The gap found in the literature related to the systematization of EI strategies in construction was divided into the following question: 1) What are the strategies for upskilling workers to contribute to their participation in the design/implementation of lean processes in construction?; 2) How can communication between workers and managers be performed?; 3) How to assign responsibility and autonomy for decision-making to workers in the context of Lean construction? The research process is illustrated in Figure 1.

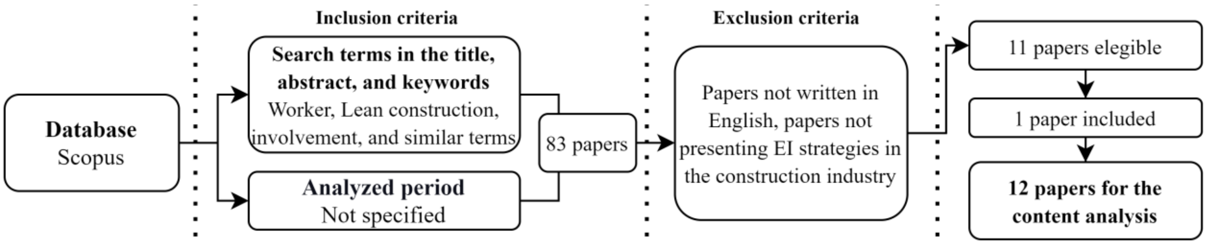

Figure 1: SLR research process adopted

The research process was composed of the definitions of the database, the inclusion criteria, the exclusion criteria, and the content analysis. The database adopted was Scopus since this search engine covers many journals and some proceedings related to construction management.

The following string was used as inclusion criteria: “TITLE-ABS-KEY ((employee* OR worker* OR workforce) AND (“lean construction” OR “lean production” OR “World Class Manufacturing”) AND construction AND (involv* OR empower* OR participat* OR engag* OR commit*))”. Papers on the subject were read to determine the most appropriate terms for the search string. Tests were made to select relevant terms and discard those that did not increase the number of publications during the search. No search period was specified. Eighty-one papers were identified at this stage.

Two exclusion criteria were adopted: discarding papers not written in English (due to the universality of the language) and not presenting EI strategies in the construction. From this stage, 11 papers were selected. If the paper presented only a part of the study addressed worker involvement strategies, the study was considered eligible for this SLR. A short paper that fulfills the criteria was also added, which was not located by the Scopus search.

The papers considered eligible for this review were analyzed and discussed based on three constructs highlighted by the scientific literature as important processes for EI: upskilling workers, communication, and autonomy for decision-making. **Upskilling workers** means improving their abilities to face new responsibilities (Vidal, 2007). **Communication** refers to improving the communication between managers and workers (Sun et al., 2000; Welikala & Sohal, 2008). **Autonomy for decision-making** refers to the attribution of responsibility to the workers for decision-making and autonomy for action at their level in the organization (Sun et al., 2000; Dimitmades, 2001; Welikala&Sohal, 2008; Tortorella et al., 2021).

RESULTS

The sample included two journal papers (16,7%) and ten conference papers (83,3%). Regarding journal papers, one was from the International Journal of Occupational Safety and Ergonomics (2021) and one from Frontiers in Built Environment (2022). Of the conference papers, eight were from the Annual Conference of the International Group for Lean Construction (IGLC) proceedings (2011, 2014, 2015, 2019, two in 2020, and two in 2021), one from European Modeling and Simulation Symposium proceeding (2017) and one from the International Workshop ‘When Social Science meets Lean and BIM Towards Industry 5.0’ proceeding (short paper) (2022). This section presents the content analysis.

The strategies identified in the lean literature for involving construction workers are presented in Table 1, divided into three groups: ‘upskilling workers’, ‘communication’, and ‘autonomy for decision-making’.

Table 1: Systematization of The Strategies Identified in the Analyzed Papers

Authors	Workers’ involvement strategies
Group 1: **Upskilling workers**	
von Heyl (2015)	Simulation game
Santana et al. (2017)	Educational animation
Hamzeh and Albanna (2019)	Training using non-digital games
Pütz et al. (2021)	Gamification components in LC training
Jacobsen et al. (2021)	Gaming environment involving multiple players simultaneously in virtual reality for LC training
Group 2: **Communication**	
Valente and Costa (2014)	Transparency practices at the construction site
Reinbold et al. (2020)	Digital visual management (VM) devices to increase workers' situational awareness (SA)
Abu Aisheh et al. (2021)	Constant and direct communication between managers and workers
Stevens (2022)	Worker anonymous Hazard Reporting app
Group 3: **Autonomy for decision-making**	
Antillón et al. (2011)	Autonomation in the context of safety
Reinbold et al. (2020) and Görsch et al. (2020)	Workers' situational awareness (SA) increased by digital visual management (VM) devices or other methods
Lehtovaara et al. (2022)	Decentralizing decision-making in production planning and control

UPSKILLING WORKERS

According to Hamzeh and Albanna (2019), all human resources involved with the process must be integrated, empowered, and trained to achieve all the benefits of lean construction. Thus, construction workers assume new roles and responsibilities and must be qualified regarding lean tools, principles, and concepts. von Heyl (2015) emphasizes the need for a systematic approach to teaching the basic lean principles and tools for the application of this philosophy to be accepted. Based on this understanding, the upskilling workers' strategies (group 1) identified in the literature are presented.

In order to teach basic Lean principles and tools to workers and site managers, von Heyl (2015) developed a systematic approach using a simulation game. A simulation of a road construction site was developed traditionally and also with the implementation of lean principles, followed by the participants' analysis. The results revealed that the simulation enabled the involvement of participants in the learning process. From the feedback provided by the workers, they felt motivated throughout the game, in which they were encouraged to experience the lean principles and reflect on possible improvements in existing processes. The author recommends that new tests be done to refine and use the proposed simulation game professionally.

Santana et al. (2017) worked on developing educational animation to transfer knowledge to workers regarding good practices related to lean construction. The material is structured for workers to have a vision of adopting lean practices in their work routine. As the authors point out, educational animation is a complementary action to training, as it illustrates how work should be carried out based on lean principles. The authors did not implement the proposed method on a construction site to collect feedback and improve the strategy. However, they encourage the development of new materials and the implementation of educational animation in future construction applications.

Hamzeh and Albanna (2019) developed a tool to assess construction workers' understanding of lean principles and concepts. A survey was conducted with workers from different construction sites to validate the tool and identify workers' weaknesses in understanding lean concepts. Based on the results, the authors proposed training for construction workers using non-digital games (House of cards, 5S number, and airplane game, among several others). The authors also present a correlation between the games with the lean categories explored in these games. According to the authors, training with games facilitates seeing lean concepts and principles applied, allowing workers to get involved with the learning process. Despite the suggestion of using games, the authors do not explore the application of these games in this paper to improve workers' knowledge.

Putz et al. (2021) also highlighted the need for efficient and targeted training to enable and motivate workers in applying lean construction methods (Last Planner System, Takt planning and takt control, 5S and A3). The authors conducted an exploratory study using gamification to improve training about lean construction principles and practices. The concept of gamification involves developing a game-like experience in a non-game context. Thus, gamification is applied by bringing game elements, such as scores, levels, and narratives, into the daily work context, creating a learning environment. The authors developed a framework for the application of gamification in LC training with several elements, such as challenges, cooperation, competition, feedback rounds, levels, points, rewards, and playing different roles, among others. They also highlight the importance of working with different elements, considering that different approaches in the game stimulate workers. The authors recommend that future studies be conducted using gamification in Lean Construction training to evaluate this strategy's contributions.

Jacobsen et al. (2021) proposed the development of a digital learning platform for teaching LC concepts using virtual reality (VR) with multiple players. As a result, VR can be used to teach lean principles and concepts in a more realistic environment when compared to using a board or other non-digital lean simulation game. In addition, the authors point out that the data collected automatically during the game can help in decision-making processes since it is possible to analyze this data. For future studies, the authors highlight the possibility that users can interact with each other within the game and also the need to implement new lean principles in the VR environment.

COMMUNICATION

Practices related to communication between managers and workers and the availability of readily accessible information for workers are part of the communication construct.

Valente and Costa (2014) developed a set of recommendations for applying transparency practices in construction based on a literature review and case studies. Among the 20 transparency practices applied, the authors concluded that 15 have an impact on the involvement of workers, such as exposure to long and medium-term planning, dissemination of short-term planning, Kanban systems, visual management boards, and quality indicators, among others. Increasing process transparency can be used for workers' motivation and participation, among other contributions. Some identified best practices were not implemented in the study but were suggested for future applications.

Reinbold et al. (2020) performed a literature review on the role of digitization in visual management (VM) to increase workers' and teams' situational awareness (SA). They highlighted using position sensors in tools, materials, and workers to collect geographic coordinates and present this information on displays in strategic places (e.g., floor entrances) in real-time. Thus, workers acquire situational awareness and can make decisions based on up-to-date information. The authors point out that future studies should be carried out to identify which VM devices could be used to display the information required in construction sites.

Abu Aisheh et al. (2021) studied the impact of lean construction principles on health and safety at work in construction projects. The authors point out that constant and direct communication between managers and workers seeking to avoid poor safety was the lean technique considered most important among respondents (in the subset related to communication). This communication can occur in daily joint meetings to improve the safety awareness of those involved. The authors indicated the limitation that the results refer only to the studied context, which may be different in other locations.

Stevens (2022) proposed a mobile computing technology for construction safety. The authors point out that workers feel uncomfortable reporting safety issues to supervisors in person. Therefore, a smartphone safety app was created, allowing the report to be done accurately and maintaining the worker's confidentiality. Although the beta version has been developed, it has not yet been tested on a construction site.

AUTONOMY FOR DECISION-MAKING

Strategies related to workers' or teams' autonomous decision-making are part of the autonomy for decision-making construct.

Antillón et al. (2011) proposed a matrix between LC and safety management practices to understand how lean practices interfere with safety. One of the results presented by the authors is the association between the concept of autonomation and the involvement of workers in the context of safety management at construction sites. According to Liker (2004), autonomation consists of not permitting a problem to pass to the next station by allowing machines or workers to interrupt production when something unusual is detected. Thus, Antillón et al. (2011) pointed out that autonomation can be directly extended to workers' involvement, indicating they can stop production whenever they feel at risk. Other Lean practices workers must participate in include root cause analysis, standardization, and continuous improvement. The authors reinforce the need for continuity of these studies to integrate safety as a target for production management.

The paper by Reinbold et al. (2020) is also included in this group since the authors discuss self-managed teams. The increased situational awareness using digital visual devices provides more appropriate decision-making for the context in which these teams are inserted. SA implies that teams have adequate levels of information to understand the project's status, which activities are in progress and where they are taking place, and the availability of materials and tools, among other information. These self-managed teams are formed of proactive workers capable of managing their activities and empowered to make decisions and introduce improvements in the process. The authors pointed out that the availability of data collected in real-time through digital visual management devices can be the link for construction workers to have greater autonomy in the decision-making process. They also highlighted that future studies should be conducted to understand which SA information should be available for different contexts. Görsch et al. (2020) conducted a literature review addressing SA for better decision-making for workers. The author investigated information capture methods and discussed how the outcomes would boost on-site productivity. However, as the authors point out, it is necessary to continue research to develop methods that explore the potential of SA.

Lehtovaara et al. (2022) proposed a framework combining decentralized decision-making with takt production involving frontline workers in construction. The main aim was to investigate how this combination could affect production planning and control (PPC) practices. In PPC construction, decentralization refers to distributing responsibilities related to production planning and control (initially centralized on project and site managers) to site teams (involving crew leaders and workers). The authors mentioned that intense involvement of the teams from the early stages of planning to the control phase is necessary for the decentralization of planning and production control to be successful. In the performed study, decentralized decision-making related to planning was partially dominated by crew leaders, with little involvement of workers. However, the authors report that decentralization in planning contributed to the commitment and motivation of the teams. In the control stage, there was a lack of worker involvement in decision-making. According to the results presented, the inadequate implementation of decentralization for decision-making in the control stage compromised the involvement of workers, causing them stress. The authors report the need for further studies, given that the present paper was limited to a single-case study.

DISCUSSION AND FUTURE DIRECTIONS

Although no time limit was established for the search, a few published papers discuss worker involvement strategies in the context of Lean Construction.

The group that refers to upskilling workers presents strategies exclusively to train construction workers to learn concepts, principles, and practices. Strategies involve simulation games, educational animation, non-digital games, gamification elements in training, and the application of VR reality for training. Based on the EI concept, new responsibilities are assigned to these workers, resulting in new demands regarding skills (Vidal, 2007). Thus, training has the potential to contribute to the improvement of workers' knowledge on the subject to fulfill these new demands.

Training using primarily non-digital games, educational animation, and gamification elements may have significant potential to be adopted to keep workers up-to-date with lean concepts, principles, and practices, improving their everyday work practices. Unlike the simulation or use of VR, implementing the first three strategies may be low-cost. However, generalizing what was pointed out by Pütz et al. (2021), it is necessary to analyze the effect of training using the mentioned resources in a structured manner to identify the actual contributions of these techniques in the learning and involvement of workers. As an example, the proposal by Hamzeh and Albanna (2019) involves the use of non-digital games for training workers. The authors did not evaluate which games are best suited to the workers' context, considering aspects such as the function performed by each of them, education, and familiarity with digital and non-digital games, for example.

None of the papers that integrate this group discusses what skills should be developed in workers to enable decision-making. The articles focus exclusively on understanding concepts, principles, and lean practices.

Regarding the communication group, strategies with different approaches were identified: using visual devices (non-digital or digital) to provide information to workers; bidirectional communication between managers and workers within the scope of safety management; and implementing a smartphone app for workers to report safety-related issues. Communication plays a crucial role in EI (Sun et al., 2000; Welikala & Sohal, 2008) since workers should propose improvements in the process. Thus, some discussions are provided as follows.

Communication is unidirectional in visual devices since workers only receive the information presented in the device (usually elaborated by managers). However, there is no communication from the worker towards the manager about improvements to be incorporated in the process, in the information representation of these visual devices, among others. Workers' participation in developing these devices can configure an interesting strategy. The worker will already be familiar with the interface and available information when using them daily.

Another aspect to highlight is that Abu Aisheh et al. (2021) do not present a systematized bidirectional communication strategy involving: the collection of workers' proposals and perceptions by managers in the field of safety; description of how these proposals are evaluated and incorporated into construction processes; how feedback is transmitted to the worker about the implementation or not of their proposals. The same occurs with the app's proposal to report safety-related issues, as it is not explicit how managers will use this collected information and how the general feedback process will be given to workers (considering that the reports are anonymous). The lack of a systematized strategy for integrating proposals and giving feedback will culminate in workers' demotivation and frustration, leading to a potential decrease in the presentation of their contributions to the organization (Sun et al., 2020).

Concerning the decision-making autonomy group, the following strategies were observed: application of autonomation in the context of safety at work; increasing situational awareness to improve the teams' decision-making; and decentralizing the decision-making process. Strategies for autonomy in decision-making represent, in the view of Sun et al. (2000) and Welikala and Sohal (2008), the effective participation of workers.

All the strategies presented involve decentralizing decision-making since this responsibility will not only be up to the project/site manager. Lehtovaara et al. (2022) mentioned that the benefits of decentralization and autonomy in the decision-making process had been the focus of interest in several production sectors, considering that this strategy contributes to increased efficiency, creativity, and well-being of workers. Despite the potential contributions observed in the literature, only Lehtovaara et al. (2022) conducted an empirical test of workers' involvement in decision-making. However, the strategies adopted in the study compromised the workers' effective participation in the production planning and control process. Thus, the latent need for developing effective strategies to ensure the involvement of workers in the decision-making process in different construction activities remains for future research.

In general, for workers to be involved in construction, there is a significant need to address efforts towards upskilling workers, communication, and adopting strategies that enable workers' autonomy for decision-making. These actions complement each other since adequate decision-making is only possible by increasing workers' skills and improving communication between managers and workers. Table 2 presents a set of questions that may help researchers advance studies on employee involvement based on the three constructs mentioned.

Table 2: Research Directions Based on the Three Constructs Related to EI

Construct	Questions to be addressed in future research
Upskilling workers	- What skills should be developed to enable construction workers to make decisions at their activity level? - How to develop the skills required for workers' participation in construction? - Which training strategies have the most significant potential to train workers in lean concepts, principles, and practices considering the characteristics of construction workers?
Communication	- How to systematically establish bidirectional communication between workers and managers to ensure workers' proposals for process improvements are collected, analyzed, and possibly incorporated into the organization's practices? - How to organize the feedback process to give feedback to workers on the implementation or not of their proposals? - How can workers contribute to elaborating visual devices (related to the principle of transparency) since they will use the available information on these devices? - How to establish interaction between managers and workers based on the information in the visual devices?
Autonomy for decision-making	- In which project production and safety activities can managers assign workers autonomy for decision-making? - What new responsibilities could managers assign to workers within the functions performed at the construction site? - What strategies should be implemented to guarantee the real participation of workers in the decision-making process without this participation being restricted to crew leaders? - How could workers be involved in decision-making at their organizational levels based on the knowledge and skills they developed and the communication strategies adopted?

Regarding the HC approach, Lu et al. (2022) point out that it is an early and unclear concept that needs urgent discussions to clarify its research agenda. Despite the concept positioning presented by the mentioned authors in the manufacturing industry, this concept still needs to be determined in the construction industry, demanding research to guide the comprehension and implementation of the HC approach in construction. Therefore, EI strategies in the context of LC have the potential to contribute to the elaboration and implementation of the HC approach in construction since placing the main human needs and interests at the center of the production process is a focus of both concepts/approaches.

CONCLUSIONS

This paper contributes to the body of knowledge by systematizing worker involvement strategies in LC based on three constructs: upskilling workers, communication, and autonomy for decision-making. In total, 12 EI strategies were identified and analyzed. Despite advances in discussions on the involvement of workers in construction in light of LC, there are still few empirical studies, mainly directed to autonomy for decision-making. In addition, the strategies identified in the literature are based on the managers' and researchers' points of view that workers must develop more knowledge and skills to participate and make decisions at their organizational levels. Further research should assess the workers' perception of how they can contribute to the organization based on their previously acquired knowledge, skills, and experience.

Based on the analyzed studies and the concept of EI, a set of questions was elaborated that can be considered for the continuity of reflections and strategy elaboration. The presented strategies and discussion might support elaborating on and implementing the HC approach. Regarding the use of digital technologies related to the Construction 4.0 paradigm in some of the identified strategies (e.g., VR and sensors), future research should also investigate how other technologies associated with this paradigm can contribute to workers upskilling, communication, and autonomy for decision-making.

UNETHICAL AND CRIMINAL – PREDICTING “DARK SIDE” PHENOMENA IN THE AEC INDUSTRY

Jardar Lohne[1], Frode Drevland[2], and Ola Lædre[3]

ABSTRACT

This paper outlines prediction of “dark side” (illegal or unethical) phenomena in the AEC industry. “Dark side” phenomena pose a substantial yet unexplored threat to Lean Construction practices. Insights from criminology are used as a starting point for the analysis. A meta-study of the findings from a small research program carried out within the Norwegian AEC industry was conducted. It was enriched by an assessment of literature on crime prediction in criminology and on “dark side” phenomena in the AEC industry. Results show that predicting “dark side” phenomena in the AEC industry ought to take in temporality (when in the process challenges occur), value chain (who in projects are likely to act) and typology (what kind of actions are susceptible to occur). In addition, contextual factors (physical surroundings, geography, belief systems etc.) need consideration. Unlike criminology, predictions within the AEC industry cannot be based on AI approaches fuelled by historical data but need to be based on insights from construction process research. The preoccupation with “best practices” in the contemporary literature ought to be complemented with assessments of “worst practices” within all parts of the built environment. This is work largely left undone.

KEYWORDS

Anti-corruption, crime, ethics, prediction models, unethical

INTRODUCTION

Unethical or criminal behaviour takes many forms occurring in different contexts and phases in construction projects. Though rising, the interest in such phenomena has long been scarce in the project literature and within Lean Construction (LC) in particular. This lack of interest seems strange, given the influence such phenomena can have on LC. Gehbauer et al. (2017), for instance, maintain that concerning questions of corruption, “[l]ittle has been published or done to fight this in Lean research or practical Lean papers”. However, they continue, this is strange, given that “[t]he number one waste in construction is corruption”. Here, we place such phenomena under the umbrella “dark side”.

By using the term “dark side”, we explicitly follow the research agenda outlined in one of the most potent contributions within the field over the last years (Locatelli et al., 2022), for whom the “dark side of projects is any illegal or unethical phenomena associated with projects”. One of the main attractions of this definition is its broadness. Permitting to include “systemic,

group, and individual wrongdoings", to be "appropriate for macro, meso, and microlevel studies in projects", and to include "wrongdoings external to projects that impact their performance or affect how projects are initiated, governed, managed, and executed at any level" (Locatelli et al., 2022). In sum, the term "dark side" denotes undesirable phenomena to be combatted.

Over the last decade, many authors have underlined the need for analyses of "dark side" phenomena within the field of project management. Jonasson and Ingason (2013) call it a "neglected area", whilst Walker (2014) lament the "dearth of papers" on the subject. However, the proposals for ethical reflection have been rather general and lack the precision needed for discussing real-life challenges. The question of potential measures has received valuable contributions though. Sichombo et al. (2012), for instance, provide the outline for third-party controls over project procedures. Despite lamenting the "paucity of research on anti-corruption measures", Lehtinen et al. (2022) analyse the effectiveness of different corruption prevention efforts reported on in the literature. In addition, ethical guidelines and normative documents specify points of contagion in which the AEC industry is particularly exposed.

It seems, however, that one crucial step is missing from the analyses carried out. To a certain extent, all prevention measures build on understanding how "dark side" phenomena occur within specific contexts. Given the significance of "dark side" practices within the industry, methodological tools for effectively anticipating unwarranted behaviour are in high demand. There is, in other words, a dire lack of a *crime prediction model* in the AEC industry. To address this challenge, the following research questions are addressed, 1) What would be the attributes of a crime prediction model within the AEC industry?, 2) What are the main obstacles to establishing such a model?, and 3) What research will be required to improve the proposed model?

In the following, we first outline "dark side" phenomena in the industry. Secondly, we argue for the need for a prediction model to be able to tackle these challenges. Thirdly, we seek input from other fields to outline a model. Fourthly, we propose a model adapted to the AEC industry before, finally, we discuss further research needed to establish such a model.

THEORETICAL FRAMEWORK

Eggen et al. (2017) estimate that not-reported turnover in the Norwegian AEC industry corresponds to approximately 28 billion NOK annually – just under 10% of the industry's total turnover. However, the analysis does not include counterfeit materials nor other criminal activities in the material chain, a figure Hastak et al. (2016) assumed to correspond to another 10% of the complete turnover of the AEC industry in the US. Given deep international links, it is likely that the Norwegian figures are similar. Research suggests that the Norwegian material chain is, in fact, the victim of significant fraudulent behaviour (Engebø et al. 2016; Kjesbu et al. 2017). In combination, it seems likely that non-reported activity in the Norwegian context comprises between 10% and 20% of the industry's total turnover, most likely closer to the highest number. In addition to this, other "dark side" phenomena that are clearly ethically doubtful yet not expressly condemned by law flourish; examples such as gaming (Skaarberg, 2016) and circumvention of contractual demands (Aure et al., 2020), are documented.

These challenges indicate that "dark side" phenomena significantly challenge contemporary AEC industry ventures. This is particularly true concerning lean approaches with flow and waste reduction as expressed core principles. Still, the literature on "dark side" phenomena within the LC literature, as in the IGLC papers available at iglc.net proves limited. A search for "crime" gave, for example, only three hits (Kjesbu et al., 2017; Aure et al., 2020; Lohne et al., 2021). Equally, "ethics" turned up three (Svalestuen et al., 2015; Drevland et al., 2017; Thameem et al., 2017), "collusion" only one (Stifi et al., 2014), price fixing none, whilst "corruption" gave six (Stifi et al., 2014; Stifi et al., 2017; Thameem et al., 2017; Daramsis et al., 2017; Rizk et al., 2018; Wold et al., 2019). The search function on iglc.net only considers the papers' titles, abstracts, keywords, and author names. Therefore, some other papers will discuss "dark side" phenomena (e.g., Gehbauer et al., 2017), without them appearing in the search results. However, few IGLC papers have "dark side" phenomena as their primary focus. This appears strange, given the attention to value creation within LC context (see e.g. Drevland et al., 2018), and that "dark side" phenomena pose significant challenges to value creation. Prediction models are key to address such challenges.

PARAMETERS OF PREDICTION IN CRIMINOLOGY

Developing a prediction model for "dark side" phenomena requires insights from other fields. The field of criminology is the arena where theoretical and practical trends can best be observed.

It needs remarking that contemporary work on prediction within the field of criminology is challenging to get an overview over. In particular, what concerns work based on advances in fields such as Artificial Intelligence (AI) and big data-driven approaches, much of the state-of-the-art work is published in conference settings rather than in journals. In addition, the implications of technological advances driving the possibility conditions for the field – face recognition, register data mining, and integrated surveillance camera systems – are challenging to assess for the non-expert. Finally, much secrecy characterises the advances in the field, as precise information can be sensitive to local and international actors with malevolent intent.

Still, this is where relevant prediction models are the most mature. The essential aspect of these – the parameters according to which prediction happens – is primarily fundamental and not determined by the influence of specific algorithms. Even though the approaches below concern solely crime prediction, they are directly relevant to "dark side" phenomena.

Shamsuddin et al. (2017) present an overview of the state-of-the-art of crime prediction models. They underline how analyses can be based on both qualitative – mainly scenario analyses – and quantitative methods. It is easy to agree with the authors' call for pluralism in approaches, given that "no standard method […] can solve the problems". Less convincing is the claim that the "biggest challenge facing crime prediction is how to efficiently and accurately analyse the increasing volumes of crime data". Given the lack of data characterising the analyses of "dark side" phenomena in the AEC industry, the most pressing area of concern within this context is developing the very foundations of such analyses. The following sections review the principal axes of analysis found in the literature.

Crime prevention depends on knowing what, where, when and under what conditions crime occurs – that is, prediction; Mansour and Lundy (2019) propose spatial and temporal aspects, in addition to weather conditions, play a significant role in crime – adequate for serving as prediction parameters. There are substantial challenges to the field. For instance, studies often lack a transparent reporting of study experiments, feature engineering procedures, and use inconsistent terminology to address similar problems (Kounadi et al., 2020). However, in our context, the principal approach to the analysis of prediction factors is of concern.

SPATIAL PREDICTION

The most prominent aspect of crime prediction appears to be the spatial dimension. There is a remarkable growth in spatial crime forecasting studies due to interdisciplinary technical work (Kounadi et al., 2020).

Several authors have underlined how crime and criminogenic factors are not homogeneous across space. For instance, Boni and Gerber (2016) highlight how crime is area-specific within cities. Furthermore, crime prediction models can be established based on statistics and machine learning techniques. Barreras et al. (2016) underline the efficiency of such approaches in their study consisting of geographical identification of areas with high crime frequency in the past to prevent future crime, relying on fixed determinants of crime.

The literature on crime prediction models sees going from the constatation of current crime (statistics) into future crime (prediction) as the critical challenge. For the case of Shamsuddin et al. (2017), as with several others, this conception stems from a relatively simple typology of crime, proposing that it can be "divided into a few types such as crime against properties (theft, burglary, and robbery) and crime of aggression (homicides, assaults and rape)". Based on this type of typological approach, quantitative prediction models can be construed. In other words, if input values are easily grasped, output values (the prediction) become a question of technique.

TEMPORAL PREDICTION

In a fascinating study, Zhao et al. (2022) expand on the spatial dimensions of crime by illustrating the existence of correlations among different types of crime from temporal and spatial perspectives. These researchers underline the potential for contemporary analyses based on big-data approaches to construct accurate crime predictions. Such studies have also been expanded to include demographic data drawn from mobile networks, showing the where's and when's of crime (Bogomolov et al., 2014). Ramasubbareddy et al. (2020) equally identify this interrelation between the spatial and the temporal, the analysis of which can serve to predict future crime in a specific location within a particular time. Several methodological approaches are suggested; for instance, Rummens et al. (2017) argue that so-called predictive analysis can be used to predict when crime will occur.

TYPOLOGY IN CRIME PREDICTION

The overall impression from the literature review is that current prediction models are oriented towards a relatively narrow band of "dark side" phenomena. For their multi-type analysis, for instance, Zhao et al. (2022) stick to seven types – burglary, felony assault, grand theft, murder, rape, robbery, and vehicle theft. Mansour and Lundy (2019) describe how "*spatial, temporal and weather features do indeed play a significant role in crime type classification – for example, drug crimes tend to happen on sidewalks, late in the evening and in cold temperatures*". Underlying social predictors – typically based on indicators of "concentrated disadvantage" (e.g., racial heterogeneity, poverty, and family disruption) – are found to be among the strongest and most stable predictors (Pratt and Cullen, 2005).

Some authors have argued against this predominant scope of prediction. One aspect of this concerns the superposition of predication parameters. Connealy (2020) found that risk factors for crime are not generalisable and that different types of crime need to be considered separately. This notion suggests that while considering different types of crime can improve the accuracy of crime prediction, risk factors for crime are not generalisable and need to be considered separately: «*risk factors are not generalisable across crime types or across cities. Researchers and law enforcement need to examine local, crime-specific contexts when assessing crime problems and generating solutions*». Another aspect concerns the very scope of the prediction effort. As Lavigne et al. (2017) underline, "*[f]inancial crime is a rampant but hidden threat. In spite of this, predictive policing systems disproportionately target "street crime" rather than white collar crime*".

EXTERNAL FACTORS

As maintained by Tang et al. (2019), traditional crime prediction models reveal the spatiotemporal dynamics of crime but tend to ignore the environmental context of the geographic areas where crimes occur. Towers et al. (2018) underline the need to consider external factors potentially influencing crime occurrence and type, mentioning "climate, daylight hours, day-of-week, and holidays and festivals". Not surprisingly, macroeconomic, demographic, and socioeconomic factors are found to influence crime rates (Hazra, 2020). For what concerns white-collar crime (significantly less discussed in the material examined), Sajid et al. (2011) identified peer support, corporate culture, lack of accountability and reporting as the most critical prediction factors. Others have proposed the inclusion of other contextual phenomena into the analysis, such as Bhattacharya (2013), who point to how differences in the religious composition of regions influence the occurrences of (at least certain types of) crimes. Still, approaches to this field lie at an exploratory level and are seemingly mainly concerned with simple phenomena – such as street-level misconduct.

KNOWLEDGE GAP

Rummens et al. (2017) underline, "*[p]olice databases hold a large amount of crime data that could be used to inform us about current and future crime trends and patterns.*" It is commonplace for the above-cited papers to suggest that incorporating data from multiple domains and using deep learning architectures may improve prediction models. In sum, as Garnier et al. (2018) maintain, "*[u]nderstanding how social and environmental factors contribute to the spatio-temporal distribution of criminal activities is a fundamental question in modern criminology*". The current response is to broaden the scope of data collection and to deepen the analytic techniques employed for prediction. Still, and crucial for the analysis here, is that tools for predicting crimes do not guarantee the avoidance of discrimination or bias due to human intervention when selecting the data that feeds into an algorithm.

The implication of such an insight for a prediction model for the AEC industry is that a proper understanding of the parameters of "dark side" phenomena within the industry is really the core premise for good predictions to come out. Such parameters are currently lacking.

Lohne et al. (2023) argue that the lack of an accurate understanding of the where, when, why, and how of "dark side" activities in the AEC industry leads governmental bodies and control authorities to focus their attention on only a limited part of the potential "dark side" phenomena actually or potentially occurring. Much of the literature discussed from the field of criminology discussed above has had relatively easily observable infractions as their object of analysis, such as street violence, drug dealing and theft. The "dark side" phenomena to address with a prediction model are more complex, and therefore, it is unlikely that we can apply contemporary statistical approaches to them. The knowledge gap is consequently twofold. First is the axis according to which a prediction model is to be operative. Second is the potential for prediction without recourse to statistical tools. Correctly understanding the parameters for prediction, therefore, becomes essential.

METHODS

The research presented in this article synthesises the results of a small research program carried out within the Norwegian context, "Mapping opportunities for criminal behaviour in the Norwegian BAE industry" (Kartlegging av mulighetsrom for kriminell adferd i norsk BAE-næring), supported by Project Norway. From 2014–2021, "dark side" phenomena in the Norwegian construction industry are analysed from a construction process perspective. Based on a prior scoping literature review (Lohne et al., 2019) and individual literature studies carried out for each of the research projects in the program, a new search for literature in Google Scholar and Scopus following the prescriptions of Yin (2015) was carried out.

The findings stem from a meta-analysis of peer-reviewed publications based on qualitative approaches. These publications were selected as they dealt with the spatial dimensions, the temporal dimensions, typology and/or external factors that could be used for crime prediction. The term meta-analysis is here not strict, with the use of statistical methods or based on series of structured reviews, but rather as outlined by Glass (1976) as an analysis of analyses. As such, the peer-reviewed publications are part of the outcomes of the research program. The publications identify responses to work-related crime from a construction process perspective. These responses concern both the identification of challenges and potential measures within the theoretical optic governing the research program.

The unit of analysis is the AEC-industry as a whole: The whole construction process from strategic definition to termination; the entire material supply chains, from primary producers to wholesalers, including how illicit materials enter the workplace; the supply chain, from clients to subcontractors carrying out the physical work on the construction site. In addition, the scope includes formal and informal rules and regulations concerning product and process awareness.

Given the magnitude of this unit of analysis, 22 peer-reviewed publications have been analysed in this meta-analysis. The potential for criminal activity in the Norwegian AEC industry is thus understood in a wide range of optics, varying from white-collar criminals to illicit workers at the construction site, potentially using below-grade materials in construction projects. It also highlights the role of rules, regulations, and ethical awareness among the actors.

For presentation purposes, the presentation of the crime prediction model here is static; in reality, the nature of “dark side” phenomena is dynamic, and the stages of the construction process where such undertakings take place vary (Owusu et al., 2019).

PARAMETERS OF PREDICTION IN THE AEC INDUSTRY

Lohne et al. (2019) broadly analysed the literature, identifying areas where research on “dark side” phenomena was relatively well established (in particular corruption), others where some research endeavours had been carried out (e.g. materials management/supply chain management), and again others that had gained surprisingly little attention (e.g. gaming and identity fraud). Still, based on what is described, sufficient evidence seems brought to the fore to establish a prediction model based on a parametric understanding of “dark side” phenomena in the industry. Still, no discussion on what parameters of analysis a “dark side” prediction model for the AEC should use was found. This chapter aims to outline an understanding of such parameters based on an assessment of insights from the general research literature and the research program. Even though inspired by insights from criminology as presented above, the proposed approach is not based on statistical models, but on insights from construction process literature on where challenges typically arise. This analysis is buttressed by comprehensive if not statistically valid empirical investigations (see also Lohne et al., 2023).

SPATIAL “DARK SIDE” PHENOMENA PREDICTION – VALUE CHAINS

The value chains play a role in “dark side” phenomena, and the value chains change during project phases. Ichniowski and Preston (1989), for instance, found that criminal activity can persist in the construction industry because of barriers to entry in certain markets and because of industry characteristics such as constant changes of work sites and restricted access to them.

Lohne et al. (2019) claim that the number of actors benefitting from crime in the AEC industry is surprisingly high. Owners, as well as main contractors, reap substantial benefits. However, legally organised workers, FM personnel and society tend to lose from such activities. White-collar workers tend to benefit and initiate activities related to the “dark side”, while blue-collar workers at entry-level positions mostly lose. However, even though the blue-collars can lose, they also seem to experience benefits. Both Gunnerud et al. (2019) and Evjen et al. (2019) registered a continuous recruitment of newcomers that was difficult to prevent. However, countermeasures were perceived as easy to circumvent. In addition, the contractors and project managers – who hired illegal immigrant workers, avoided taxation etc. – perceived the probability and consequences of being caught red-handed as small. Øversveen et al. (2022) identified an opportunity space for criminal behaviour in construction projects – for quality assurers, among others – due to high workloads and a high level of trust. A positive outcome with limited risk and a high level of trust can explain the existence of the “dark side” phenomena.

TEMPORAL "DARK SIDE" PHENOMENA PREDICTION – PHASES

A general insight from the research program and the international literature is that crime in the construction industry is most common during specific phases of construction projects. Given the "myriad activities" encompassed at separate phases of the construction process (Owusu et al., 2019), the notion that "[d]ifferent ethical issues […] arise at different stages of the project life cycle" (Jonasson and Ingason (2013:16)) is a view that resonates within the literature.

Several authors also underline that different phases in the process are prone to different types of "dark side" phenomena. This insight can be used as an analytic tool to search for the occurrence of specific types of "dark side" phenomena within different phases of a construction project. Kankaanranta and Muttilainen (2010), for instance, found economic crimes in the construction projects most common during the bid evaluation and tendering phases. Bowen et al. (2012) found corruption prevalent during project bid evaluation and tendering phases. Owusu (2019) found corrupt practices to be most common at the pre-construction stages. In fact, the prevalence of corrupt activities at early stages is repeatedly maintained.

Less seems to have been done to explore the characteristics of the different phases as enablers of "dark side" phenomena. In the research program, several papers examine how phase characteristics are enablers, notably at the design phase (Lohne et al., 2017; Svalestuen et al., 2015), in operations (Gamit et al., 2022), at handover (Lohne et al., 2020), at project termination (Iversen, 2020) and in phase transitions (Selvik et al., 2022). Among the findings is that sets of challenges correspond to different phases and that these are predictable to a certain degree. For instance, introducing illicit workers to the construction site is common immediately before handover. Firing et al. (2016) found that right before the handover of a shopping centre – when a need for speeding up the finishing activities appeared at the same time as all workers were working overtime – the construction site was chaotic and easy to exploit.

TYPOLOGY IN "DARK SIDE" PHENOMENA PREDICTION

There have been several attempts to establish (some sort of) a typology of "dark side" phenomena. The Chartered Institute of Building (CIOB), for instance, used quite a broad view of crime in the AEC industry and included the following themes in their list of phenomena (CIOB, 2009), notably theft, vandalism, arson, fraud, bribery, intimidation, assault, racketeering, illegal drug dealing or use, health and safety neglect, forced labour, illegal working, kidnap, illegal waste disposal, identity theft, data loss/theft, and handling stolen goods. Davies (2022) found that construction industries provide significant opportunities for criminal and harmful practices; including fraud, tax evasion, poor health and safety, and underpayment of workers. Kankaanranta and Muttilainen (2010) found that economic crimes were committed in the construction industry and mainly were related to dealing in receipts. In addition, phenomena such as collusion, corruption, and other types of organised crime are not included in the list from CIOB (2009), even though these have long been recognised as constituting significant challenges to industry practice (e.g. Locatelli et al., 2017; Thomas, 1977).

Complementing these, Bowen et al. (2007) also outline common types of criminal behaviour and add to these a set of unethical behaviours – collusion, bribery, negligence, fraud, dishonesty and unfair competition. Shah and Altabi (2018) continue this effort, listing unethical practices identified including untimely legal action, changing project manager's responsibility and delays in payment processes from the owner/client perspective etc. Though being numerous in their listing of unwarranted activities, the overall impression from the literature review is that current interest is oriented towards a relatively narrow band of "dark side" phenomena.

In addition, few authors discuss the systematicity of the "dark side" phenomena occurring. Certain exceptions to this exist; not surprisingly, this is typically the case of studies concerned with organised crime within the industry. An example of this is Thomas (1977), identifying theft of heavy equipment from construction sites as an organised, systematic, criminal operation sustained by contractors. In particular, there is a lack of literature seriously discussing the interrelationship between types of crime and AEC industry characteristics. Exceptions to this are Reeves-Latour and Morselli (2017), with their description of how bid-rigging activities are feasible through conspiracies (politico-business) organised around public construction bids. Equally, Hertog (2010) explains how public construction works are vulnerable to collusion.

The individual publications from the research program report on several types of "dark side" phenomena. Though the nature of counterfeiting limits the accessibility to data, Engebø et al. (2016) still identified counterfeit materials as a well-known problem in the AEC industry that had received limited attention in the literature. Kjesbu et al. (2017) identified widespread knowledge about counterfeit and substandard steel products among a relatively random selection of construction project participants. Richani et al. (2017) found that contractors who employ labour immigrants with false identities, launder money, and avoid paying taxes achieve a competitive advantage over legit contractors.

EXTERNAL FACTORS IN "DARK SIDE" PHENOMENA PREDICTION – CONTEXT DEPENDENCY

In parallel, the development of analyses of increased precision has been observable. This concerns, for instance, an increased interest in context dependency (e.g. Locatelli et al., 2017, on the exposure of megaprojects to corruption issues).

Still, external factors have not seen significant interest from the research community. Based on the experience gained through the research program, the suggestion is that such factors ought to include owner characteristics, contract regimes, geography (both centre/periphery and other human geography factors such as gender, ethnicity, class issues, educational levels, homogeneity/not and stability/flux). Anecdotal evidence exists; in Norway, there is a predominance of "dark side" phenomena detected in the most densely populated south-eastern region; still, this is where most of the police control activity has been situated – the reliability of the figures is low. Until such factors are properly examined, it is difficult to assess the role of external factors in AEC industry projects.

Findings from the research program reveal that projects cannot be studied without regard to their context dependency. Engebø et al. (2018) found that contractors – on the outside – clearly distance themselves from work-related crime and actively prevent criminal actors from entering their projects. However, the year before Engebø et al. (2017) found that the 50 largest contractors in Norway – of which only 19 had official ethical guidelines – struggled to close the gap between operating "legally and unethically" and "legally and ethically". As a result, there seems to be room for manoeuvre for many roles in construction projects. For instance, Wold et al. (2019) found that officials issuing building permits can go far without stretching the authority delegated to them. Despite extensive contractual and contracting measures in two airport development projects, Skovly et al. (2017) found that "dark side" phenomena will probably exist as long as someone benefit.

DISCUSSION AND CONCLUSION

This paper has addressed three research questions, notably 1) what would be the attributes of a crime prediction model within the AEC industry? 2) what are the main obstacles to establishing such a model? and 3) what further research will be required to improve the proposed model have been the three research questions addressed. Given the the analysis, the answers to the questions are inconclusive, yet point towards future analytic pathways.

Firstly, the analysis has shown that a crime prediction model for the AEC industry based on statistical approaches is unsuitable. Rather, there is a need for an analytic approach taking for starting point industry characteristics. The above analysis illustrates how insights from the field of criminology might serve as the foundation for a prediction model for "dark side" phenomena within the AEC industry. Secondly, the examined literature illustrates how parameters such as place, time and the combination of these serve as input to advanced modelling approaches. Still, as Shamsuddin (2017) points out, there are limitations to current accuracy of prediction. The main obstacle to such a model is to render it operationalisable. Prescriptions of simplicity, transparency and relevance are challenging to apply. In addition, given the lack of data, statistical models are of little help; prediction within the AEC industry needs to be based on analytic models, that is, insight into the very workings of the industry. Thirdly, what is presented in this paper is exploratory work, and the following analysis must be assessed with the clear need for such a model in mind. As described above, the processes prescribed by LC literature and practice are hampered by "dark side" phenomena – to a more significant degree than what is acknowledged. Further, the literature clearly states that the prevention methods employed today by police and other controlling agencies are far from achieving what is wished for. Future research should explore practical approaches based on the parameters identified to improve these practices, including deepening the understanding of these parameters.

INVESTIGATING AND SIMULATING COLLABORATION AMONG THE LPS PHASES

Elyar Pourrahimian[1], Lynn Shehab[2], and Farook Hamzeh[3]

ABSTRACT

Although heavily studied, collaboration in construction is still perceived as an elusive or intangible aspect because of its complex nature. Its complexity roots in the unfeasibility of quantifying it or its impacts on the performance of a construction project. While some studies acknowledged the need to evaluate or assess collaboration, empirical and numerical methods that pertain to direct quantification of either collaboration or the impacts of collaboration on the performance of a project are still unaddressed. This paper aims to address this gap from a Lean perspective by investigating the effects of collaboration throughout the different phases of the Last Planner System. After a thorough analysis of the collaborative points occurring in each phase, computer simulation is employed to model the progression of a construction project from pull planning to lookahead planning and finally to execution while also modelling collaboration among the project members. Findings on how collaboration during each phase impacts the project performance differently are presented. This study's contribution lies in highlighting the importance of early collaboration in construction projects and emphasizing the need for accurate quantification of such qualitative aspects.

KEYWORDS

Collaboration, Last Planner® System, agent-based modelling, and simulation.

INTRODUCTION

Construction projects are often described as unique and complex due to their ever-changing methods, distinctive objectives, and uncontrollable factors (Howell 1999). Among these are labor factors such as supervision, incentive schemes, leadership skills, overtime, and worker interactions (Jarkas and Bitar 2014). Interaction in construction includes collaboration and cooperation, which (Schöttle et al. 2014) attempted to distinguish between. Their study described collaboration as "an inter-organizational relationship with a common vision." In contrast, cooperation was described as "an inter-organizational relationship among participants of a project, which are not commonly related by vision or mission". This paper will address collaboration, where project participants collectively strive to successfully complete the project.

One of the significant enablers of collaboration is Lean construction, along with its tools and techniques. The Last Planner® System (LPS) is one Lean tool (Ballard 2000) that not only fosters but also entails collaboration as a vital component for the success of its implementation. Developed to improve workflow and increase reliability in construction planning, the LPS is a production control system widely used in construction projects (Ballard 2000; Ballard and

Howell 2003). It may be described as a mechanism for transforming work that "should" be done into work that "can" be done, then into work that was actually "done" (El Samad et al. 2017). LPS includes four main planning phases: (1) Master Scheduling, (2) Pull Planning, (3) Lookahead Planning, and (4) Weekly Work Planning (WWP).

While collaboration in construction generally and the LPS specifically has been frequently promoted, attempts in quantifying it have been limited to identifying its influencing factors through surveys and questionnaires. However, the direct quantification of either collaboration or the impacts of collaboration on project performance is still unaddressed. Therefore, this paper aims to highlight (1) the importance of investigating and accurately quantifying the impacts of collaboration on construction projects, (2) the change in the impacts of collaboration when occurring during the different LPS phases, and (3) the importance of early collaboration in construction projects. To achieve these objectives, a discussion over how collaborative points manifest in the different LPS phases is carried out, followed by agent-based modelling and simulation of the project members and tasks during the progression of a construction project from pull planning to lookahead planning and finally to execution. In the simulation model, collaboration among the project members throughout the different phases is also modelled and manipulated to study its impacts on performance. Finally, an analysis and discussion of the results are presented, and conclusions and future recommendations are suggested.

RESEARCH METHODOLOGY

A simulation-based research (SBR) approach is adopted to achieve the mentioned objectives. SBR may be divided into two methodologies: (1) research on the efficacy of simulation as a training methodology and (2) research using simulation as an investigative methodology (Cheng et al. 2014). This study follows the latter methodology to address research questions whose answers are unattainable through real-life experimentation without being too expensive or time-consuming. Therefore, after a rigorous discussion of the collaborative points in construction planning and in the LPS, collaboration is modelled through computer simulation and its influencing factors identified in the literature. Different scenarios depicting the different collaborative practices along the LPS phases are simulated, and their results are analyzed to deduce where collaboration has the most substantial impact on the project.

COLLABORATION IN CONSTRUCTION PLANNING

As collaboration is one of the "Five Big Ideas" presented by (Macomber 2004), along with optimizing the whole, coupling learning with action, viewing projects as networks of commitment, and increasing relatedness, collaboration must be investigated through the context of LPS to weave and embed its implementation from within. (Schöttle et al. 2014) defined collaboration and compared it against cooperation sometimes used interchangeably with the former. Among the presented definitions of collaboration was the phrase "the process of shared creation" (Schrage 1995), where several individuals with "complementary skills" engage in an interaction that creates a newly achieved understanding (Schöttle et al. 2014). Other researchers have defined collaboration as "a process of joint decision-making among key stakeholders" (Gray 1989).

Several studies investigated key strategies for effective collaboration in construction, such as one by (Shelbourn et al. 2007), who identified people, business, process and procedure, and technology as driving factors for successful collaborations. Moreover, a sense of familiarity, willingness, and level of engagement were described by (Skinnarland and Yndesdal 2010) as a set of collaboration indicators that describe the collaborative development process. Based on their study, all three indicators may have a positive functional relationship with the degree of collaboration in construction projects.

Collaboration has been a topic of interest for several researchers, each addressing it from a unique perspective, as it is essential for the success of any construction project. A study by (Jara et al. 2009) adapted a methodology called Extreme Collaboration in an AEC project to accelerate the design process of a multidisciplinary team that must optimize the architecture, structure design, energy efficiency, and cost of wood houses simultaneously. They also suggested a methodology for integrating Extreme Collaboration in the Pull Planning phase. Another study reviewed and analyzed the experiences of project managers and foremen with implementing the Last Planner System on a construction project from a collaborative perspective (Skinnarland 2012). They found that one of the most prominent outcomes of the LPS implementation was the establishment of an arena for collaboration. (Schöttle and Gehbauer 2012) showed the importance of a working incentive system to foster collaboration among project members and presented a model for managing such a system. (Abdirad and Pishdad-Bozorgi 2014) highlighted the importance of collaboration on participants' success in an Integrated Project Delivery (IPD) system depends. They proposed developing a framework of metrics to assess collaboration in IPD by investigating the traits of collaboration in IPD and linking them with respective metrics. Most recently, (Malvik 2022) viewed collaboration from an entirely different lens by putting the collaborative style of a successful football team in a Lean construction context. They conceptualized the ideas a famous football coach brought forward by viewing them from a Lean construction perspective and investigated whether collaboration techniques from another performance environment can inspire the Lean construction theory.

MEANS TO MEASURE COLLABORATION IN CONSTRUCTION

Collaboration may be perceived as an intangible or qualitative concept whose measurement may not be as feasible as other concepts in a construction project, such as productivity, budget, schedule, accident rates, and so on. However, some attempts at measuring or quantifying collaboration in construction were introduced, such as the one by (Abdirad and Pishdad-Bozorgi 2014), where collaborative traits within Integrated Project Delivery (IPD) are investigated and linked with respective metrics. A framework based on the identified traits and metrics is developed to achieve a proactive collaboration assessment within IPD. Identified traits included co-location of the project team members, diversity in skills, education, or organization roles, team productivity, the cost impact of collaboration, training, communication methods, and individual human aspects such as absence rate and turnover. Another study by (Marek et al. 2015) recognized the need for evaluating collaboration and presented a seven-factor model of effective collaboration alongside the Collaboration Assessment Tool (CAT), which the U.S. Department of Agriculture developed to evaluate partnership processes and identify key factors to successful collaboration. The seven factors were adopted from a study by (Mattessich and Monsey 1992) and included Context, Members, Process and Organization, Communication, Function, Resources, and Leadership. The developed model included a Likert-scale questionnaire, where participants were asked to rate several items of the identified factors. (Thomson et al. 2009) also relied on a questionnaire-based approach to "measure" collaboration among organization directors. Their guiding dimensions were Governance, Administration, Organizational Autonomy, Mutuality, and Norms. Collaborative planning is a vital aspect of construction projects, and Elsayegh et al. (2021) introduced the Collaborative Planning Index (CPI), a holistic rating system that considers all factors influencing collaborative planning. The CPI offers tailored experiences and strategies to improve collaborative planning practices, contributing to the body of knowledge on the subject. Partially implementing LPS can also yield positive results, as observed by Priven and Sacks (2013), who found that LPS fosters social networks among subcontractors, enhancing communication, reliability, trust, and coordination. Duva et al. (2022) compared the network topologies of two Architectural, Engineering, and

Construction (AEC) project teams to identify how network parameters impact knowledge transfer and project outcomes. Additionally, Cisterna et al. (2018) examined the suitability of Social Network Analysis (SNA) in the AEC industry and identified the influence of project complexity and cultural aspects. Lastly, Lagos et al. (2022) studied the LPS adoption levels, team collaboration, and project performance by comparing two Chilean construction projects, finding that mature LPS adoption significantly aids collaboration and performance. While these studies introduced a much-needed perspective on how collaboration may be assessed and evaluated, empirical and numerical methods that pertain to the direct quantification of either collaboration or the impacts of collaboration on the performance of a project are still unaddressed.

COLLABORATIVE ACTIONS IN THE LAST PLANNER SYSTEM

This section will discuss the LPS phases and the various tasks that constitute each LPS phase, followed by an investigation of the different collaborative actions that enable each task's success and effectiveness. The Master Schedule phase is a crucial aspect of the Last Planner System (LPS) in construction project management. This phase involves creating a high-level project schedule that provides an overview of the entire project. This schedule aims to help the project team understand the critical path and identify potential constraints that could impact the project timeline. The Master Schedule is typically created at the start of the project and is based on the project scope, resources, and constraints. It shows a high-level view of the project timeline, including major activity start and end dates and dependencies between activities. During this phase, the project team should also identify the critical path and any constraints that could affect the project timeline. The Master Schedule is then used as the basis for the Pull Planning and Lookahead Planning phases of the LPS. As one main principle in the LPS is planning in greater detail as you get closer to execution (Hamzeh and Aridi 2013), Master Scheduling includes setting major project milestones and highlighting deliverables to release once the milestone is complete. It also ensures that the perspectives of various project partners for each milestone are aligned (Hamzeh et al. 2009). It is important to align the perspectives of various project partners for each milestone to ensure this phase's effectiveness. This can be achieved by engaging all relevant stakeholders in creating the schedule. The Master Schedule should include major project milestones and highlight deliverables to be released once the milestone is complete. It should also identify potential constraints that could impact the project timeline so that the project team can take steps to mitigate these risks. The Master Schedule should be used to monitor project progress and ensure that the project is on track to meet its deadline. It provides a high-level overview of the entire project, including major activity start and end dates and dependencies between activities, so the project team can better understand the critical path. By engaging the project team, including all relevant stakeholders, the Master Schedule ensures that everyone clearly understands the project timeline and their respective roles and responsibilities.

In the Pull Planning phase of LPS, the project team comes together to plan the work that needs to be done in the next two to four weeks, creating a detailed and accurate plan for the work to be executed. This phase is crucial for the project's success, as it enables the team to identify and resolve any issues before they become problems and complete the project on time and within budget. During the Pull Planning phase, the project team identifies the work to be performed, determines the resources required, and sequences the activities in the most efficient manner possible. The team also engages project stakeholders to ensure that everyone is on the same page and that the plan is feasible. By working together, the team can coordinate their efforts and ensure that the project is executed smoothly and efficiently. One important aspect of Pull Planning is the identification of potential bottlenecks or risks and the development of contingency plans to mitigate these risks. This is crucial for the project's success, as it helps the team anticipate and resolve problems before they occur. In addition, the team regularly reviews the work that has been completed, assesses the status of the work in progress, and identifies any changes to the work plan. This helps to ensure that the project stays on track and that the timeline is updated as necessary (Hamzeh et al. 2009). Another key aspect of Pull Planning is the engagement of the project team, including all relevant stakeholders, which ensures that everyone clearly understands their respective roles and responsibilities and that everyone is working together towards a common goal. By working together, the team can create a detailed plan for the next four weeks, including the work to be performed, the resources required, and the sequence of activities. This allows the team to coordinate their efforts and ensures that the project is executed smoothly and efficiently. Pull Planning is a critical phase in the Last Planner System. It enables the project team to identify and resolve issues, coordinate their efforts, and ensure that the project is executed smoothly and efficiently. By working together, the team can complete the project on time and within budget while ensuring that everyone is on the same page and that the project timeline is updated as necessary.

The Lookahead Planning phase is a crucial aspect of construction project management utilizing the LPS. This phase is dedicated to creating a comprehensive plan for the upcoming work period based on the current state of the project and any potential changes that may impact the schedule or scope of work. This phase aims to ensure that the project is progressing smoothly and efficiently and that the team is prepared to execute the work as planned. The process of Lookahead Planning starts with the project team meeting to review completed work, assess the status of work in progress, and identify changes to the work plan. The team then collaborates to develop a detailed plan for the next four weeks, including the work to be performed, the resources required, and the sequence of activities. This plan is crucial in ensuring that the project is executed efficiently and effectively, as it provides a roadmap for the team to follow. One of the key benefits of Lookahead Planning is its ability to anticipate and resolve problems before they occur. This proactive approach ensures that the project remains on schedule and that the team is prepared to handle any challenges. The team can identify potential bottlenecks or risks and develop contingency plans to mitigate these risks. This level of preparation and foresight is essential in construction project management, as it helps to minimize the risk of delays and ensures that the project is completed on time and within budget. To further ensure the project's success, the team reviews the plan with project stakeholders to ensure its feasibility and ensure everyone is on the same page. By involving all stakeholders in the process, the team can ensure that everyone knows the project's goals and objectives and understands the work that needs to be done. This level of transparency and collaboration is critical in ensuring that the project stays on track and that all parties are aligned in their efforts (Sheikhkhoshkar et al. 2023). Lookahead Planning provides a comprehensive plan for the following work period and ensures that the team is prepared to execute the work as planned. By anticipating and resolving problems before they occur, the project remains on schedule, and the team can coordinate their efforts efficiently. Through regular meetings and collaboration with project stakeholders, the team can ensure that the project is executed smoothly and that everyone is aligned in their efforts toward its success (Hamzeh et al. 2009).

The Weekly Work Planning (WWP) phase of the LPS in construction project management is crucial to ensure the successful execution of the project. This phase involves creating a detailed plan for the work to be performed in the upcoming week based on the Lookahead Plan and the project's current state. In the WWP, extensive collaboration is required to aid each other in executing tasks and among workers and their superintendents to obtain instructions and directions. Also, deviations from the schedule are detected, analyzed, and addressed by all participating project members, and handoffs among different trades and members are handled and finalized, necessitating continuous and thorough discussions and collaboration (Hamzeh et al. 2009; Seppänen et al. 2010). The first step in the WWP phase is a meeting between the project team to review completed work, assess the status of work in progress, and identify changes to the work plan. The team then develops a detailed plan for the work to be performed in the upcoming week, including work, resources, and activity sequence. Through these collaborative efforts, the WWP phase aims to ensure that the project is progressing efficiently and that the team is prepared to execute the work as planned. By planning the work every week, the team can coordinate their efforts, ensure that the work is performed as planned, and identify and resolve any potential issues before they become problems. Finally, the weekly work plan is reviewed with stakeholders to ensure that everyone is on the same page and that the work plan is feasible. Day-to-day collaboration on site is key, either to abide by the plan or to adjust to the plan when necessary. Through these collaborative efforts, the Weekly Work Planning phase of the Last Planner System helps to ensure the successful and efficient execution of the construction project. The discussed collaborative actions are classified into the different LPS phases and represented in Table 1 below. While Table 1 is not exhaustive, and some additional collaborative actions might occur during the LPS phases, it exhibits the main actions that require collaboration among the project members during the planning and execution phases of a construction project.

Table 1: Collaboration Actions in the LPS

Master Scheduling	Pull Planning	Lookahead Planning	Weekly Work Planning
Aligning perspectives	Understanding the scope	Reviewing completed work	Reviewing completed work
Setting major project milestones	Identifying activities	Assessing work in progress	Assessing work in progress
Identifying potential constraints	Sequencing activities	Identifying work plan change	Identifying work plan change
Providing a high-level overview	Identifying required activity resources	Developing a detailed plan for the lookahead period	Developing a weekly work plan
Engaging the project team	Allocating resources	Assigning task responsibilities	Reviewing weekly work plan
	Agreeing on planned activity dates	Reviewing the plan with project stakeholders	Analyzing constraints
	Identifying critical activities	Sharing knowledge to identify constraints	Resolving potential issues
	Designing successful handoffs	Agreeing on which risks are allocated and which risks are shared	Addressing schedule deviations
			Sharing efforts and instructions to execute tasks
			Discussing handoffs finalization

AGENT-BASED MODELLING AND SIMULATION OF COLLABORATION DURING THE LPS

In order to investigate the impacts of collaboration carried out at different phases throughout a construction project, an agent-based simulation model was built using AnyLogic v. 8.7.10. The model included two agent populations: tasks and members. Data from a sample project were used. Agent-based modeling (ABM) is a computational modeling that focuses on simulating the actions of individual agents and how they interact with one another and their environment. ABM is useful for studying multi-interacting complex systems, such as social, economic, and ecological systems.

MODEL DESCRIPTION

The task population included 14 agents representing 14 individual tasks. It was assumed that the project included five trades, so each modelled task was randomly assigned to one of the five trades. Each task agent was assigned a set of attributes, including an ID number, a trade it belongs to, a planned duration, a planned date for pull planning, a planned date for lookahead planning, a planned date for execution, and a set of predecessors. It also included a statechart, where the task agent moves from one state to another based on its progress. The statechart was divided into three main sections representing (1) pull planning, (2) lookahead planning, and (3) weekly work planning, each containing parameters that specify the required number of superintendents, the required number of workers, the required number of collaborations among superintendents, and the required number of collaborations among workers.

Conditions and functions in the model drove the behavior and progress of the task agents along the different states. The overall behavior of each task agent is described as follows: Once a task's pull planning date is due, it moves from the "not_due_yet" state to the "plan_pull" state, where it starts preparing for its pull planning phase by checking that all superintendents are idle. Once checked, the task agent sends all superintendents messages to start pull planning and moves to the "start_pull" state. Once the number of completed collaborations among the superintendents reaches the required number of collaborations, the task agent moves to the "wait_for_lookahead" state, where it waits for one week after its actual pull planning start date. It then moves to the "plan_lookahead" state, where is starts preparing for the lookahead planning phase by checking that the superintendent of the trade it belongs to and another superintendent for another trade are idle. Once checked, it moves to the "Start_Assigning" state, where it assigns several worker agents based on the prespecified required number of workers belonging to the same trade. Once the required number of workers is achieved, is moves to the "start_lookahead" phase until the number of completed collaborations among superintendents and number of completed collaborations among workers reach the required values. Afterwards, the task agent waits for one week after its actual lookahead planning start date to pass before going through the "Weekly Work Planning" phase states, which are identical to those of the "Lookahead Planning" phase, except for the values of the required numbers of workers and superintendents and the required number of collaborations among workers and superintendents, which vary based on each phase. Once the required collaborations are achieved, the task agent moves to the final "complete" state and notifies the tasks that follow it that they may start. The simulation is stopped once all 14 tasks are completed.

As for the members agent population, it included five superintendents (one for each trade) and several workers. Each member agent was given an ID, a role specifying whether they are superintendents or workers, and a trade they belong to. Each member was also given "willingness" to collaborate, "engagement" in the process, and "scope familiarity" parameter values. These parameters were used to calculate each member agent's "probability of collaboration". They were chosen based on the literature review carried out in the previous sections, proving that positive functional relationships may exist between the three factors and collaboration. The values of these three parameters vary among the different scenarios, which will guide the analysis process in this study. Finally, the probability of collaborating for each member agent is calculated as the average of the aforementioned three parameters. During each phase, if the member agent's probability to collaborate is higher than 5, they collaborate. Otherwise, they do not. In this case, they return to their phase and increase their probability to collaborate by a specified value. Member agents moves between the "Idle" state and the three states of the different phases, i.e. "pull planning", "lookahead planning", and "execution", based on messages received from the task agents to start or stop working on a specified phase.

SIMULATION SCENARIOS

Various scenarios were simulated to investigate the impact of collaboration on the different LPS phases. The scenarios were driven by the changing values of the modelled factors impacting the chance of collaboration among agents, which are each agent's "willingness" to collaborate, "familiarity" with the scope of the tasks in hand, and "engagement" in the process. The different modelled scenarios are shown in Table 2. The terms "high" and "low" refer to the modelled probability of collaboration among agents during the different phases. For example, in scenario 1, member agents were assigned low ranges of factor (willingness, engagement, and familiarity) values to decrease the probability of collaboration among all LPS phases.

Table 2: Modelled Scenarios and Their Assigned Collaboration Probabilities

Scenario	Pull planning	Lookahead	WWP
1	Low	Low	Low
2	High	Low	Low
3	Low	High	Low
4	Low	Low	High
5	High	High	High
6	Low	High	High
7	High	Low	High
8	High	High	Low
9	Average	Average	High
10	Average	Average	Low

ANALYSIS AND DISCUSSION

The model was run for various scenarios as outlined in Table 2, and the results are displayed in **Error! Reference source not found.**(a) and **Error! Reference source not found.**. These fi gures illustrate the obtained durations (in days) based on the different scenarios in the simulation model. The study variables represent the level of collaboration in the pull planning, look-ahead planning, and weekly work planning phases. For a methodical analysis of the different scenarios and results, the two extremes in the levels of collaboration are examined as a first step: high collaboration in all phases (referred to as “best” scenario) and low collaboration in all phases (referred to as “worst” scenario). Doubtlessly, the highest level of collaboration in all three phases leads to the shortest project duration (86 days), emphasizing the vital role of collaboration in each stage of the LPS, while low collaboration in all three phases leads to the longest project duration (168 days), stressing the need for collaboration throughout the entire LPS and the involvement of all stakeholders in the planning and execution process.

When collaboration is high in the pull planning and look-ahead phases but low in the weekly work planning phase, the project duration extends slightly (94 days) compared to the best scenario, highlighting the importance of collaboration in the weekly work planning phase for maintaining project momentum and ensuring that all team members are on the same page. However, this scenario generated the second shortest duration among all scenarios, implying that despite the lack of collaboration during execution, the undertaken collaboration attempts early on in the project during the planning phases guaranteed a safe degree of satisfactory duration results.

On the other hand, when comparing this 94-day result with its neighbouring and high 116-day result obtained by only decreasing the level of collaboration in the pull planning, we can deduce the significance of collaboration carried out in the early stages of the project. This result indicates that early involvement is crucial for an efficient performance and a successful construction project.

The second longest duration among all scenarios was obtained from the one with low collaboration in pull planning and lookahead planning but high collaboration in the weekly work planning (142 days). This result indicates that despite collaborative efforts being exerted during execution, the lack of early collaboration during the planning phases rendered the early project completion near impossible. To further reinforce this hypothesis, by analysing the scenario right above it, which is obtained by only increasing the collaboration level in the pull planning phase, a 103-day duration was obtained, showing a significant reduction in the duration of the project by enforcing collaboration in the early pull planning phase.

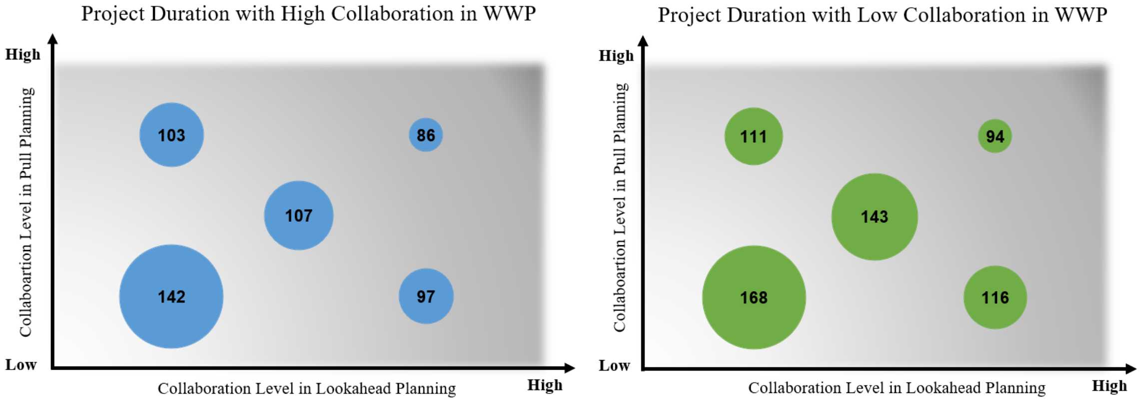

Figure 1: The project duration in case of high, average, and low collaboration in pull planning and lookahead planning with (a) high collaboration in the WWP and (b) low collaboration in the WWP

Figure shows the percent increase in project duration for different scenarios compared to the "best" scenario with high collaboration in all phases. As the level of collaboration decreases, the difference from the best result increases. For example, when collaboration is low in all three phases, the difference from the best result is 95% (168), which highlights the importance of collaboration in all phases of the LPS for a successful and efficient construction project. When collaboration is high in the pull planning and lookahead phases but low in the weekly work plan phase, the difference from the best result is only 9% (94), which further reinforces the importance of early collaboration.

The difference from the best result serves as a measure of the impact of collaboration on project duration and demonstrates that high collaboration results in shorter project durations. The difference from the best result is a useful benchmark for assessing the impact of collaboration on construction projects using the Last Planner System. It demonstrates the importance of collaboration in all phases of the LPS for a successful and efficient project outcome.

This study emphasizes the complexity of collaboration in construction, underlining the need for accurate quantification of its impact on project performance. Effective implementation of LPS relies on fostering a culture of communication and collaboration among all stakeholders involved in the construction project. LPS has been proven to be an effective way of improving workflow in construction production systems and creating a social network among subcontractors, which enhances coordination among trade crews. Thorough implementation of LPS can strengthen social networks, contributing to improved coordination among construction teams and building relationships. However, the success of LPS is dependent on the whole system's thinking and learning culture. Avoiding excessive centrality in LPS meetings is important, as this can affect the necessary distribution of connections and responsibilities. While social network metrics such as network density, average degree, diameter, and average path length are significant factors in project performance (Castillo et al. 2017, 2018; Priven and Sacks 2015a; b), the quality of communication and relationships among team members in different phases of LPS should also be considered.

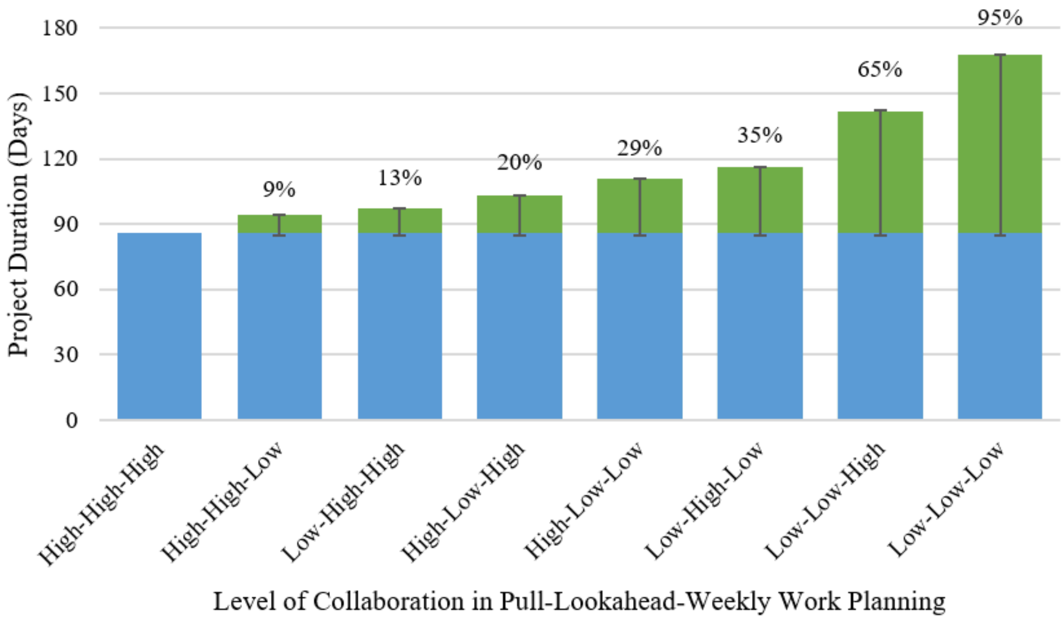

Figure 2: Percent Increase of Project Duration in Each Scenario Compared to "Best" Scenario

CONCLUSION

The findings of this study emphasize the critical role of collaboration in various phases of the LPS in ensuring successful and efficient construction projects. Clearly enough, high collaboration in all three phases of the LPS was found to result in the shortest project duration, while low collaboration in all phases resulted in the longest duration. Simulation results also highlighted the significance of early involvement of project members in the collaboration process, as scenarios with high collaboration in the planning phases resulted in short durations, while those with low collaboration in the early pull planning phase resulted in longer durations, despite having high collaboration in the later stages. The difference from the best result serves as a valuable benchmark for evaluating the impact of collaboration on project duration, emphasizing the need for prioritizing communication and cooperation among all stakeholders in the LPS.

The varying duration results prove the importance of investigating and accurately quantifying the impacts of collaboration on construction projects. They also demonstrate how changes in the levels of collaboration during the different LPS phase have different impacts on the durations, which proves that impacts of collaborative efforts vary depending on when they are being exerted. Finally, the importance of early collaboration in construction projects is clearly manifested in the conducted comparison and analysis.

The study sheds light on the complexity of collaboration in the construction and the need for precise quantification of its impacts on project performance. The study aimed to address this gap by investigating the impact of collaboration in different phases of the LPS and utilizing computer simulation to model collaboration among project members. The conclusion highlights the importance of early collaboration in construction projects and the need for further research to accurately quantify qualitative aspects of collaboration in construction.

The limitations of the study include the lack of detailed investigation into the specific factors that influence collaboration on project performance. The study does not account for individual factors that may impact collaboration, such as a member's familiarity change with the project scope and their role within the construction team. For instance, the study did not investigate the varying degrees of engagement between a superintendent and a construction worker during different phases of the project. Future research could address studying the impacts of individual factors that influence collaboration on performance.

METHODOLOGY TO QUANTITATIVELY ASSESS COLLABORATION IN THE MAKE-READY PROCESS

Camilo Ignacio Lagos[1], Rodrigo F. Herrera[2], Alejandro Mac Cawley[3], Pablo Maluk[4], and Luis F. Alarcón[5]

ABSTRACT

The Last Planner System (LPS) promotes collaboration to plan, prepare and execute work systematically. Make-Ready Planning (MRP) is a key LPS component, connecting mid- and short-term planning by proactively identifying and removing constraints. However, systematic deficiencies in MRP implementation have been observed, and MRP assessment mechanisms are limited to constraint management indexes and qualitative assessment of practices. Hence, finding easy to apply ways to quantitatively assess MRP collaboration and its impacts on LPS performance is identified as research opportunity. To address this, a Design Science Research approach was used to propose a methodology for evaluating MRP collaboration using Social Network Analysis (SNA) of objective LPS information captured by existing Information Technology (IT) support systems. This approach allows for the creation of a directional social network of interactions between constraint removal (source) and task execution (target) last planners. Assessing the average degree, centrality, heterogeneity, number of connected components and density allows to identify collaboration improvement opportunities as well as understanding the impact of collaboration on LPS performance, as the project progresses.

KEYWORDS

Last Planner System ®, make-ready planning, constraint analysis, collaboration

INTRODUCTION

The Last Planner System (LPS) is a highly effective production planning and control system that is based on the principles of Lean Construction (Ballard & Howell, 2003). It uses a pull framework, in which upcoming work is planned in increasing detail as required for preparation and is only pulled to execution once all potential constraints have been removed (Ballard & Tommelein, 2016). This aims to increase planning reliability through a collaborative effort to stabilize the workflow (Alarcón et al., 2014). LPS takes its name from the concept of last planners, the direct personnel in charge of preparing and executing work on site (Ballard & Howell, 2003). Last planners can be directly or indirectly responsible for task execution,

through the identification and removal of constraints such as materials, equipment, information, labor, or conditions (Retamal et al., 2020). Instead of relying on a traditional top-down approach, last planners form cohesive horizontal networks in which execution compliance and plan reliability are facilitated by the collaborative assessment and preparation of work, in a process known as Make-Ready Planning (MRP) (Ebbs & and Pasquire, 2018).

MRP is the key link between Lookahead Planning and Short-term Planning (F. R. Hamzeh et al., 2015). The first is the process of identifying, detecting, assessing, and planning upcoming work in a three to six weeks scope, and the second consists of selecting executable work in a scope of one to two weeks, establishing commitments that will be followed throughout, and assessing compliance at the end to determine improvement opportunities (Ebbs & and Pasquire, 2018). The effective transition from Lookahead to Short-term Planning requires a sufficient workflow of executable tasks aligned with the mid-term goals (Hamzeh et al., 2015). Hence, MRP focuses on generating a Workable Backlog (WB) of constraint-free tasks, ready for commitment and execution. A larger WB allows last planners to better align commitments with their capacity, and establish more reliable commitments with flexibility to pull work in Lookahead Planning (Pérez et al., 2022).

MRP relevance is well-documented, and researchers have found a direct relationship between MRP effectiveness and long-term project performance as well as statistically significant positive correlations between the Percent of Constraints Removed (PCR) (Ballard & Tommelein, 2016), the Percent Plan Complete (PPC) and Schedule Performance Index (SPI), indicators that capture the results of the MRP, short-term and long-term planning, respectively. Nevertheless, MRP has been found to be one of the weakest implemented LPS components, significantly lower than aspects such as commitment-based short-term planning and searching for Reasons of Noncompliance (RNCs) (Daniel et al., 2015). Thus, researchers argue that implementing LPS with a short-term focus instead of a systematic mid-term planning and work preparation approach significantly limits its potential benefits (Lagos et al., 2022).

Improving MRP requires continuously assessing the effectiveness of constraint identification, committing and removal; employment of correct practices and benchmarking its results (Ballard & Tommelein, 2021). The results of MRP can already be captured using LPS indicators such as the PCR, Tasks Made Ready (TMR) and Tasks Anticipated (TA) indicators, while practices can be assessed using multiple implementation guidelines, maturity and adoption surveys (Lagos et al., 2019). However, there is a gap in the systematic assessment of last planners' collaboration to identify, manage, and remove constraints in an effective and efficient manner. Construction management requires multiple stakeholders, from suppliers to engineers and subcontractors to work in coordination under fast changing conditions (Ebbs & and Pasquire, 2018; Lagos et al., 2022). Without MRP collaboration, Last Planners can plan to execute constrained work packages or fail to detect executable packages when committing in short-term. In a high-performing LPS team, silos are replaced with closely tight networks, where Last Planners communicate actively to commit work or request its preparation (Castillo, Alarcón, & Salvatierra, 2018; Ebbs & and Pasquire, 2018)

Social Network Analysis (SNA) has been used as a diagnostic tool to assess collaboration and information flows in Lean Construction and AEC (Herrera & Alarcón, 2022). Its use in research and practice allows discovering unknown patterns of information flow and comparing them against expected interactions, also allowing to surpass preconceived perceptions of team collaboration (Priven & Sacks, 2013). SNA can be applied to multiple networks from general interaction to planning, problem-solving and learning (Alarcon et al., 2013). Also, it provides a wide array of indicators for objective representation of these networks, such as density, centrality, homogeneity, and isolated components, among others (Marin & Wellman, 2011).

SNA has mostly been applied in Lean Construction via perception surveys and required significant information preprocessing through tools to obtain representative graphs and indicators (Castillo, Alarcón, & Salvatierra, 2018). However, the AEC industry has considerably increased its technological adoption during the past decade, especially since the start of the pandemic (Assaad et al., 2022; Elrefaey et al., 2022). This has prompted the adoption of IT support systems for LPS, which can be easily use in combination with data science tools in a single stream, to facilitate the use of SNA applied to existing information being captured periodically by LPS software, instead of relying on surveys.

This research proposes a methodology to evaluate MRP collaboration and its impact on LPS performance, by applying SNA to objective LPS information captured by IT support systems for LPS. Resulting metrics from mapping interactions between constraint removal (source) and task execution (target) last planners (LPs), can complement existing LPS indicators, facilitating the identification of improvement opportunities.

RESEARCH METHODOLOGY

This research aims to propose a methodology to assess last planner collaboration on the make-ready process, based on objective information generated through mid- and short-term planning. The Design Science Research (DSR) methodology was selected as it facilitates the generation of prescriptive knowledge to model and solve complex problems. DSR focuses on designing artifacts, such as methods, models, or tools, that capture the existing understanding of the problem, its requirements, key factors, and their relationships, as well as goodness criteria necessary for potential solutions (Da Rocha et al., 2012). Thus, artifacts, can be iteratively refined by testing their fitness to model and facilitate finding solutions to the intended problem.

The following two questions were formulated to structure the research: "How can MRP collaboration be assessed using existing LPS information?" and "How can MRP collaboration metrics complement existing LPS indicators to assess performance?", consequently, the research was structured into four stages:

1. **Problem space:** Assessing the existing body of knowledge to model how MRP collaboration and its impacts LPS performance.
2. **Solution space:** How to capture MRP collaboration using existing LPS information.
3. **Artifact design:** Proposing a methodology matching the problem and solution spaces.
4. **Artifact testing:** Validation with empirical information from LPS case studies.

LITERATURE REVIEW

BODY OF KNOWLEDGE REGARDING THE PROBLEM SPACE

LPS promotes horizontal collaboration to assess, prepare and commit upcoming work, reliably, through systematic short-term cycles (Priven & Sacks, 2013). According to the supporting body of knowledge, failing to assess upcoming work will limit the team's capability to identify constraints and plan accordingly, while failing to prepare it through constraint removal will limit their capability to formulate and accomplish reliable execution commitments (Retamal et al., 2020). Previous transversal studies have observed statistically significant correlations between the PCR, PPC and SPI (Lagos et al., 2019). In despite that a full understanding of these relationships would also require connecting them to mid-term assessment and work preparation indicators, such as Tasks Anticipated (TA) and Tasks Made-Ready (TMR), these missing links have been partially covered by constraint management indicators such as the Constraint Identification Time (CIT) and Constraint Removal Efficiency (CRE) (Ballard & Tommelein, 2016; Pérez et al., 2022). CIT measures how far ahead are constraints being identified, compared to the Lookahead scope, while CRE compares the actual time needed to remove them, against the planned time committed when the constraint was identified (Lagos & Alarcón, 2021).

Both the CRE and CIT exhibited empirical correlations with the PCR and PPC (Pérez et al., 2022).

On the other hand, transversal studies using SNA to assess LPS interactions have discovered statistically significant relationships between SNA metrics of collaboration, LPS indicators and project performance measures (Castillo, Alarcón, & Salvatierra, 2018; Retamal et al., 2020). Particularly, stronger collaboration in the exchange of relevant information, as well as planning and problem solving, captured through SNA metrics of density and average degree, showed statistically positive correlations with constraint release and planning effectiveness, measured by the PCR and PPC (Castillo, Alarcón, & Salvatierra, 2018). A subsequent study by the same authors also correlated the network strength metrics with benefits in quality, safety, costs, and productivity (Castillo, Alarcón, & Pellicer, 2018). Furthermore, a case study using a similar methodology to compare two projects of similar characteristics and LPS experience, observed that the project with higher horizontal collaboration in planning and problem solving exhibited significantly better MRP practices and long-term schedule compliance, while the project with a more traditional top-down management approach exhibited work-preparation silos that allowed to obtain high PPCs but prevented them from sustaining high long-term schedule performance due to the lack of flexibility of the WB (Lagos et al., 2022).

These studies support the statement that horizontal collaboration in planning and work preparation is key to support the LPS virtuous cycle of proactive planning, committing and control, which in terms of MRP, corresponds to (1) efficient constraint identification and (2) reliable removal (Ballard & Tommelein, 2016). Horizontal collaboration facilitates that last planners take part in this process (Lagos et al., 2022), while the strength of these interactions, i.e. close collaboration between multiple parties, leads to work preparation reliability (Castillo, Alarcón, & Pellicer, 2018). Also, since the goal of MRP is to facilitate the reliable commitment and execution of upcoming tasks, MRP effectiveness can be assessed by three subsequent factors: Effective work preparation, reliable work commitment and schedule compliance (Ballard & Tommelein, 2016). Therefore, based on these relationships and supporting evidence, the problem space is modeled by a six steps process from lookahead planning to sustained schedule compliance, aided by strong horizontal last planner collaboration, as shown in Figure 1.

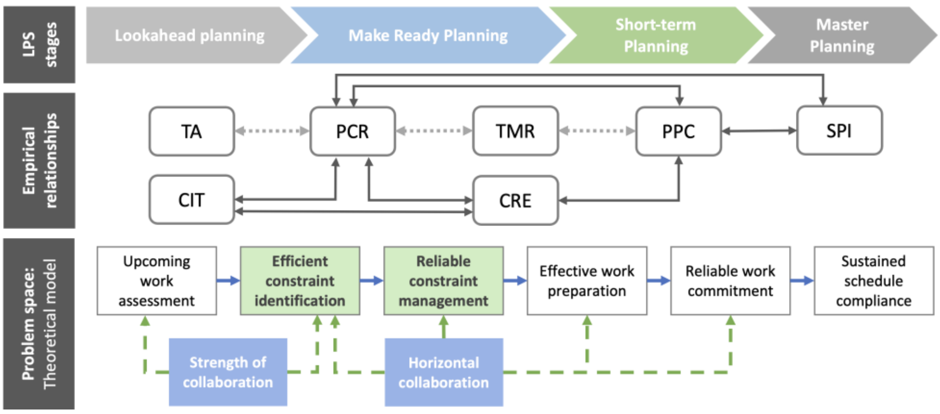

Figure 1: Theoretical Design of the Problem Space

Body of Knowledge Regarding the Solution Space

Social network analysis (SNA) studies the relationships and connections between individuals in a network, allowing to represent them in quantitative metrics as well as graphs (Marin & Wellman, 2011). It allows to study the structure and dynamics of a network, as well as the roles and influence of the different actors within it. SNA has been used in LPS to study the communication and collaboration patterns among the different stakeholders, including project managers, contractors, subcontractors, and the wider project team (Priven & Sacks, 2015). SNA facilitates identifying key roles such as connectors, bottlenecks, influencers, and decision-makers, as well as areas with lacking communication or collaboration (Flores et al., 2014).

Researchers have mainly captured social networks by employing indirect means, consisting in surveys of perceived interactions, applied to all members of the network (Herrera & Alarcón, 2022). These surveys cover general as well as specific interaction such as information exchange, planning and problem solving, learning, leadership, and feedback, among others. The surveys ask each team member a linking question, that can be (1) bidirectional, such as with "whom do you interact for this specific purpose?" Or directional, such as "who provides you key information necessary to carry out your work?" Also, responses can be binary or weighted, usually by a perceived frequency or relevance of the interaction (Alarcon et al., 2013).

Although researchers have used both bidirectional and directional links to capture networks, the later are preferred, since they allow to assess an individual's interactions based on the times it was targeted by other team members (incoming links), instead of by their own perceived interactions (outgoing links), helping to remove respondent bias (Cisterna et al., 2018; Herrera et al., 2020). Also, the way in which the question is formulated and the use of incoming or outgoing links can affect the network's representativeness. For example, if outgoing links are used to map an information exchange network, asking "to who do you provide relevant work information?" would have a higher risk of bias than asking "who provides relevant information for your work?". The use of objective information captured by IT support systems employed in LPS can help remove the risk of biased responses.

Regarding the assessment of MRP collaboration, some of the metrics used to quantify and describe the structure and dynamics of a network include the (Arif, 2015):

Density: Represents the strength of the network, as the number of existing connections over the total possible connections between its nodes. Hence, the higher the density, the higher the number of direct connections between the network's individuals.

Clustering coefficient: This measures the degree to which an individual's connections are connected to one another. It is often used as a measure of the cohesion of the network since it provides a representation of how likely is an individual to reach all others through its connections.

Closeness: Distance of an individual to all remaining nodes of the network. Equates to the number of interactions required to reach the remaining individuals. Therefore, is a measure of easiness of communication or the spread of information.

Path length: Average distance between any two individuals in a network. It is often used as a measure of the efficiency of information or resource flow through the network.

Degree: Relevance of an individual in a network via the number of connections (links) it possesses. It can be measured by the outgoing, incoming, or bidirectional links, using weighted or binary connections.

Betweenness: This measures the extent to which an individual is a "bridge" between other individuals in a network. It is often used as a measure of an individual's potential control or influence over the flow of information or collaboration within the network.

Eigenvector centrality: This measures the importance of a node in a network based on the importance of its neighbours. It is often used as a measure of how likely a node is to be reached by a random individual through its connections in the network.

Since the focus is placed in the assessment of network collaboration during MRP, individual metrics should be transformed to represent the cohesion, efficiency, and efficacy of the make-ready planning network, and not of a specific individual. Common practice is averaging individual metrics to represent the network, for example, using the average degree and average clustering coefficient as measures of cohesion. On the other hand, the following LPS metrics were selected to represent the short-term cycle's components (Hamzeh et al., 2019):

Percent Constraints Removed (PCR): Represents the constraint management reliability, measuring the number of constraints effectively removed during a short-term period, over the number of constraints planned to be removed during that cycle.

Percent Plan Complete (PPC): Represents the short-term planning reliability, measuring the number of short-term task execution commitments accomplished over the number of commitments made.

Schedule Performance Index (SPI): Represents the accomplishment of the master plan at the end of each period, by comparing the accumulated progress against the expected progress according to the initial plan, i.e., the Baseline.

SOLUTION ARTIFACT

To support LPS, IT systems require to capture and monitor commitments on a short-term basis. Therefore, they must contain four sources of information: (1) Tasks, which conform the master plan, (2) Constraints, which are linked to tasks, (3) Last Planners, who identify, plan, commit and manage tasks and constraints, and (4) terms, which contain the constraints and tasks committed in every period and their compliance. As last planners manage their short-term cycles, they will take tasks from the master-plan, pull them to the lookahead plan, assess them in search of constraints to be committed and once these are removed, the tasks are committed and executed accordingly. This process is captured periodically as terms.

The solution artifact represented in Figure 2 was developed with these four sources of information in consideration, to represent the transition from Lookahead Planning to short-term and master planning outcomes, via make-ready planning. The existing LPS indicators PCR, PPC and SPI are used to represent compliance and variability of performance in make-ready, short-term and master planning, respectively. In addition, a PWC indicates the Percent of Work Complete (PWC) indicator, explained in detail in the following sections. Finally, the relationship between constraint identification, reliable removal, the strength and horizontalness of collaboration is expanded using a set of SNA metrics taken from the existing body of knowledge and the aforementioned LPS indicators.

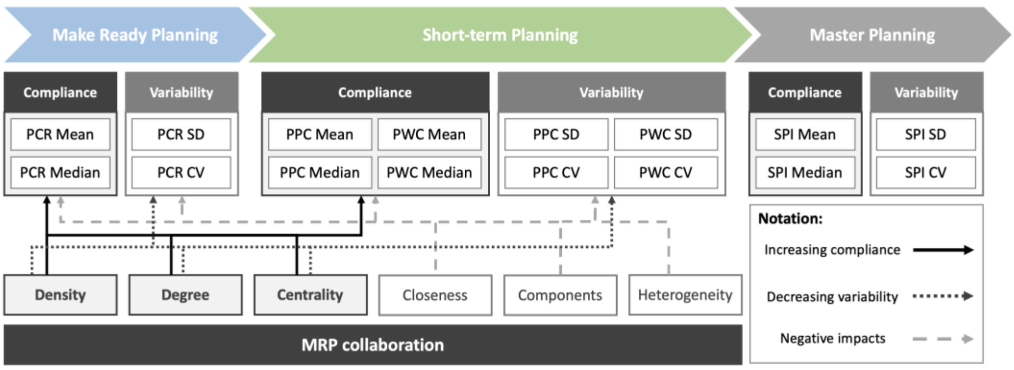

Figure 2: Solution artifact design

MRP NETWORK

Since MRP focuses on committing constraint removal to prepare the work, the MRP collaboration network can be mapped using the relationships between constraint Last Planners, the tasks' constraints, and the tasks' Last Planners. The MRP represents directional relationships, where the Last Planners committing the constraint removal, or Indirect Last Planners (ILP) prepare the work of the Last Planners that subsequently commit the execution of the task being prepared, i.e., the Direct Last Planners (DLP). Hence, MRP forms directional networks linking an ILP to a DLP. The indirect last planner acts as a source node, who removes constraints for the direct last planner, i.e., the target node. An ILP who prepares more work for a given DLP would have a higher relevance, giving way to a directional weighted network.

These interactions were obtained from the empirical data captured in the terms, by listing the last planners in a symmetrical two-dimensional matrix, with one dimension representing their role as DLPs and the second as ILPs. Each interaction is represented by the number of constraints which an ILP commits to remove for a DLP and the number of tasks that the DLP has committed. The ratio between the number of ILP's constraints over the DLP's tasks serves as a weighting factor. The connectivity of an individual node is given by the strength of the MRP collaboration, hence, its captured by the sum of incoming weights to a node, indicating that more constraints are being removed to prepare its tasks. Since the main characteristics of interest of the network are its strength and horizontalness the following indicators were calculated from the matrix:

Degree: Strength metric obtained as the arithmetic mean of all individuals' degrees, where each degree corresponds to the sum of incoming weight.

Density: Strength metric obtained as the number of directed links observed, divided by the total potential links between individuals, where a density of 1 indicates that every individual prepares work for each of the remaining nodes.

Connected components: Inverse strength metric representing the number of disconnected sub-groups in the network. The presence of two or more components indicates that one or more individuals are disconnected from the remaining group.

Heterogeneity: Inverse homogeneity metric representing the coefficient of variation of the mean degree, calculated as the standard deviation over mean. A higher coefficient of variation indicates disparity among individuals.

Closeness: Calculated as the arithmetic mean of the closeness centrality, which represents the average distance from anode to all other nodes, i.e., the average number of interactions required to reach any individual.

Centrality: Obtained as the arithmetic mean of the nodes' Eigenvector Centrality. Eigenvector centrality compares the degree of the nodes directly accessible by an individual, against the degrees of the network, where greater centrality indicates that an individual is closely connected to relevant ones.

LPS METRICS

In addition to obtaining the PCR and PPC as the percent of accomplished commitments in each term, for constraint removal and task execution, respectively, the authors also calculated the actual progress, SPI and Percent Work Complete (PWC) for each term. The SPI compares actual accumulated progress and expected progress; therefore, a baseline progress was calculated using the planned task dates at the start of the masterplan. Each task was assigned a weight equivalent to its planned execution days over the total planned execution days from all tasks in the initial plan. Each task would provide progress according to its weight distributed linearly across its execution days. The progress added by all tasks being executed was summed for each term, and the accumulated progress at the end of each term was calculated to obtain the Baseline expected progress (BL). The progress of each task was calculated at the end of each term, multiplied by the task's weight, and summed to obtain the actual accumulated progress (AP) at the end of each term. Then, the SPI divided the AP by the BL in each term.

The PWC represents the ratio between the percent of work completed in each period and the percent of work committed, using the progress, commitment, and weight of the tasks in each term. The numerator of the PWC corresponds to the weighted sum of the relative progress achieved by the tasks of a term, and the denominator, to the weighted sum of the relative progress committed for these tasks. Hence, as Equation 1 shows, the relative progress of a task is the difference between the progress achieved at the end of the current term, minus the progress achieved at the end of the previous. On the other hand, the relative commitment corresponds to the commitment in the current term, minus the progress achieved in the previous. The relative progress of each task participating in the term is multiplied by its weight and summed to obtain the relative progress of the term, and the same is done to obtain the relative commitment for that term. Then, their division represents the ratio between the actual progress gained in a term, and the progress expected by the commitments made.

$$PWC_{term\ j} = \frac{\sum_{task\ i}^{N} \left\{ \left(Progress_{i,j} - Progress_{i,j-1} \right) \cdot Weight_i \right\}}{\sum_{task\ i}^{N} \left\{ \left(Commitment_{i,j} - Progress_{i,j-1} \right) \cdot Weight_i \right\}}$$

The PCR, PPC, PWC and SPI of each term are aggregated for each project, using their descriptive statistics of mean, median, standard deviation (SD), and coefficient of variation (CV). The mean and median are used as measures of performance compliance, and the standard deviation and coefficient of variation, used to represent variability across terms.

RESULTS AND DISCUSSION

ARTIFACT TESTING METHODOLOGY

The proposed methodology was tested using empirical information from 68 projects that employed the same IT support system for LPS. All had implemented LPS for at least 8 weeks prior to the data collection and were followed for at least 10 weeks, capturing, in average 50% of their execution scope. Table 1 presents the sample's descriptive statistics. The solution artifact was validated by (1) its fitness to capture relevant relationships between indicators, as well as (2) the usefulness of MRP indicators to discover impacts in LPS metrics.

Table 1: Sample's Descriptive Statistics

Statistic	Tasks	Duration (days)	Captured scope	Terms	Constraints	Constraints per task	DLPs	ILPs
Mean	1104	494	50%	32,5	148	0,3	12,7	10,9
Median	585	494	41%	25,0	86	0,2	11,0	9,5
SD	1146	255	29%	20,3	172	0,4	8,7	5,5

The fitness was assessed with statistical correlation analyses, using the Spearman Correlation test with the raw variables and the Pearson Correlation test with the normalized variables. Normalization was performed using the standard conversion and outliers with absolute $z > 3.0$ were removed. A correlation was deemed statistically significant if the resulting p-value was lower than 0.05 and categorized as weak with $R \geq 0.3$, moderate if $R \geq 0.5$ and strong if $R \geq 0.75$.

The usefulness was assessed using statistical mean difference analyses. Each the median of each MRP metric was used to divide the universe into two samples. Then, the samples were compared in each LPS variable. The normality of both samples was assessed, and the t-test was used to compare normal distributing samples, while the Mann Whitney's U test was used if any sample was not parametric. Both tests required a $p\text{-value} < 0.05$ to detect a statistically significant difference and the process was repeated using the 6 MRP metrics to assess differences in the 12 LPS indicators.

VALIDATION RESULTS

Figure 3 maps the relationships found between the SNA and LPS metrics. As observed, MRP collaboration is directly correlated to master plan and MRP performance metrics. Also, its impact is visible through the existing correlations between the complementary LPS metrics. Out of the 58 significant correlations found, 47 were weak, 6 were moderate and 5 strong, nevertheless, all correlations presented a statistical p-value<0.05. It must also be noted that the moderate and strong correlations were found only between PPC and PWC indicators. Table 2 presents the differences in LPS indicators (Tested KPIs) detected when splitting the sample using each the SNA indicators (Sampling KPIs). Each sampling KPI was used to divide projects into groups above and below the median, and then, the groups were tested to find statistically significant differences in their LPS indicators. The table shows the 17 statistically significant differences (23.6%) found, covering all LPS indicators, except the PWC Mean and the SPI.

Table 2: Statistically Significant Mean Differences

Sampling KPI	Tested KPI	Top group	Bottom group	Difference	p-value
Density	PCR Mean	66.1%	74.9%	-11.7%	0.037
Density	PCR Median	65.7%	78.9%	-16.8%	0.020
Degree	PPC Median	69.0%	77.1%	-10.5%	0.046
Centrality	PPC Mean	67.8%	74.9%	-9.4%	0.039
Centrality	PPC Median	68.7%	77.4%	-11.2%	0.032
Centrality	PPC STD	19.4%	16.4%	18.4%	0.028
Centrality	PPC CV	31.0%	22.9%	35.0%	0.004
Centrality	PCR Mean	64.8%	76.2%	-15.0%	0.006
Centrality	PCR Median	65.0%	79.6%	-18.4%	0.012
Centrality	PCR STD	25.8%	21.3%	21.0%	0.020
Centrality	PCR CV	42.6%	30.3%	40.6%	0.007

Closeness	PCR Median	64.8%	80.7%	-19.7%	0.005
Components	PCR STD	27.0%	22.6%	19.2%	0.038

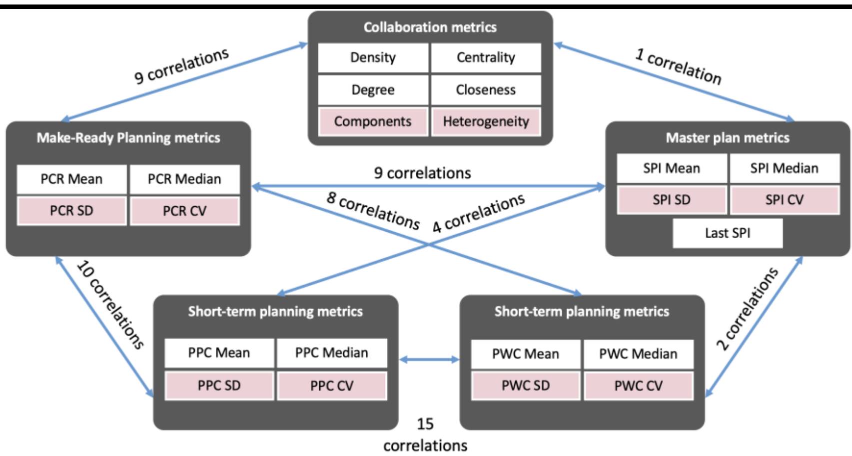

Figure 3: Correlations found Between MRP Collaboration and LPS Components

DISCUSSION

First, the results indicate that the methodology can detect relevant relationships between the 18 combined LPS and MRP indicators, as well as discovering potential impacts of MRP collaboration on LPS performance; thus, the artifact is deemed valid and provides answers to both research questions. Although most correlations found were weak, it must be noted that these were tested in a relatively small universe of case studies (68) and that the case studies presented significant variance regarding the number of tasks, constraints, DLPs, ILPs and, particularly, the number of terms registered, with half of the sample capturing between 15% and 41% of their scope. Nevertheless, the observed connectivity across all five LPS components, including the MRP collaboration poses a relevant opportunity for research that can lead to the discovery of key insights. This opportunity is also supported by the significant differences observed in LPS metrics obtained through the statistical sample comparisons.

On the other hand, it must be noted that all 17 statistically significant differences showed lower LPS indicators in the upper half of the MRP samples. These translate a potentially negative relationship between MRP collaboration indicators and LPS metrics, which must not be mistaken as a negative effect. For example, a greater number of components indicates a weakly connected network, thus, the decrease in compliance and increased variability observed are consistent with expectations. The same applies to the Closeness indicator, as a greater number indicates the necessity to go through more interactions to reach an average node. On the contrary, the network strength metrics degree and density showed relationships opposite to the expected. Authors assumed that higher density and degree would correlate to higher LPS indicators of compliance and lower variability, which was not the case. Two possible causes were inferred and should be addressed with subsequent research: The first, is that larger networks tend to be less connected. Thus, teams with less Last Planner involvement would reflect in higher network strength metrics, explaining the negative relation found between density, degree and the LPS indicators. The second is that, since the networks are weighted on the constraints to tasks ratio, a stronger network can indicate more constraints, leading to a more complex MRP process and difficulty to accomplish commitments. Finally, given that the results signal the need to further research the topic, the authors propose the continuation of this study, employing a larger sample with empirical schedule outcome indicators.

CONCLUSSIONS

This article proposed a methodology to quantitatively assess collaboration in the Make-Ready Planning process and its impacts on LPS performance, to help tackle the systematic deficiencies in MRP implementation, signalled as a gap by researchers. The authors used the DSR approach to match the current understanding of the problem with existing opportunities and designed an artifact capable of leveraging existing LPS information captured by IT support. The solution artifact employs six SNA indicators to assess MRP collaboration and complements with 12 LPS indicators to assess impacts on performance. Although the results showed mostly weak correlations between the LPS and SNA metrics used to capture MRP collaboration, the statistical differences analyses showed that when dividing projects using the SNA metrics, differences from 10% and up to 40% were found in their LPS metrics. These results allowed to validate the fitness of the methodology to identify key relationships among LPS components, captured in multiple indicators, as well as finding evidence of the impacts of MRP collaboration on LPS performance. Finally, the author acknowledge that the research should be expanded using a larger project sample with empirical schedule outcome indicators to assess its potential contributions to the state of art and practice in modelling and explaining LPS impacts on performance and the key role of MRP collaboration.

ACKNOWLEDGEMENTS

The authors would like to acknowledge financial support from ANID through project FONDECYT Regular N°1210769 and Beca Doctorado Nacional N°21181603 as well as thanking the Production Management Centre GEPUC from Pontificia Universidad Católica de Chile for facilitating this study.

PERSPECTIVES ON ROLES AND RESPONSIBILITIES OF PROJECT TEAM MEMBERS TO ENABLE COLLABORATIVE DECISION-MAKING PROCESS

Randi Christensen[1], Paz Arroyo[2], and Annett Schöttle[3]

ABSTRACT

The owners, architects, engineers, and contractors (OAEC) industry needs to enable a collaborative decision-making process to include different perspectives and thereby find the best solutions regarding some of the challenges we face, e.g., environmental impacts, social responsibilities, and economic pressure. Decision-making is a key element through which innovation and changes can be introduced to construction projects. The need for a collaborative decision-making process and the methods used to make decisions have been discussed in previous research. However, changing the way we make decisions calls for a new definition of the roles and responsibilities of the involved parties. In this paper, we analyze three different cases to identify the concerns of the different stakeholders and recommend how roles and responsibilities could be defined with the aim of making more collaborative, transparent, and value-adding decisions in the OAEC industry.

KEYWORDS

Collaborative decisions, choosing by advantages, roles, responsibilities, sustainability.

INTRODUCTION

This paper explores the need to change the way project team members make decisions in the owners, architects, engineers, and contractors (OAEC) industry to solve the challenges it faces, such as reducing environmental impact and improving performance. According to the World Green Building Council (2019), the construction industry is responsible for almost 40% of CO_2 emissions, and as explained by Flyvbjerg and Gardner (2023), megaprojects go over both budget and time again and again. One of the key elements to allowing for more innovation and improvements is to support more cross-disciplinary collaboration (Christensen, 2022). An idea is often born outside of the field of implementation. Therefore, to allow this cross-fertilization to happen, different disciplines or functions on the projects should meet, discuss, and agree on a way forward. However, the construction industry has a reputation for being somewhat conservative (Renz & Zafra Solas, 2016), and with the rapid changes to the constraints and context of the projects in the OAEC industry, this could work against the flexibility and change needed. Traditional organizational structures of the industry, and thereby the roles and

responsibilities, do not allow for such flexibility and innovation, as many projects do not have a formal collaborative decision-making process, and others follow a hierarchical process (e.g., Schöttle, 2022; Whelton et al., 2001). More critical thinking is needed to question the choices we make and how we are organized to make them. It is necessary to shift from decision-making as a discrete event made by a single person in authority to a collaborative process that aligns different perspectives of a decision (Garvin & Roberto, 2013). Challenging a unique perspective better enables the recognition of the biases of others in a decision-making process (Kahneman et al., 2013). Decision-making is therefore a key element through which innovation and changes can be introduced in construction projects. Here, the authors argue for the need for more critical thinking to be introduced in projects through a well-designed process to avoid personal conflicts and biases.

With the introduction of lean construction, practitioners realized that the delivery system must shift towards a more collaborative system (e.g., integrated project delivery [IPD]). The implementation of lean methods also includes methods for decision-making, such as choosing by advantages (CBA), where teams can make decisions in a collaborative way and find innovative solutions. Tillman et al. (2012) show that IPD enables a collaborative environment in which value can be co-created, allowing for customer expectations and supplier assumptions to be challenged. Meanwhile, it has been shown that CBA is a system that allows for more innovative ideas and solutions to be integrated into the design and project execution (Christensen, 2022), potentially generating a social process in which debate, argumentation, and rhetoric play an important role in the final resolution (Martinez et al., 2016). Additionally, CBA enriches the decision-making process and cultivates a shared understanding among project team members, even when they have conflicting values, allowing for all perspectives to be included (Parrish & Tommelein, 2009). When compared with other traditional methods, CBA allows for reaching a consensus faster and with less frustration for the team (Arroyo et al., 2016). It can also foster psychological safety and inclusiveness within the project team to overcome group thinking (Schöttle et al., 2019). As such, CBA has the potential for allowing project teams to collaborate and find innovative ways to address the challenges faced by the OAEC industry. However, implementing CBA as a new lean tool can meet resistance from the project team, and there is a need to explore team members' perspectives to engage in such a collaborative decision-making process.

Without clarity on the roles and responsibilities in both preparation and governance, the introduction of new decision-making methods might lead to confusion and frustration as hierarchies and power balances shift to make room for collaboration. According to Schöttle et al. (2018), a decision-making process should consider: (1) a decision method, (2) the structure of the process, (3) governance, and (4) documentation of the decision. In the related literature, the focus has mainly been on the process of reaching a decision using different decision-making methods, while less attention has been given to participants' roles and responsibilities in relation to these methods. Some papers that look at the roles in the decision-making process are specific to a case study considering one decision on a project (e.g., Martinez et al., 2016, look at formwork system selection, and Parrish and Tommelein, 2009, discuss structural system selection). Few papers document the roles and responsibilities of multiple decisions (e.g., Arroyo and Long, 2018, who consider interiors, mechanical systems, and landscape decisions of an IT campus, and Kpamma et al., 2017, who explore participatory design).

Therefore, in this paper we focus on an initial study to assess the key elements of the roles and responsibilities in collaborative decision-making in the OAEC industry. The aim of this research is to enable better and more collaborative and transparent decision-making processes, which could allow for the integration of innovation into the projects. The study focuses on the key roles of the client, the engineers/architects, and the general contractor. The investigation is based on three cases in which we analyze the concerns of different stakeholders regarding engaging in a collaborative decision-making process before drawing preliminary recommendations.

RESEARCH METHOD

This paper aims to answer the following research questions: (1) what are the concerns of the different stakeholders regarding implementing a collaborative decision-making process on projects, and (2) how do these concerns translate into recommendations for roles and responsibilities in a project to enable a collaborative decision-making process? The nature of these questions is best aligned with a case study methodology (Yin, 2014). To answer these questions, the authors conducted three case studies in which they had direct access to the project team and acted as either internal or external consultants, therefore using an action-research approach (Dickens & Watkins, 1999; O'Brien, 1998). The three cases cover a variety of construction markets and regions: a hospital project in Connecticut, the main station in Munich, and a port in Denmark. The sources of evidence used were (1) direct observation, since some of the authors were coaching the owner or design team to implement a collaborative decision-making process, (2) project documentation based on public media, meeting minutes, surveys, and A3 reports, (3) interviews with project team members, and (4) in one case, a lessons learned workshop. The data collection details of each case study are further specified in each of the following sections.

CASE STUDY 1: CHILDREN'S HOSPITAL

This case study presents the interaction between stakeholders for a children's hospital project in the United States. The following sections present the background, data collection, and key takeaways from different stakeholders' perspectives.

BACKGROUND

The project is an urban addition of an eight-story, 185,000-square-foot children's hospital in the United States. The project duration is expected to be approximately three years, and it is scheduled to open in mid-2025. The team is set up as an IPD-lite, where the owner is a private entity with strong incentives to finish the project on time and on budget to serve a growing community. Although the owner decided not to pursue any environmental certification, they are interested in evaluating decisions and considering improvements with regards to sustainability. The project team is currently in the design phase and is composed of the owner, owner's representative, architects, general contractor, and a dedicated lean consultant.

CASE STUDY PROTOCOL AND DATA COLLECTION

The following protocol was followed to learn about the roles and responsibilities of different stakeholders and their decision-making process. (1) The researcher met with the general contractor to understand the project background and current decision-making process. (2) A presentation was held in which the CBA system was explained to the entire project team, including the owner representative, architect, general contractor, and lean consultant. Both a recording and a transcript of the meeting were shared among the stakeholders. (3) The researcher met with the design manager, who led the internal decisions for the team. The researcher gave coaching and feedback on the first two decisions using CBA. The team documented these decisions using decision-making software that all stakeholders have access to and created A3 reports that can easily be shared with the owner and other stakeholders. (4) An interview with the design manager was conducted to evaluate the project's decision making process and provide feedback.

TEAM RESULTS

The researcher was able to document the stakeholders' reactions when reading the transcripts of the presentation regarding how to set up a collaborative decision-making process. In the presentation, the researcher covered (1) why CBA is a useful method for managing decisions; (2) a description of CBA basics, including principles, vocabulary, and methods; (3) a simple but practical example; (4) several case studies that were applicable to the project team; and (5) a guided discussion on the next steps for the team. There were several key takeaways from the discussions:

- The project manager from the general contractor was pleased to be able to explore alternatives and price them in parallel, as opposed to having to wait. He pointed out that they can change their previous strategy (wait for the pre-construction estimator to price some options, and then start the discussion on whether it makes sense to go for an alternative that was more expensive than the lowest priced one). After learning about CBA, they understood they could evaluate the alternatives simultaneously and therefore potentially cut the decision time in half.
- The architects were concerned with the time needed to implement the process and who would be responsible for creating the documentation and developing the A3 reports. One of the architects asked for proof that this method saves time and money on real projects, and the researcher presented a case study (Arroyo & Long, 2018).
- The project manager from the general contractor also pointed out the need for external support from both the CBA expert and the lean consultant to help facilitate this decision-making process, stating that "many people will feel uncomfortable leading a CBA decision with their cluster."
- The project superintendent seconded that idea, stating that the team must build their own success stories rather than simply learn about others' success stories and attempt to replicate them. He also proposed that each cluster identifies one or two decisions to be made as a team.
- The owner's representative was supportive of implementing the CBA method in the clusters.

After the discussion, the researcher met with the design integration manager of the project and helped guide the implementation of CBA for selecting the type of anchoring for footings and the pharmacy trailer location. At the time of writing, the team is still working on creating a more collaborative approach to making decisions. They defaulted to the design manager to oversee all decisions instead of having each cluster lead their decisions.

CASE STUDY 2: MUNICH MAIN STATION

This case study presents an owner's strategic decision to change the project delivery system from design-bid-build (DBB) to IPD by using CBA to develop the argumentation to obtain approval from the management board of the company.

BACKGROUND

Part of the expansion of the city train service involves the reconstruction of the main station. This megaproject includes the demolition of existing buildings and constructing new buildings and a new tunnel. The anticipated cost is estimated to be €1.2 billion. The owner's project team, Deutsche Bahn Netz AG (DB Netz AG), is organized in a matrix structure. Currently, the project delivery system remains DBB, with some early contractor involvement.

CASE STUDY PROTOCOL AND DATA COLLECTION

Action research was used to collect data, with the researcher facilitating a series of workshops. In this case study, the protocol was as follows. (1) The researcher briefly explained CBA to the project lead. (2) The researcher met with the project lead and two cross-divisional leads to explain the procedure. (3) The team agreed to apply CBA for a strategic project decision (question 1: whether the project should be delivered with DBB or IPD, and question 2: if IPD was chosen, what the scope of the IPD [multiparty agreement] would be). (4) A series of five workshops were held over a period of two months (October–December) to address both questions. The workshop series started with introducing CBA via a presentation and brief examples. Different participants were involved in the workshops, based on their expert knowledge and availability. Table 1 presents an overview of the participants, including the researcher (A), different team leaders of a subproject/cross-division (B, C, D, G, H, I), one expert (E), and the project leads (F and J). The decisions were made using paper and post-its and documented via photos and an Excel spreadsheet. (5) Information on the final decision was collected in January to start the approval process. The consultant was not part of this meeting. (6) In February, the researcher interviewed both responsible project leads regarding their experience, as they had little to no involvement in the workshops. (7) In April, a survey evaluating the decision-making process was administered to all eight participants, and data were collected.

Table 1: Research Protocol

	Date & Duration	Participants	Content
Working on Q1	10/06/2022 3.0 hours	5 (A, B, C, D, E)	• Short introduction to CBA • Defining the decision steps based on questions • Defining factors, criteria, attributes, and advantages
	10/12/2022 9.5 hours	8 (A, B, C, D, E, F, G, H)	• Building knowledge regarding CBA & IPD • Adjusting factors and criteria • Defining attributes and advantages • Identifying the Paramount Advantage (PA), sequencing the highest advantages
	11/14/2022 3.0 hours	6 (A, B, C, D, E, H)	• Defining the importance of advantages • Writing down the argumentation • Defining the alternatives of Q2
Working on Q2	11/28/2022 2.0 hours	5 (A, B, C, H, I)	• Defining factors, criteria, and attributes for Q2
	12/05/2022 2.0 hours	3 (A, B, C, I)	• Determining the advantages • Defining the importance
	01/26/2023 1.0 hour	5 (B, C, D, F, J)	• Making the final call to start the approval process

TEAM RESULTS

As the researcher learned the current state of the owner's project organization, she could observe two major pain points reported by the project leads: the project managers and project engineers are afraid to make decisions, and doing so takes too long. These could be due to prior experience or the lack of a defined decision-making process. As the owner wants to change the delivery system from DBB to IPD, the decision-making process must be adapted to suit the collaborative approach and thereby enable the project engineers and project managers to take responsibility in making decisions.

After deciding on an alternative through the workshops, the team prepared an easily understandable presentation to start the approval process. The data from the interview with the project leads and from the survey indicated that, due to the transparent process and the common understanding the team created by going through the CBA Tabular method and considering different perspectives, the team felt confident enough to proceed with the argumentation to obtain approval and implement the decision.

Differentiating between DBB and IPD, the importance of having a faster decision-making process (which the team sees in IPD) was scored as 80 on a scale of 0–100. The consensus was, "The faster decisions are made, the better." Even though more people need to be integrated in the decision, the owner's project team understands that having a shared understanding created through the discussion of different perspectives will result in a stable outcome, as "everybody [will have] had a [say]" (J). This is essential, since excessive deliberations will delay decision-making and risk the project not being delivered on time. Furthermore, one survey participant pointed out that having a collaborative decision-making process helps everyone better understand the reasons for the decision, which is necessary for proper implementation. Another participant (G) replied that "conflicts or difficulties are identified and resolved at an early stage" by having an interdisciplinary team working together in a decision-making process. In addition to this data collection, the researcher facilitated production planning workshops with the owner's team. The operating division (Station & Service) also participated in these workshops, and the owner's project team experienced the value of having different perspectives working together on a plan.

CASE STUDY 3: PORT OF AALBORG

This case study presents the lessons learned from an extension of a port in Denmark. In this case, the owner had a strong focus on sustainability and therefore initiated a lessons learned workshop to bring experiences on making sustainable choices forward to subsequent projects.

BACKGROUND

The 20,000 m^2 expansion of one terminal's quay is one of two test projects after the Port of Aalborg signed up for the standard ISO-14001 Environmental Management Systems (Dagens Byggeri, 2022). After realizing that Scopes 1 and 2 (operation emissions controlled by the port) only accounted for 4% of their total CO_2 emissions, they started focusing on reducing Scope 3, which includes the CO_2 emissions from the supply chain (e.g., building materials and construction processes). In this case, it was decided to use a partnering contract with the main partners (the engineer and the contractor) and use open-book accounting. The client had separate contracts with the main contractor and the engineers, and the partners were selected based on organization and collaboration (50%), personal references (30%), and overheads (20%). The CBA methods were not applied, but several important decisions were made collaboratively to make the project as sustainable as possible. The project resulted in a 40% reduction of CO2 emissions compared to a reference design (Dagens Byggeri, 2022) and a quay that was 40% stronger than prescribed, and the project was delivered on time and within budget (Molio, 2023).

CASE STUDY PROTOCOL AND DATA COLLECTION

The client initiated a lessons learned workshop to identify key takeaways from this successfully delivered project to bring forward to subsequent projects. One of the researchers was engaged as an external facilitator for a lessons learned workshop following project delivery, using the following protocol. (1) The researcher met with one of the partners to discuss the scope of the workshop. (2) A survey was sent to the main team members (three from each of the three project partners) to collect individual insights (with a 100% response rate). (3) Analyzed data were used as the basis for planning the lessons learned workshop. (4) The researcher led a full-day lessons learned workshop with the same people who responded to the surveys, in which budget, schedule, stakeholder management, collaboration, conflict management, and risk were discussed. 5) Key takeaways from the workshop were documented, which resulted in an A3 report that contained actions for each partner and was commented on by the participants. Furthermore, this case was built on available articles from public media (e.g., Dagens Byggeri, 2022), and a presentation made at Circular Build Forum 2023 (Molio, 2023).

TEAM RESULTS

In Dagens Byggeri (2022), Brian Dalby Rasmusen, Chief of Engineering, Port of Aalborg, noted: “The project became much more sustainable than we dared to hope for.” The lessons learned workshop was initiated to identify key learnings as to why the project had been a success and what could be further improved.

Five out of nine responded in the survey that trust and collaboration were the main reasons for the success of this project. At the same time, six out of nine wrote that they were at unease with the contract and the risks owned by the client and pointed to the need for a more reliant contract in subsequent projects. Respondent 9 (client) stated that “We ended the project well, but for [the] next project we need a stronger contract to support the collaboration in case a conflict arises.” Respondent 3 (engineer) suggested that “[the contract] needs to be made more bulletproof, so the client does not own the same economic risk.” Therefore, it was concluded that in future, the client will require a decision log in which all partners anticipate future decisions, including risks related to the decisions and ownership of the risks. The engineers should be those responsible for planning the decisions. The contractor stated that they found it relevant that they managed the risk and budget but were also aware that this was a huge responsibility when working with open books, and it required clear roles and responsibilities (Respondent 2).

Another barrier was convincing suppliers that more sustainable solutions were valued. The suppliers automatically offered the alternatives with the lowest cost, despite a clear message that the project was focused on sustainability. They simply did not believe that cost was not the main constraint (Dagens Byggeri, 2022).

CROSS-CASE ANALYSIS

All three cases have different decision-making approaches, and in each case, the approach taken is a key element in the outcome of the project. In Case 1, the team started the discussion on roles and responsibilities to implement a more collaborative approach to making decisions, rather than simply asking the general contractor to focus on pricing alternatives and then asking the owner to make decisions. Even with the right stakeholders early in the project and an IPD-lite structure, most of the stakeholders did not know about CBA and needed support to implement it. They expressed the desire that every cluster presents a decision to the owner; however, in practice, this was delegated to the design integration manager of the project. Although training on CBA and support for people in leading roles is an investment of time and resources, it is essential to achieving collaboration in decision-making. Those who have the knowledge are not necessarily the same as those who have the authority to make decisions. The team needs architects/engineers who are willing to make decisions and cluster members willing to share their perspectives to evaluate the advantages of each alternative—the owner can then take that input into consideration in making the final decision. Finally, someone on the team must document the decisions (which in this case was the general contractor).

In Case 2, the project has a traditional delivery system and traditional contracts, and the team experienced the limits of transparency and collaboration that come with this traditional system. Furthermore, in this system, responsibilities cannot be transferred to the person/group of people who are best able to make decisions. Roles are defined in a hierarchical way such that the team loses too much time in making decisions-making it difficult to stay on schedule and handle unforeseen situations that arise in any project (especially megaprojects). With this realization, the owner's project team made the decision based on CBA to change the delivery system to IPD, resulting in a clear structure of the decision-making process.

In Case 3, all the survey participants indicated that they were satisfied or extremely satisfied with the collaboration of the project and the outcome. In the survey responses and in the workshop discussions, it became clear that they were somewhat relieved and/or surprised that no major misunderstandings or conflicts had occurred. As one of the participants responded in the survey: "Exciting collaboration with great potential if we can just bottle it up [and bring it with us to the next project]." With the strong focus on collaboration, the roles and responsibilities shifted from what they were used to. They ultimately decided to focus on defining roles and responsibilities at the beginning of subsequent projects. As part of the actions agreed upon in the workshop, it was stated that for future projects, stricter risk management should be put in place to support better and more transparent decision-making. Furthermore, the client stated that the future would require a more systematic approach to decision-making, where benefits, risks, and financial consequences were more clearly stated and presented in a timely manner such that a final decision could be made.

In Table 2, the concerns of each stakeholder in each case are summarized and commonalities among the cases are highlighted. By focusing on concerns, we can identify where the focus should be directed to enable more efficient and transparent decision-making processes in the future.

DISCUSSION

In general, for all the stakeholders, we have seen that to move from traditional to recommended practices, an IPD (or IPD-like) contract is not enough to break the barriers for collaborative decision making. Collaborative behaviors need to be reinforced, and the team must be intentional and deliberate in creating new roles and responsibilities that allow for new ideas and concepts to be incorporated. In short, it all starts with the owner and the user. The owner must define and communicate their vision to provide direction regarding the project strategy and the embedded decisions. This means the owner must be involved in the decision making process early on (not only at the end by questioning the recommendations). For example, in Case 2, the owner realized that there is a gap in taking responsibility by project team members within their own organization, which in turn leads to slow decision making. By understanding the importance of roles and responsibilities, the team can work on the definition earlier in the project, and roles and responsibilities can change in long-term projects as new team members and partners join the project.

Table 2: Concerns of the different stakeholders that influence the decision-making process

	Case 1:	Case 2	Case 3
Owner	Finish on time and within budget. Obtain the right value for patients. Set up an effective decision-making process.	Finish on time. Have a stable schedule. Some are afraid of making decisions. Concerns over decision-making taking too long.	Integrate sustainability into the project as far as possible. Some concerns over the risk related to economy and quality.
Architects/ Engineers	Provide design solutions on time. Manage documentation. Decrease the time spent on meetings and decision-making.	NA	Concern for the client, as the client owned all the risk.
General Contractors	Manage team clusters efficiently. Provide budget and make decisions in a timely manner.	NA	Manage the budget on behalf of the team. Felt responsible for the trust shown by the client. Concerns over receiving the right input from suppliers.

In the three cases, we see the owners moving away from being focused primarily on cost and time, to focusing more on value creation within constraints and understanding cost and time as an output of collaboration. In Case 3, we saw that it was difficult for the rest of the supply chain to understand that the main constraint was not time or cost, but sustainability. In comparison, in Cases 1 and 2, the owner understands that the project's goal of finishing on time needs the integration of different stakeholders to find the best solutions by creating a common understanding of project needs. Therefore, the owner has a great responsibility in guiding the rest of the team to focus on values rather than only focusing on schedule and cost. If the focus is on sustainability or creating the best project for users, this should be communicated and followed through. For example, if focusing on sustainability, cost, and time cannot come across as the main constraints, they must be dealt with case by case unless the client defines a minimum criterion for these.

Engineers and architects seldom hold the main responsibility for risks related to time, cost, or quality, but they hold the main responsibility for informing the client of the alternatives available and the consequences, risks, and assumptions following a decision. It can be somewhat uncomfortable to focus on factors beyond cost or time, which may not be expressed in quantitative terms. Focusing on adding value to the project could be difficult for some to handle, as this is seen as more subjective and not as definitive as, say, cost and schedule. This is when a method such as CBA is important to allow teams to account for qualitative and quantitative information to describe the value of alternatives.

General contractors often have an overview of the cost, time, and opportunities for creating alternative solutions. They also have contact with many of the experts, such as subcontractors, superintendents, and craft workers. Furthermore, they have intel from suppliers and can provide advice to counter the volatility in the supply chain, especially on long lead items due to global challenges. Therefore, general contractors are also responsible for communicating the project's priorities to the wider team and gathering information on alternatives. In addition, general contractors can provide information to inform the design alternatives regarding constructability, maintenance, and long-term performance of facilities.

For users in a traditional setting, the feedback they provide is extremely difficult to incorporate without a structured decision-making process. Therefore, users need to be proactively involved in the process to specify criteria based on "needs" and "wants" and not wait until the decision is made to provide input. If the expectations of the owner and users are clear, the architect, engineers, and contractors can work on specific decisions together. This means that from the very beginning, the decision-making process needs to be defined, the responsibility of every role must be clarified, and specific stages need to be determined to set up the process structure. Due to different perspectives, the team will need to adopt a method that helps them understand each other and see the overall impact of the decision within the project. Transparency and learning about the difference by comparing the attributes of the alternatives will help the team instill a constructive conversation. Table 3 presents an overview of the roles and responsibilities.

Table 3: Traditional vs. recommended roles and responsibilities

	Traditional	**Recommended**
Owners' responsibilities	Focus on time and budget. Unstructured and slow when making decisions.	Be specific in values and set a shared vision. Own the decision processes and related risks. Advocate for diverse perspectives and including users.
Architects'/engineers' responsibilities	Provide one design solution and push for acceptance (point-based decision-making). Make decisions *in silos* without gathering expert information.	Help structure a transparent process by setting up feasible alternatives (set-based decision-making). Include experts from the execution phase.
General contractors' responsibilities	Evaluate decisions based on cost and time. Make decisions *in silos* without gathering expert information.	Gather information on alternatives based on value creation. Add information on risk, opportunities, and cost. Include cluster experts in making decisions.
Users' responsibilities (if included in the decision-making process)	Feedback on decisions already made by others (reactive).	Be specific in must haves and nice to haves as input to decision-making (proactive).

CONCLUSION

This paper documents the concerns of different stakeholders in implementing a collaborative decision-making process. Our recommendations are based on the three case studies, and we reference the traditional decision-making process to demonstrate the contrast. In this research, we conclude that owners are responsible for defining a shared vision to guide decisions, architects/engineers are responsible for creating feasible design alternatives, general contractors/trade partners are responsible for providing their perspective in the evaluation of alternatives and providing pricing and schedule impacts, and users are responsible for distinguishing between "needs" and "wants." In addition, consultants and/or trainers to support the team are likely needed because (1) even when the stakeholders are aligned through a collaborative contract, teams struggle with decision-making, as roles and responsibilities are not defined in advance, and (2) most people will need to learn a sound decision-making method, such as CBA.

The discussion of the roles and responsibilities within a project team is relevant and far from being resolved. This research is somewhat limited, and we encourage other researchers to document and experiment with different roles and responsibilities among construction team members to allow them to draw knowledge and expertise from a variety of project participants and support the creation of value using innovation. The authors believe that only through this inclusive and collaborative process can more sustainable designs be created in construction projects.

ACKNOWLEDGMENTS

We would like to acknowledge the support of the practitioners that allowed us to obtain data from the case studies in this research: the DPR Construction project team for collaborating in the research of the hospital project; the project team of DB Netz AG Munich main station for their willingness to try new methods and approaches, as well as share their lessons learned; and the Port of Aalborg for openly sharing experiences and allowing these to be distributed for the benefit of others.

ANALYSIS OF LEAN CONSTRUCTION CASES IN IRELAND

Trevor McSharry[1], Kevin McHugh[2], and Lauri Koskela[3]

ABSTRACT

The purpose of this paper is to identify what lean tools and techniques construction companies are using in Ireland and what common challenges and benefits exist for their implementation. Currently, research on lean construction (LC) implementation in Ireland is weak and fragmented, and this paper will help address this gap in literature and provide an overview of this activity.

Through analysis of the 17 cases gathered through the Lean Construction Ireland (LCi) "Book of Cases 2022," this paper identifies that most case studies originated from large, privately owned, general contracting companies and a wide array of lean tools are being used. All cases indicated benefits from LC, the most common being an improvement in quality, then cost, followed by time and safety. Covid-19 was found to be a catalyst for lean initiatives. Leadership support, staff training, piloting lean initiatives, developing a collaborative culture and continuous improvement were identified as important factors for implementing and sustaining LC. Although the sample size is limited, this paper does provide a useful indicator of overall LC activity in Ireland that will be of interest for academics and practitioners to consider and build upon.

KEYWORDS

Case study analysis, Lean tools, culture, leadership

INTRODUCTION

Ebbs et al. (2015) suggest that LC field research and case studies are very limited in Ireland. Over the last five years, a book of cases has been published annually by Lean Construction Ireland (LCi), each containing a collection of case studies from the Irish construction industry that demonstrate the challenges and outcomes of implementing LC. However, most of these case studies have not been incorporated into formal research papers. The first author of this paper is a director with LCi and was the editor for the LCi Book of Cases in 2022. The aim of this paper is to utilise the Book of Cases 2022, to identify what lean tools and techniques companies are using in Ireland and what common challenges and benefits exist for their implementation. An overview of LCi will be provided initially to set the context, followed by a literature review. The research methodology will then be outlined, followed by an overview of the Book of Cases 2022. The results will then be presented followed by a discussion and conclusion.

In 2018, the LCi community of learning and practice became a company limited by guarantee. Its objectives are to promote lean thinking and practices in the Irish construction sector by making available information, guidelines, and support. With directors from both industry and academia, LCi has approximately 90 corporate members as well as hundreds of individual members. LCi has facilitated over 50 LC webinars, published five Book of Cases, and is focusing on capability development by sharing best practices and helping upskill and develop the workforce through its activities. By identifying lean construction case studies in industry and compiling them into book-form for annual publication, LC practices have been shared throughout the construction sector. Through academic research, the value of these cases can be strengthened so that further insights can be gained and disseminated via various research groups such as the IGLC.

LITERATURE REVIEW

In this literature review, LC will be introduced and the importance of collaboration between industry and academia highlighted. The topic of learning will be discussed as well as the various LC tools and techniques used. Gaps in research from an Irish case study perspective will then be discussed. The benefits of LC will be outlined and key factors for LC successful adoption reviewed.

Our understanding of lean principles and LC is evolving. Lean manufacturing has been studied by academics for 30 years and the MIT International Motor Vehicle Program (IMVP) benchmarked Toyota's superior performance and coined the phrase lean to describe this system (Womack et al., 1990). The findings of this prompted the formation of lean groups by practitioners including the Lean Enterprise Institute in the USA (www.lean.org), the Lean Enterprise Academy in the UK (www.leanik.org), and 15 other non-profit institutes across the globe (Netland & Powell, 2016). Similarly, the International Group for Lean Construction (IGLC) was formed to develop new principles and methods for product development and production management, specifically tailored to the AEC industry, but akin to those defining lean production that proved to be so successful in manufacturing (IGLC.Net, 2023).

The call for change in the construction industry has been well documented in terms of how this sector operates (Egan et al., 1998; Koskela & Howell, 2008; Latham, 1994;). This paradigm change is still ongoing today. The main objective of lean production is to eliminate waste by reducing or minimizing variability related to supply, processing time, and demand (Shah & Ward, 2007). In construction, the role of Lean is to improve the processes and delivery methods of a project to better meet the needs of the owner through the elimination of waste and non-value adding activities (Ghosh & Burghart, 2021).

The collaboration between industry and academia through the IGLC and communities of practice like LCi are promoting change in the industry. With the increase in the adoption of lean tools and principles in the construction industry, it is pertinent to investigate the experience of the contractors to facilitate widespread adoption of lean for improvement of industry performances (Ghosh & Burghart, 2021). Companies that collaborate with academia have shown to prosper (Pizam et al., 2013). Research has indicated that construction management research has not made a lasting impact on the sector because of misalignment of research methods and problems targeted with developments in the industry (Koskela, 2017). Collaboration between universities and industry is not straightforward and Aouad et al. (2010) suggest a "shared pace whereby the work being undertaken by the research community has meaning in both the academic and industrial world." Case studies are a suitable method to extract data for complex situations (Taggart et al., 2019) and can facilitate a meaningful collaboration between industry and academia.

Learning is important for a lean construction team. Organisational learning and knowledge creation are interdependent as learning is a dynamic process that promotes the knowledge creation process (Lyles, 2014). Lean teams must be aware of practices for improving knowledge generation that can improve construction processes, eliminate waste, and pursue perfection (Zhang & Chen, 2016). When LC managers implement a lean tool, they unintentionally facilitate the knowledge creation. Therefore, attention should be paid to keep new knowledge recorded and to build a more holistic and efficient knowledge management system (Zhang & Chen, 2016). Case studies are a useful way of recording knowledge created from lean tools.

A broad range of LC tools exist to reduce waste and improve efficiency. For example, Zhang and Chen (2016) considered lean techniques that have transferred from lean manufacturing including concurrent engineering, daily huddles, Kanban, value stream mapping, quality management tools including Plan Do Check Act (PDCA), Just in Time (JIT), Total Quality Management (TQM), and Human Resource (HR) management. Examples of other LC tools are 5S and First Run Studies (Noorzai, 2022). In addition, Schia et al. (2019) reviewed the topic of Artificial Intelligence (AI) for the construction industry and indicated that AI can automate several operations to increase efficiency and thus minimise waste.

LC implementation case research in Ireland is limited to a few academic papers and there is no consolidated overview. Existing literature relates to the Line of Balance production planning (Taggart et al.,2019), The Last Planner System (Power & Taylor, 2019) and the integration of Lean and BIM processes (McHugh et al., 2019). A cloud based digital LPS is also reviewed by McHugh et al. (2021a) as well as reality capture (McHugh et al., 2021b). By carrying out academic research on the Book of Cases 2022, it is hoped that the range of tools and techniques currently being used in Ireland are identified and associated benefits and challenges uncovered.

In relation to the benefits from LC, Lavikka et al. (2019) identified an improvement in build time, cost, quality and health and safety, when comparing hospital construction projects that have implemented lean construction with ones that don't. Frequently, research focuses on the success of lean processes and less on the obstacles to their deployment (Simonsen et al., 2014). By identifying and understanding the barriers to implementing change and LC, more opportunities are provided to succeed and recognise the need for organisational change (Cano et al., 2015; Perez & Ghosh, 2018). Sarhan & Fox (2013) identified the top three barriers to implementing lean as the lack of adequate lean awareness and understanding, culture issues and a lack of top management commitment. This is further supported by Sarhan et al. (2016) who identified 12 critical success factors for implementing LC, such as providing education and training for lean construction, promoting a culture of teamwork and adopting continuous improvement. Xue et al. (2014) identified the importance of collaboration and culture to support innovation also. Thus, education and training, culture, collaboration, top management commitment and continuous improvement have been identified in literature as key factors for LC adoption. By assessing LC cases in Ireland, it can be determined how applicable these factors are in this local context.

RESEARCH METHODOLOGY

The aim of this paper is to identify what lean tools and techniques companies are using in Ireland and what common challenges and benefits exist for their implementation. Figure 1 below outlines the research methodology used, which initiated with a survey used to get preliminary data and finalise the case study template. Case studies were then gathered and completed. The last stage was qualitative analysis of the cases using NVIVO software.

To utilise the LCi Book of Cases for this research, the first author, who was also the editor for the Book of Cases, arranged a short, online survey of LCi members to get some insights into the relevance and suitability of the LCi Book of Cases and identify opportunities for improvement. Survey feedback was reviewed, and various improvements identified for the book of cases format and template. During 2022, 17 LC cases were drafted by 16 companies and submitted to the editor. Following an interactive process, all complete cases received in the revised template were then refined by the editor, proofed, categorised into themes, and then compiled into a Book of Cases 2022 publication (Lean Construction Ireland, 2022).

A qualitative analysis of the Book of Cases 2022 was then undertaken. According to Burke, Johnson & Onwuegbuzie (2004), qualitative research is useful for studying a limited number of cases in depth and for understanding people's personal experiences of phenomena in local contexts in vivid detail. For case study analysis, NVIVO software was used for coding of the cases and various qualitative analytical tools such as word frequency, word searches etc. Discussions also took place with industry-based case authors to get a deeper understanding of various cases and to address clarifications. This data and analysis helped identify LC tools and benefits. Emerging themes across the 17 cases were also identified (Braun & Clark, 2006). Building on this work, a matrix was then developed to capture the key elements of each case for ease of further analysis. This matrix will be discussed later and lists the case number and key details of each case study, including indicative benefits.

Figure 1: Research Methodology

PRELIMINARY SURVEY

The first author arranged a survey with all LCi corporate and individual members to identify if improvements could be made to the book of cases format so that a case study template could be finalised. This survey identified that 72% of respondents felt that their company was at the early to intermediate stage of lean adoption. 93% of respondents agreed/ strongly agreed that the book of cases was appropriate to their organisation and was a valuable asset. In addition, 92% of respondents said that they read at least a few, if not all the case studies.

Several recommendations were made by respondents to improve the book of cases. These recommendations included the addition of an introduction section, which would provide a summary of the cases, a dedicated section on BIM/Digital Technology, making case titles clear and breaking cases into categories. These findings from this survey were implemented and facilitated the refinement of the case study template used for the Book of Cases, 2022.

CASE STUDY COMPILATION

Based on survey feedback, a new standardised template for the cases was developed with the following headings: case study title, company overview, overview and background of lead initiative, lean initiative undertaken, lean initiative improvements and impact and lessons learned. In addition, an "Introduction Chapter" was included in the Book of Cases and appropriate chapters/ themes were formed to gather related cases and make the book easier to navigate.

In 2022, a call for abstracts was issued to the construction sector through emails and social media channels. The editor recommended that all abstracts were progressed to full cases by the company-based authors using the new case template. Cases were then reviewed, edited, and refined by the editor, following consultation with the case author. All cases received were included in the Book of Cases, categorised into themes and then the book was compiled, proofed, printed, and circulated.

CASE STUDY OVERVIEW

In this section, an overview of the 17 case studies (Lean Construction Ireland, 2022) will be presented. The cases have been categorised into the following themes: Operational Excellence, Digitisation, Modern Methods of Construction and Resource Management. See the Case Study Matrix in Table 1 at the end of the paper for a full case overview. Cases have been numbered, where C1 denotes the first case, C2 the second and so on.

OPERATIONAL EXCELLENCE CASES

The following is a summary of the operational excellence related cases:

- C1: The Coffey Pillars of Lean were presented, including 6S, 8 Wastes, Visual Management, Standard Work, DMAIC and the Last Planner.
- C2: Duggan Brothers identifies 107 tasks for improvement through the involvement of 27 senior managers across eight departments.
- C3: Hawthorn Heights mapped out processes, used the LCi Lean Audit Tool and achieved significant improvements.
- C4: Kirby's developed a framework using DMAIC for determining the cost of quality and utilised Fish Bone diagrams and 5-Why tools.
- C5: Mace improved safety, quality, productivity, and schedule compliance by using an A3, 5S and 8 waste tools.
- C6: OPW developed a Dynamic Purchasing System and decreased supervision and management costs.

DIGITISATION CASES

The following is a summary of the cases listed under the digitisation theme:

- C7: Arup provided an overview of their HIVE (Human Immersive Virtual Environments) which has helped clients gain a better appreciation of proposals.
- C8: Errigal used DMAIC and digital tools to develop a data driven framework to identify and eliminate inefficiencies in processes.
- C9: John Paul Construction demonstrated the benefits of using the Last Planner and the cloud-based Field View system for achieving project milestones.
- C10: Mannings Construction Group outline how they have utilized digital solutions such as dashboards, timelapse cameras, vehicle recognition systems and the common data environment to improve overall efficiency.
- C11: SISK demonstrated the use of Artificial Intelligence (AI) to automatically read form data. Through automation and digitization, significant time is being saved and the quality of data capture has improved.
- C12: Walls first case study outlines the significant benefits of upgrading IT infrastructure and software to provide a better controlled environment with reduced administration and energy overheads.
- C13: Walls second case demonstrates employee accessibility of BIM 3D models using Dalux BIM mobile viewer as well as a reduction in waste.

MODERN METHODS OF CONSTRUCTION AND RESOURCE MANAGEMENT CASES

Cases related to modern methods of construction and resource management are:

- C14: ACB group focus on Modern Methods of Construction (MMC) using lean principles. They utilized BIM and the PDCA tool to develop its prefabrication model further by seeking to incorporate additional building finishes.
- C15: Horizon Offsite increased productivity and reduced non-conformances through workplace and factory optimization, performance tracking and data visualization.

- C16: Ardmac used a High-Performance Team model and human behavior was improved to promote collaboration and increase productivity.
- C17: DPS Engineering developed an effective resource mobilisation process using lean thinking and the DMAIC tool.

RESULTS

This section will analyse the profiles of companies that submitted cases as well as the lean tools used. In addition, indicative benefits from LC implementation will be provided. The themes that emerged from qualitative analysis will then be presented.

COMPANY PROFILES AND LEAN TOOLS USED

Table 1 at the end of the paper shows a matrix, which summarises the key elements of the case studies. This matrix lists the case number, company name, size, type, sector case title and tools used. It also identifies the theme that the case was aligned to and the indicative benefits from a time, cost, quality, and safety perspective. In terms of company profile, six companies were small to medium sized organisations (SMEs), with less than 250 employees, while ten companies were large. Only one company was publicly owned (C6), the rest were privately owned. C6 was the only client-based company represented in these cases. A multitude of sectors were represented with the most common being general contractors.

A wide variety of tools were identified within the case studies. Tools used more than once were identified and sorted by frequency and are presented in Figure 2 below. The most common tools used were DMAIC and 8 wastes, followed by BIM/ 3D viewing, LPS, 5S, and the use of Cloud Data. Value stream mapping or process mapping, PDCA, A3, and Artificial Intelligence were other tools used in two case studies. Overall, 10 tools were referenced in at least 2 of the 17 cases.

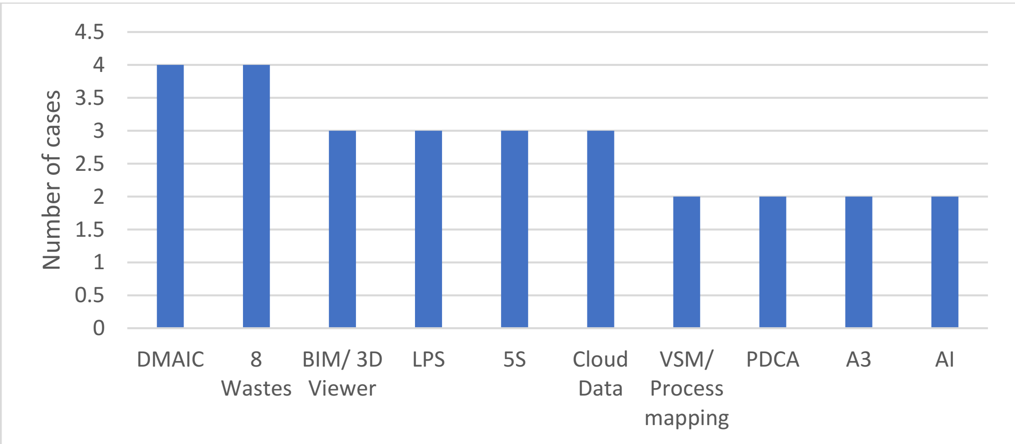

Figure 2: Lean Tools Referenced in More Than One Case Study.

BENEFITS

A range of benefits were identified in the case studies as listed in Table 1. In Figure 3 below, the main benefits are presented in terms of the percentage occurrence in the cases. 88% of cases indicated an improvement in quality, 71% of cases referenced a saving in cost, 47% indicated a saving in time and 35% had a safety related benefit. All cases except two (C4, C7) had at least two benefits indicated.

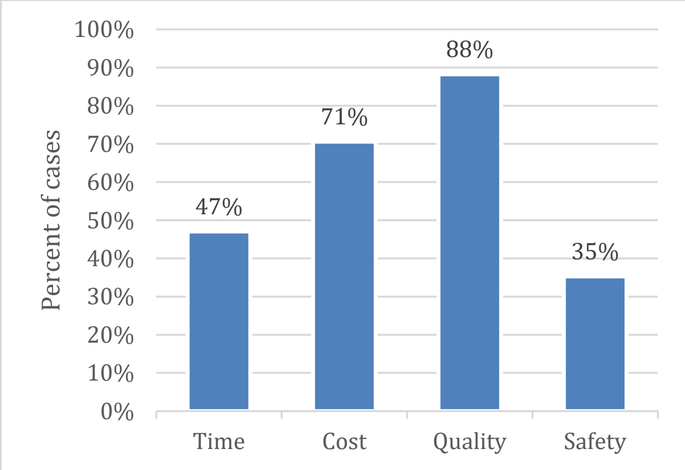

Figure 3: Benefits Identified from Lean Initiatives.

KEY THEMES IDENTIFIED

Through iterative thematic analysis throughout this study, several key themes were identified in the cases, relating to potential enablers, challenges, or barriers to lean implementation. These themes are: Covid-19, piloting initiatives, training, culture, and leadership.

Covid-19 was found to be a strong catalyst for change and an opportunity to put in place continuous improvement and lean plans (C1). It also helped drive the adoption of cloud technology to facilitate remote working (C13). Due to Covid-19 related resource constraints and rapid sudden start-up of projects, lean was applied to resource planning to improve resource mobilisation (C17).

Piloting lean initiatives on a smaller scale to prove the concept and get buy in was a regular and robust approach to rolling out change initiatives (C1, C2, C6, C11, C12). C2 used the Deming cycle (Plan, Do, Check, Act) to implement change and allow for a dynamic and flexible outcome.

Training of staff has been identified as a key enabler to lean adoption. Training has been referenced in 11 of the 16 companies (69%) as a key enabler to lean implementation and continuous improvement (C1, C2, C4, C5, C7, C8, C10, C11, C12, C15, C17). A structured approach for lean principles was sought through lean green belt training, attending LCi webinars (C1) and LPS (C1, C10). Internal training was carried out on IT systems and dashboards (C2) as well as lessons learned (C2, C10). A training programme on the cost of quality was an outcome for C4, while training on understanding waste was carried out for C5 and on virtual reality software (C7). In C8, a survey was carried out to identify what training was required by the staff. Training a machine learning model was also completed (C11). In addition, enabling staff to utilise lean and digital tools was seen to be key to improving capability (C12).

Culture was referenced in seven cases. A continuous improvement culture was referenced in C1, while a culture to improve collaboration and reduce silos was referenced in C4, C5 and C6. To sustain change and improvements, culture was seen as important (C8, C15), while generating a proactive culture was referenced in C9. Companies need to be inclusive with staff to facilitate lean adoption, so that there is buy-in to the change and staff need time to reflect on change and consider the impacts and upskill as required (C2, C8, C10). Bottom-up changes from new staff should also be facilitated (C11) and start with easy wins (C2). Tools are available and effective to specifically improve the performance of teams (C16). Overall, the case studies reveal a desire for a continuous improvement culture through collaboration, inclusion, upskilling and the use of digital and lean tools.

Leadership is also identified as an important factor in lean initiatives and was referenced in six cases. Leadership training was referenced (C1), while leadership support and buy in also featured (C1, C14, C16). Company commitment and leadership were considered in C4. Leaders fostered and maintained a creative and innovative environment (C12) and were convinced that change was needed (C15).

DISCUSSION

This study analysed 17 cases contained in the LCi Book of Cases 2022 to get an insight and overview of current tools being used in Ireland as well as associated benefits and challenges. This research also helped address the lack of case study research in Ireland. The preliminary survey results indicated that the Book of Cases is a valuable asset to construction companies. It has also connected academia and industry (Pizam et al., 2013) in a meaningful way (Aouad et al., 2010) and facilitated the investigation of experiences of contractors. Doing so has helped the adoption of LC in the construction industry as recommended by Ghosh & Burghart (2021).

A broad range of LC tools have been researched by academics (Noorzai, 2022; Schia et al., 2019; Zhang & Chen, 2016). In Ireland, LC case study research is limited to a few academic papers by Taggart et al. (2019), Power and Taylor (2019), McHugh et al. (2019), McHugh et al. (2021a) and McHugh et al. (2021b). This paper has further developed and consolidated case study literature in Ireland and has highlighted associated tools, benefits, and themes from 17 cases in 2022.

As cases were mainly from large contractors, there is scope to potentially target more diverse stakeholders in future so that a broader perspective is gained. All cases reviewed indicate multiple benefits for LC implementation, including improvements in cost, schedule, quality and health and safety. These benefits align to those of Lavikka et al. (2019). The themes that emerge from the cases include the significance of Covid-19, piloting lean initiatives, training, culture, and leadership in these case studies. These themes align to those identified in literature (Lyles, 2014; Zhang & Chen, 2016). Covid-19 has facilitated improvements in LC and piloting initiatives has helped improve buy in. Training was seen as instrumental for LC adoption. A collaborative culture with support from leadership is also seen as important for LC adoption. These findings support those from Sarhan and Fox (2013), who identified the top three LC barriers as lean awareness (training), cultural issues and lack of top management commitment.

Findings from this study resonate with those from the study of Ebbs et al. (2015), who found that short term wins are the primary focus rather than a management philosophy for LC, and that practice has not caught up with the theory. Although LPS has been used in Ireland and the potential benefits of using Line of Balance highlighted (Taggart et al., 2019) no reference to takt planning exists and there is still a lot of progress needed to enable a more mature, production management approach to LC. The Irish lean construction community will need to actively monitor trends and developments overseas so that they can be incorporated into practice and help evolve LC activity.

Although six operational excellence focused cases were developed in 2022, there was no consistent approach on how LC is adapted into companies. It appears there is a mixed approach, both from the top-down through policies and strategies and from the bottom-up through pilot projects. Ward and Caklais (2019) concur and believe that ad hoc deployment of tools and techniques is frequent, but business transformation is very rare. They examined the first use of the new international lean standard ISO 18404:2015 and suggest that it could act as a useful roadmap for those seeking to transform.

Although this study has provided an overview of multiple LC cases in Ireland and associated benefits and key factors, it is limited to a snapshot in time. Further similar research on previous and future cases will help develop a deeper understanding of LC activity in Ireland so that its maturity can be thoroughly assessed and trended over time. In addition, the maturity of various tools was not part of this study, and the assessment of benefits of LC is indicative only. Further research on tool maturity and benefits would be helpful.

However, the Irish construction sector appears to be moving in the right direction, where culture and leadership are important elements for organisational change such as LC adoption. Published case studies are a valuable resource to both industry and academia. Further insights have been identified and shared with academia through this paper that builds upon existing literature. By continuing to carry out academic research on LC cases, further consolidation and insights can be uncovered to help improve LC adoption and maturity.

CONCLUSION

This paper has achieved its purpose of identifying what lean tools and techniques construction companies are using in Ireland and what common challenges and benefits exist for their implementation. The Book of Cases is an asset that shares insights and helps facilitate collaboration between academia and industry and help the adaption of LC. Indications are that Ireland is at an early to intermediate stage of LC maturity, as companies are deploying lean tools to reduce waste, rather than taking a wider production management approach to LC adoption. Findings relating to the lean tools, benefits and challenges support existing literature reviewed, and highlight the importance of training, culture, and top management commitment.

LC activity in Ireland is still at an early stage of adoption where the focus seems to be on short term wins, rather than on long term transformation. Opportunities to develop a lean production management approach exists, and consideration should be given to a more standardised way of business transformation.

As this paper focuses to the Book of Cases 2022, it is limited to a snapshot in time. It is recommended that further academic research on future and past book of cases should be carried out to get a deeper appreciation for LC activity in Ireland as well as to consider ways to assess tool maturity and LC benefits in a more comprehensive way.

Covid-19 has been a catalyst for digitisation of many systems and processes, which has provided new opportunities for streamlining processes and reducing administration. A more collaborative and team focused approach for LC adoption is suggested from this study, through the inclusion of all stakeholders in change initiatives, which leads to better engagement, understanding, adoption and sustainability of improvements. By developing the enablers of leadership, training, and cultivating a collaborative culture, the focus can go from individual LC initiatives to the overall creation of effective production systems.

ACKNOWLEDGMENTS

We would like to thank all authors and companies who submitted cases to LCi in 2022 and allow the compilation of the LCi Book of Cases. Without your openness and generosity, this paper would not have been possible.

Table 1: Case Study Matrix

No.	Company	Size	Sector	Case Study Title	Tools Used	Time	Cost	Quality	Safety
C1	Coffey	Large	Civil Contractor	Lean and Collaborative Planning at Coffey	6S, 8 Wastes, DMAIC, LPS.			Q	S
C2	Duggan Brothers	SME	General contractor	Make the change and implement lean	8 wastes, VSM, LPS, DMAIC, 5S, FMEA, PDCA, A3, Pareto.	T	C	Q	
C3	Hawthorn Heights	SME	Civil Contractor	The use of process mapping and 5S to optimise tender success and profitability	Process mapping, 5S, LCI lean waste audit tool.		C	Q	
C4	Kirby Group	Large	M&E contractor	Framework to determine Cost of Quality on Construction Projects.	DMAIC, Prevention Appraisal Failure, SIPOC, fishbone, 5 Whys, 6M, Process Mapping, TQM.			Q	
C5	Mace Group	Large	General contractor	5S Project Improvement Programme	A3, 5S, waste walks.			Q	S
C6	Office of Public Works	Large	State Buildings	OPW Lift Replacement Programme	Two stage procurement framework, IPD.	T	C		
C7	Arup	Large	Consultancy	The Lean Approach to Immersive Technology at Arup	VR.			Q	
C8	Errigal	Large	Manufacture	Improving Productivity The Errigal Way	Big Data, AI.	T	C	Q	
C9	John Paul Construct.	Large	General contractor	The Grange Development	Last Planner, Field View, other digital tools.	T	C	Q	S
C10	Mannings Group	SME	General contractor	Mannings Construction's Digitalisation of Systems and Processes	Digitisation of systems and processes.		C	Q	S
C11	SISK	Large	General contractor	Capturing Quality Information Using Artificial Intelligence	AI form reading, Microsoft flow.	T		Q	
C12	Walls	Large	General contractor	Walls Construction Cloud Based Solutions Development	BIM 3D viewer.		C	Q	
C13	Walls	As above	As above	The Journey to Our Digital Transformation	Centralised cloud-based docs.		C	Q	
C14	ACB Group	SME	General contractor	ACB Manufacturing – Towards Modern Methods of Construction Using Lean Principles	PDCA, Prefabrication, JIT, BIM.			Q	S
C15	Horizon Offsite	SME	Steel Prefab.	Horizon Offsite – Adopting a CI mindset to their Design for Manufacturing & Assembly operations	DfMA, Visual Mgt., prefabrication.	T	C	Q	S
C16	Ardmac	SME	General contractor	Data Led Approach to Developing Lean Behaviours on Complex Projects	High Performance Teams.	T	C	Q	
C17	DPS Eng.	Large	Project mgt. and engineering	Development of an effective Resource Mobilisation Process using Lean Thinking	DMAIC for resource mobilisation process.	T	C	Q

WHEN WE DEVELOP COLLABORATION, WHAT EXACTLY DO WE DEVELOP?

Sol Skinnarland[1] and Trond Bølviken[2]

ABSTRACT

In this paper we will expand further on the literature focusing on collaborations within the construction industry. In the articles that are concerned with collaborative efforts, the authors present definitions. Often a common denominator is that collaboration is carried out by two or more parties to reach a goal. Little operationalization is offered in terms of understanding collaboration contextually. What are we actually talking about when we are concerned with collaboration, and in particular how to develop collaboration between actors in the construction industry?

This paper aims to discuss the term collaboration from the collective viewpoints of actors at a construction site, who consist of skilled workers and apprentices, supervisors, foremen and site management. The basis for this discussion is a previous review of collaboration in the literature, as well as previous research undertaken by the (first) author, which operationalizes collaboration in terms of six underlying dimensions.

The argument posed in this paper is that if correct measures were to be identified and taken to improve and develop constructive collaborative relationships between interorganizational actors on the construction site, we would need to address the term collaboration in greater depth. Rather than operating with an overarching and insufficient definition of "collaboration", we need to operationalize and sufficiently understand how actors themselves understand collaboration within a specific context.

KEYWORDS

Collaboration, interorganizational relationship, trust, communication, perspective-taking, motivation, the Last Planner System

INTRODUCTION

Collaboration happens when two or more people perform a set of actions that enables them to achieve a goal. Appley and Winder (1977) defined interorganizational collaboration as a process in which two or more firms work closely together to achieve mutually beneficial results. Jacobsen (2004) stressed the fact that entering a collaboration was a voluntary act in which interdependent contractors sought each other to fulfil the quest of achieving the desired results. Collaboration optimally takes place when actors enter a relationship where they display commitment towards each other, and where they value the team relationship as much as they value their own self-interest (Appley & Winder, 1977). Wood and Gray (1991) offered the following definition: "Collaboration occurs when a group of autonomous stakeholders of a

problem domain engage in an interactive process, using shared rules, norms, and structures, to act or decide on issues related to that domain".

In terms of collaboration taking place at a construction site, the stakeholders, in question, are the contractors who participate in the project. They represent independent decision-making firms, they act voluntarily, and they are normally expected to follow a set of industry norms and rules for this type of collaboration. An underlying premise is that the contractors together engage in, and form, a voluntary change-oriented relationship, in which they produce the result, e.g., a building, together. Although industry rules, norms and structures may be implicit in the collaboration, contractors may still explicitly agree on rules and guidelines that will govern the collaboration in the specific construction project.

The above initial descriptive take on what constitutes collaboration, as often found in the literature, is in line with what the readers would have expected. From these initial definitions of collaboration, readers often perceive they have sufficient knowledge of the concept to start tackling any problems thereof, and to follow the author's argument towards a solution to improve collaboration. But is it necessary so? How can the industry know how to develop and strengthen collaboration without more in-depth understanding of what the concept implies? The argument put forward in this paper is that there is a need to develop knowledge as to what constitutes collaboration in the context of the construction industry generally, and specifically the collaboration taking place at the construction site, to initiate the correct measures to develop a collaborative effort. Because, as stated by Howell et al. (2004), "[p]eople are at the beginning, end, and center of projects". Thus, in this paper we offer an in-depth analysis of what constitutes *collaboration*, as viewed by the actors themselves at a construction site.

Researchers have been concerned with collaboration from different perspectives over the last decades. Alves et al. (2021) investigated how the language used in contracts might influence collaboration, specifically in terms of developing and implementing schedules. They found that contract clauses mainly focused on the compliance, and they found overall a limited mentioning about collaborative efforts beyond expectations in the clauses (Alves et al., 2021). Willis and Alves (2020) investigated the language used in construction contracts with the purpose of identifying the keywords commonly associated with collaboration. Interestingly, they found that in traditional contracts, such as design-bid-build contracts (DBB), there was a lack of language to support collaboration. In integrated-project-delivery projects (IPD), on the other hand, keywords associated with collaboration were employed in the contract clauses to promote collaborative behaviors and processes.

Salazar et al. (2019) pointed to the need to teach actors on the project how to make reliable promises. They built on the previous work by Salazar et al. (2019) on how to generate reliable commitments and proposed an updated version of indicators to measure and control the management of commitments in construction projects. Retamal et al. (2021) presented the results from a case study about construction projects in Colombia that demonstrated the importance of enhanced understanding with the linguistic action process. This resonates well with the argument in this paper, that a conscious and practical approach to the use of language is needed to establish a reliable commitment.

Davoudabadi et al. (2022) described a research project in the UK in which a Lean-BIM joint implementation effort at an engineering design firm was evaluated. They found several barriers to effective collaboration between Lean-BIM teams as well as a lack of motivation and desire to engage in the collaboration. This was explained by a lack of awareness of the mutual gains from such a collaboration. Other barriers reported were that Lean and BIM experts exerted different work mentalities and lacked a common approach to accomplish their joint task, hence; group think biases were detected.

Research has pointed to various measures that need to be considered to develop collaborative relationships. Salam et al. (2019) proposed that designers and contractors need to align their knowledge and views about the actual interactive processes to which they engage. In their paper, they emphasized a concern about the lack of knowledge about what participants did in the active collaboration process. Schöttle and Tillmann (2018) discussed the development of shared goals as a means to support collaboration. They found evidence that there was a positive functional relationship between goal-setting activities and a) increased communication and coordination, b) a guide for team action, and c) enhanced team motivation. Gomes et al. (2016) specifically studied collaboration in the context of the early design phases and discussed how shared understanding can serve as a basis for collaboration. In their paper, they developed a model about the process of building a shared understanding, in which the key features are: a) division of labor, (as a condition for collaborative actions), b) coordinated perception and situational awareness, i.e. understanding co-workers' situations, and c) mediated coupling and boundary objects. Garcia and Murguia (2021), stressed the need to understand collaboration not only in theory but also in practice. In their study, they aimed to investigate which factors influenced collaboration and they set out to develop a model for inter-organizational collaboration. They concluded that collaboration can be nurtured by improved operational capacity, taking measures to reduce uncertainty, promote trust and to apply a longer-term view in developing fruitful partnerships.

The above review shows that research on collaboration in the construction industry varies not only in terms of the specific topic of interest, but also in terms of which phase (design or making) in the collaboration process is being assessed and which actors are the focal point.

METHOD

The present paper builds on a recently published curriculum book written for master students in Norway, which summarized the findings of research that had been carried out over the past two decades. This research explored the crucial question: "What is good collaboration to you?", and this same question was directed to various actors at a construction site. Thus, the scope was to discuss the term collaboration from the collective viewpoints of actors at a construction site.

This paper further builds on previous research and practice by the authors as well as a review of recent IGLC papers. Firstly, the collective data gathered from observations, interviews, and surveys for the doctoral thesis of Skinnarland (2013) served as a starting point for the conceptual discussion on collaborative relationships in the construction industry. In her doctoral thesis, collaborative relationships were the focal point of the research. The author established six dimensions for the term collaboration, based on a literature review and research on the collaborative practices on and among the actors at a construction site. These six dimensions are described in detail from page 5 onwards. Secondly, we build the paper on a review of the authors' collected research on construction site production and management, in which collaboration is viewed more implicitly. And, thirdly, a review of recent IGLC conference papers containing *collaboration* in the title, was conducted for the sole purpose of establishing a knowledge base for writing this paper.

DIMENSIONS OF COLLABORATION

Much like the type of collaboration that takes place in a surgical suite, where different professionals collectively prepare for the actual surgery as well as post-surgery activities so that the surgical process does not result in an unsuccessful outcome for the patient, so can a similar collaboration process take place in certain situations at a construction site. For example, two carpenters can help each other lifting beams, one holding while the other carries out the work. The crane operator collaborates with the carpenters to lift materials to a specific area on the construction site.

The above examples, whether in a surgical unit or the loading of materials at the construction site, demonstrate a *simultaneous* collaboration, a slightly different type of collaboration than the collaboration on the construction site that most frequently takes place, which is more *sequential* in form (Kalsaas & Ose, 2017). In sequential collaboration, each trade carries out their tasks in a given order, up until a finished result is handed over to the client. For a more thorough understanding of this, we may view collaboration within the concepts of work flow and coordination. When studying organizations, we cannot escape the very basic premise that all organizations need coordination (Van de Ven et al., 1976). We can borrow insight from Thompson (1967) who proposed a theory of a hierarchical relationship in which the nature of workflow is determined by an increased level of task interdependence. According to Thompson (1967), workflow is either a) *independent* (or pooled), b) *sequential* or c) *reciprocal* in form. These are additive linkages as work flow interdependence increases (Van de Ven et al., 1976). Independent, or pooled, activities (Thompson, 1967), are activities which are carried out simultaneously but they are not linked to each other. An example would be a worker who installs windows on the first floor while another installs windows on the second floor. Sequential and reciprocal work flows are both mutually dependent. A sequential work flow is e.g. the first worker who installs the window, then the second worker installs the moldings. In a reciprocal work flow the activities will flow both directions as two of more workers rely on each other to accomplish the task, such as with the loading of materials.

Flow may be discussed in a psychological sense, as *intuitive qualities* (Bølviken & Kalsaas, 2011) as well as *production* (a physical sense). These two are different concepts, yet related. In the psychological sense, flow is the experience of an ultimate balance between task demands and perceived skills (Csikszentmihalyi, 1990). In production, flow is a physical reality. Kalsaas and Bølviken (2010) review the term flow in production conceptually and Kalsaas (2012; 2013) in later works develops the operationalizing of workflow. In measuring these two conceptual terms of flow, the authors found indications that for the skilled workers the measurement of perceived flow corresponds well with physical flow.

The point of departure in this paper is primarily sequential workflow and collaboration, where, for the work to be coordinated and carried out in an agile manner, with efficiency, good quality, and be performed only once, a *sequence* is required. All work activities carried out by the various trades on the construction site are part of a production where the result depends on everyone's input that is collectively given in a correct order. This brings us to the very core of collaboration in construction site production, dependence, in agreement with Thompson (1967). To complete the construction project, all trades depend on each other and each other’s input.

It is the question of *dependency* which urges the question of “What is good collaboration on the construction site?”. “What are the characteristics of interdisciplinary collaboration being perceived as good?” Researchers have been concerned with interdisciplinary collaboration, not only within the construction industry, but in all industries in which the project constitutes a form of work. A review of the literature (Skinnarland, 2013), that focused on collaborations at construction sites, suggested that characteristics of (good or bad) collaboration could be summarized into six dimensions of collaboration. In several Norwegian studies, skilled workers and apprentices, supervisors, foremen and site managers had been asked; “When do you experience good collaboration on the construction site?”. “What goes on between you and the other project participants when you perceive the collaboration to be good?” The answers to such questions revolved around: 1) the feeling of knowing each other, a sense of community and that they worked towards a common and known goal (dimension 1). Many interviewees described good collaboration as good involvement, good communication and a good flow of information (dimension 2). Others described collaboration as good when there was a large degree of trust between all trades and a lack of conflict (dimension 3). Still others reflected upon good collaboration as a feeling of being motivated, a feeling of being comfortable with each other and a feeling of having a good day at work (dimension 4). Others described further good collaboration in terms of experiencing a high degree of understanding, mutual respect, taking each other's perspectives and acknowledging each other's needs (dimension 5). When asking skilled workers, many reflected upon the experience of production predictability as proof of good collaboration (dimension 6). Skilled workers are concerned with the production flow and predictable work processes. When they experienced that, this was often to them perceived as good collaboration. In the coming section of the paper we will discuss each of the above six dimensions of collaboration and how they are intertwined to form good collaboration at a construction site.

A SENSE OF COMMUNITY AND FAMILIARITY

In inter-organisational collaboration, where trades are so dependent on each other's deliveries and efforts for the overall project to make good progress, many experience that the familiarity and common ground that develops, becomes a guarantee that the trades, to a larger degree, can work according to plan. Getting to know the people in the project gives the participants a sense of unity and a community. Experiencing community and togetherness affects well-being and the desire to help others.

It is, however, not sufficient for developing collaborative relationships, that project participants get to know each other on a social level. They also need to develop a familiarity professionally. "What is important to us to achieve trustworthy production flow?". Trades that communicate and articulate how dependencies between them affect production flow, invest in a type of professional conversation, which complements and strengthens the social relations and bonds between the project participants.

Early kick-off meetings *may* provide opportunities to develop relationships as project participants spend time together. As such, kick-off meetings, is a strategy to increase chances of success (Cooke & Hilton, 2015). Often participants report several positive experiences from kick-off meetings. They receive sufficient knowledge of the overall project, of the client's desires and ambitions, and what goals they will work on together to achieve success with the project. Project participants report a satisfaction with having met and gotten to know the other co-workers they will work with on the project (Skinnarland, 2012; Skinnarland, 2015). Such an early *sense of community, a we-in-this-project-feeling* and *a sense of familiarity* with both the project (and goals) and the participants from the various contractors, is often described as providing a sense of good collaboration. It may be possible to collaborate even without the tight social relationship; however, collaboration will gain from such familiarity (Skinnarland, 2013).

FEELING INVOLVED, GOOD COMMUNICATION AND FLOW OF INFORMATION

The second dimension of collaboration is *involvement* and *communication*. The basic idea of involving even the skilled workers and apprentices is twofold. One is that plan reliability increases as more informed input is provided, and another is that the more people take ownership and commit to following the plans, the greater the chances are that the work processes will flow well, and everyone will collaborate towards reaching the project goal. This last point addresses the giving and receiving of reliable promises.

Being involved increases understanding of the process and a feeling of knowing what one is a part of, what one's efforts contribute towards. Furthermore, the dependency between project participants calls for sufficient information sharing and a multi-trade approach to communication. Being involved and the way that project participants communicate within the project organization mutually influences and reinforces each other's strengths and weaknesses. Many of the actors interviewed in construction projects highlighted the driving force they experienced when they felt fully involved, which explained the association to involvement and communication.

Involvement and communication matter at the individual level, as it enhances well-being, and provides meaning to both the work itself and collaborative relationships. However, involvement also matters at the project level, as involvement strengthens the trade's will to help each other (the project community), to take more responsibility, and to be more committed. Coffey (2000) therefore emphasizes the importance of involvement and communication and states that involvement is an active manifestation of commitment.

PERCEIVED TRUST BETWEEN ACTORS

The third dimension of collaboration revolves around *trust issues*. Many researchers who have studied interpersonal relationships and interactions have been particularly concerned with trust, and the importance of trust in these relationships. Trust is built and torn down in a social and interactive process, in which the actors' interactions change the nature of the trust (Swärd, 2017). Social psychologists have studied what kind of behaviours between individuals creates or destroys trust whether at the individual or group levels. Trust understood at the interpersonal level can be defined as "the expectation of the other party in an interaction, the risk associated with believing them, and the acting on such expectations as well as the contextual factors, which either enhances or inhibits the development and maintenance of trust" (Lewicki & Bunker, 1996).

Given the great dependence, which exists between the actors at a construction site, there is a need to trust each other to experience a positive flow in their work production. Again, dependency requires that activities in an area are completed in a planned sequence as promised. Joint multi-trade planning makes apparent which trades will work on what, where and when. If performance (or quality thereof), or the timeframe is not in accordance with what was promised, there will be consequences for the trades who come later in the production process.

When promises are broken, project participants who take subsequent action based on the expectations of these promises will be disappointed. They become annoyed and frustrated. An occasional broken promise will most likely not significantly change the character of the trust. However, a pattern of broken promises can lead to broken trust. Thus, a high level of trust makes it easier to avoid conflicts in a project and easier to create a good collaborative climate. Again, the dependency on others to produce their project inputs demonstrates the sense of the participants' trust as a way to describe good collaboration.

FEELING OF BEING MOTIVATED AND HAVING A GOOD DAY AT WORK

The fourth dimension of collaboration is *motivation and well-being*. Many, when challenged to dwell upon the notion of good collaboration, express opinions in lines of; "to me good collaboration is feeling motivated and having a good day at work".

Many are highly motivated to take responsibility, to contribute to a joint project, and to work as a team and with other trades, to enhance production flow. Work motivation can be defined as "a set of energetic forces that originate both within as well as beyond an individual's being, to initiate work-related behavior and to determine its form, direction, intensity, and duration" (Pinder, 1998, p. 11). So, what is it that motivates those actors at a construction site? What motivates the site management is not necessarily the same as what motivates the middle management, which in turn may differ from what motivates the workers (Skinnarland, 2013). While the foremen are most concerned with daily production control and an overview of what is happening on the construction site, the site management is most concerned with organizational and structural conditions that facilitate optimal project implementation. By looking at what respectively middle managers (who are closer to production) and site managers (who take care of the administrative responsibility around project implementation) report in terms of what issues are of concern to them, we may deduce what it is that motivates them at work, and what they emphasize most in the collaboration.

In terms of worker motivation, Midtdal (2017) found that: a) piecework as a pay system is a motivational factor, alongside b) the working environment; and c) the feeling of self-efficacy. However, there is a need to voice caution regarding piecework. An incentive system based on piecework may be perceived as a motivator as long as production is flowing according to plan. If not, the pay system may result in decreased motivation, as lower pay becomes the central issue. Skinnarland (2013) also found that workers are motivated by being informed about the project, and by a sense of pride in their contribution to the project. All in all, it is useful for management to be conscious about what motivates the various participants in a construction project.

EXPERIENCING UNDERSTANDING, MUTUAL RESPECT AND PERSPECTIVE-TAKING

The fifth dimension of collaboration is *taking each other's perspective*. Therein lies a fundamental respect for the fact that what one's own trade produces affects what other trades can do. Respect is the core of understanding each other's needs and being able to understand each other's situation. Showing respect for others' finished work and showing a positive attitude towards finding solutions for each other are core values in communication between the trades. When, for example, supervisors get involved and discuss dependencies between trades and familiarize themselves with the needs of other trades, they may be able to help themselves too. When the trades communicate with a view to what others need and what is in the projects' best interest, they also consider their own needs. Thus, taking each other's perspective concerns two things. Firstly, it is drawing attention to the interdependence between the trades in order to achieve an optimal production flow. This is done by ensuring that the work is carried out in a way that meets the needs of all trades. Above all, the overarching point is doing work in the right order (sequence). Secondly, taking each other's perspective demonstrates positive attitudes. When project participants experience others consideration, and that others show interest in one's own trades' production and needs, this reinforces one's own willingness to meet the needs of others, and to show interest in other trades' production. Thus, one aspect of taking each other's perspective is purely result oriented, in that the trades collectively achieve a better construction process through finding optimal production solutions. Another aspect is the purely relational one, an interpersonal relationship in which the trades show each other respect and the ability to understand each other's point of view.

EXPERIENCING PRODUCTION PREDICTABILITY

The sixth dimension of collaboration concerns experiences of *predictability in work processes*. Particularly among skilled workers, there was an almost unanimous response to the question of what characterizes good collaboration, which concerned predictability. Predictability means that workers can bring materials and tools to a work zone and can start and finish work without disruptions or obstacles, and in line with what the plan dictates. Predictability is linked to the notion of flow. As explained with reference to Csikszentmihalyi (1990) one way of understanding flow is the positive psychological experience of devoting oneself entirely to work, free from distractions, and where the employee simultaneously experiences a good balance between professional challenges and own professional competences. Another way of approaching the concept of flow is by directing attention to the prerequisites that must be present to achieve production flow, where work processes proceed without distractions or stops. In line with the Last Planner System (Ballard, 2000) attention to the prerequisites for creating optimal flow takes place at several planning levels in the project organisation. Participants with roles and responsibilities further away from the actual production direct their attention to activities with a longer time perspective, typically two or three months in the future. For example, this could include planning the right staffing, or making sure to order deliveries with a long delivery time. Other types of prerequisites take place closer in time to the actual production, by other roles, such as supervisors and foremen. By working systematically with involvement at all levels of a project organization in the planning and preparation of upcoming activities, the total work and attention towards removing obstacles contributes to creating predictability. When skilled workers experience work predictability, they report well-being and a lower degree of stress in the work situation as positive consequences.

THOUGHTS ON CONCEPTS, DRIVERS AND CONCEQUENCES

As demonstrated, the concept of collaboration is multidimensional. Although researchers initially define collaboration, both in its simplicity as well as in its more complex and theoretical terms, we may summarize that there are multiple ways to understand collaboration. When these six dimensions of collaboration are highlighted in this paper, it follows from reviewing empirical studies of collaboration (Skinnarland, 2013). At the same time, reflections concerning what constitutes good collaboration, inevitably also conveys what the drivers are such as the conditions and premises under which good collaboration unfolds, and what the results are from this optimal collaboration. These are three ways of talking about collaboration which during reflection overlaps somewhat.

As an example, consider the trust dimension. We can summarize findings by saying that "Well, collaboration to me means that we have trust in each other» and reflects a consideration of what collaboration *is*. We can also summarize by saying that "Well, in order to experience good collaboration, we are dependent on creating trust in each other" as a reasoning around trust as a *driver* for, or a foundation for good collaboration. We can also summarize by saying that "Well, when we collaborate well with each other, we increase trust in each other", meaning that trust arises as a *consequence* of good collaboration. This is in line with Swärd (2017) who postulates that trust can be both the dependent and independent variables, as good collaboration conditions support trust and trust provides conditions for good collaboration. In similar manners, we can also reflect upon the other five dimensions of the concept of collaboration. Collaboration per se can be expressed by each of the dimensions. At the same time, all these dimensions are necessary conditions, or premises for creating and strengthening optimal collaboration, and also consequences of good collaboration.

Thus, to develop good inter-organisational collaboration at a construction site, we argue that it will be useful to gain more in-depth knowledge of what the dimensions of collaboration entail in the specific context of construction site production. What are we really talking about when we are concerned with involvement and communication? What does communication mean? How can we understand the communication process that takes place at the construction site? What do we really mean by the term involvement? How can we link the understanding of involvement to commitment? And how can we understand involvement and communication in terms of structural and systematic aspects on the one hand, and relational aspects on the other? And when we talk about trust, how can project participants use their language actively to articulate the network of commitments? (Slivon et al., 2010). How can motivation be linked to one's own interests and what is of value to oneself? What do we really mean when we talk about taking each other's perspectives? What importance do we attach to the mutual interdisciplinary dependence when we talk about taking each other's perspectives? And how can we understand predictable work processes by linking the discussion to prerequisites for healthy activities (Ballard & Howell, 1994), as stated by the Last Planner System? How can we reflect upon the concept of flow in a way that we gain a deeper understanding of what it really means when the project participants experience flow? By engaging in conversations concerning these and similar questions concerning collaboration, we argue that clarifying and understanding more in-depth the terms used daily may in fact constitute the best preparation for optimal collaboration processes.

MUTUAL IMPACT ON COLLABORATION

Following each of the dimensions in isolation, we may gain understanding of different ways to talk about collaboration. The argument so far is that taking collaboration as a concept apart, as demonstrated above, enables practitioners to direct discussion and attention to the aspects that really matter to enhance collaboration and collaborative efforts.

We have argued that one dimension of collaboration can form the basis for good collaboration and at the same time constitute a consequence of good collaboration. However, we may develop our argument further by stating that the dimensions of collaboration also may mutually influence each other. Meaning, we need to consider the dimensions of collaboration as interweaving aspects of each other. The dimensions influence and reinforce each other in both positive and negative ways. When elements in one of the dimensions falters, this can affect others, and conversely, when collaboration feels good in terms of one dimension, it also affects and strengthens other dimensions positively. A few examples may illustrate this point. Getting to know each other both professionally and socially is shown to affect the relationships of trust in the project. Involvement leads to greater commitment and well-being, which leads to more control both for the individual participant and for the overall project. In addition, greater commitment to produce according to planned activities leads to more predictable work processes. The degree of trust affects the willingness to share information, and involvement already from the outset of the project can contribute to establishing a good project culture founded on trust. Involvement and communication are prerequisites for developing trust. Another prerequisite is that commitments are kept, and that each trade delivers results according to the plan. Thus, a high degree of trust, and communication and information sharing, lead to more predictable work processes. This complexity may help explain the lack of an unambiguous "best practice" and why good production results are so difficult to reproduce from project to project; the results follow a number of complex intertwined factors that cannot be reproduced in exactly the same way.

LPS; COLLABORATION INTO A SYSTEM

Ballard et al. (2009) argued that a framework is needed to explore principles, functions, and methods for production control. The Last Planner System (LPS) principles "guide thinking and action, the functions it enables to be performed, and the methods or tools used to apply those principles and perform those functions" (Ballard et al., 2009). We argue that the in-depth knowledge of the multifaceted term *collaboration* as presented in this paper will benefit from being operationalized and put into collaborative practice within e.g., the LPS framework.

The Last Planner System (LPS) is a methodology for production control based on the idea of a need to actively coordinate human and material resources during the construction process. Ballard (2000) introduced the LPS as a critique of the traditional way of approaching planning, which commonly involved a centralized and detailed plan already from the outset of the construction project. The plan was produced by actors further away from the actual site production, thus separated from the production phase. LPS in large is concerned with involvement in interdisciplinary planning and continuous preparation for future production, through systematically removing obstacles to future work activities. LPS also has an inherent principle that the project participants, by getting involved and communicating with each other, commit to keeping promises made about production (Ballard et al., 2009). LPS is ultimately a methodology specifically for planning and managing the flow of construction site production. According to Bertelsen (2005), the Last Planner System thus provides for better collaboration across professional boundaries in the construction project.

Lookahead plans are central to LPS and the understanding of flow, discussed above. These plans fill the gap between master plans for the entire project and weekly work plans (Ballard, 1997). The main task in lookahead planning is to create healthy activities. That is, to remove any obstacles to the execution of the activities, so that the activities, when they have been transferred to a weekly work plan, can actually be carried out. Traditional weekly work schedules have been shown to be unreliable (Ballard & Howell 1994), and downstream production therefore traditionally is inherently unstable and unreliable. The idea of lookahead planning is to create predictable workflow. According to Ballard (2000), LPS increases reliability in three ways: 1) through lookahead planning and the preparation process, 2) through controlling for any previously planned work that needs to be completed; and 3) through involving and committing managers and employees. Ballard's description of the purpose and how to utilize lookahead planning is empirically supported (Fiallo & Revelo, 2002; Skinnarland, 2010; Skinnarland, 2013).

CONCLUSION

LPS has proven to be constructive, (see e.g., Salazar et al., 2019; Retamal et al., 2021), and contractors worldwide are currently carrying out construction projects within the framework of this methodology. However, implementing LPS has proven to be far more demanding than what one would have expected from a theoretical perspective. We argue that our discussion noted in this paper may reveal rationale for this observed experience that LPS promotes collaboration, but LPS is also dependent on collaboration itself.

Again, returning to the dimensions of collaboration, we need to pay attention to how project participants communicate. Do they understand each other's contributions and needs? Do they communicate with each other or is communication more in form of one-way information? Equally crucial is how the project participants behave towards each other. Do they act towards each other in a respectful manner despite professional disparity and different needs? The way that participants in the project talk to each other and behave towards each other may greatly impact how collaboration develops (Skinnarland, 2022). Previous research emphasizes the need for the project participants to focus their attention on structures and systematic aspects on the one hand, and the relational aspects on the other. These two perspectives need to be seen in parallel to enable strengthened collaboration (Skinnarland, 2013). Stated alternatively, the project collaboration needs to stand on two legs to be able to stand firmly. Thus, if research and practise are to succeed in developing good collaboration in project-based production, a necessary starting point must be to understand what we are really talking about when we talk about collaboration.

Every construction project consists of a plurality of roles, trades and various personalities, and although all participants should put in an effort to make sure collaboration works at its best, the management's role, for a fact, is prominent and absolutely decisive, in creating the best conditions for developing good collaboration. Research should particularly emphasise the manager role in attending to the multifaceted contents of collaboration. We also advise that future publications further develop in-depth knowledge of the term collaboration provided by the current paper. Future work should build on these findings and develop knowledge of how to improve collaboration in practice. One such framework to study collaboration in practice, however not limited to, is within the Last Planner System for production planning and control.

ORGANIZING THE ARGUMENTATION FOR CHANGING THE DELIVERY SYSTEM USING CHOOSING BY ADVANTAGES (CBA)

Annett Schöttle[1], Rafael Guerreiro[2], André Haubrich[3], Michael Ditandy[4], and Fabian Behme[5]

ABSTRACT

Megaprojects contain strategic decisions that must be approved outside of the project. A clear and understandable argumentation is required to communicate and push through such decisions. As shown in the literature, Choosing by Advantages (CBA) helps teams create a shared understanding regarding a decision resulting in a strong argumentation of the decision outcome. Therefore, this research aims to better understand how CBA helps to make a strategic decision that impacts all project levels and creates the argumentation to get the approval of the management board of the company. This paper describes why and how the Deutsche Bahn team of the project Munich main station proceeded with the decision to change the project delivery system from design–bid–build (DBB) to integrated project delivery (IPD) while the project was already in different design stages using the CBA tabular method. As all authors (consultant and client) were involved in the research, participatory action research was used as the research approach. The paper demonstrates how CBA (1) helped to create a shared understanding of IPD, (2) helped to understand the scope of the multiparty agreement, (3) helped to organize the argumentation, and (4) helped to create trust regarding the argumentation.

KEYWORDS

Choosing by Advantages, collaboration, Integrated project delivery, megaproject, Munich main station.

INTRODUCTION

When starting a project, the owner must explain how the project will be delivered to begin the procurement process and get stakeholders on board. In megaprojects, there is the challenge that the time between defining the delivery system at the beginning of the project and the point when all stakeholders are on board can be years or even decades. Additionally, there is the challenge that megaprojects might not benefit from new management approaches that did not exist when the project started. Because megaprojects contain many unforeseen challenges and risks (e.g.,

Flyvbjerg & Gardner, 2023; Priemus et al., 2013) as the project proceeds, they require adaptation to new findings from research and development to achieve the project goal.

Changing the delivery system impacts all organizational levels of a project, from the strategic level to the operational level. This requires courage from the owner and a project team that stands behind the change. Therefore, every member of the owner's team must understand the content of a decision and why the change is necessary, with all its advantages and consequences, to change the existing project structure. As some strategic decisions need support outside the project, a stable and comprehensive argumentation is required to get approval from the management board. Obtaining this approval can be a struggle if certain aspects are not considered or if the argumentation is not presented understandably.

Choosing by Advantages (CBA) is a multicriteria decision-making system developed by Suhr (1999) that differentiates between alternatives based on the importance of advantages. The most applied method of the CBA system is likely the CBA tabular method. Figure 1 shows the different steps of the tabular method. Studies show that using the tabular method helps project teams make stable decisions based on a shared understanding by including different perspectives that can contain conflicting interests (Arroyo et al., 2022; Arroyo & Long, 2018; Martinez et al., 2016; Parish & Tommenlein, 2009; Schöttle et al., 2019; Schöttle & Arroyo, 2017). Thus, having a reliable decision-making process is especially important for megaprojects "because the interests and power relations [...] are typically very strong, [...] given the enormous sums of money at stake, the many jobs, the environmental impacts, the national prestige, and so on" (Flyvbjerg et al., 2003, p. 7).

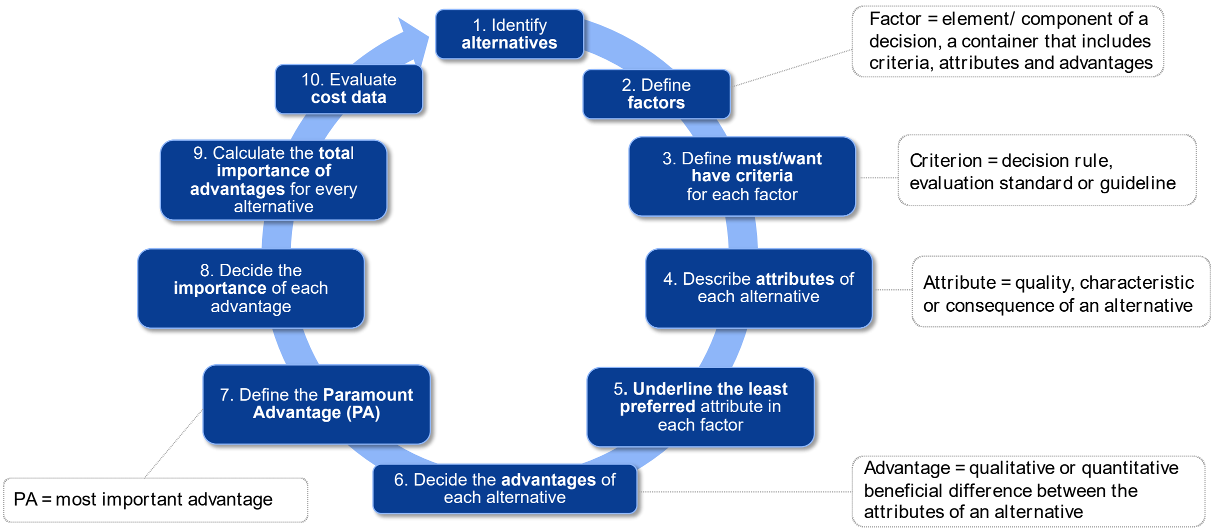

Figure 1: CBA Tabular Method (Schöttle et al., 2019, based on Arroyo, 2014)

A review of the literature shows that applications of CBA were explained in terms of tendering (Arroyo et al., 2022; Schöttle & Arroyo 2017; Schöttle et al., 2017) to decide between proposals, to decide between design alternatives (Arroyo et al., 2012; Arroyo et. Al. 2017; Arroyo & Long, 2018; Kpamma et al., 2017; Parrish & Tommelein, 2009), or for operational decisions (Martinez et al., 2016). Furthermore, all the papers mentioned above claim that the decision was made within the project and did not require approval outside of the project team.

This paper aims to show that CBA can help the project team organize their argumentation for a strategic decision that needs approval outside the project. First, the research method is explained, then the case will be presented, followed by an analysis and discussion of the collected data.

RESEARCH APPROACH

This research aims to better understand how CBA helps to make a strategic decision that impacts all project levels and needs to be approved by the organization. Therefore, the research question asks how CBA can help to reason the change in the delivery system.

Participatory action research was used as all authors (consultant and client) were involved in the research of changing the client system (Greenwood et al., 1993; Kindon, 2007; Tharenou et al., 2007). During the process, issues were identified and intervened on (Dickens & Watkins, 1999). **(1) Deciding to apply CBA:** The first author (A) briefly explained CBA to the project lead (H), then met with the project lead (B) and two cross-divisional leads (B, D) to explain the procedure of decision-making using CBA. In the meeting, the decision was made to apply CBA for a specific strategic question. **(2) Execution of workshops:** A series of workshops was executed to decide whether (Q1) integrated project delivery (IPD) should be applied and (Q2) which scope should be delivered using IPD to understand different perspectives better and, thus, create a strong argumentation for the approval process and the implementation of the decision. After each workshop, the participants defined the next steps for the following workshop. Because the workshops were assigned to two questions, there were two cycles. Due to availability and knowledge integration, there were different participants involved in the workshops. Table 1 gives an overview of the different participants involved. Overall, eight people from the project management team participated in the decision-making process. Figure 2 represents details regarding the position and the years of working experience of the participants. During the process, the first author (A) trained the team in CBA and guided them through the process. The second author (B) participated in all workshops. The third author (F) was partly involved in the second workshop and the final meeting. The fourth author (I) only discussed the decision outcome in the last meeting, and the last author (D) was partly involved in the workshops. The third and fourth authors were positively biased regarding IPD and therefore excluded themselves from the CBA workshops so as not to drive the discussion. **(3) Reflection of the procedure:** In February, the first author (A) briefly interviewed both project leads (F, I) regarding their experience as they were not or were only minorly involved in the workshops. At the beginning of April, an online survey with open-ended questions was carried out and answered by all eight participants to reflect on the procedure and to verify if the goal was achieved. The survey consisted of three parts. First, general questions were asked about the participants. Second, general questions were asked regarding strategic decision-making. Finally, questions were asked regarding the workshops. The first author decided to collect the reflection through a survey to minimize the biases such as anchoring or confirmation bias. Survey answers were analyzed based on content analysis (Mayring, 2010).

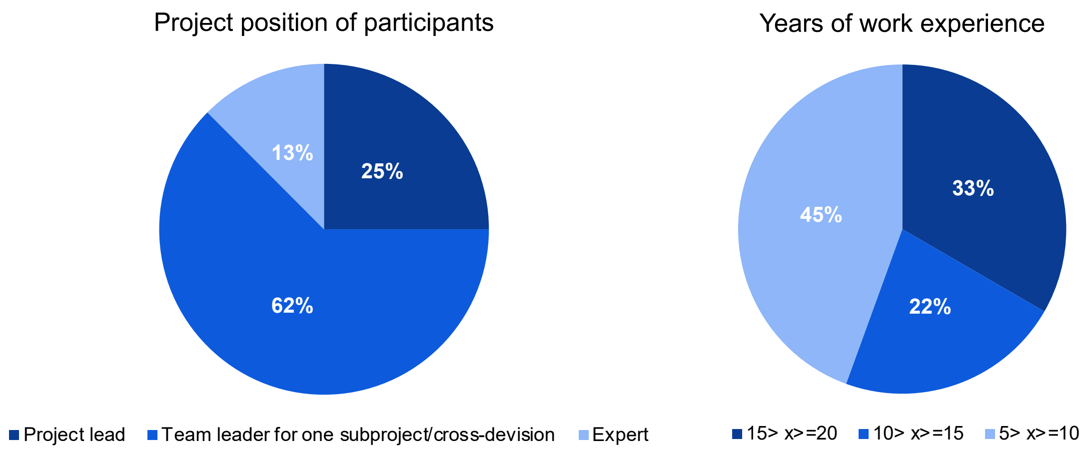

Figure 2: Details about Workshop Participants (excluding consultant)

Due to the degree of involvement in the workshops, all authors' knowledge regarding CBA was different. In short interviews, the second, third, and last authors were asked to give their opinion regarding the procedure of using the CBA tabular method and the outcome of the decision.

CASE STUDY

Due to the high traffic volume of the first core line of the city train (1.SBSS) in Munich, the line itself, as well as the main station, needs to be expanded. The 1.SBSS was opened in 1972, right before the Olympic Games, and was designed for 250,000 passengers per day. Today, up to 840,000 passengers per day (DB Netz, n.d.-a) use the line, often resulting in a two-minute *takt*, meaning that every two minutes a train is driving through the core line. This makes the 1.SBSS the busiest line in Europe. As the city, as well as the number of passengers using the line, will continue to grow, the line needs to be expanded by two more tracks parallel to the existing line called the second core line of the city train (2.SBSS) to overcome the bottleneck (see Figure 3). Both core lines contain underground stations at Munich’s main stations. The addition of the 2.SBSS to the infrastructure system means the main station has to be extended and modernized. Munich's main station is one of the biggest infrastructure hubs in Germany, with 450,000 passengers per day, 34 tracks overground, and 8 tracks underground. The main station is a megaproject itself that includes overground and underground work. Only buildings of 1.SBSS, the subway lines U1, U2, U4, and U5, as well as the tracks for the trains, and the historically protected track roof, will be sustained and remain in operation throughout the whole construction phase (see Figure 4). All other existing buildings will be demolished or updated, and new buildings will be built, including services areas, areas for restaurants, shops, and office space. Furthermore, the project contains a precautionary tunnel for another subway line (U9), the complete renovation of the track hall roof, and a new cross-platform roof. The anticipated cost for the main station (overground) is estimated at €1.2 billion.

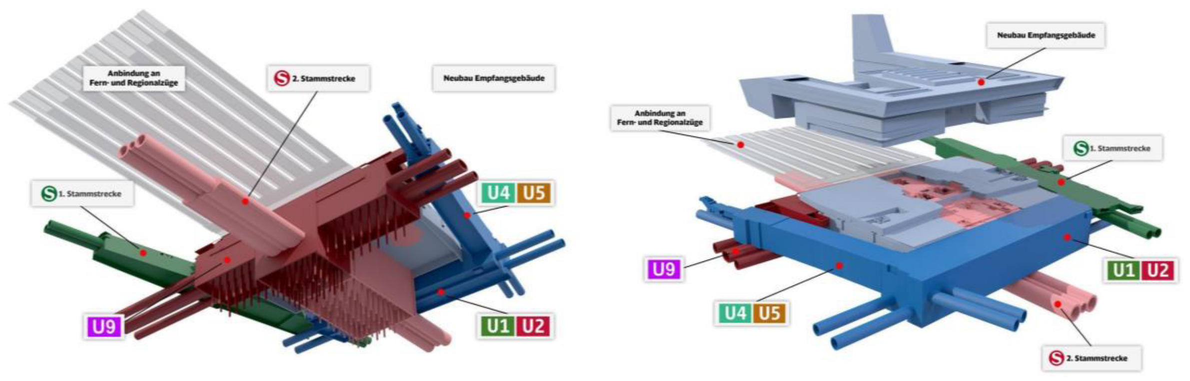

Figure 4: Visualization of Munich Main Station (left: underground system, right: overground buildings) (DB Netz, n.d.-c)

The owner's project team is currently organized based on a matrix structure with a cross-divisional project management level. The project delivery system is design–bid–build (DBB) with some early contractor involvement. Due to many interfaces, limited laydown and construction areas, many different design stages, and different financial funds, considerations were made that IPD could be the best way to deliver the project and achieve the overall goal of finishing the project on time. In addition, the project lead initially thought that IPD could help to reduce the interfaces and support communication across organizational borders operating as an aligned team. This should also help to handle change orders more quickly without the installation of a big claim management process and instead focus on finding solutions through innovation. At all times, the team was aware that due to the constraints imposed by public procurement law, it might be with great difficulty that the procurement process can be designed to include IPD with all its key features (multiparty agreement, modified reimbursement, an incentive system, a modified distribution of liabilities, modified risk allocation, etc.). However, there was a consensus that the greater effort involved in preparing and coordinating the procurement process is far outweighed by the benefits of a subsequently reduced effort for the management of contractors' claims and all the negative implications that come along with it.

In order to change the project delivery system to IPD, the team must analyze and define the scope of the multiparty agreement and be able to communicate the advantages of starting an IPD pilot project to the management board of Deutsche Bahn (DB).

DECISION QUESTIONS

The decision-making questions must be defined to decide if IPD should be applied to the projects. Based on a quick brainstorming, the team identified two questions:

- Q1: Should the project be delivered with DBB or IPD?
- Q2: Which work scope should be part of the IPD (multiparty agreement)?

Workshops were conducted using the CBA tabular method to answer the decision questions. If the decision outcome of the first question was not to do IPD and stay with DBB, then there would be no need for the second question. The second question focused on the scope of the IPD implementation.

OVERVIEW OF THE CBA WORKSHOPS

The workshops were executed with paper and post-its to drive the discussion among the participants and make the process as easy as possible, as it was the first time for the whole group to use CBA (see Schöttle et al., 2022). Before starting with the decisions, the team was introduced to CBA via a presentation and brief examples. During the first workshop, a core group started to prepare the decision for the second workshop, which would have an extended group. Table 1 gives an overview of workshop execution and the progress the team made during the workshop.

Table 1: Overview of Workshop Execution

Workshop Date & Duration	Participants (incl. trainer)	Content
1 (10/06/2022) 3.0 hours	5 (A, B, C, D, E)	• Short introduction to CBA • Defining the decision steps based on questions • Defining factors, criteria, attributes, and advantages for Q1
2 (10/12/2022) 9.5 hours	8 (A, B, C, D, E, F, G, H)	• Building knowledge regarding CBA • Developing a common understanding regarding IPD • Identifying road stoppers for IPD • Clarifying the decision questions and the current organizational setting • Adjusting factors and criteria for Q1 • Defining attributes and advantages for Q1 • Identifying the Paramount Advantage (PA) and sequencing the importance of the highest advantages of every factor
3 (11/14/2022) 3.0 hours	6 (A, B, C, D, E, H)	• Defining the importance of advantages for Q1 • Writing down the argumentation • Defining the alternatives for Q2
4 (11/28/2022) 2.0 hours	4 (A, B, C, H, I)	• Defining factors, criteria, and attributes for Q2
5 (12/05/2022) 2.0 hours	3 (A, B, C, I)	• Determining the advantages for Q2 • Defining the importance for Q2
6 (01/26/2023) 1.0 hour	7 (B, C, D, F, J)	• Presenting the outcome of the tabular method • Reflecting on the tabular • Making the final decision

ANSWERING QUESTION 1

The alternatives DBB to IPD were compared to answer the decision question based on the project context. The factors and criteria were quickly set up using the nominal group technique. The attributes were described, and the advantages were defined (see Figure 5). During the reflection of the defined advantages, the team recognized that there were four factors that were already included in other factors, and thus, decided to eliminate these factors from the CBA tabular. Answering the first question was important for the team to create awareness regarding the difference between DBB (scores of 240) and IPD (scores of 600) and to create a common understanding of IPD. Furthermore, the team identified challenges that need to be considered: (1) convincing stakeholders to do IPD, (2) financing rules based on the different funding, and (3) influences of public procurement law that can impede the successful awarding of contracts containing (key) components of IPD (incentive system, modified risk-allocation, a modified distribution of liabilities, inspection and notification requirements, etc.). Based on the decision outcome (see Figure 6) of the table, the team formulated their argumentation for IPD based on the tabular:

- Significantly higher joint identification with the project goal due to a multiparty contract and the joint definition of the project goals and team goals
- Significantly higher reliability to achieve milestones due to shared goals, transparency, and shared responsibility
- Better decision-making based on the early integration of project participants and their knowledge
- Higher willingness to innovate due to diverse perspectives on a problem
- The complexity of the claim management decreases significantly due to the jointly agreed target costs
- Mutual consideration leads to a higher execution quality due to the overall project view.

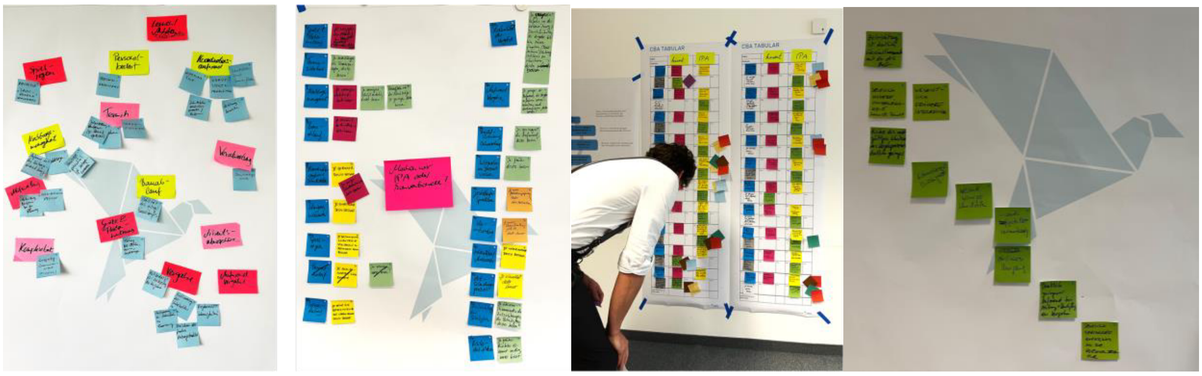

Figure 5: Progress of Workshops 1 and 2 to Answer Q1

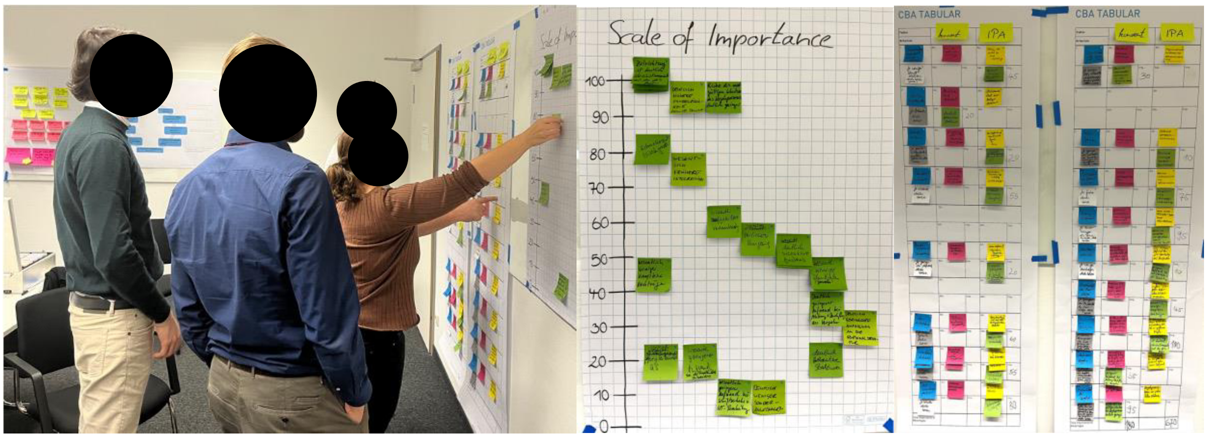

Figure 6: Progress of Workshop 3 to Answer Q1

Answering Question 2

The second question consisted of five alternatives that were identified based on the work scope:

- Alternative 1: Civil engineering underground
- Alternative 2: Civil engineering underground plus building construction (overground)
- Alternative 3: Technical building equipment and interior for over- and underground
- Alternative 4: Building construction (overground) plus technical building equipment and interior for over- and underground
- Alternative 5: Civil engineering underground plus building construction (overground) plus technical building equipment and interior for over- and underground

As the team understood the method better, the second table was quickly set up, and the importance of advantages was assigned (see Figure 7). For better communication, the table was transferred into an Excel spreadsheet to present at the final meeting. Figure 8 shows the completed tabular.

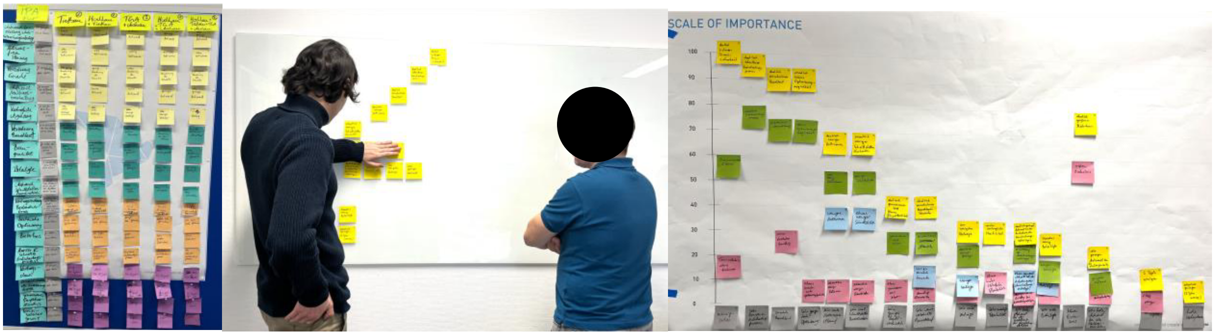

Figure 7: Progress of Workshops 4 and 5 to Answer Q2

Factor / Criteria	Alternative 1: Civil engineering underground		Alternative 2: Civil engineering underground plus building construction (overground)		Alternative 3: Technical building equipment and interior for over- and underground		Alternative 4: Building construction (overground) plus technical building equipment and interior for over- and underground		Alternative 5: Civil engineering underground plus building construction (overground) plus technical building equipment and interior for over- and underground	
Effort for the preparation of tender documents	Very significant effort		Significant effort		Average effort		Low time and effort		Low time and effort	
Less effort for preparation is better.			Insignificantly low time and effort in the preparation of tender documents	5	Somewhat low time and effort in the preparation of tender documents	10	Insignificantly low time and effort in the preparation of tender documents	25	Significantly low time and effort in the preparation of tender documents	30
Collision-free planning	Lots of collisions		Very many collisions		Few collisions		Minimal collisions		No collisions	
Fewer collisions is better.			Imperceptibly fewer collisions	5	Fewer collisions	35	Few collisions	50	Significantly fewer collisions	65
Interlocking of trades	Very little interlocking of the disciplines		Lower interlocking of the disciplines		Average interlocking of the disciplines		High interlocking of the disciplines		Maximum interlocking of the disciplines	
The more interlocked the trades, the better.			Somewhat more interlocked trades	5	Less interlocked trades	10	More interlocked trades	25	Significantly more interlocked trades	40
Time and effort for supplementary processing	Very significant time and effort		Significant time and effort		Significant time and effort		Low time and effort		Low time and effort	
Less is better.			Less time and effort in the subsequent processing		Less time and effort in the subsequent processing	5	Less time and effort in the subsequent processing	10	Very low time and effort in the subsequent processing	20
Contractual delimitation	Very many contracts		Many contracts		Few contracts		Very few contracts		Practically a contract	
The less contracts, the better.			Insignificantly fewer contracts	5	Fewer contracts	10	Significantly fewer contracts	20	The least contracts	30
Interlocking construction process	Very minimal interlocked construction process		Little interlocked construction process		Little interlocked construction process		Moderately interlocked construction process		Completely interlocked construction process	
The more interlocked the construction process, the better.			Somewhat interlocked construction process	25	Somewhat interlocked construction process	25	More interlocked construction process	70	Significantly more interlocked construction process	90
Participants	Very many participants		Many participants		Moderate number of participants		A low number of participants		Very few participants	
The less participants, the better.			imperceptibly fewer participants	5	Slightly fewer participants	10	fewer participants	15	Particularly few participants	25
Time and effort for interface coordination	Very many interfaces		many interfaces		A moderate number of interfaces		Few interfaces		Very few interfaces	
The less interface coordination, the less time and effort, and the better.			Imperceptibly less interface coordination	5	Slightly less interface coordination	35	Less interface coordination	50	Significantly less interface coordination	65
Contract change of existing contracts	Change in civil engineering (moderate flexibility)		Change in civil engineering (moderate flexibility)		Change technical building equipment + interior (low flexibility)		Change technical building equipment + interior (low flexibility)		Change civil engineering + technical building equipment + interior (very low flexibility)	
The greater the contractual flexibility, the better.	More contractual flexibility	30	More contractual flexibility	30	Somewhat more contractual flexibility	10	Somewhat more contractual flexibility	10		
Technical optimization potential	Very low technical optimization		Low technical optimization		Very low technical optimization		High technical optimization		Very high technical optimization	
More optimization potential is better.			A litte bit more optimization potential	5			Higher optimization potential	70	Much higher optimization potential	90
Number of bidders	Very large group of bidders		Very large group of bidders		Large group of bidders		Very large group of bidders		Small group of bidders	
The more bidders, the better.	Significantly larger group of bidders	75	Significantly larger group of bidders	75	Larger group of bidders	55	Significantly larger group of bidders	75		
Fast decision-making process	Very slow decision-making process		Very slow decision-making process		Fast decision making process		Fast decision making process		Very quick decision making process	
The faster, the better.					Quicker decision-making process	75	Quicker decision-making process	75	Significantly faster decision-making process	95
Contract duration	Short contract duration (approx. 6 years)		Long contract duration (approx. 11 years)		Long contract duration (approx. 10 years)		Long contract duration (approx. 10 years)		Long contract duration (approx. 12 years)	
The less, the better.	Significantly less (6 years less)	5								
Interconnection of the financing pots	2 pots (U9 + UG)		3 pots (U9 + UG + building construction)		3 pots (UG + building construction + XXX)		3 pots (UG + building construction + XXX)		4 pots (U9 + UG + building construction + XXX)	
The less pots, the better.	2 pots less	15	1 pot less	5	1 pot less	5	1 pot less	5		
A common understanding of the project	Very low understanding of the project		low		low		A high understanding of the project		A very high understanding of the project	
The more common and clearer, the better.			Somewhat more common and clearer	5	Somewhat more common and clearer	5	More common and clearer	25	Significantly more common and clearer	40
Total scheduling security	Not very safe		Secure		Somewhat secure		Secure		Very secure	
The more secure, the better.			More scheduling security	55	Scheduling security somewhat more secure	15	More scheduling security	55	Significantly safer scheduling security	100
Total importance of advantages		125		230		305		580		690

Factor / Criteria	Alternative 1:		Alternative 2:		Alternative 3:		Alternative 4:		Alternative 5:	
Number of bidders	Very large group of bidders		Very large group of bidders		Large group of bidders		Very large group of bidders		Small group of bidders	
The more bidders, the better.	Significantly larger group of bidders	75	Significantly larger group of bidders	75	Larger group of bidders	55	Significantly larger group of bidders	75		
Fast decision-making process	Very slow decision-making process		Very slow decision-making process		Fast decision making process		Fast decision making process		Very quick decision making process	
The faster, the better.					Quicker decision-making process	75	Quicker decision-making process	75	Significantly faster decision-making process	95
Contract duration	Short contract duration (approx. 6 years)		Long contract duration (approx. 11 years)		Long contract duration (approx. 10 years)		Long contract duration (approx. 10 years)		Long contract duration (approx. 12 years)	
The less, the better.	Significantly less (6 years less)	5								

Figure 8: CBA Tabular for Q2 and Exemplary Extract

The most important advantages of the decision were significantly higher schedule reliability, the advantage of much faster decision-making, the advantage of having significantly higher technical optimization possibilities, and the advantage of a significantly more integrated/interlinked construction process.

On January 26, 2023, the team came together to reflect on the tabular to finalize the decision. By doing so, they recognized that a certain condition needed to be considered. As the second city train line is connected to the main station, the underground works of the main station have to reach a certain point in their structural work so that the schedule of start-up and commissioning of the second line can be achieved. Thus, the civil engineering of the underground needs to be executed as quickly as possible and cannot wait for the delivery system change as this could result in a delay in the completion of the 2.SBSS. This risk must be mitigated by proceeding with the structural underground work as soon as possible, resulting in exclusion from the IPD scope. As the technical building equipment must work as one system for underground and overground and because there is enough time between the start of installation and changing the delivery system, the equipment for the overground buildings, as well as the underground buildings, will be included in the IPD to avoid producing a big interface. Therefore, although alternative 5 (score of 690) achieved the highest overall importance of advantages, the team decided to apply alternative 4 (score of 580) due to the strategic consideration on start-up and commissioning.

The next step in moving forward with the IPD approach is a conceptual presentation by the final decision-making team outside the project team, as this will be an outstanding pilot project for the DB. Furthermore, the funding stakeholders, the city of Munich, the Free State Bavaria, and the federal government must agree too.

FINDINGS FROM DATA COLLECTION

FINDINGS FROM SURVEY

General questions regarding strategic decision-making

To better understand the baseline, the survey participants were first asked why the preparation of the decision was important. Paraphrasing, the following answers were given: (1) Setting the strategic direction/structuring the overall project and the procurement process, (2) transparent/comprehensible documentation of the decision and the decision-making process, (3) argumentation support/decision preparation for the approval process, (4) determination of synergies and potential savings, (5) collaborative, objective, and fast-track decision-making. Participants were then asked what it takes to push through and communicate such a strategic decision. The answers can be clustered into four factors: **(1) Conviction**—vision, courage, confidence, will of everyone, interest in doing something new, keeping focus in the event of backlash, political openness, discourse with IPD, collaborative mindset, consent of those involved, and convincing important stakeholders. **(2) Unity**—close coordination with the procurement and legal department, strong network within the company's management level, and secured financial funding. **(3) Knowledge**—knowledge-building CBA and IPD at a very high decision-making level, basic knowledge of all project phases and trades, and experience in megaprojects. **(4) Documentation and communication**—considering the different perspectives, good preparation, structured way, traceability of decision, informative presentation (including risks and opportunities)/reasoning of the benefits and explaining the why.

Questions regarding workshops

Participants were asked if the application of CBA helped to reason the change of the project delivery system. Seven of the participants said yes, and one participant (I) said no. The negative response could be an indicator of lack of training as the participant missed the first workshops, which set the basis and gave clarity regarding the process.

Retrospectively, the participants observed that the team made the decision together and achieved fast consensus by discussing different interests openly and honestly. Working with the tabular created information symmetry easily, although it showed the complexity of the decision. Moreover, one participant responded that factors were considered that would not have arisen in classic decision-making. The method promotes the consideration of different perspectives and therefore represents the multitude of topics and different interests of the project. Nevertheless, due to the lack of consistent participation and the degree of involvement, the decision result might include a bias due to the assignment of importance (scoring). One participant reflected that the result was not fully objective. This response aligns with previous findings that decisions always contain subjectivity by nature (Schöttle et al., 2020; Suhr, 1999).

In summary, participants answered that CBA helped to communicate and enforce the decision within the project team to onboard stakeholders and achieve commitment to proceed with the decision. As participant (J) stated, "Involving a large number of people in the discussion is exhausting, but necessary and faster in the end since everyone is involved, and all issues are directly discussed."

FINDINGS FROM SHORT INTERVIEWS

During the short interview, participant (J) said that the tabular structures all relevant aspects. Participant (F) mentioned in his interview that the tabular was very comprehensible and contained more aspects than he anticipated. Furthermore, participant (F) stated that the degree of detail was more than he expected and that the detailed analysis of the alternatives helped to understand the decision resulting in confidence and reliability regarding the outcome. Participants (F) and (J) observed that the team stood behind the outcome and showed confidence, as different perspectives were integrated through the process, and the team worked together on the decision. Thus, stakeholders that were not involved in the decision-making process and stakeholders that might be joining the project can understand why the delivery system must change to IPD without asking the same questions that came up during the workshop. This is an important indicator for the project lead that they developed a stable and comprehensible argumentation as stakeholders outside the project need to give their approval.

Participant (J) stated: "CBA fits great with IPD because decisions can't be made in the same manner as before. [...] We need to make decisions collaboratively to include different perspectives." The findings also show that the team already has a collaborative mindset necessary for the change. As the owner knows, the lack of experience on all ends in the owners, architects, engineers, and contractors (OAEC) industry in Germany regarding IPD will require a joint learning process from all stakeholders.

DISCUSSION AND CONCLUSION

The process created clarity regarding the alternatives that should be considered in the decision-making process. The process showed the team which advantages are more important and which differences between alternatives are less relevant to the decision. Moreover, the tabular gives a clear overview of where the highest importance of advantages is located so that the team was able to make a sound decision. As the difference between alternatives 4 and 5 of the second question was not as big as the other alternatives (Alternative 1: 125 scores, Alternative 2: 230 scores, Alternative 3: 350 scores, Alternative 4: 580 scores, Alternative 5: 690 scores), the team was questioning whether to go with alternatives 4 or 5 by taking certain conditions into account.

Furthermore, the transparent and easily understandable documentation helped them to communicate the decision outcome. For example, seeing the CBA tabular for the first time at the final meeting and without any knowledge regarding CBA, the fourth author was able to understand the tabular but needed to get a further explanation about the way the scores were assigned. Using the method the first time, the second author (B) was able to present the tabular and answered questions regarding the procedure to the group. This shows that with an open mindset, training, and a coach guiding the team to use the method correctly, CBA can be easily learned, and although CBA was new to the team, the time spent working on the decision was short. Thus, it was important that a facilitator guided the team through the process and helped participants to voice their thoughts.

Based on the presented case, it can be stated that the CBA tabular method helped to (1) create a shared understanding of IPD, (2) understand which scope should be part of the multiparty agreement, (3) organize the argumentation, and (4) create trust regarding the argumentation. In this context, the CBA tabular method was not only used to make the decision but was also used to create a common understanding of IPD and the difference between IPD and DBB. Within a short time, the team was able to share their understanding regarding IPD and discuss the consequences of the system change. Moreover, determining the advantages showed the team the differences regarding the work scope that should be part of the multiparty agreement and supported the identification of constraints that the team was not aware of from the beginning. CBA is an enabler for conversations in a structured and productive way while focusing on the relevant facts. In doing so, CBA helped to reason the change in the delivery system.

ACKNOWLEDGMENTS

We would like to thank all workshop participants for their support, collaboration, and open mindset, and for answering the survey.

CAPABILITY-BUILDING FOR CONSTRUCTION INFORMING DESIGN

Dean Reed[1], Chad Arthur[2], and Charlie Dunn[3]

ABSTRACT

The research question is whether Takahiro Fujimoto's theory of capability-building to create the Toyota Production System (TPS) is useful to understand the creation of a capability for Construction knowledge to inform design (CID). This paper attempts to reveal what was done in sufficient detail to compare it against Fujimoto's explanation of how Toyota's capability-building created TPS. The method used was to create and analyze data using the Fujimoto framework explained in his book, *The Evolution of a Manufacturing System at Toyota*. Fujimoto's theory allowed the authors to confirm that Toyota-style capability was created and delivered a significant competitive advantage in 2 of 4 projects where CID was attempted. The capability was created without knowledge of Fujimoto's theory of Toyota's capability-building. As with previous studies, it was impossible to identify routines developed to implement the process steps. It was also not possible to distinguish process steps for learning from others for production. Industry fragmentation is an obstacle to the level of integration this capability requires of designers and builders. The capability for construction knowledge to inform design can be created and requires vision and leadership to challenge the traditional design process.

KEYWORDS

Theory, capability, autoethnography, emergence, evolutionary.

INTRODUCTION

This paper is autoethnographic research about building capability to solve the problem of late and insufficient construction knowledge to inform design as it develops, especially early. The first author is the ethnographer, and the second author is the participant entrepreneur, designer, and manager of the capability-building, reflecting on his experiences to report what transpired. The third author, another ethnographer, has prior experience with this specific capability-building in the nuclear industry, but for this paper has focused primarily on the communication strategy and next steps for the general construction industry. Although conceived to test through Action Research, the research methodology is a variant of autoethnography, specifically "layered accounts," which is "author's experience alongside data and abstract analysis, and relevant literature." (Ellis et al. 2011) The research is post hoc looking back on experience considering a method that was not known to participants at the time.

The purpose of the research is to determine whether and how Takahiro Fujimoto's explanation of how Toyota continually improved is useful for leaders trying to do that within Construction. The real-world problem is the architects and engineers design without builders'

knowledge of construction constraints. The supply chain requires design intent before builders, fabricators, and product suppliers are procured, which limits the possibility of using Design for Manufacture and Assembly (DfMA) principles (Pasquire and Connolly 2003). Currently, design is conveyed through documents without a rigorous constructability review, leaving the Request for Information (RFI) process as the only mechanism for the general and trade contractors to call attention to problems and offer solutions. BIM clash detection is then started without alignment between design/engineering, and fabrication and assembly information. Preferred building methods, especially prefabrication, are not reflected in the design and the opportunity for design innovation that would create cost and schedule savings is lost.

The second author realized this several years ago while working as a designer on a Design-Build project and decided that he wasn't going to detail solutions that would become obsolete once the build partner was brought on board. He decided to focus on conveying design intent between systems and allowed the trades' subject matter experts to help drive overall constraints of the building systems and provide details that they could build, creating cost savings and innovations in overall design of the building.

After joining a large U.S. General Contractor (GC) as a Virtual Design and Construction (VDC) specialist, the second author, the "protagonist" in this story, was asked to assist a Design-Build student housing project team implementing a prefabricated structural cold-formed steel stud wall panel and flooring system in which the GC team was committed to informing the design team about constraints in the prefabrication process. The dormitories were very repetitive, so the protagonist selected a corner of one of the middle floors and set some clear objectives to work through for 6 weeks, including: trade partners preferred details, and the coordination of a detailed model in that strategic location. The decisions made during this process were then scaled across the project in early design phases. During this work he created templates to use across the GC's multiple offices throughout the country. Figure 1 shows this process.

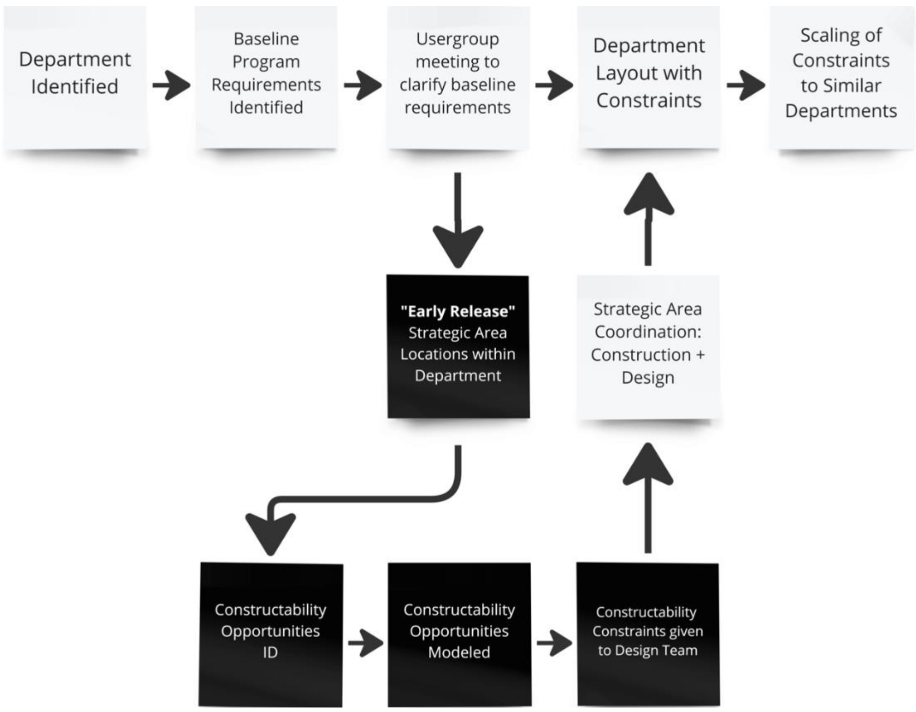

Figure 1: Typical Construction Informing Design Workflow

This typical workflow for Construction Informing Design is intended to be repeated through multiple typologies that exist in a project. Incrementally releasing functional program for strategic in-depth analysis creates the opportunity for programming, conceptual design, and constructability to happen concurrently. Key release points at user group review meetings and initial department layouts, as depicted in Figure 1, are critical to the success of this process and trigger key consolidation points to incorporate constructability constraints into the design.

Based on this experience, the authors decided to research whether and to what extent Takahiro's explanation of Toyota capability-building could explain what transpired on the 4 projects on which the second author organized project teams to enable Construction to Inform Design. This paper is an attempt to answer that question.

LITERATURE REVIEW

The only reference to Fujimoto the first author found prior to initiating a prior study reported in a 2019 IGLC paper was in a 2001 IGLC paper titled "System View of Lean Construction Application Opportunities" by Flavio Picchi (2001). He noted Fujimoto's evolutionary perspective starting from 3 levels of manufacturing capability anchored in routines for manufacturing, learning, and developing new capabilities by combining ones already developed. Niklas Modig and Par Ahlstrom also mention these 3 types of Toyota capability in their book, *This Is Lean* (Modig and Åhlström 2012), and point to Fujimoto's explanation of how the Toyota Production System emerged through trial-and-error capability-building. Their praise led the first author to read Fujimoto' book, *Competing to Be, Really Really Good* (Fujimoto and Miller 2007), followed by *The Birth of Lean* (Shimokawa and Takahiro Fujimoto 2009), a compilation of interviews with men who worked alongside plant manager Taicihi Ohno, and finally *The Evolution of a Manufacturing System at Toyota* (Takahiro Fujimoto 1999), all of which are essential to undertake researching Toyota-style capability-building. However important these are, the first author needed Mike Rother's explanation of Toyota's improvement and coaching practices, "katas," (Rother 2010) to develop the research methodology used in this and 3 previous IGLC papers. (Berg and Reed 2019) (Berg et al. 2020) (Reed et al. 2021)

THEORETICAL FRAMEWORK

This research uses Fujimoto's definition of organizational capability as the power or ability of an organized group to do something using effective routines. Our work is based on Fujimoto's explanation of how and why Toyota's capability to build capability led to the Toyota Production System (TPS). He begins by explaining that the purpose of building capability for Toyota and other automakers is to become more competitive in the marketplace by solving potential customers' problems better than competitors. According to Fujimoto, the starting point for understanding capability-building is the process steps that become routines for coordination, developing information, or fabricating and/or installing components and assemblies to improve production, and learning to improve processes.

Fujimoto identifies 3 levels of manufacturing capability as follows:

1. Routinized Manufacturing Capability. Its produces competitive performance in a stable environment where necessary prerequisites flow and the product can be made predictably. Its primary characteristics are a firm or project-specific pattern of steady-state and efficient transfer of accurate information.
2. Routinized Learning Capability. It allows for changes or recoveries of competitive performance in a dynamic environment. Its primary characteristics are a firm or project-specific ability of handling repetitive problem-solving cycles or an expected pattern of system changes.
3. Evolutionary Learning Capability. It enables changes in patterns of routines that contribute to capability. Its primary characteristic is the ability of handling system

emergence, i.e., dealing with non-routine patterns of system changes to form new routine capabilities.

TPS-style process steps are comprised of actions that can be measured or assessed against a desired outcome by the people who perform them, which enable learning and improvement. Routines can be effective for safety, quality, accuracy, and production goals, so it's important and often imperative that these adhere to guidelines that allow for inherent human differences. People must be encouraged and rewarded to continually improve these "best practices" as well as to invent better ways to do their work. The role of managers is to ensure that the people who perform the work are provided the training, information, and tools they need in the safest possible environment. The why loop must be closed by managers and performers through assessing whether the capability is achieving the success criteria established as targets. "The Toyota Way" is for people to strive to reach a future state by working towards intermediate target conditions (Rother 2010). This is the engine of continuous improvement.

Fujimoto identified 5 pathways for solving problems, as follows.

1. Rational Calculation: classic product design problem-solving.
2. Environmental Constraints: circumstances negating a usually viable solution.
3. Entrepreneurial Vision: pursuing solutions advocated by leaders.
4. Knowledge Transfer: following the advice of experts within or outside the project.
5. Random Trials: testing a variety of possible solutions.

Fujimoto also defined 4 ascending levels of capability-building within Toyota. The first is system change, activities that lead to change within the system to which a capability contributes. The second level is "Multi-Path System Emergence" when a variety of patterns (sequence and arrangement) in system changes can be seen in combination without a clear relationship between the pattern and content of system changes. Multi-Path System Emergence coupled with routinized capability indicates the capability to build new capability, which Fujimoto named "Evolutionary Learning Capability." As noted above, Fujimoto also defined this as the third level of manufacturing capability, and the key to Toyota's success. Fujimoto identified a fourth, penultimate level of capability-building, which he called "Dual-Layer Problem-Solving." This is when Multi-Path System Emergence and Evolutionary Learning give leaders the opportunity to create new solutions at a higher organization level based on solutions emerging from lower lever problem solving (Takahiro Fujimoto 1999).

RESEARCH METHOD

The method incorporates steps that were not explained by Fujimoto and are necessary to execute TPS capability-building to improve competitiveness in the marketplace. All would be used in Action Research and were used in this autoethnographic research, based on reflection.

The first author asked the questions based on his understanding of Fujimoto's explanation of how Toyota's capability-building led to TPS. The second author, who designated the objectives and process for achieving them and taught these to new members of each of 4 project teams, answered the questions. Reporting on what was done and accomplished for this study, he was able to draw upon project information such Building Information Models, work plans, meeting agendas and minutes, correspondence, schedules, budget, and cost reports. He also kept and could refer to extensive personal notes to answer questions based on the research method described above.

INFORMATION REQUESTED FROM THE PARTICIPANT AUTHOR

1. Identify projects attempting to build and implement the capability.

2. Articulate the “Direction or Challenge” (Toyota Improvement Kata step 1) stated as the purpose.
3. Define the “Current Condition” (Toyota Improvement Kata step 2).
4. Establish the "Next Target Condition” objective, which are the “Competitive Success Criteria” for the capability (Toyota Improvement Kata step 3). (Rother 2010)
5. Identify key people contributing to the new capability and describe their roles.
6. Define the process developed collaboratively with the team by describing each step to achieve the Next Target Condition including the next customer for the step, responsibility, frequency, time span, and expected results.
7. Evaluate “Routinized Capability,” the use of process steps by determining the extent each step was used on a 1-5 Likert Scale, step used as intended: 5, strongly agree; 4, agree; 3, neither agree nor disagree; 2, disagree; 1, strongly disagree.
8. Evaluate Competitiveness by assessing the impact of all capability process steps considered together on each of the competitive criteria with each success criteria contributing an equal percentage to the total competitiveness score for the capability on the same 1-5 Likert Scale.
9. Determine “Effective Use.” This requires both routinized capability (the sum of steps used equal to or greater than 75%) and “Capability Competitiveness” (capability improvement equal to or greater than 75%) This is outside the Fujimoto framework, done to see the relationship of routinized capability and competitiveness.
10. Identify “Problem-Solving Paths” by answering yes or no to whether each of which the 5 paths to solving problems described by Fujimoto contributed to the capability.
11. Determine “System Change Impact” for only the projects having Routinized Capability by answering yes or no to whether there were changes in the system/subsystem to which the capability contributed, in this case “Constructable Design Development Documents within Allowable Cost.”
12. Determine “Multi-Path System Emergence” for only those projects with System Change Impact by first answering yes or no to whether there were variety of patterns (sequence and arrangement) in system changes; and second by answering yes or no to whether a clear relationship between the pattern and content of system changes could be seen. If there was no relationship between pattern and content, there is Multi-Path System Emergence.
13. Determine Evolutionary Learning Capability by answering yes or no to whether Routinized Capability and Multi-Path System Emergence were present.
14. Determine Dual Layer Problem Solving, separate from and regardless of whether there is Evolutionary Learning Capability, by answering yes or no to whether intentional selection and modification of capability solutions to produce new capability to solve other problems could be seen.

DATA

The second author reported the following.

1. Direction/Challenge. CID purpose is for Construction subject matter experts (SMEs) to proactively provide constructability information for building systems and components including procurement lead times, installation durations, cost and schedule impacts, prefabrication possibilities, and BIM details to architects and engineers according to mutually agreed dates in formats that can used to develop construction documents.
2. Current Condition. Architects and engineers design without builders’ knowledge of construction constraints.

3. Next Target Condition success criteria stated as objectives are as follows.
    a. First, no unplanned negative iteration in the design process.
    b. Second, content provided by design team has been reviewed and signed off by project member companies responsible for putting the work in place.
    c. Third, design intent dimensioning is in alignment with construction detailing.
    d. Fourth, prefabrication opportunities are incorporated into the construction documents.
4. Key contributors to the capability are as follows.
    a. Preconstruction Manager (PCM). Procurement and financial setup to allow trade partners to engage in the early phases of design. Setup of project estimates to capture strategic deep dive information that will inform overall costs.
    b. Design Manager (DM). Packaging and alignment of client information, designer content, and contractor provided content. Leads early alignment session on timing and overall objectives for the process. Provides example content for similar proposed solutions or leads charrettes to gain team alignment.
    c. Superintendent (SI). Identifies locations in the project or specific program scope that will inform the overall schedule and logistics plan. Sets goals for flow of work and prefabrication approaches that will impact design.
    d. VDC Manager or Senior Engineer (VDC). Sets up the model environment and clearly conveys to the extended team where they should focus in the 3D environment. Creates 3D views and sheets to capture design decisions as they are made and tracks actions in a single location for the team to update in the model.
5. Process steps, responsibilities and Next Target Condition success criteria for projects are shown in Table 2.
6. Table 1 describes the projects on which teams attempted to build and implement the capability and summarizes what transpired.
7. Routinized Capability, the use of process steps, is shown in Table 2 for each the 4 projects studied. Use of process steps reached the 75% threshold for only the first 2 projects.
8. Next Target Condition Competitiveness scores are also shown in Table 2. Three of the 4 CID capability projects substantially improved competitiveness.
9. Effective Use scores are also reported in Table 2.
10. Problem-Solving Paths. All 4 project teams employed 3 of the 5 problems-solving paths identified by Fujimoto: Rational Calculation, Entrepreneurial Vision, and Knowledge Transfer. Environmental Constraints and Random Trials were not used.
11. System Change Impact. The Constructable Design Development Documents within Allowable Cost subsystem, which the CID capability supported, was changed, and improved in the first 2 projects, the ones with Effective Use (high use and competitive scores), but not in the other 2 where it was not achieved.
12. Multi-Path System Emergence. Both projects with System Change Impact displayed a clear relationship between the pattern and content of system changes. Since Emergence is indicated by no clear relationship between the content and pattern of changes, neither could be said to have it.
13. Evolutionary Learning Capability requires Routinize Capability and Multi-Path System Emergence. None of the projects achieved this.
14. Dual Layer Problem Solving. Intentional selection and modification of capability solutions to produce new capability to solve other problems was not visible in any of the projects.

Table 1: Capability Application on Projects

#	Descr	What Worked	Contract Type	Integration
1	Higher Education Student Housing	Builder details incorporated into overall design intent of the project.	Design-Build Guaranteed Maximum Price	The architect and extended team were fully committed to the process.
2	Higher Education Teaching and Learning	Alignment with principal designer early on intent. Trade coordination and Construction Document level information was produced out of the process to inform design.	Design-Build Guaranteed Maximum Price	The team would have liked to continue the process once they were done with the first strategic location was complete on the project.
3	Corporate Office	Detailed trade models quickly identified dozens of design issues and potential design solutions.	Construction Manager at Risk	The architect stopped the process after a few weeks and stated it was too early in the process.
4	Higher Education Healthcare Provider	Alignment with cost program modelling process helped identify building and area specific variables. Detailed pull plans for key work informed overall pull planning activities.	Design-Build Guaranteed Maximum Price	Multiple pauses due to the overall project deadlines and concurrent incremental packages.

Table 2: Use of Process Steps

Step	Description	Who	Prj.1	Prj.2	Prj.3	Prj.4
1	Early alignment with project leadership on approach and execution	DM	5	5	2	4
2	Early alignment on timing of process to inform procurement strategy	PM	5	5	1	3
3	Stakeholders are identified and procured for the duration of the activity	PM	4	5	2	3
4	Extended team alignment on benefit and approach	DM	5	5	2	3
5	Clear program and building areas are defined and known information for the given scope is categorized into a single location	DM	5	3	5	3
6	Standard templates and program data are reviewed and agreed upon as a baseline for design intent	DM	4	5	2	4
7	Model is setup and extended team members models are linked in with matching coordinates	VDC	5	5	2	5
8	Boundaries are clearly defined in 3 dimensions	VDC	4	5	5	3
9	Model updates and tasks are tracked in a single location and shared with the extended team	VDC	4	5	3	1

Table 3: Projects Process Steps Use Summary (continued)

Step	Description	Who	Prj.1	Prj.2	Prj.3	Prj.4
10	Locations variables are identified and labelled	DM	5	5	5	3
11	Overall building systems impacted in each area are identified and labelled	DM	4	2	5	2
12	Overall duration and cadence are set with clear goals at each cadence interval	DM	5	5	1	3
13	Builder details are proposed, and locations are identified within the defined boundary	DM	4	5	3	4
14	Prefabrication opportunities are proposed and identified within the defined boundary	SI	5	5	1	3
15	Cost impacts are estimated for proposed building systems and compared to industry baselines	PCM	4	4	1	4
16	Schedule impacts are predicted for proposed building systems and compared to industry baselines	SI	5	5	1	4
17	Builder intent is integrated into construction documents, and prefab opportunities are identified and published	DM	5	5	2	4

	Routinized Use Score		92%	93%	51%	66%
	Capability Competitiveness Score		100%	95%	35%	80%
	Effective Use (Use & Competitiveness =>75%)		Yes	Yes	No	No

ANALYSIS

The first author compiled and performed the simple calculations required. Without more data from other projects, no statistical analysis was possible. Proceeding, the authors focused on sense-making and application. Even during information gathering, it was apparent that the questions made sense and were not difficult to answer. This was true of the data; it produced insights that hadn't occurred to the second author. Similarly, the second author realized that the method and findings could be applied to future projects, making it easier for him to explain his approach and describe possible outcomes to project team members.

RESULTS

FINDINGS

All the process steps and resulting work routines contributed to Routinized Learning Capability. None were for Routinized Manufacturing Capability. Three of the 5 pathways were used on all 4 projects: Rational Calculation (classic product design problem-solving), Entrepreneurial Vision, and Knowledge Transfer. This was because the protagonist second author brought all three. The CID capability was used effectively on 2 of the 4 projects evaluated. In the other 2, the architect refused to collaborate on one, and the GC team members responsible for process steps did not execute them well enough on the other. In the 2 projects with Routinized Capability, the Constructable Design Development Documents within Allowable Cost subsystem was created to the benefit of the project. The General Contractor earned high success criteria scores and met their own competitive advantage goals.

The process steps were well conceived, including a very robust use of BIM, information sharing, and collaboration practices. And they could be taught to people willing to learn. Integrating the efforts of participating companies required their project leaders to commit to executing the process steps. While this was done by GC team members on all 4 projects, it succeeded on only 2 because other team members did not participate fully. Multi-Path System Emergence, Evolutionary Learning Capability, and Dual-Layer Problem-Solving were not visible on any of the 4 projects.

LIMITATIONS OF THE RESEARCH

The most significant limitation is that the CID capability was created without awareness of the Fujimoto framework, and the derivative research questions because the second author was not aware of them until he worked on this paper. Had it been otherwise, and Action Research been possible, participants and the researchers may well have learned and accomplished more.

Although Fujimoto speaks of routines, he only describes them at a high level. This is not surprising because that would require near constant attention from an informed manager or observer in the workplace. This is because routines are actions taken by people to execute their responsibilities. There could be just a few or many routines required to complete a process step by an individual or team. Even the second author could not recall and describe routines for action within the process steps. In the experience of the authors, designers and builders rarely define process steps, and even when this is done, transforming them into effective routines is left to individuals. This is why the primary element in this study is process steps. These did not include those for manufacturing, what Construction people think of as off and on-site production and assembly of building elements, so nothing was learned about this critical piece of the capability puzzle.

DISCUSSION

MEANING

Even though it is very different from current practice, CID capability can be created on this GC's projects where the second author is present. As with the 3 other capabilities studied in previous IGLC papers, the CID capability is fragile, meaning that it can be implemented where a protagonist can contribute vision, knowledge, and lead effective problem-solving, i.e., 3 of the 5 problem-solving paths. CID teams that fail to memorialize and communicate durations, the extent of BIM, and tracking progress are not as successful. New competencies such as Virtual Design and Construction and Design Management are required. The Project Superintendent must be involved earlier and to a greater extent than in current practice. Engaged project leadership and team alignment with design team customers is critical for success of CID capability. Cost and schedule metric tracking is yet to be defined and will require additional project team effort as well as greater rigor. The CID capability improved effective use substantially in 2 of the 4 projects, making it worthwhile to improve and implement whenever team members are willing to give it a try.

QUESTIONS THAT COULD NOT BE ANSWERED

How the CID process impacted the design team from their perspective is not addressed in this study. Similarly, the challenges faced by individuals implementing CID is not documented. The biggest question for the authors is how much better outcomes would be in an Action Research implementation with frequent team reflections and problem-solving focused on the process.

IMPLICATIONS

CID capability requires greater collaboration between team members. The fragmentation of design and construction is reflected within contractor organizations and is a barrier to implementing CID. Resources with deep construction knowledge are often not available, or are not encouraged to integrate early, both at the GC and the trade levels. Implementing CID requires people who are open to change and willing to learn, which is difficult without company and project cultures which support working in an integrated way.

CONCLUSION

KNOWLEDGE GAINED BY PARTICIPANTS, AND VALUE FOR PRACTITIONERS

It is both possible and desirable to create CID capability to provide greater value to the Owner. The design team must want early builder constructability input for the CID capability to impact the Constructable Design Development Documents within Allowable Cost subsystem. Without that, CID capability is wasted. Client contracting methods such as IPD and Design-Build are evolving and creating the opportunity for this process to occur. Builders and fabricators can create CID capability, which will extend its impact.

VALUE FOR PRACTITIONERS

The reluctance of the design team in the project where it was not successful was surprising. The traditional design process has been disrupted by the BIM process for years but has still not fundamentally changed how design is done and the cost of projects is predicted. The ability to connect design intent with builder execution is worthwhile because doing so eliminates waste and rework in design while making it possible for project teams to deliver significantly greater value to the customer.

RESEARCH INSIGHTS

The CID process challenges our current contracting method and the silos that exist within the AEC industry. Earlier procurement of trade partners and utilization of 3D collaborative environments make faster design iteration possible, leading to higher levels of cost and schedule certainty.

SPECULATIONS AND QUESTIONS

The authors' intuition is that integrated ecosystems composed of designers, builders and fabricators would want to develop CID capability, and at some point, make it a condition of entry. The capability to model cost at the space program level, studied in a 2020 IGLC paper (Berg et al. 2020) could and should be paired with CID capability. This would make it possible for integrated project teams to consistently capture cost and schedule impacts to feedback for clarification of design intent early in Conceptual Design. A big question is how CID capability can impact procurement and the supply chain to make outcomes more predictable.

FURTHER RESEARCH

Use Action Research to study another set of CID capability projects where the second author is engaged, and another where he is not, and the effort is led by other Design and VDC managers. Extend the CID capability to associate cost and schedule impacts of prefabrication opportunities that can be identified and memorialized earlier using the process. Capture and catalogue rules, constraints and assumptions made through the CID process to inform future projects with similar scopes.

LEARNING FROM DELAYS IN DAILY DESIGN WORK – COMPARISON OF ROOT CAUSE ANALYSIS AND FUNCTIONAL RESONANCE ANALYSIS

Eelon Lappalainen[1], Aku Hänninen[2], Petri Uusitalo[3], and Olli Seppänen[4]

ABSTRACT

Procurement and construction work depend on error-free and on-time designs. However, the design process may be erroneous and behind schedule, which often causes cascading delays and problems in the construction process. Hence, when a major delay occurs, practitioners often query the design process, and much time and many resources may be required to find the root cause. However, minor delays and mistakes that occur in everyday work are not usually investigated, even though they can contain information necessary to avoid significant adverse events. This study aimed to determine how three deviations that occurred in a normal, well-progressing project can be investigated using two different methods, as well as the significance of small errors and events in preventing larger errors and events in the future. Root cause analysis and functional resonance analysis were the research methods. The findings of this study showed that slight variability in trivial design and design management tasks generated a considerable number of unnecessary tasks and delays. Therefore, examining variability in the outputs of tasks could benefit designers and design management.

design, root cause analysis, Ishikawa diagram, functional resonance analysis, FRAM, RCA

INTRODUCTION

A building project consists of a conceptual design, schematic design and detailed design. Each design discipline considers the others' knowledge, processes and solution proposals in meeting the client's needs and requirements (Wang et al., 2014). The daily work of a designer involves a great deal of technical expertise in the field, which includes many different phases of the design process, such as clarifying tasks, searching intuitively for solutions, working through solution principles and concept options and making various qualitative choices (Robinson, 2012). A significant part of the designer's daily work involves non-technical tasks. such as reporting, personal work planning, information retrieval and social interaction (Hales, 1987). However, the multidisciplinary design process is prone to delays, which can also affect the construction process during the detailed design phase (Pikas et al., 2020).

Design delays have several adverse effects. Delays in design are a significant risk for construction projects, which can lead to extreme changes in the production phase (Mbachu, 2011). Design delays can also affect the work of the project team by reducing trust among the parties involved (Uusitalo et al., 2019). Therefore, design delays in the construction industry have been studied extensively, and efforts have been made to learn from them through both research and practice.

Root cause analysis (RCA) is a common technique used to learn from mistakes. The goal of RCA is to enable individuals to learn from their mistakes and gain a deep understanding of their root causes (RC), thus preventing their recurrence (Cerniglia-Lowensen, 2015). The target of RCA is to repeatedly ask "why" questions to determine the RC and remove it to prevent the harmful event from recurring. This method is often called the five times why (5 x why) method. By asking at least five times in a row about the RC, the most common and intuitive reason often reveals complex and hidden factors related to the occurrence of the event. RCA has become widespread in research and business. One of the earliest developers and users of this method was Professor Kaoru Ishikawa, who introduced RCA in a factory environment in Japan in the 1940s to improve quality (Doggett, 2005). The most typical graphical use of RCA is the Ishikawa diagram, which is also called a fishbone or cause-and-effect diagram (Ishikawa, 1976). The purpose of the diagram is to describe in an easy-to-understand visual form the reasons that led to a certain consequence and to categorise them systematically. It has been described as a fishbone because of the method analyses the causes of the event, moving from the general (big fishbones) to the specific (small fishbones). Figure 1 shows a typical example of the Ishikawa diagram used in this study.

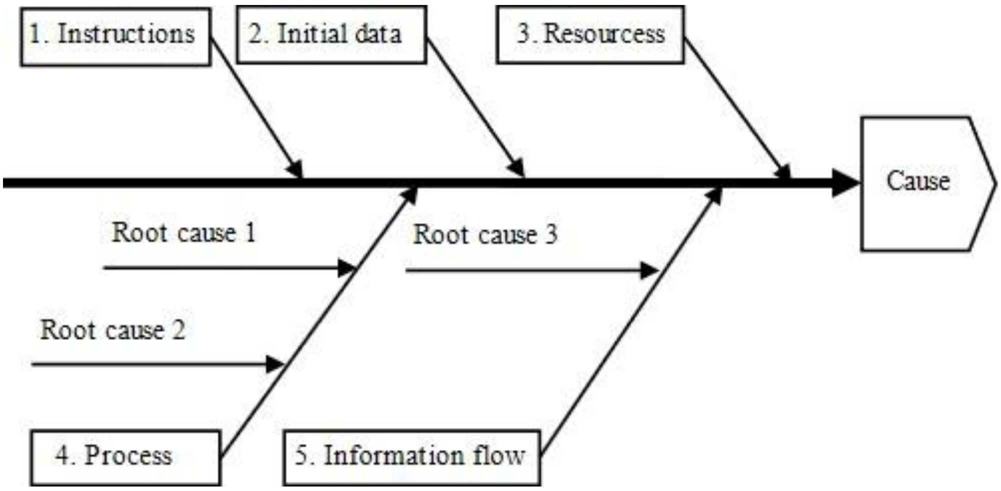

Figure 1: Ishikawa diagram in this study

Ishikawa emphasised the method's potential for learning: simply participating in the creation of the diagram is educational (Martínez-Lorente et al., 1998). However, the RCA assumes that causes or events related to an event are related to each other, and by following these interrelationships, it is possible to determine where the problem originated. RCA has become popular in daily safety work because of its simplified visual representation. Moreover, if the analysis is accurate, it also saves the practitioner's time (Hollnagel, 2017, p. 188). However, problems might arise if the results of a complex world are unclear, meaningless or too difficult to understand. To address such situations, Hollnagel (2017, pp. 30–31) presented a functional resonance analysis method (FRAM) that represents a complex nonlinear approach.

FRAM is based on resilience engineering techniques, which offer an alternative way to evaluate and design complex systems (Rosa et al., 2015). The FRAM and RCA methods can be viewed as a continuum of the domino model, in which events unfold as cause-and-effect chain reactions in which the first domino to fall is the RC (Riccardo et al., 2018). Both methods can be used for the qualitative analysis of outliers, although FRAM itself can also be used to conduct a quantitative analysis (Zinetullina et al., 2021). Hollnagel (2017, p. 40) developed FRAM as a method for analysing past events, like RCA, FRAM can be used to analyse past events as well as probable future events and failures. FRAM is based on four principles: 1) things go right and wrong for the same reasons; 2) sociotechnical systems always adapt to circumstances; 3) observations of results are described as emergent; and 4) relationships and dependencies in the system's functions are described in relation to the development of the situation using functional resonance (Hollnagel, 2017, p. 41). FRAM does not focus on the probability that a single function or task will go wrong; instead, it describes what can happen during typical daily work and how variability affects the situation, either positively or negatively (Rosa et al., 2015). In FRAM, the term *resonance* is an analogy of how variability in everyday events and performance can lead to unexpected results (Adriaensen, 2019). In individual events, such as the quality of the initial information in design work or the communication between designers, there are always natural variability, which can be thought of as vibrations or oscillations, which in a certain situation can increase unexpectedly (i.e., into resonances), thus causing an unexpected event.

The current version of the FRAM process has four stages: the first step identifies the functions that make up the FRAM model; the second step characterises variability in the functions; the third step examines the connections between the functions and determines how variability can lead to an unexpected event; and the fourth step suggests ways to manage and limit the observed variability (Yang et al., 2017). Figure 2 shows a typical FRAM model in which the function is represented as a hexagon from which the functions of the event under study are connected by branches. The process of making a cup of tea is used as an example. The functions are as follows: 1) boiling water; 2) heating the teapot; 3) adding boiled water to the teapot; 4) adding tea leaves to the teapot; 5) placing the lid of the teapot on the pot; 6) steeping and waiting; 7) straining the solid parts of the tea; and 8) pouring the tea into teacups.

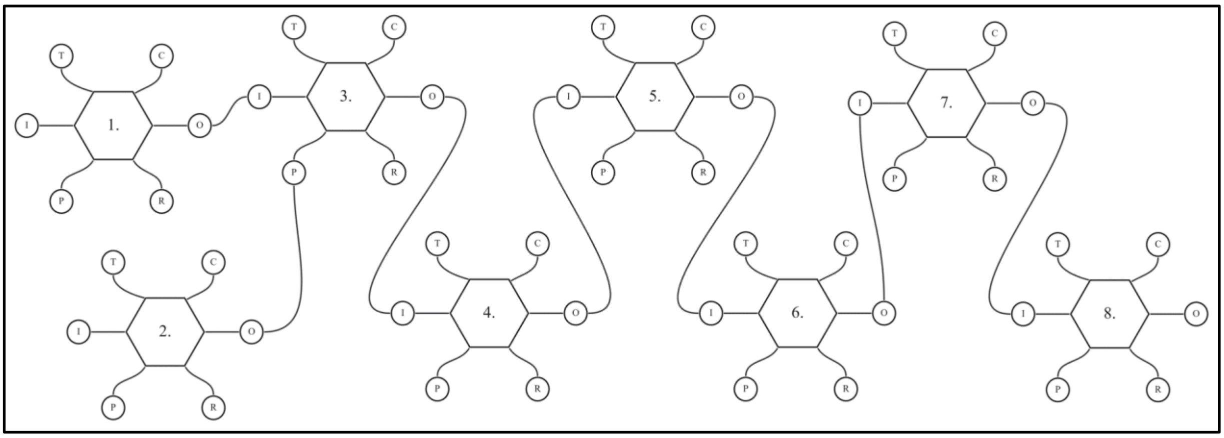

Figure 2: Typical FRAM model of the tea-making process

Variability occurs differently in functions. For example, it can arise from the machine or device used, from human activities or from organisations and social settings (Hollnagel, 2017, p. 100–106). Variability also occurs in the connections between functions, such as input, precondition, resource, control and time (Grabbe et al., 2022). For example, the output can be too fast or too slow, it can be too long or short (e.g., a machined product), it can be the wrong output (e.g., wrong information delivered), it can be too much or too little, it can leave too early or too late, and so on. As shown in the teapot example in Figure 2, the graphic description of even a simple model requires a set of interconnected function hexagons with links, which is difficult to view and interpret. Consequently, FRAM data are typically represented in table form, as in the present study (Saurin, 2016).

RCA is a well-known method used in the construction industry (Hsu et al., 2020), especially in lean construction (Enshassi et al., 2019). In lean construction, RCA is an essential and well-established component of the Last Planner® system (LPS) (Ballard, 2000; Khan & Tzortzopoulos, 2015; Abbasi et al., 2020). However, there is limited knowledge about the benefits of FRAM in the construction industry (Patriarca et al., 2020). Rosa et al. (2015) applied FRAM to identify work-related hazards on a construction site and piloted the method in the construction industry in Brasilia. Saurin (2016) also focused on the safety aspect and used FRAM in occupational safety inspections of data collected from 13 Brazilian construction sites. Ransolin et al. (2020) investigated the interactions between patient safety and well-being in a built environment using FRAM. Del Carmen Pardo-Ferreira et al. (2020) focused on concrete frameworks and modelled successes during a workday using FRAM.

This study contributes to knowledge about the use of FRAM. Neither the RCA nor the FRAM has been investigated comprehensively from a design point of view. Instead, the emphasis of previous studies on both methods has been on occupational safety. However, design work is a complex sociotechnical system that greatly affects many aspects of construction projects, including occupational safety. Therefore, focusing on the use of both the RCA and the FRAM to analyse design work is justified. The aim of this study is to use both methods to determine what can be learned about the effects of small errors and events and how the findings of the RCA and FRAM differ. The selected research approach was exploratory and data-oriented.

METHODS

SOURCE OF THE RESEARCH DATA

Because the goal of the study was to explore and learn from the RCA and FRAM methods, the research was limited to one project and three event chains. Research data were collected from a Finnish hotel renovation site of approximately 40,000 m^2, which, according to the project manager, "proceeded normally on schedule without significant problems." This was one of the basic criteria for the selection of the research site. The researchers were interested in day-to-day design work in a normally running project in which case the events under investigation would not be affected by actions and thoughts caused by major problems. A project management consultant, five design offices and the company responsible for building information model (BIM) coordination participated in the study.

APPLICATION OF ROOT CAUSE ANALYSIS

The RCAs were conducted to explore the cases to gain as many insights as possible. The aim was to gather information on the RCs of delayed design activities and the chain of events that led to delays. Of the 723 tasks in LPS sessions, three were selected for the study and subjected to detailed RCAs. The selection of topics was based on the following four principles: 1) the topic involved one or more delayed design tasks (suitability); 2) the events of the topic were ongoing during the research (timeliness); 3) the project management evaluated the study of the topics to determine their usefulness for the project (practical relevance); and 4) the topics were suitable for research (academic interest). The RCA consisted of four steps: 1) preparation; 2) open group interviews; 3) analysis; and 4) cross-comparison.

RCAs were prepared by consulting plans, meeting minutes and relevant emails. This information was provided by the project management and collected from the project's cloud service. The researcher also received documents and emails forwarded from different stakeholders involved in the project. The collected data were stored in the Microsoft Teams environment and then evaluated in collaboration with the project's management. This procedure was intended to provide a documented understanding of the events leading to the

RCA, in which the researcher relied on oral information from the respondents. The documentary-based researcher's understanding of the events was visualised as a swim lane diagram (Waterhouse, 2021) and sent as pre-material to the respondents. In the interviews, the case was examined using the *5 times why* method, in which the researcher observed and notated the conversations. Several rounds of interviews were conducted to allow for in-depth exploration and clarification of the issues raised.

In the next phase, conclusions were drawn from the analysis of the collected data. The classification of the RCs identified was based on Ballard et al.'s (2007) LPS method, which is commonly used by LPS users. The researchers added a fifth category related to information flow gaps. Finally, the results of the RCAs were cross-compared to find commonalities.

APPLICATION OF FUNCTIONAL RESONANCE ANALYSIS

In the FRAM analysis, the researchers identified the functions of the RCAs and added these to the spreadsheet, including a detailed description of the function and its aspects. The factors that caused variability are presented in Table 2. In this stage, the research was limited to examining only variability in outputs. Based on the table, three visual models with links connecting the functions were prepared. In the final stage, the researchers summarised potential approaches to reduce variability in the studied cases and compared the results of the RCA and FRAM. Figure 3 presents the research design.

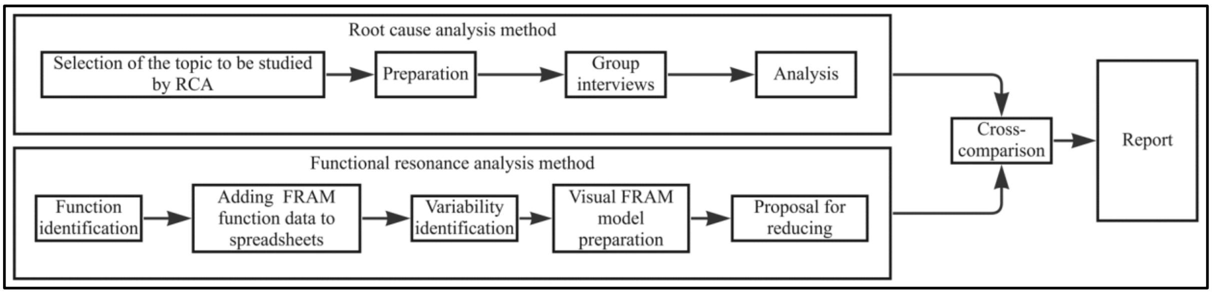

Figure 3: Research design

FINDINGS

FINDINGS OF ROOT CAUSE ANALYSES

The findings of the RCA were classified as chains of events that are represented in an Ishikawa diagram. The researchers reflected on the findings with the project management team, and based on the discussions, the RCs were assessed as appropriate and logical. The Ishikawa diagram of RCA No. 2 is presented in Figure 4.

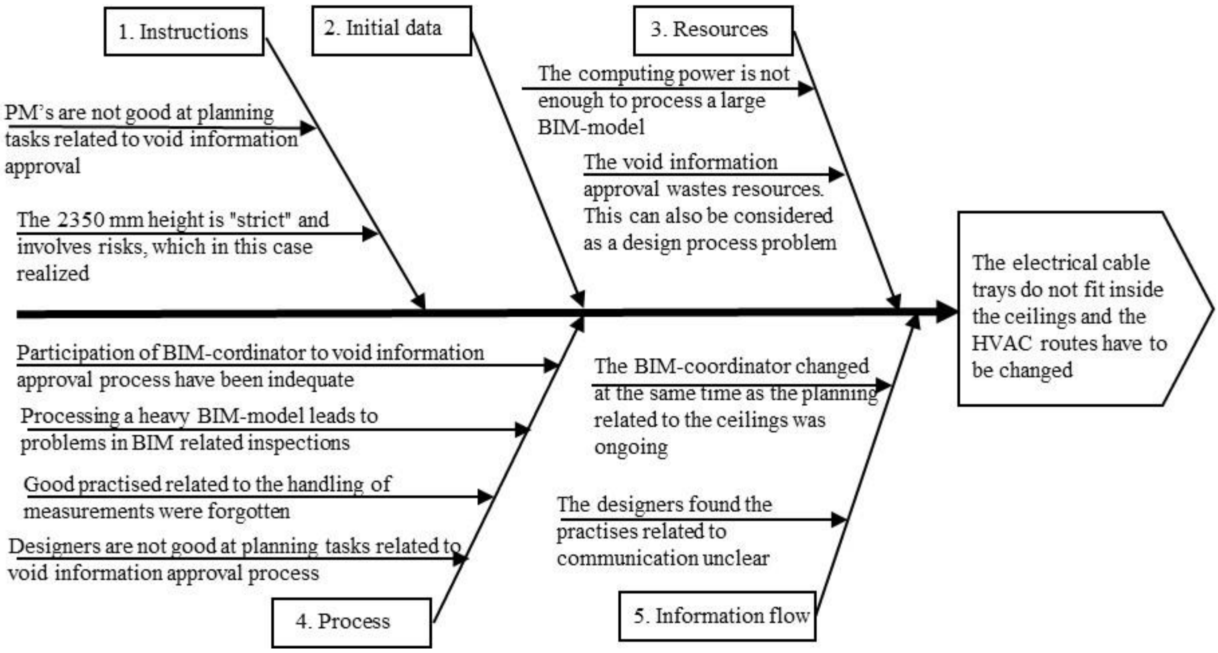

Figure 4: Root cause analysis number 2

Figure 4 presents the RCs that negatively affected the design process. A cross-comparison of RCAs is presented in Table 1.

Table 1: Summary of the Results of the Root Cause Analysis

RCA	Instructions	Initial data	Resources	Process	Information flow
1			X		X
2	X		X	X	X
3	X		X	X	X

Based on the results of the RCAs, all three cases had problems in design coordination, especially in the flow of information between designers. In all three cases, site personnel detected problems that caused stoppages in production. In all cases, there were personnel changes in the project's organisation, which were perceived in the RCA sessions as having a negative effect on the events. This was connected to problems related to the flow of information. In addition, the analyses revealed that the design was not implemented according to the pre-described process, but according to personal experience. Deviation from the process and person-centredness combined with personnel changes affected these three cases.

No observations were made regarding the initial data on the RC. However, in the RCA sessions, the respondents often referred to a lack of initial data. In all RCAs, information about the events was fragmented because it had to be gathered from several sources, and extensive networks of events were formed. The complexity of the relationships between the data and events made it difficult to identify and communicate problems.

Findings from Functional Resonance Analysis

The results of the FRAM analysis are summarised in Table 2, including the functions. Table 3 presents the output variability. Detailed descriptions of the functions have been omitted because of limitations on the length of this short paper.

Table 2: Functions and Output Variabilities

Function	I	O	P	R	C	T	Output variability (qualitative)
Case 1							
1.1 Updating LPS board	X	X	X	X	X	X	Inaccuracy: HVAC designers' task of the ventilation machine serviceability report missing from the LPS board.
1.2. Preparing a serviceability report on the ventilation machine	X	X	X	X	X	X	Late: task started late due to a task missing (serviceability report) from the LPS board.
1.3. Marking the hauling opening in the structural roof plan		X		X	X		Inaccuracy: the plan is updated needlessly, the opening is not necessary, but the data from serviceability report were late.
1.4. Marking the hauling opening in the architectural roof plan		X		X	X		Inaccuracy: the plan is updated needlessly, the opening is not necessary, but the data from serviceability report were late.
1.5. Updating the hauling opening to the structural plan	X	X		X	X		Inaccuracy: the plan is updated needlessly, the opening is not necessary, but the data from serviceability report were late.
1.6. Definition of the construction method (of the roof)	X	X		X	X		Inaccuracy: unclear communication about the construction method; task missing from the LPS board.
1.7. Commenting on the hauling opening	X	X	X	X			Inaccuracy: task for commenting missing from the LPS board
1.8. Removing the hauling opening from architectural plans	X	X		X	X	X	Late: the task was started late because the serviceability report was delayed.
1.9. Removing the hauling opening from structural plans	X	X	X	X	X	X	Late: the task was started late because the serviceability report was delayed.
1.10. Demolition work on the roof	X	X	X	X	X	X	Late: waiting for detailed drawings
Case 2							
2.1 Updating LPS board	X	X	X	X	X	X	Inaccuracy: the void information approval tasks are missing from the LPS board.
2.2 BIM coordination meeting	X	X	X	X	X	X	Inaccuracy: discussion about the unnecessary voids is missing from the BIM coordination meeting agenda.
2.3 Schedule planning for void information approval	X	X	X	X	X	X	Late: schedule planning for the void approval started after the void approval started (approx. eight months earlier).
2.4 Void information from structural designer to HVAC and EIA designer	X	X	X	X		X	Too early: the void information approval started eight months before the real need of the site.
2.5 Void information from HVAC and EIA designer to structural designer	X	X	X	X		X	Inaccuracy: lack of process or instructions for removing unnecessary voids from the BIM models
2.6 Re-routing of duct routs in HVAC BIM model	X	X		X		X	Late: due to the detected rebar on site, the HVAC ducts will have to be re-routed.
2.7 Re-routing of cable trays in EIA BIM model	X	X		X		X	Late: due to the re-routing of the HVAC ducts, the route of the cable trays must be changed.
2.8 Publishing coordination BIM model	X	X	X	X		X	Inaccuracy: Unnecessary voids are not removed from the coordination BIM model.
2.9 Observation of rebars in diamond drilled hole	X	X	X	X	X	X	Late: information about the effects of the rebars in the drilled holes is provided to HVAC and EIA designers when the technical routing was already done in BIM models.
2.10 Publication of the void drawing of the 5th floor roof	X	X	X	X	X	X	Late: HVAC re-routing delayed the release of the floor plan
2.11 Examining the need to change the ceiling height	X	X	X	X		X	Late: HVAC re-routing led to a redesign of the architects ceiling plans

Note. I = Input, O = Output, P = Precondition, R = Resource, C = Control, T = Time, EIA = Electrical, Instrumentation and Automation, HVAC = Heating, Ventilation and Air Conditioning

In Case 1, the recurring sources of variability in function output were the absence of the task from the LPS board, unnecessary design changes and starting the task late. In Case 2, recurring sources of variability were inaccurate because of unnecessary voids, which was related to a lack of process and guidelines for removing them. This issue was not discussed in the BIM coordination meetings because it was not on the agenda. Moreover, during the inspection and publishing of the coordinated BIM model, unnecessary voids were not addressed. A common source of variability in Case 1 was the absence of tasks; in Case 2, void approval process tasks were missing from the LPS board.

Figure 4 shows the functions in Case 1 and the links between them. Although the graphical presentation is difficult to interpret because of the high number of links inherent in complex systems, it is nevertheless possible to observe the central role of the LPS board in this chain of events. The numbering of the functions in the figure corresponds to the numbering in Table 2.

In contrast to Table 2, functions marked "0" have been added to Figure 4; this control function defined cycles of the LPS sessions and board updates, which in this case was the project plan.

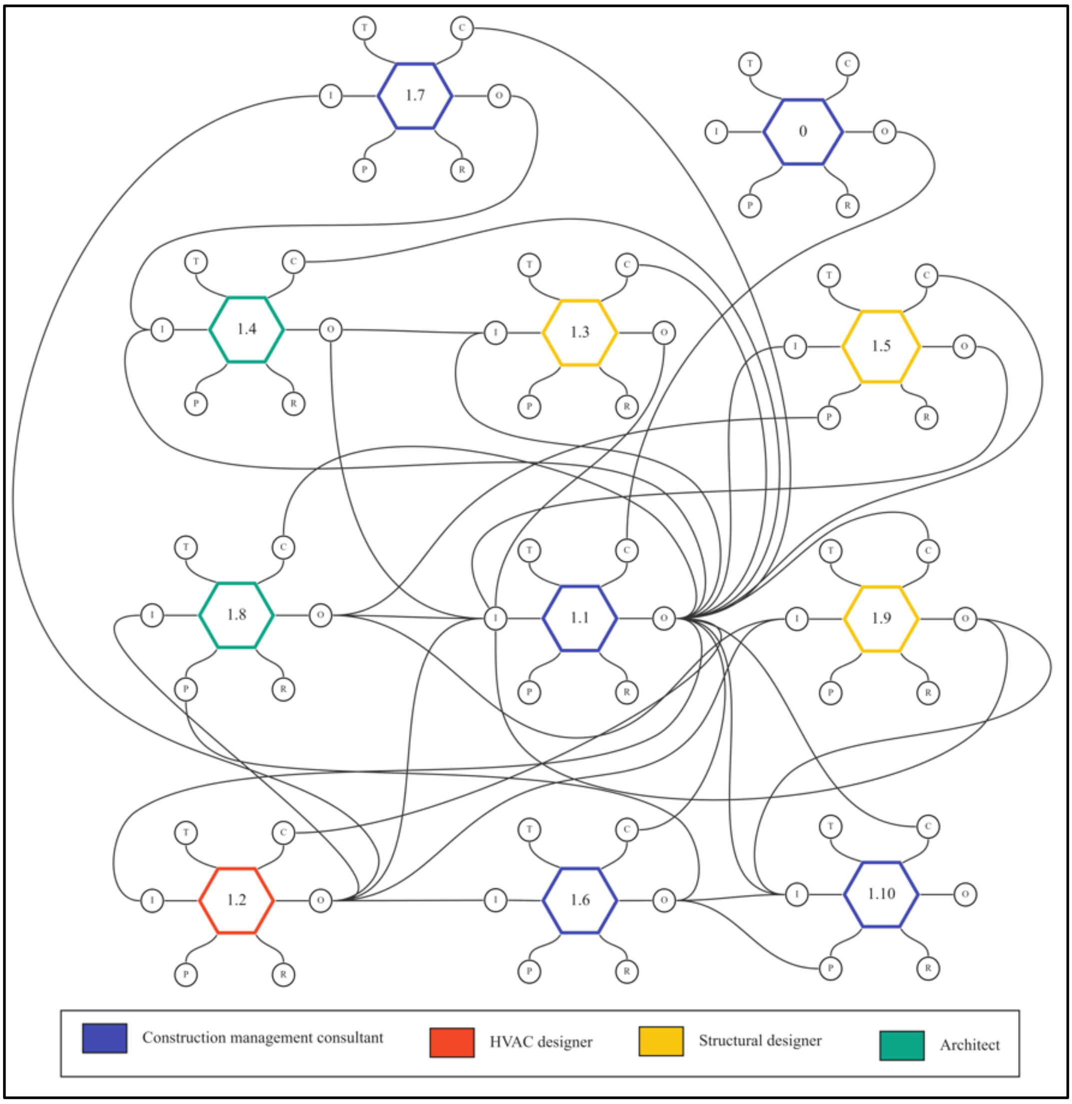

Figure 4: FRAM analysis of Case 1

As shown in Figure 4, colours were added to the functions representing the resources: blue indicates a construction management consultant; red indicates an HVAC designer; yellow indicates a structural designer; and green represents an architect. Table 2 and Figure 4 show the central role of the LPS and the variability associated with the missing tasks.

Summary of Findings

In Case 1, the RCA identified the fragmentation of information into several conflicting documents and a lack of clarity regarding the need to build hauling openings were the RCs of delay. The FRAM identified recurring variability in missing LPS tasks and unnecessary design work, which caused delays. Variability of LPS tasks prevented HVAC reporting functions from being implemented, while other functions in the system (e.g., design tasks and modelling work) continued to progress, causing unnecessary rework later in the project.

In Case 2, the RCA identified the RCs of the delay as follows: the design deficiencies of void approval-related tasks by both the construction management and the designers; the BIM coordinator's low participation in the void approval process; unclear communication by the construction managers; lack of computing power in the computers used for BIM coordination; insufficient tolerances for the renovation site; deficiencies in the presentation of dimensions in the drawings; and key personnel changes in BIM coordination. In Case 2, the variability identified by FRAM included the following: inaccuracy in the void approval process; and variability in the outputs of the three functions, which can also be defined as incomplete coordination. Time variability occurred in both directions in Case 2: void approval began eight months before the real need of the site, which was too early. Correspondingly, these tasks were planned eight months after the work began, which was too late.

DISCUSSION

The investigation of the RCs confirmed that chains of events in the design process are complex and involve multiple design disciplines (Bertelsen, 2003; Luo et al., 2017). Researching such complex, albeit daily, design-related tasks and chains of events by applying RCA was time-consuming. This may be one reason that learning-from-mistake techniques, such as RCA, are not widely used in construction and design (Dave et al., 2015). However, several interesting results were revealed by the RCAs.

In the RCAs, the initial data usually emerged as the respondents' answers to the first "why" question, but as the analysis progressed, the importance of the initial data decreased. In none of the three cases was the lack of initial data identified as the RC but a consequence of an actual RC. Although the sample comprised only three RCAs, this result was interesting, especially in terms of the typical narrative often heard by project designers, that is, a "lack of initial data". This finding contradicted those of previous studies in which a lack of initial data was often identified as the most important RC in design deviations (e.g., Khan & Tzortzopoulos, 2015; Koskela, 2004). This contradiction raises a question that should be investigated further: Does using RCA lead to a deeper and novel understanding of the RCs of design problems? For example, the event, "the drawings printed from the BIM model are incorrect", which was the cause of the delay found in the RCA, can be first classified as "initial data". However, the event "the BIM model has void reservations that are not needed" can be classified as a "process" because the void approval process was inadequate in this case. The RC was suggested to be the initial data, but after further investigation, the real situation was comprehended by the participants, and the actual RC was changed. This finding is consistent with that of Parchami et al. (2019).

The RCAs also supported previous research on the significance of planning person-centredness and key personnel changes for the success or failure of planning, as in the three cases in the present study. In a construction project, key personnel are subject to turnover, which can have serious effects on its progress (Chapman, 1999). Combined with the turnover of design experts and variability in their expertise (Manavazhi, 2004; Wang & Leite, 2014), the phenomenon observed in the results of the RCA is a model example of the variability related to the resource link used in the FRAM method.

In this study, the basic form of the FRAM was used because the researchers aimed to explore its applicability to design work. The basic form of FRAM has six characteristics: input, output, precondition, resource, control and time. However, as Hollnagel (2017, p. 194) pointed out, nothing prevents the use of other characterisations in applying this method. This freedom creates interesting possibilities, such as in design and lean construction. For example, in design, one characteristic could be value (Salvatierra-Garrido & Pasquire, 2011), and in the context of lean, one characteristic could be flow (Tommelein et al., 2022). Managing variability in these two properties is important for the operation of the system (Mossman, 2018; Lehtovaara et al., 2021). However, when new characteristics are added to the method, it should be considered that FRAM aims to determine how everyday activities are conducted. Therefore, adding, changing or removing characters should not weaken the underlying principle of the method.

Although the application of RCA and FRAM to the same chain of events yielded differing results, combining these methods could improve learning from mistakes in the construction industry. For example, the reason for the low use of RCAs (Dave et al., 2015) could be that a conventional construction project involves several tasks. On average, two-thirds of LPS tasks are completed on time (Aslam et al., 2020). Hence, when LPS is used, an RCA should be performed on one-third of the activities each week. In the example used in the present study, the LPS board contained 723 tasks, of which, according to the above principle, 241 RCAs would be performed. One author of this paper used four RCAs in his entire master's thesis. Therefore, it would have taken the working hours of 60 master's degree students to study two-thirds of the delayed LPS tasks in this hotel project, which is too much work to achieve an accurate and precise RCA. Could the FRAM perspective, which focuses on reducing variability in functions and the links between them, be a less resource-intensive way to learn from mistakes? Alternatively, could a FRAM analysis of RCA practices in the LPS session help better understand why RCA is so time-consuming? These questions and the use of FRAM in practice should be investigated further in construction studies.

CONCLUSION

This study applied the FRAM and RCA methods to two chains of events in design work. The findings showed that variability in event chains may have potential importance for the construction industry. The findings on the use of RCA and FRAM differed, which raised the question of whether the joint application of these methods could lead to learning from mistakes in the construction industry. The systemic perspective of the concept of variability in FRAM revealed aspects of the process that differed from traditional RCA. This focus on the variability of FRAM may be useful for lean construction researchers and practitioners, although further research and experiments are needed. A significant limitation of this study was the limited amount of data on only two chains of events in one geographically limited renovation project. Future research is recommended to explore a larger amount of diverse data (both by project type and geography), which could yield a more holistic picture of the RCs of design delays and provide further insights into their analysis. Further limitations are that the FRAM was focused on learning in daily work, which was hindered by the retrospective approach used in this study. Regarding learning from variability in daily work, FRAM may facilitate researchers and practitioners because the method does not require the existence of faults, errors or delays, which may enable the discussion of systemic problems without feelings of guilt, which often hinder the use of RCA.

ACKNOWLEDGEMENTS

We thank the Haahtela Group for the opportunity to use their project data in our study.

A FRAMEWORK FOR DESIGN WASTE MITIGATION IN OFF-SITE CONSTRUCTION

Danial Gholinezhad Dazmiri[1] and Farook Hamzeh[2]

ABSTRACT

The recent global pandemic has presented unprecedented challenges to the construction industry's survival. Therefore, even minor improvements and the elimination of small sources of waste are crucial. Although they constitute a small percentage of total construction costs, hasty designs and design errors have the potential to be one of the most significant sources of waste within the industry. Also, offsite construction involves a high degree of precision and efficiency. Any waste during the design process can result in time delays, cost overruns, and suboptimal final product performance. The design process should aim for minimal waste to avoid potential delays or errors during construction or manufacturing that could lead to wasted resources and money. To address this challenge, a framework based on lean principles has been developed to minimize waste during the design process for offsite construction.

The primary objective is to incorporate lean principles and tools to address waste reduction quantitatively and measurably. Proposed solutions aim to eliminate or reduce these activities, and a framework is presented to guide organizations in mapping out the necessary steps. To assess the recommended interventions, statistical analysis and simulation methods are introduced. The framework is intended to help evaluate processes and increase efficiency during the design phase for off-site construction and built-to-order companies. The innovation of this framework lies in its precise procedures and guidance for improving these phases using Lean tools, which could provide significant benefits for off-site construction and built-to-order companies.

KEYWORDS

Off-site construction, waste, value stream, design science, simulation.

INTRODUCTION

The Architecture, Engineering, and Construction (AEC) industry is known for its dynamic nature and variability, making it challenging to achieve efficiency. As defined by researchers, efficiency is utilizing the fewest resources necessary to perform a job (Wandahl et al., 2021). In the context of Lean production and construction, the fundamental objective of efficiency enhancement is reducing waste and adding value (Koskela, 2000). The AEC industry generates substantial waste (Bølviken and Koskela, 2016). It has been utilizing Lean technologies such as Just in Time and Last Planner for the past two decades to reduce this waste.

In the context of Lean, waste refers to the improper use of time, money, or other resources due to inefficient utilization of machinery, supplies, employees, or other assets (Formoso et al.,1999). It is defined as any work or resource that does not add value to the product (Koskela,

[1] MSc graduate, Department of Civil and Environmental Engineering, University of Alberta, Edmonton, Alberta, Canada, gholinez@ualberta.ca, orcid.org/0000-0003-1196-7340

[2] Associate Professor, Department of Civil and Environmental Engineering, University of Alberta, Edmonton, Alberta, Canada, hamzeh@ualberta.ca, orcid.org/0000-0002-3986-9534

1992). According to Womack and Jones (1996), "any activity" that consumes resources without adding value is considered waste in design. Time is a valuable waste indicator, particularly when assessing the proportion of non-value-adding tasks. Delays, waiting, design flaws, excessive processing, and negative iteration or rework also contribute to waste in Design (Ballard, 2000; Tzortzopoulos et al., 2020). Such wastes can significantly impact building projects, with design errors primarily contributing to cost and value loss (Tzortzopoulos et al., 2020). Rework and non-value-adding activities during the design process can also prolong the time required for design improvement and cause delays (Mryyian & Tzortzopoulos, 2013).

While many construction components are mass-produced (made-to-stock), some essential components are designed, manufactured, and delivered on demand (Build-to-order) in fabrication shops (Ballard & Arbulu, 2004) as part of the off-site construction industry. While off-site construction has many benefits, such as shorter construction times, less waste, better quality, cost-effectiveness, flexibility, and increased safety, it also has some limitations and challenges (Hussein et al., 2021), such as delayed design information receipt, frequent design revisions, altered installation timing and sequence, and demand variability (Ballard & Arbulu, 2004) and improper design work (Pasquire & Connolly, 2003).

Despite accounting for a small percentage of total construction expenses, proper design is essential for the long-term success of a project, as it affects everything from customer satisfaction to operating and maintenance expenses (Kalsaas et al., 2020). Hasty designs, design processes, and design management practices are at the root of many long-standing production and construction issues (Pikas et al., 2020). During the construction and maintenance of buildings, design errors have been the leading cause of structural failures, time and cost overruns, and catastrophic accidents (Chapman,1998; Love & Li, 2000; Love et al., 2008; Pikas et al., 2020). Rework, change orders, and preliminary estimates, resulting from poor designs, lead to overbudget spending or delays and are potentially one of the AEC industry's most significant sources of waste (Breit et al. 2008).

Several studies aim to enhance the design process in the AEC industry, focusing on integrating design with modern technology such as BIM to increase efficiency. However, there are few studies on mitigating waste in the design process, particularly in midsize and small size built-to-order plants for off-site construction. This research uses lean principles to evaluate and analyze waste in the design process, identify non-value-adding activities or processes and propose solutions to eliminate or reduce them in offsite construction. This research offers a framework for standardizing the identification and elimination of waste to assist organizations in improving their productivity and reducing costs and time. This framework addresses the challenges encountered in off-site construction and built-to-order production, including low utilization of processes, prolonged design lead times, and negative iterations. By evaluating and analyzing waste in the design process through lean principles, this framework aims to identify non-value-adding activities or processes and provide solutions to eliminate or reduce them. The proposed framework provides a transparent and standardized approach for organizations to follow in order to improve efficiency and optimize the design process in off-site construction and built-to-order production.

METHODOLOGY

The methodology adopted in this study is Design Science Research (DSR). DSR is a methodology that aims to enhance human understanding by creating new artifacts (Brocke et al., 2020). This methodology includes three steps: problem identification and objectives definition, designing artifacts to address the problem and evaluating the artifacts using a case study.

The initial step involves identifying the problem and justifying its significance, as posited by Brocke et al. (2020). To ascertain the issues that may arise during the design phase, a comprehensive review of the relevant literature was conducted, as mentioned in the last section, to identify potential problems and sources of waste.

For the second step, a case study was selected as a primary data-gathering source to better understand the design phase within off-site construction. Following an exhaustive analysis of the case study, coupled with the execution of interviews, the research objective was established to incorporate lean principles and tools to quantitatively and measurably address waste reduction. This study focused on a case study of Company X, a build-to-order offsite construction/manufacturing company in Alberta, and its design processes and procedures. To collect data, two methods were used: Semi-Structured Interviews and an Enterprise Resource Planning (ERP) database. The first method used for problem identification was structured interviews. The proposal for the study was submitted to the Research Ethics Office of the University of Alberta with all necessary information and sample interview questions and was approved by the mentioned office. Multiple interviews were conducted to understand the design process better and identify any missing information.

Along with a focus group interview with the design team, 17 interviews were conducted with the general manager, design manager, designers, production manager, order desk manager, and operations personnel. Focus group interviews are in which participants are encouraged to interact and share their thoughts and insights. A focus group interview with the design team can provide valuable feedback on the design process. It was found that the ERP system poses significant challenges and causes excessive processing time within the process. Additionally, the number of revisions due to customer feedback is high. During the interviews, the interviewees were also asked to estimate how long it would take them to complete their design tasks and the probability of rework in the design process. These probabilities can be used to estimate the system's rework, revisions, and Yield.

Data was also collected from the ERP database. There are two types of jobs based on the lead time in this process: Standard and Rush delivery. Standard delivery jobs are prioritized according to the order in which they were received, while rush deliveries are given priority in all cases, and designers begin working on them immediately. Due to their exceptional nature, rush deliveries are not included in the analysis. Based on the classification of jobs, there are four distinct categories. In retail, a customer is an individual person, and the company directly interacts. Builder, where the customers are developers and construction companies. Dealer, where the customer is typically another architecture firm or office that has utilized the manufacturing services of Company X. Lastly, Project, where the customers are primarily construction companies, and the job pertains to high-rise buildings with repetitive designs.
The duration of each step in the design process was calculated as a probabilistic distribution to reflect the actual situation more accurately.

For the third step, a robust framework was developed after consulting with the experts involved in the case study and thoroughly scrutinizing the measures necessary to identify and reduce waste. The framework specifically targets the design process, improving it through digitization and providing quantitative evidence using a simulation model. The framework employs value-stream mapping, a powerful tool for identifying and analyzing a process's current state and forecasting future processes after minimizing waste. The mapping exercise aims to identify waste areas in the design process, such as rework, multiple revisions and waiting time or latency, and provide a general guideline that outlines clear and concise step-by-step approaches for suggesting and implementing improvements to mitigate process waste.

The first stage of the framework is the definition stage, where the method of data collection and the type of information that needs to be collected as input for the process are defined. It is crucial to identify the metrics to understand how to evaluate the desired outputs and what types of outputs are expected to be controlled to identify waste. Figure 1 shows the proposed framework. The identification stage is the next step, where data is transformed, and the current situation is analyzed to find waste using value stream mapping. The way to map the value stream was adopted from Rother and Shook (1999). At the end of this stage, a simulation model was developed to get visibility into the process. The proposed framework is presented in Figure 1.

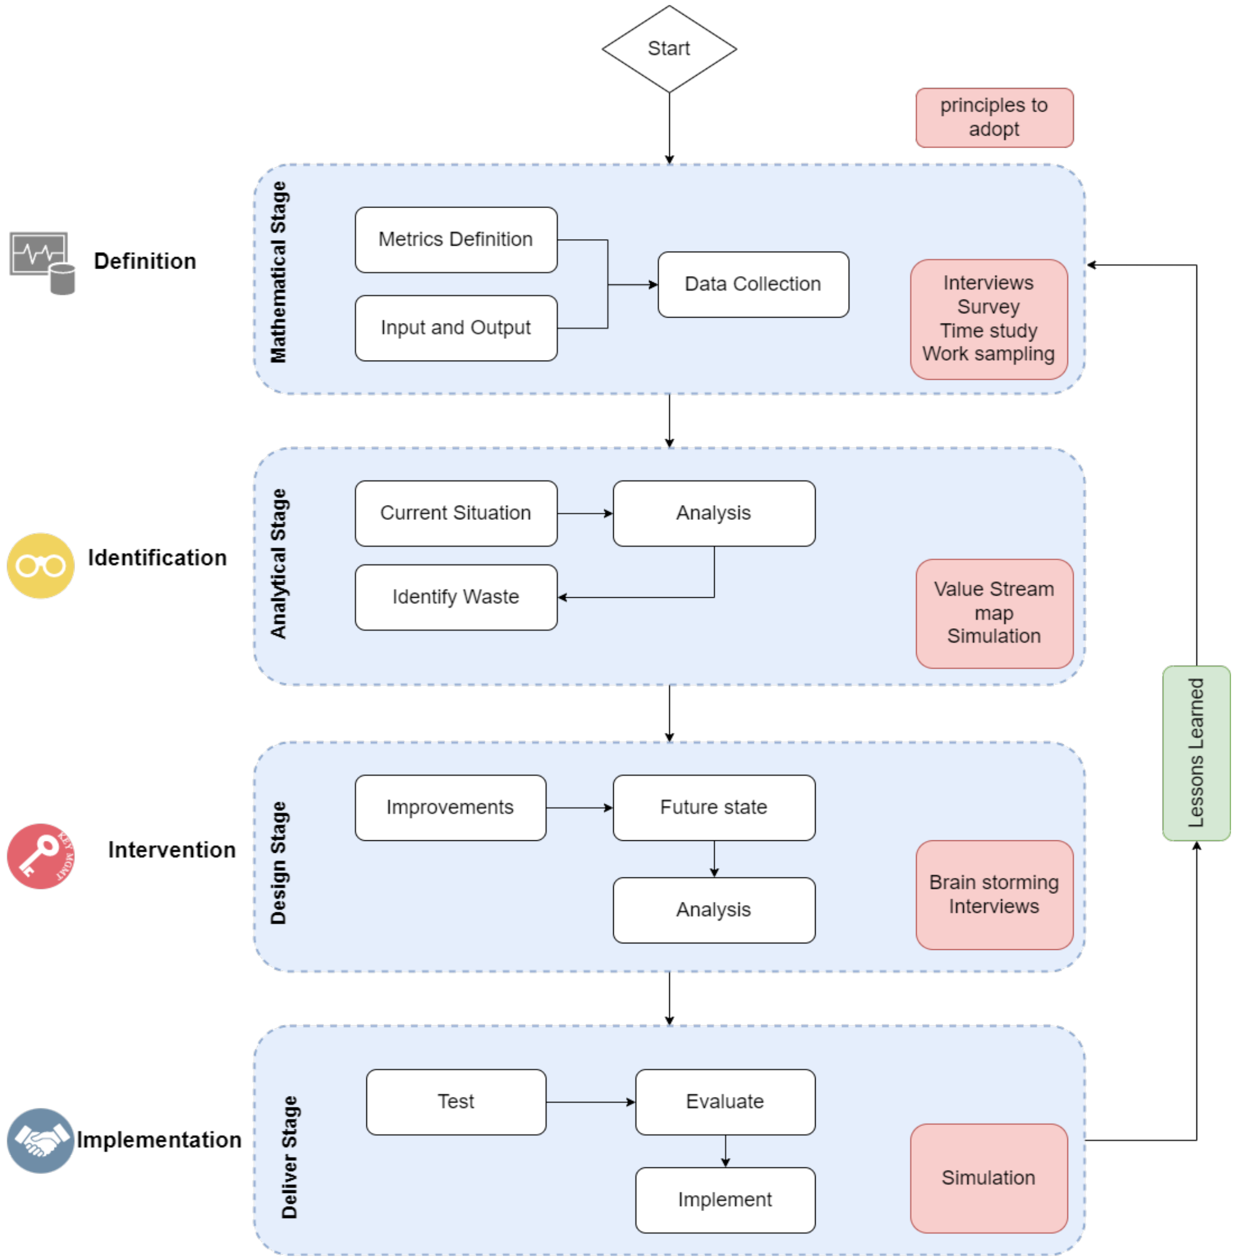

Figure 1: Proposed framework for identifying process waste.

The design stage is the third stage, where artifacts and interventions are created to address the process waste identified. At this stage, the improvements were determined by conducting expert interviews or conducting a brainstorming session with them to forecast how the process would develop in the future. The final stage of the suggested framework is to test the improvements and validate the beneficial effects on the process using the model developed in stage two. Before implementing these improvements, one must ensure their effects on the process and the organization. This can be accomplished using simulation to verify both present and potential future conditions. The company could put their improvements into practice after they are proven to be successful. This framework is generic and may also be used by others. This framework will aid and standardize efforts to boost productivity by reducing the number of non-value-adding activities.

The proposed framework reflects a comprehensive and integrated approach designed to optimize resource utilization, minimize waste, and enhance the overall efficiency of the design process in off-site construction. Statistical tools are applied to evaluate the framework, which is tested through simulation and recording of results.

Before developing the simulation model, several metrics were adopted as well to analyze the captured data. The first one was the Utilization Ratio (Equation 1), which compares the total process time (DPT) with the overall lead time (DLT). The potential for improvement in operational efficiency can be significantly increased when there is a significant difference between operational time and lead time (Berndt et al., 2016).

Another metric for assessing process performance was the Rolled Throughput Yield (RTY), which evaluates the overall performance of a process by calculating the Yield for each process phase (Graves, 2002). The Yield, or success rate, represents the percentage of units that pass through a process without defects. Rework is often an indicator of design defects. By knowing the percentage of defects per unit (dpu) for each process step, the Yield for each step could be calculated using Equation 2, and the RTY could be calculated by multiplying the Yield of each step, as shown in Equation 3.

Equation 1: Utilization Ratio = DPT/DLT

Equation 2: Yield = e ^ (-dpu)

Equation 3: RTY = $Y_1 * Y_2 \ldots * Yn$

Because the time required to complete a task varies depending on the designer and job, the data must be fitted to specific distributions to calculate task duration. These distributions can be computed using software such as EasyFit and evaluated using the Kolmogorov-Smirnov (K-S) test.

The simulation validated the design process's current state and evaluated the proposed intervention's impact. Once validated, simulation was used to evaluate the impact of each proposed intervention and its combinations. Simphony.Net 4.6.0 was used to develop the simulation model and test the improvements to the design process. The simulation model was generated based on the general template and elements of the Simphony, presented in Figure 2.

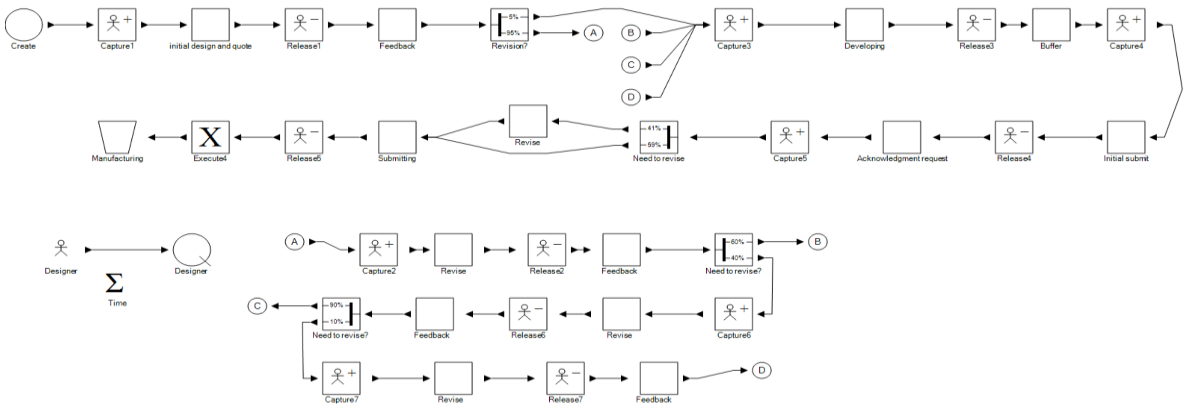

Figure 2: The general layout of the current state map simulation

Multiple approaches were used to verify that the model accurately represents the target concept to ensure the created simulation model's accuracy. These approaches were based on the methodologies proposed by Al-Hattab and Hamzeh (2018) and included verifying the consistency of input and output data, monitoring the logical performance of the model through basic indicators, and making the appropriate modifications to ensure an accurate simulation.

Through the monitoring of these approaches, it was determined that the model was correctly implemented. Additionally, the case study model, its input and output, were presented to experts for validation. It was confirmed that the simulation results accurately reflect the real-world process being studied. It is important to note that while the simulation results indicate a significant reduction in design lead time, the research method has limitations, and the results should be interpreted with caution.

RESULTS

From the data collected, it has been determined that, on average, the initial designs require 2.5 revisions. The probability of the design being revised for the first time is 95%, and for the second time, 45%. During the interviews, the interviewees were also asked about the challenges and threats in the design process that could cause waste or non-value-added activities in the system. Table 1 shows the results from the interviews regarding the task durations.

Table 1: Task duration results from interviews

Task	Unit	Time			
		Optimistic	Most probable	Pessimistic	Average
Designing the initial designs and quote package	hours	2.44	3.4	5.8	3.63
Getting feedback from the client	days	2.2	4.2	10	4.83
Revising the designs based on the feedback	hours	1.3	2.3	4.4	2.48
Revising the designs a second time	hours	0.5	1	2	1.08
Developing final package	hours	1.2	2.4	4.2	2.5
Reworking because of the initial blueprint	hours	1	1.7	2.8	1.77
Generating the contract	hours	0.45	0.7	1.05	0.71
Building the file in the ERP	hours	0.3	0.45	0.85	0.49
Receiving feedback from the control department	days	2.8	4.2	6.6	4.37
Making final changes based on an acknowledgement	hours	0.3	0.6	1	0.61
Submitting final copy	hours	0.35	0.55	1.1	0.60
The whole design process	days	16.4	47.3	106.4	52

The proportion of each delivery type can be seen in Figure 3, and general information on each class is summarized in Figure 4.

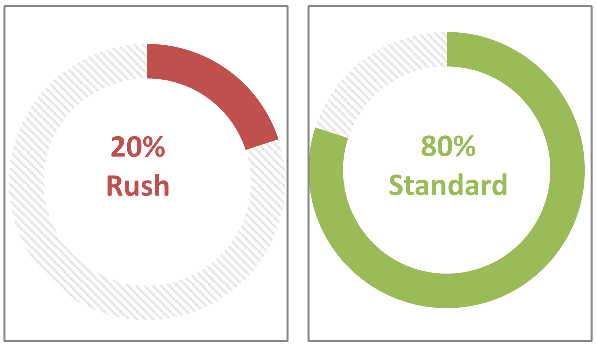

Figure 3: Type of job delivery in Company X

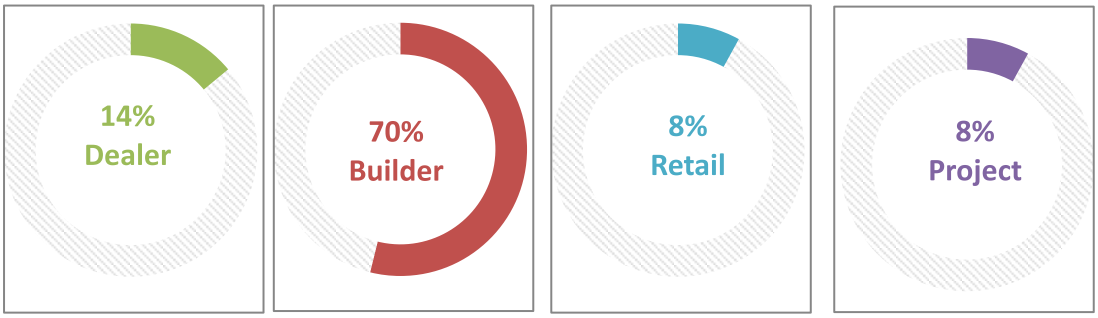

Figure 4: Available data on each job category

Upon completing the current state map, evaluating the parameters identified for value stream mapping is essential. The first parameter to evaluate was Design lead Time (DLT) and design process Time (DPT) which were 50.74 and 4.16 days, respectively. Using these two parameters, the Utilization Ratio is 8.2%. The rolled Throughput Yield (RTY), calculated using Equations 2 and 3, is 13.95%.

The case study highlights the need to improve the design system and process to increase efficiency. These improvements can be made at three levels: the designer level, the organizational level, and the client level. Addressing waste at the designer level is the most targeted approach, while organizational-level improvements require a coordinated strategy and may involve higher costs. Lastly, addressing client waste is crucial to improving the overall design process. Table 2 summarizes the suggested interventions to improve the system and process.

Table 2: Suggested improvements for the case study

#	Interventions	Related Challenge	Improvement
1	Reducing negative iteration	Insufficient information	Client
2	Reducing the waiting time	Waiting time	Client
3	Increasing Yield in the initial submission	Design errors	Designer
4	Levelling the process	Workforce	Organization
5	Reduce the redundancy associated with	Redundancy in the process	Organization
6	Using new drawing software	Drawing software restrictions	Organization
7	Reducing acknowledgment waiting time	Waiting time	Organization
8	Reduce buffer time after the contract	Buffer	Designer

The scenarios for the system's future state were developed by incorporating the interventions outlined in Table 3. Initially, individual interventions were simulated. However, as there is potential for more significant improvements, Intervention Combinations (IC) were constructed by combining two, three, four, and so on, up to eight interventions. It should be noted that due to the complexity of the existing system, it may be difficult to implement multiple interventions simultaneously. A total of 255 ICs were constructed and simulated to evaluate the system under different conditions. The simulation results indicate that implementing multiple interventions results in a more remarkable improvement in the design process. The combination of all eight interventions shows the most significant improvement, with a 47.3% reduction in design lead time and an increase in utilization ratio to 13.7%. This highlights the importance of considering a holistic approach when implementing changes in the design process. Table 3 shows the most significant reductions in DLT, and Figure 4 also shows the DLT for different interventions.

Table 3: Simulation results for intervention combinations based on DLT reduction.

Intervention Combinations	DLT (days)	Utilization	RTY
1&2&3&4&5&6&7&8	27.79	0.137	0.39
1&2&3&4&6&7&8	27.99	0.136	0.39
1&2&4&5&6&7&8	28.35	0.134	0.26
1&2&3&4&5&6&7	29.64	0.128	0.39
1&3&4&6&7&8	29.65	0.128	0.39
1&2&3&4&5&7&8	30.28	0.132	0.39
1&3&4&5&6&7&8	30.3	0.125	0.39
1&2&3&4&6&8	30.4	0.125	0.39

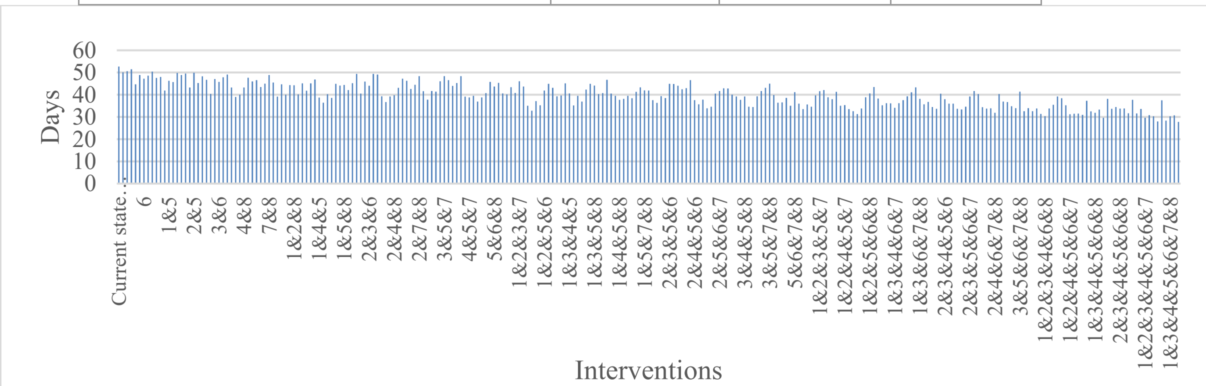

Figure 5: Design Lead Time for suggested interventions

The value classification pr project for the current state situation and implementing eight interventions is presented in Figure 5, showing a considerable improvement in reducing non-value-adding activities.

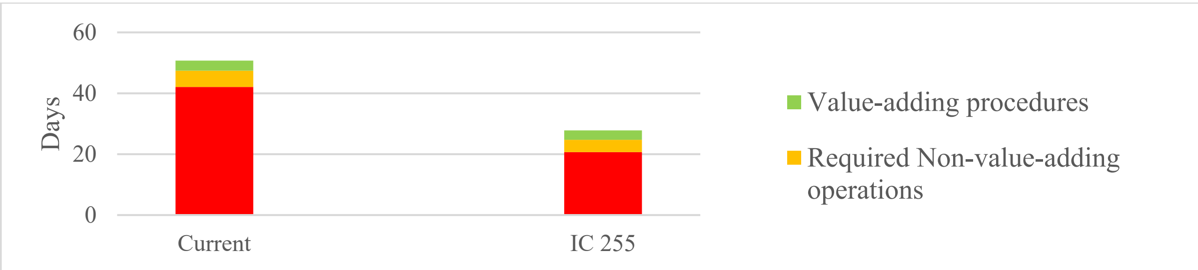

Figure 6: Value classifications per project

DISCUSSION

After eliminating irrelevant data and information, the Value Stream Mapping (VSM) was performed. As previously stated, VSM helps to gain a more comprehensive understanding of the process. The first parameter to evaluate is the average Design Lead Time (DLT), which is 50.74 and Design Process Time (DPT) is calculated to be 4.16 days, which shows that if there was no disruption in the flow of information, design jobs should go through the whole process in only 4.16 days. Compared to the time it takes to go through the process, the Utilization Ratio is found to be 8.2%, indicating that only 8.2% of the time allocated for design is used for the actual design process. While the time buffer in the process may be attributed to a designer's workload, the utilization rate of 8.2% is still deemed insufficient.

Another critical parameter to calculate is RTY, calculated by considering the number of reworks and revisions required for each job and is used to determine the Yield for each station. As per the calculation, only 14% of design jobs pass the process without defects. This low percentage indicates room for improvement in the design process to reduce reworks and revisions.

Numerous iterations between the customer and the designers often hinder the design process. This can be caused by a lack of clear direction from the client or inadequate information from the marketing team. Communication gaps and requests for minor design changes between designers and other departments also contribute to this challenge. Currently, revisions in the design process are a source of waste. It is essential to focus on creating more value in the initial design to reduce the number of revisions.

One of the significant challenges identified in the interviews is using the ERP system. The system is difficult to navigate and was not explicitly designed for this company. Additionally, the requirement to upload information to the ERP system and an internal server results in redundant work. This causes difficulties for designers and other employees in making changes and updating information.

Customization refers to the process of creating a product that is tailored to a specific customer's needs or preferences. This can include unique designs or patterns that are difficult to produce. All departments in the manufacturing process can face challenges when it comes to customization, particularly in areas such as design, sourcing unique materials, and production. Designers may not have the specific knowledge or skills to create the custom design that a customer requests. Finding unique materials or colours can be difficult, and purchasing small quantities can be costly. Specialized machinery and operators may be required in production, causing disruptions and increasing costs. Additionally, the production of custom designs may require more time and effort, resulting in longer lead times. To minimize these challenges and save time and money, it may be more efficient for the company to reduce variability and avoid customization by focusing on producing standard products.

The proposed interventions were simulated to assess their potential impact on the design process. The simulations included individual interventions and combinations of up to eight interventions. The results of the simulations show that levelling the process and implementing new drawing software and generative design approaches have the most significant potential to improve the design lead time, resulting in a 15% reduction in DLT and a 17% increase in the utilization ratio. Additionally, interventions 1 and 3 effectively reduced rework and increased Yield, as evidenced by improvements in RTY.

It is anticipated that the implementation of all interventions will result in a reduction of time for not only non-value-adding activities but also required non-value-adding and value-adding activities. This presents an opportunity to optimize the system and increase efficiency.

This study validated the proposed framework and interventions by surveying the company under examination. A 5-point Likert scale was utilized in the questionnaire to gather feedback on the effectiveness and applicability of the interventions, with scores ranging from 1 (very poor) to 5 (excellent). The results of the survey are presented in Table 4.

Table 4: Survey results for evaluating the effectiveness and applicability of interventions.

Interventions	**Effectiveness**	**Applicability**
1: Reducing negative iteration	4	3
2: Reducing the waiting time for feedback	3.5	3.5
3: Controlling the designs	4.5	4.5
4: Add additional designers as needed	4	3.5
5: Reduce the redundancy	4	4
6: Using new drawing software	4.5	3
7: Reduce waiting time for the Order desk	4.5	3.5
8: Reduce buffer time after the contract	4	3

Overall, the proposed interventions effectively reduced waste and improved the design process. However, there are some concerns regarding implementing specific interventions, such as collecting customer feedback in a timely manner and the unfamiliarity of designers with new software. These concerns can be addressed through further training and education to ensure the successful implementation of the proposed solutions. Additionally, reducing the invoice validation period may be challenging and requires further examination to identify ways to reduce the buffer time after the contract effectively.

CONCLUSIONS

This research aims to develop a methodology to improve the design process by identifying and eliminating waste and non-value-adding activities. This research primarily employs value stream mapping as the method of investigation and simulation to evaluate the proposed improvements. Various methods were employed to gather data on the duration of each task in the design process and to provide a statistical overview of the process.

The proposed framework aims to provide organizations with a systematic approach to identifying and addressing waste in the design process. The framework utilizes various Lean tools and methodologies, such as statistical analysis and simulation, to evaluate and improve the efficiency of the design phase in off-site construction and built-to-order companies. The simulation results indicate a significant design lead time and utilization ratio improvement due to implementing the proposed interventions. However, it is essential to note that further cost reduction can be achieved by implementing additional Lean tools. The proposed framework is validated through an evaluation process, which compares the stated objectives to the actual outcomes of its implementation and may employ various evaluation procedures depending on the context and topic being assessed.

The objective of identifying waste in the design process in build-to-order off-site construction/manufacturing was achieved using value stream mapping as a Lean tool. This process-oriented approach allowed for the study and evaluation of the system, focusing on identifying and eliminating waste and non-value-added activities. In addition to value stream mapping, interviews and simulations were used to gather information and gain insight into the design process. These methods provided a comprehensive understanding of the process, enabling the identification and elimination of waste, ultimately leading to an improved design process.

In the case study context, additional issues required more comprehensive managerial solutions. These issues were rooted in the high level of customer involvement in the design process, which resulted in increased variability and a need for rework. This challenged the designers and made it difficult to standardize the design process.

The limitations of this research should be acknowledged. One limitation is that the data collection method used was interviews with a limited number of experts, which may not fully represent the entire population. The study did not consider the participants' demographic characteristics, which could have provided more results. Furthermore, only a few process classes were mapped using value stream mapping, which may not have captured the full scope of the process. Additionally, the metrics used to monitor waste were limited to time and reworked, and other factors could have been beneficial for identifying hidden waste within the process. Furthermore, the proposed interventions were based on the availability of technology for small and medium-sized businesses, and future research could benefit from evaluating other interventions and their impact on the design process. Finally, future research could explore the development of a digital platform or dashboard to integrate all design processes and tools, including enterprise resource planning (ERP) and design software, which could aid professionals in reducing waste and increasing value delivery.

PRODUCT PLATFORM FLOW TO DEVELOP NEW PRODUCTS IN AN OFF-SITE COMPANY

Tainara P. Nievola[1] and Sergio Scheer[2]

ABSTRACT

The civil construction's cost has increased since the beginning of the pandemic, bringing insecurity to the sector. In addition, civil construction is largely responsible for environmental impacts related to greenhouse gases and waste generated globally. Several industries, such as the auto industry, use the product platform concept to optimize their processes, bringing more efficiency and control to their productions and products. The existing theory on the application of a product platform in construction shows that it can be a means of controlling fluctuating costs and reducing environmental impacts, but there is a gap, with few studies showing the application in real cases and the gains obtained. To assess this, the literature review aims to understand how product platforms work in other industries and what we have so far on their application in the construction sector. An action research method is used, applying the product development flow created, to meet two demands for new products in the studied company, using other platform solutions already developed by the company – such as application of common items - to achieve cost reduction. The result of the practical application reached the company's expectations, achieving a significant cost reduction.

KEYWORDS

Product development, product platform, off-site construction, industrialized construction, standardization.

INTRODUCTION

From January 2020 to January 2022, the annual increase cost of Brazilian civil construction more than doubled in relation to the period from January 2018 to January 2020, as can be seen in Figure 1 (FGV, 2022). And even though the index shows a reduction in 2022, it is still considerably above the index in the pre-pandemic years. According to European Commission (n.d. a) data on construction cost indexes, in Europe, between 2011 and 2016, cost increases were around 1.5% per year, from 2017 to 2019 around 2.3% and even though in 2020 it kept stable, in 2021 the cost increase in construction averaged 6.5%.

Besides, constructions and demolitions are responsible for 44% of the waste produced by industrial sectors annually (Chen et al., 2022). Along the same lines, Liu et al. (2015) report that in England, activities related to construction and demolition are also responsible for 44% of all waste generated. On a global scale, around 40% of the material dumped in landfills is construction waste (Banihashemi et al., 2018). Waste means extra cost to the construction companies and residents.

The product platform is a strategy widely used in manufacturing such as the automobile industry (Alizon et al., 2009), it consists in identifying commonalities that can be applied to more than one project, product, or process, with the aim of creating and grouping common items (components, processes, knowledge, and people). The creation of standardizations allows product derivatives to be developed and produced more efficiently (Popovic et al., 2021 and Hanafy et al., 2017), that includes standard processes as well. Furthermore, studies such as that by Tseng et al. (2008) show how modular design and '*platformization*' can lead a product to a more sustainable lifecycle.

The existent literature brings a solid theoretical approach on general product platforms, but there are few studies showing the application in real cases and the gains obtained. This research addresses this existing gap by using the Action Research Methodology, identifying through existing literature ways in which the use of product platforms can address the cost challenges, bringing with it a gain in sustainability and then creating a new product development flow based on the reviewed literature, and applying it in the company's process observed in this study, to capture the real gains in cost reduction with the use of product platform solutions.

PRODUCT PLATFORM

The clustering of different assets (e.g., components, processes, knowledge) in order to define standards that will be used in the creation of new products is the basic concept of a product platform (Robertson et al., 1998). As Lennartsson et al., (2018) described, “Through product platforms, companies achieve high levels of product variety, a reduced time to market, improved operational efficiency and responsiveness to market needs”.

Standardization also has benefits related to a company's supply chain. As shown by UK Research and Innovation & Construction Innovation Hub, 2022, the constant and repeated use of the same components brings three main benefits:

1 – allows working with stock, which allows companies to take advantage of promotions or cost reductions to control their own production costs;

2 – allows the development of different suppliers for the same element, limiting the market control of only one supplier, which normally means high cost;

3 – reduces the risk of delays resulting from a long lead time from suppliers.

These risks of delay in the conventional construction process (due to project delays or material delivery) are further compounded by delays related to low productivity, lack of labour, and operational stoppages (strikes, absences, delays) (Bryden Wood et al., 2018). These risks are minimized or eliminated with the adoption of platform strategies.

All the benefits mentioned above can be converted into financial gain, as presented by Bryden Wood et al. (2018). The net present value (NPV) – which is the cash flow assessment of an investment in a given period – in a process with a platform approach is optimized by requiring a smaller initial investment, reducing the time to payback on this investment and increasing the value end when compared to a conventional process.

A successful platform requires a balance between custom elements, unique to each project and impossible to avoid, complementary elements, which are similar but not the same (such as colour or material variation), and standard elements, common to all projects. This balance allows companies to meet the desires of their customers (UK Research and Innovation, 2022).

The use of standardization is not unknown for general manufacturers, such as the automobile industry (Alizon et al., 2009). Within this type of industry, the customization of the final products - cars and trucks, for example - by the end customer does not involve structure, such as chassis. Their customizations include colour, electric windows and air conditioning systems, for example, that does not – or have minimal - change the production line. In civil construction, the case is different, the end customers are residents, and they tend to want a personalized house, often designed exclusively for them (Gibb, 2001). This makes the standardization process more complicated to the production line, and to address this point, there is the mass customization strategy.

MASS CUSTOMIZATION

Mass customization is a technique that firstly involves in-depth knowledge of the customer to meet their specifications using standard assets that, combined with each other, bring customization of the final product without losing scale economies (Duray et. al, 2000). A good example of this is the computing industry, which has standard modules (video cards, batteries, memory cards) that when combined can form different end computers, serving customers looking for the simplest to the most complex computers capable of running heavy software (Piller et. al., 2006).

In civil construction, mass customization can work through the architectural modularization of roof types, window and door frames, and hydraulic kit solutions, one can even think of the spatial modularization of entire environments, such as kitchens and bathrooms, even transforming electrical and hydraulic elements in default. Figure 3, below, shows standardized solutions, that combined in different ways can create different products, and helps to better understand this idea.

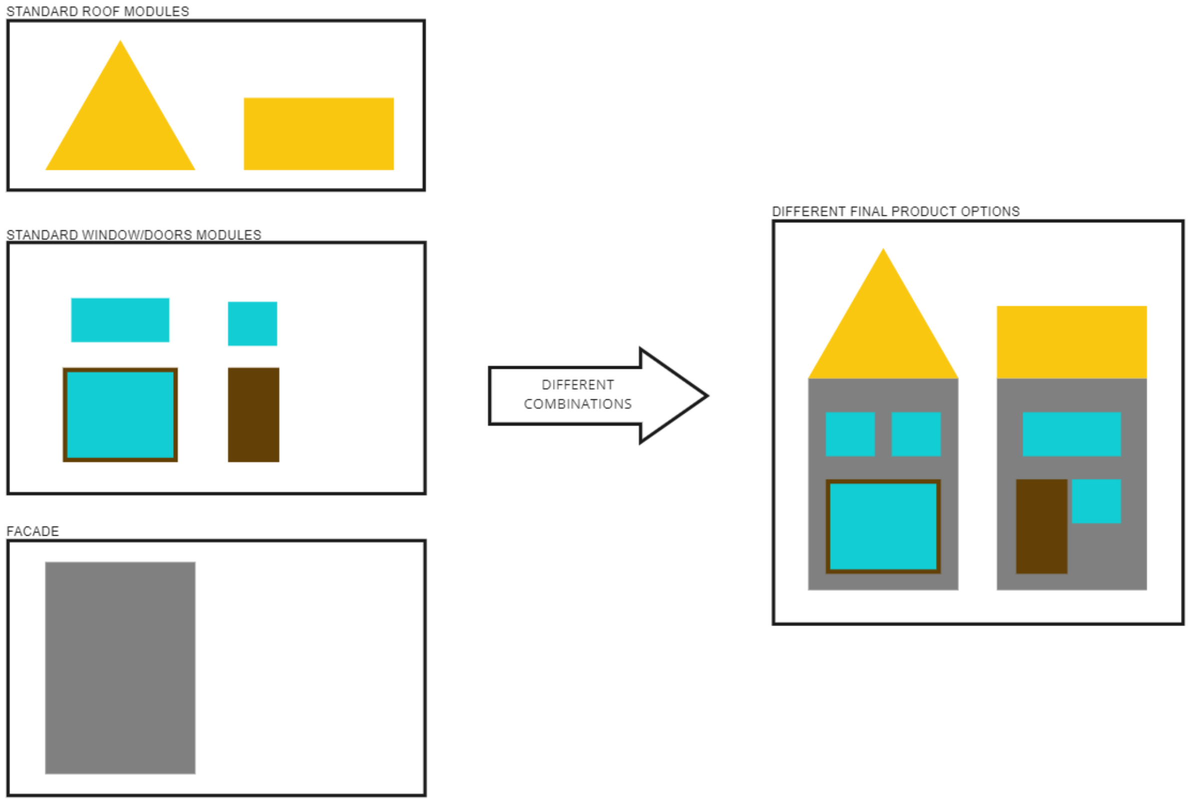

Figure 3: Mass customization in civil construction

The use of mass customization and product platforms is related to sustainability through increased efficiency since the teams that work in production only work with the repetition of modules, thus, they are able to specialize and continuously improve in what they are doing. This reduces errors, therefore reducing rework and therefore reduces the use of raw materials. Also, the participation of the customer reduces or eliminates the reforms, which reduces the waste generated with them (Rocha, et al., 2015).

In addition, as Gibb (2001) demonstrated in his case study, the repetition of modules, solutions, and processes reduces the work of the project team and brings more efficiency to the engineering team, and reduces costs and risks related to accidents at work and delays. This information is corroborated by UK Research and Innovation & Construction Innovation Hub (2022).

The greatest gain with the use of the platform exists when its application happens from the product development phase when the conception of a new product is done collaboratively with commercial, project, operational, and supply chain teams (Ortega *et al*., 2022). And integrating all stakeholders in the design stage is a challenge within civil construction (Jaillon & Poon, 2010), but it is fundamental for the success of a product (Ortega *et al*., 2022).

MAKE TO ORDER AND CONFIGURE TO ORDER

Inside a platform, the products can be placed in different categories. A new product that is fully developed (e.g., complementary projects, DfMA) before being launched in the market, fits into the Make-to-Order (MTO) category. MTO products cannot be modified by the customer, they are adamant about changes. But mass customization allows some modifications to meet customers' specifications, in this case, when a new product is developed based or not on a previously existent project, but still only uses solutions and processes that belong to the platform, they are called Configure-to-Order (CTO). Figure 4, based on Gatehouse.design (n.d.), shows the different categories, and the line is the decoupling point of the customers' specifications – the further to the right, the more specifications are created in the development phase, before the customer order, and to its left, more specifications are created following the customer order, customized.

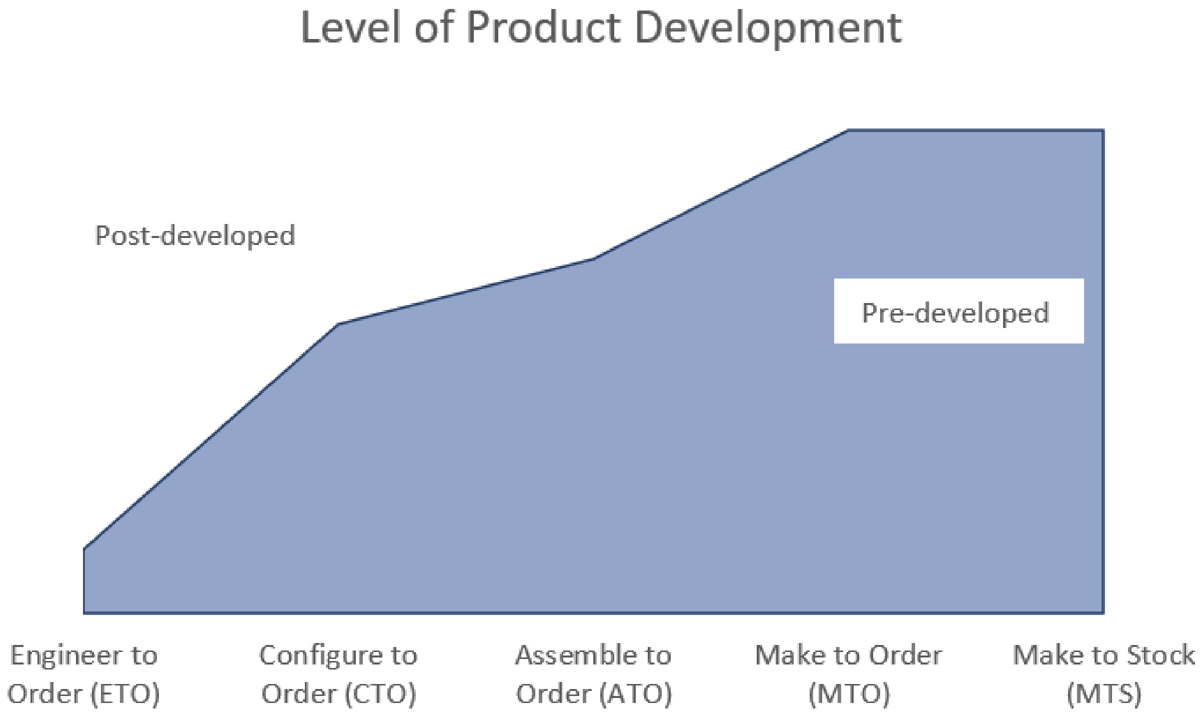

Figure 4: Customer Order Specification Decoupling Point

PRODUCT DEVELOPMENT FLOW

A new product development flow was proposed and put into practice within an offsite company in Brazil, called Company A, seeking to involve all stakeholders from the beginning of the process. The company is changing its way of creating new products, looking for more efficiency in its processes and operations.

As one of the authors works in Company A, it was possible to apply the Action Research (AR) method. The company's internal demands call for speed in changing processes, and according to O'Brien (2001), AR is suited to cases like this. It also was possible to apply multiple interactive cycles to reach the flow used, aiming to put into action all the research made on creating new products in a product platform strategy (Conte et al., 2022).

Initially, Company A didn't have a consolidated flow to develop new products, and the process was disintegrated. Figure 5 shows the proposed new product development's flow, that was created from the observation of all stakeholders involved in the process, how many times and at what moments they were involved and gave inputs in the process - it was common for an interested party to decide to change something in the product after it had already been budgeted, causing rework. Based on this, an analysis was carried out seeking to reduce the number of times that a stakeholder is involved to provide inputs, involving him only at the right moment of decision making.

The flow starts with a commercial demand – that can be a new product or a customization of an existing one - united with the constraints of the platform in which it fits. The platform is the clustering of the standard solutions that can be used, and a product with these solutions belongs to said platform. These two things are the trigger to start the development of the architectural project, which goes through evaluation by the commercial team, evaluation by the engineering team, and general evaluation in a back-and-forth cycle until it is approved by all.

With general approval, the product's CTO budget is drawn up, within a flexible spreadsheet that allows for project changes. If the cost is not approved, it goes back to the development of the architectural project. If it is approved, the process has a decoupling point, from which nothing in this product can be changed after all the necessary validations were made – *this decision-making point with no possibility of return brings more seriousness to the evaluations and avoids rework*. After that, begins the preparation of the commercial material for launch on the market, in parallel with the development of a details book that aims to identify the materials that have the most critical delivery lead time. The product remains in the portfolio until a sale takes place. With the sale and with the details book, the executive projects (e.g., complementary, production, assembly) and the final DfMA of the product are made. With all the projects ready, the final bill of materials is made, which is then passed on to the supply chain team, and this product becomes MTO.

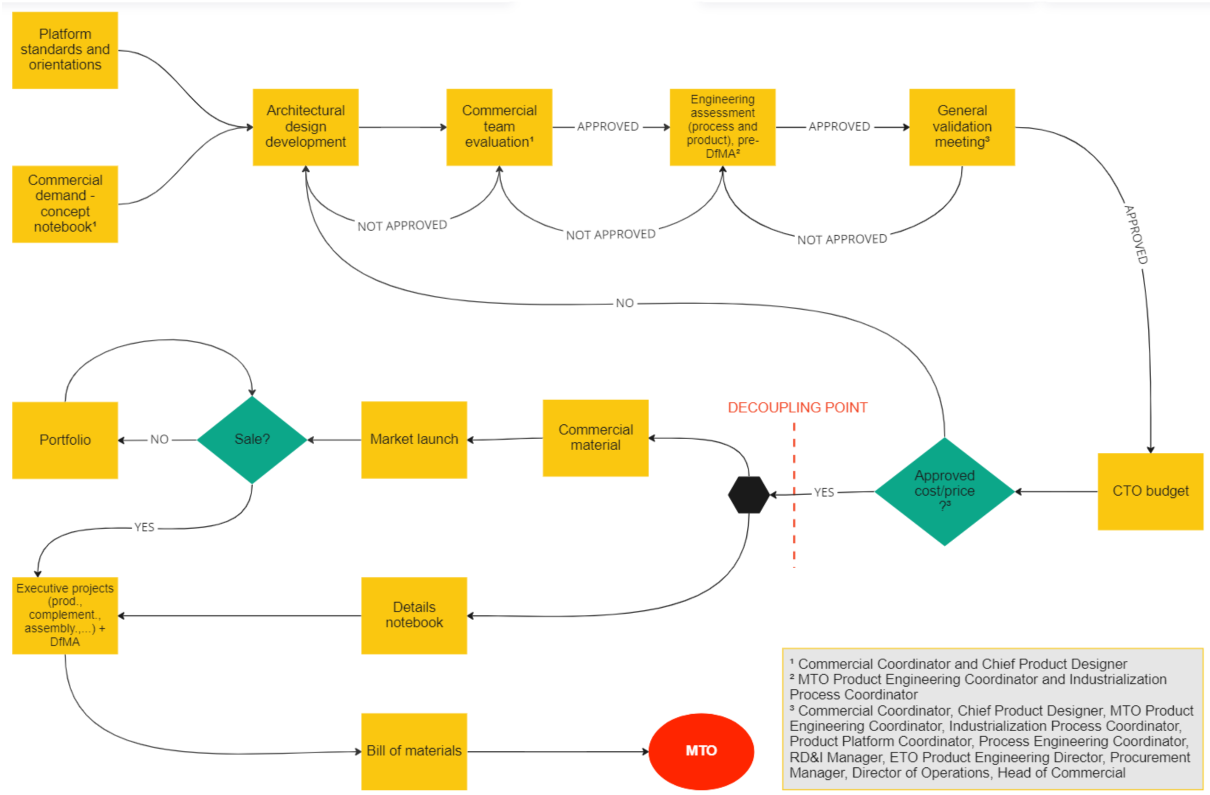

Figure 5: Integrated New Products Development's Flow

This flow takes place within any created platform, and the creation of platforms within the company takes place from the identification of needs that are not met with the existing ones, that means that if some products need solutions that are not part of an existing platform, it can be the case to create a new one based on commercial demand. For the creation of a new platform, Company A has an RD&I team that has the function of bridging the gap with the commercial team to understand new market demands, assess whether these demands can be met with existing solutions and elements or not. If not met, new solutions are studied, prototyped, evaluated and validated to become, then, a new platform.

With this flow, any changes in an already existing product can be easily and quickly met. So, if a customer wants an existing product (MTO), but with bigger rooms, or a different set of windows, for instance, he can have. His product will start as CTO and will belong to the platform characterized by the solutions and standardization used. As the solution for the company will be the same, and the client will have the desired modification, it can be said that the company has now adapted its process and caters to mass customization.

APPLICATION

The product development process shown above in Figure 5 was applied in the development of two new products in Company A, with solutions from the Single-Story House Product Platform. The demand brought by the commercial team was for two different products, Product 1 is a single-story house of approximately 50 m², and Product 2 with approximately 100 m², with the required minimum areas listed in Table 1.

Table 1: Minimum Areas for Products 1 and 2

	Product 1 (50 m²)	**Product 2 (100 m²)**
Integrated living and dining room	8.00 m²	16.00 m²
Kitchen	4.00 m²	7.00 m²
Laundry room	2.50 m² or easily adaptable to 2.50 m²	4.00 m²
Suite (bedroom + bathroom)	12.50 m²	15.00 m²
Bedroom 1	10.00 m²	10.00 m²
Bedroom 2	-	8.00 m²
Social Bathroom	2.50 m²	2.50 m²
Toilet	-	1.80 m²
Covered parking space	-	12.00 m²

For Product 1, the objective was a 15% cost reduction compared to the existing reference product. And for Product 2, the objective was a cost reduction between 10% and 15% compared to the existing reference product.

The development of the two products was carried out with integration between commercial, platform, and engineering teams, and each one took approximately 45 days for the final architectural project to be approved by all. Both products were created using solutions and standardizations previously developed from the Single-Story House Product Platform, such as bathroom modules, standard window frames, roof solution and grouping of wet cores in few hydraulic walls.

In Figure 6 it is possible to observe the base reference for Product 1 and in Figure 7 final architectural plant of Product 1.

Figure 6: 50 m² Reference Product

Figure 7: 50 m² New Product

In Figure 8 it is possible to observe the base reference for Product 2 and in Figure 9 final architectural plant of Product 2.

Figure 8: 100 m² Reference Product

Figure 9: 100 m² New Product

The application of solutions developed by Company A's RD&I team for the Single-Story House Product Platform together with the application of the new product development flow, brought about a 16.7% cost reduction in relation to the base project of 100m² house and 18.9% cost reduction in relation to the base project of the 50m² house in the estimation costs. Both results surpassed the initial target, showing the success of the strategy. When the products are executed, it will be possible to measure the savings from the predicted waste reduction, considering that the applied standard solutions are completely mastered by the operations teams, and according to the revised theory, this mastery brings waste reduction, therefore, less cost with materials (Rocha, et al., 2015 and Gibb, 2001).

DISCUSSION

It is a fact that the cost increase that has occurred in civil construction in recent years has had a negative impact on the sector. Reduction in the number of real estate launches and companies going bankrupt was the reality faced since 2019 in the Brazilian market.

As seen in the literature analysis carried out, the use of the product platform has the potential to bring more control, predictability, and sustainability to the sector. The difficulty encountered is the same as reported by Rocha et al. (2015), there are still many differences between construction and manufacturing, and although there is a growing interest in industrialization and off-site construction, they still represent a small portion of the market.

The results with the application of the integrated product development flow proposed in this study meet the results expected in the study made by Ortega et al. (2022), where every stakeholder participates in the process, bringing ideas that can optimize and make the project more efficient. Moreover, the evaluations are more decisive and with a holistic view, and that reduces the rework that exists when different stakeholders participate in different stages of the development process.

As exposed by the UK Research and Innovation & Construction Innovation Hub (2022), the major gains from using product platform strategies are primarily related to the supply chain, where the advantage lies in the standardization of raw materials, which allows for better cost control through inventory and a diversified supplier portfolio. Company A's supply chain has already benefited from the product platform strategy and has reduced the quantity of different items in their bills of materials and managed to improve negotiations by concentrating a larger volume of standard material with its suppliers. The cost reduction can revert to a more competitive price, which leads to increased sales and reaches to lower-income groups where there is a large housing deficit.

This implementation could be done with small steps - for example, a construction company/developer could always work with the same sets of frames in different projects, this allows stock and makes them less susceptible to the increase in the cost of wood and steel - and gradually increase the standardization where to find possibilities. Secondly, the advantage related to the reduction of risks, which can be the risk of accidents at work – the more an employee repeats a function, the more he masters what he does – the risk of delays, whether due to lengthy lead-times, correction of projects, labour delay, among others, and risks of rework, since in the repetition, the activity is already validated and with reduced chances of error. This is also related to the third advantage, which is the environmental one. The less rework, less waste generation, and less carbon added to activities - UK Research and Innovation & Construction Innovation Hub (2022) even calculated a process with a 70% carbon reduction using a product platform.

All these advantages were part of the gains brought with the use of the new product development flow along with the standardization solutions already existing in the company. And as the study results show, there is a significant financial gain in standardizing, integrating decision-making processes and reducing waste.

Also, with the usage of the proposed flow, it is now possible for Company A to accept some level of customization by customers, without prejudice to production and process. With the client's participation and customization, their need to renovate their homes after the construction will be reduced, as proposed by Rocha et al. (2015), which also reduces the waste generated.

In this way, we can also observe that the use of a product platform can meet the economic, social, and environmental trinity.

CONCLUSIONS

As noted, the platform strategy is best applied in manufacturing, and off-site still has a small share in the construction industry. In this way, this transition will have a potential impact on the sector, when it reaches a large portion of the market. The potential impact may be a global reduction in costs since the results of this research show a significant cost reduction in a real case.

The cost reduction obtained was possible due to the integrated product development flow, that enabled important decisions to be made in the right timing, avoiding rework. Also, it allowed designers and decision makers to calmly and concentratedly evaluate which existing solutions would bring the best gain for each product, without external interference at inopportune moments.

The process and results in this study - where it was possible to put into practice the theories to validate them in the market - are important for Company A, as they are addressing recurring problems with new solutions that can reduce aspects that are currently negative, such as the amount of waste generated and the lack of control over raw materials and labour, or the lack of customization possibilities when standards are created. The opportunity to apply all the research in a real company was essential to measure the real gains from the application of product platform strategies and to report compliance with the initial cost reduction target expected by the company. Even though it was a limitation that one of the authors works in Company A, this research was only possible because of that and supports more integration between theoretical investigations and practical applications. Another limitation found is that the company started recently to apply and focus in product platform strategies. In a company that has their product platform consolidated, other gains not even approached in this study may be possible – such as standardization of processes in the production line. And the last limitation found in this case-study, is that the gains from waste reduction are not measurable in the project phase, only in the execution, therefore, this specific gain remains theoretical.

For the most part, the literature found is related to sectors other than civil construction, which indicates a large space for research and development.

COLLABORATION IN THE DETAILED DESIGN PHASE OF CONSTRUCTION PROJECTS – A STUDY OF INTERDISCIPLINARY TEAMS

Mona Salam[1], Perry Forsythe[2], and Catherine Killen[3]

ABSTRACT

Collaboration in construction projects has become a primary requirement in common delivery methods, especially in the detailed design phase to achieve value for the client. The involvement of multiple organisations, such as the client, architects, design consultants, project managers, contractors, and subcontractors, increases the complexity of implementing successful collaboration. Recent studies have focused on the financial aspect of collaboration but undervalued the social dimension which reflects behavioural actions that can lead to goal misalignment. There is less known about the highly dynamic nature of collaboration at a project level between participants with different views, objectives, and working practices. Through a study of two interdisciplinary teams in the detailed design phase of large-scale construction projects, participants' perceptions of collaboration were analysed to reveal that participants have different ways of viewing their collaboration, ranging from facilitation factors, working processes, and outcomes. The study advances the theory of collaboration in design management by adopting an inter-organisational practice-based perspective to assess collaboration. The findings suggest a more tailored management approach based on understanding the processes and outcomes and regular monitoring of the behaviour actions for collaboration to succeed.

KEYWORDS

Collaboration, interdisciplinary teams, design management, early contractor involvement

INTRODUCTION

Collaboration in large-scale construction projects is challenging due to the presence of multiple organisations and skilled professionals representing the client, architects, design consultants, project managers, contractors, and subcontractors forming interdisciplinary teams (Emmitt 2010; Winch 2009). Although these participants have different backgrounds, goals, and preferred working practices that affect their discussions and methods of resolving conflicts, they are required to work closely as a cohesive team to improve value for the client (Baiden, Price & Dainty 2006). In common delivery methods such as design and build and managing contractor, the detailed design phase involves several design reviews and evaluations between designers and contractors to finalise design decisions and the associated cost, which requires a good understanding of the interdependent relations between these actors (Kalsaas, Rullestad & Thorud 2020).

In large-scale construction projects, the finalisation of design documents during the detailed design phase can take more than a year, creating challenges for participants to maintain their collaboration efforts and exchange information and technical knowledge constructively (Walker, Davis & Stevenson 2017). Recent research on the detailed design phase revealed designers' concerns about delays and late changes when finalising designs due to the uncertainty of receiving feedback from the contractors in a timely fashion (Kalsaas, Rullestad & Thorud 2020). Further, late design changes in the design phase are the leading cause of rework in the construction phase, according to research showing that the average cost of design changes was up to 14.2% of the construction cost (Lopez & Love 2011). A such, managing interdisciplinary teams in the detailed design phase is particularly challenging as the contractors' focus shifts to cost and scheduling to finalise design documentation, which conflicts with the iterative nature of architects' work (Forbes & Ahmed 2010). These differences in working practices are reflected in design documents that may be incomplete and not precise enough for the subsequent disciplines in the supply chain (Ballard et al. 2007; O'Connor James & Koo Hyun 2020; Tzortzopoulos, Kagioglou & Koskela 2020).

Successful traits of collaboration in multi-party projects included sharing risk and reward models and aligning financial interests (Walker & Lloyd-Walker 2020). These traits tend to focus on the financial aspect of collaboration and undervalue the social dimension reflected in behavioural actions that can lead to goal misalignment and miscommunication among interdisciplinary teams (Manata et al. 2020; Suprapto, Bakker & Mooi 2015). Understanding the highly dynamic nature of collaboration is therefore important at a project level where interdisciplinary teams include different personalities, objectives, and working practices (Bresnen & Marshall 2002; Eriksson & Westerberg 2011).

Given these insights, this paper presents an empirical investigation on collaboration as a perception-based phenomenon to understand how participants perceive and evaluate their collaboration and the impacts on their working practices in detailed design meetings of large-scale construction projects in Australia. It draws upon the inter-organisational theory that differentiates between antecedents of collaboration, processes, and outcomes and pays special attention to the subjectivity aspect of collaboration (Gray 1989; Gray & Purdy 2018; Huxham & Vangen 2013) to study the research question*: How can team members' perceptions of collaboration in the detailed design meetings of construction projects provide insights into improving interdisciplinary collaboration?*

LITERATURE REVIEW

Interdisciplinary collaboration is considered a solution to persistent issues in large-scale construction projects, such as adversarial relationships, poor communication, schedule and budget overruns and high uncertainty (Deep, Gajendran & Jefferies 2020; Walker, Davis & Stevenson 2017). Successful collaborative practices that rely on multi-party contracting frameworks have demonstrated an ability to control cost and improve performance in construction projects. However, recent studies have reported practical problems such as lack of commitment, inefficient communication, sharing limited financial information, conflicting personalities, and lack of team building activities and workshops to rectify goal misalignment (Koolwijk et al. 2018; Manata et al. 2020). Contracting frameworks are not considered sufficient to shift participants' mindsets to a fully collaborative one in large-scale construction projects due to the gap between agreements at the formal organisation level and what happens at the project team level (Bresnen & Marshall 2002; Suprapto, Bakker & Mooi 2015).

From an inter-organisational perspective, collaboration is defined "as the process through which parties who see different aspects of a problem can constructively explore their differences and search for solutions that go beyond their limited vision of what is possible"(Gray 1989, p. 5). This definition is adopted for this research, as it focusses on the interactive process of interdisciplinary collaboration and recognises that participants have different backgrounds, which aligns with this research. However, the integration of knowledge and experience in design and construction to collaboratively solve complex problems in construction projects needs some clarification.

Interdisciplinary collaboration has been discussed extensively in the lean construction literature to cope with uncertainty, reduce process waste and improve workflow to deliver value to the client by using tools that follow structured methods and procedures (ex.Ballard et al. 2007; Pedó et al. 2022; Tzortzopoulos, Kagioglou & Koskela 2020). The formation of an interdisciplinary team at the outset of the project is a fundamental aspect to improve the design processes and reduce constructability problems (Nguyen, Lostuvali & Tommelein 2009; Raviv, Shapira & Sacks 2022).

In the design phase of construction projects, set-based design (SBD) approach integrates construction expertise into the process of selecting design solutions to align viewpoints regarding design concepts from the start of the design phase to reduce negative design iteration (Parrish et al. 2008). Another useful method is the Choosing by Advantages (CBA) which is a structured approach of multi-criteria that prioritises the importance of advantages when making decisions by integrating construction knowledge into the design decision-making process (Schöttle, Arroyo & Christensen 2020).

Lean construction tools also focus on cost control in the design phase by integrating design and construction knowledge through the adoption of the target value design (TVD) concept. The TVD approach encompasses various lean methodologies and tools such as SBD, co-location of the project team in a common space, and expands to address constructability issues (Nguyen, Lostuvali & Tommelein 2009; Smoge, Torp & Johansen 2020). The TVD concept allows interdisciplinary teams to collectively manage and control target cost by moving money across trade packages to optimise the project as a whole (Ballard & Pennanen 2013).

The interactive process of interdisciplinary teams was also examined in the integrated project delivery (IPD) approach that operates at the project level by integrating design and construction teams, working practices and the business structures of organisations involved in a construction project (El Asmar 2012). The IPD method is an adaption of the Australian project alliancing approach, which shares a similar project delivery approach and has been commonly used in the infrastructure projects (Walker & Lloyd-Walker 2020). Research on the collaborative working environment in IPD projects has focused on identifying features of integrated teams, such as sharing information, defined roles and responsibilities, co-location, and trust in expertise (Abdirad & Pishdad-Bozorgi 2014; Baiden, Price & Dainty 2006; El Asmar, Hanna & Loh 2013).

Collaboration traits of interdisciplinary teams can be categorised into antecedents, interactive processes and outcomes (Salam, Forsythe & Killen 2019). These traits are 1) antecedents such as defining roles and responsibilities, having a common goal, co-locating the team in a common place, and a common means of sharing information, 2) interactive process traits including interactive coordination, collective decision making, and aligning cost interests, 3) outcomes traits include achieving value for the client, cost and time efficiencies, and trust in expertise. The interactive process has the least traits and still needs some clarification.

To advance the discussion on the interactive process in construction projects involving multiple organisations and skilled professionals, the role of the inter-organisational theoretical approach is discussed next to gain a deeper understanding of what conceptually constitutes interdisciplinary collaboration processes in the detailed design phase of construction projects.

THEORETICAL BACKGROUND

Theoretically, the inter-organisational practice-based stream differentiates between antecedents, processes, and outcomes of collaboration (Gray 1989; Gray & Purdy 2018; Huxham & Vangen 2013; Thomson & Perry 2006). Gray's (1989) collaboration model focuses on processes and outcomes, and advocates that collaboration efforts proceed linearly: 1) problem setting, 2) direction setting and 3) objective and 4) subjective outcomes.

In the *problem setting* phase, participants define the problem by performing a detailed analysis to develop a common understanding of each other's concerns. They then proceed to the *direction setting* phase where they refine the solutions and agree collectively on the best solution that satisfies their technical concerns. *Objective* measures are then used to document the implementation of the solution while *subjective* measures monitor participants' satisfaction with the results achieved (Gray 1989; Gray & Purdy 2018). The inter-organisational practice-based stream also recognises the long-term nature of the collaboration process (Gray 1989; Gray & Purdy 2018). As Gray notes, "respect for differences is an easy virtue to champion verbally and much more difficult to put in practice in our day-to-day affairs" (1989, p. 11). In conflicting situations, participants tend to forget that their underlying concerns are primarily intertwined and that their interdependence is much needed to solve complex problems (Gray 1989; Gray & Purdy 2018).

These inter-organisational concepts align with the practices of participants in the detailed design phase of large-scale construction projects due to the long duration, where conflicts are expected to occur between designers and contractors due to the inherent differences in their working practices and procedures (Eynon 2013). These circumstances put designers and contractors under continuous pressure in the detailed design phase to achieve the design objectives within the project time and budget constraints, which might influence participants' perception of their collaboration efforts (Winch 2009). Building on the perspectives of the inter-organisational theory to conceptualise collaboration, this study is expected to contribute to our understanding of project team dynamics in the AEC industry. Moreover, the study of the perceptions of participants about their collaboration in large-scale construction projects can help managers and professionals recognise and monitor the working process, foresee the impacts on the outcomes and potentially take actions to improve performance.

METHOD

To better understand collaboration as a perception-based phenomenon and how participants perceive their collaboration and the impacts on their working practices, the study collected collaboration scores in detailed design meetings of two large-scale construction projects in Australia followed by interviews. The research design adopted a longitudinal case study approach utilising replication logic (Yin 2017) to explore interdisciplinary collaboration in the detailed design phase of two contrasting case studies having different design environments. The two case studies were part of the same overarching educational building project and in methodological terms, this aimed to help minimise the effects of intervening variables such as different contract types, means of sharing information, and location and building type. The selection of the case study was based on (i) the case had enough stakeholders representing the client, architect, design consultant, main contractor, and subcontractor to form the interdisciplinary team, and (ii) the case represented a different degree of design complexity to reflect the contrasting design environments.

The chosen overarching educational building project included a five-storey podium (case study B), and a 10-storey tower (case study A). Case study A involved a relatively standard façade design, which used a closed-cavity façade (CCF) system developed by the subcontractor firm and demonstrated fewer design challenges due to the extensive knowledge of the subcontractor about the facade components. Case study B involved a bespoke façade type that created several challenges related to the design of the supporting structural system. These cases were treated as two separate work packages in terms of subcontractors' firms and budgets. Representatives of the client, main contractor, architects, and façade consultant were the same for both case studies. The different participants were the subcontractors' representatives assigned to each façade package.

DATA COLLECTION AND ANALYSIS

A simple perception-based method was used to capture the collaboration rating of the participants after each meeting over a year to cover the detailed design phase. Each firm assigned a key participant as the point of contact for the projects. These key participants were involved in the data collection method and were asked to rate their collaboration experience after each meeting using a Likert (1932) scale level of quality of 1–9, where 1 is very poor, 5 is neutral, and 9 is excellent. The perception question was emailed to each key participant shortly after the meeting to make sure that participants rated their collaboration very soon after the meeting to capture their emotive thoughts as well as objective outcomes. The survey question was: *Can you please rate your collaboration experience in [insert trade package name] meeting [insert date] using a scale of 1 to 9 (where 1=very poor, 5=neutral, 9=excellent)?* A total of 215 collaborating ratings were collected. The ratings were analysed following a systematic approach using quantitative statistical results to direct the next step in data collection.

The perception measure was followed by targeted interviews focused specifically on participants who gave contrasting collaboration scores from the same meeting. These interviews included an open question asking for the reasons behind their extremely low or high collaboration ratings. A total of 34 interviews were conducted and analysed using pattern matching (Miles, Huberman & Saldana 2014), where the codes were categorised and grouped according to the antecedents of collaboration and the four phases of Gray's (1989) collaboration model discussed above.

FINDINGS

The client procured the overarching project as a managing contractor with a cost-plus contract. Another set of separate consulting contracts existed between the client and the architectural firm and the façade consulting firm. The main contractor had a separate design, construct and maintenance contract with each of the subcontractor firms. Although this procurement setting has a traditional essence, it was found suitable for this study as the proposed collaborative environment is imperative in the detailed design phase to achieve value for the client (Koolwijk et al. 2018). In addition, the integrated business model used in the multi-party contractual setting is still limited in commercial construction projects in Australia (Rankohi, Bourgault & Iordanova 2022).

CASE STUDY A

The detailed design phase for case study A included 21 meetings and a total of 100 collaboration scores collected after each meeting. Key participants involved in the data collection (ratings and interviews) were the client's delivery manager (L1), the main contractor's project engineer (C1), the architectural firm's senior architect (R2), the façade consultant (F1) and the subcontractor's senior project manager (T2) for case study A. Figure 1 below, collaboration scores for case study A are presented on the y-axis in the 21 meetings (shown as Mtg) on the x-axis.

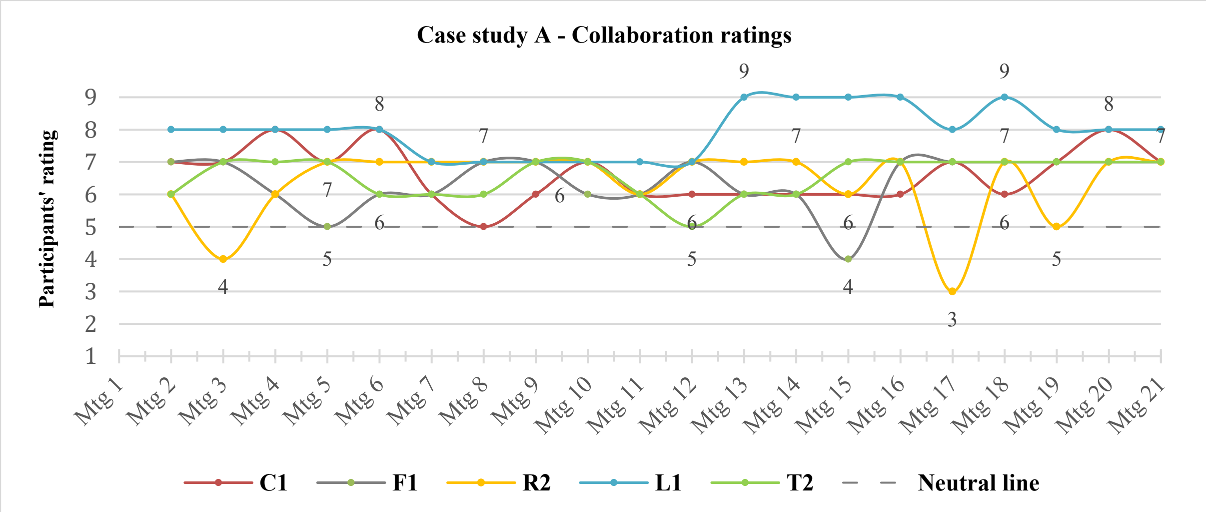

Figure 1: Case study A – Collaboration ratings by meeting

Analysis of the ratings revealed that there was no consensus among participants about their collaborative experiences, as the ratings did not align at any meeting. The most common ratings were 7 (50%) and 6 (26%). Most of the ratings were in the positive part of the graph above the score of 5, and only three ratings were below the neutral line. The client (L1) believed that collaboration was excellent (rating 9) in meetings 13, 14, 15, 16 and 18. The client was assured that the subcontractor firm could accommodate the design requirements and match the architects' vision, given that they developed the closed cavity façade CCF system as explained in a targeted interview: *"The process is positive because they know their system; they are looking at winter gardens, glass curves and everything. The meetings are generally positive" [L1, rating for meeting 6].* The constant satisfaction with the collaborative environment in the meetings was also seen in the subcontractor (T2) ratings which did not change much as the majority were 6 or 7. Subsequent interviews revealed that the subcontractor's senior project manager rated collaboration positively due to the team formation, including the designers and client. The formation of such an interdisciplinary team allowed the subcontractor to get instant feedback on the proposed design solutions from the designers and the client's approvals as quoted: *"Because the meetings are mainly related to the facade. So, it wasn't just a normal meeting that has everybody else on the project in the meeting, but for the façade to have an understanding of the design" [T2, rating of 6 & 7 for meetings 8 and 9].*

A different view of the collaboration experience was seen in the ratings of the main contractor (C1), architect (R2) and façade consultant (F1) which fluctuated between a high of 8 and a low of 3. For instance, the senior architect (R2) gave a low score of 4 in meeting 3 indicating an early sign of dissatisfaction. In the early meetings of the detailed design phase, the discussions included the scope register, information about façade components and their costs, and explanations about the façade system and how it works. The architects were concerned about whether the subcontractor had fully understood the design intent before approving the scope as quoted in the interview: *"I guess it is a complex façade stepping in stepping out, twisting... it is a closed cavity façade system and there is a lot of sort of services and extra constraints along with that façade type...it is just more complex than a traditional façade type" [R2, rating of 4 for meeting 3].*

Despite the above two low ratings of collaboration experience, the senior architect (R2) showed satisfaction with the working experience because of the subcontractors' continuous detailed feedback given in the meetings about the proposed design options, including dimensions, manufacturing process, installation processes and tolerance needed for the construction crew to secure connections, and cost breakdown. These thorough explanations including the cost associated with each design component informed the designers about which part of the design was expensive thus they could choose the best design solution that satisfied both practicality and cost as quoted: "*They gave us how much it costs; they break it up for us, it is easy to see if we make this decision, it will cost this much money" [R2, rating of 7 for meeting 8]. "They are really receptive towards our idea; they do not just say no and don't back it up with any sort of information… they seem to take on board what we want… giving us choices" [R2, rating of 7 for meeting 18].*

The contractor's project engineer (C1) had constant positive collaboration ratings above the neutral line. However, the ratings decreased from 7 in meeting 10 to 6 in meetings 11 and 12 due to excessive design reviews and coordination actions. Some of the minor design tasks required investigation including design options, cost analysis, and seeking the client's approval which generated several coordination tasks to gather and disseminate information and was rejected later due to cost overrun causing dissatisfaction to the main contractor (C1) quoted in the interview: *"I sent many correspondences between meetings outlining everything fully, it takes me a lot of time to outline the history, the marked-up drawings, and this is option A and this option B, but no response" [C1, rating of 6 for meeting 12].*

CASE STUDY B

The detailed design phase for case study B included 24 detailed design meetings where 115 collaboration scores were collected after each meeting. The key participants involved in the data collection (ratings and interviews) were the client's delivery manager (L1), the main contractor's project engineer (C1), the architectural firm's senior architect (R2), the façade consultant (F1) and the subcontractor's project manager (P3). Figure 2 below, collaboration scores for case study B are presented on the y-axis in the 24 meetings (shown as Mtg) on the x-axis.

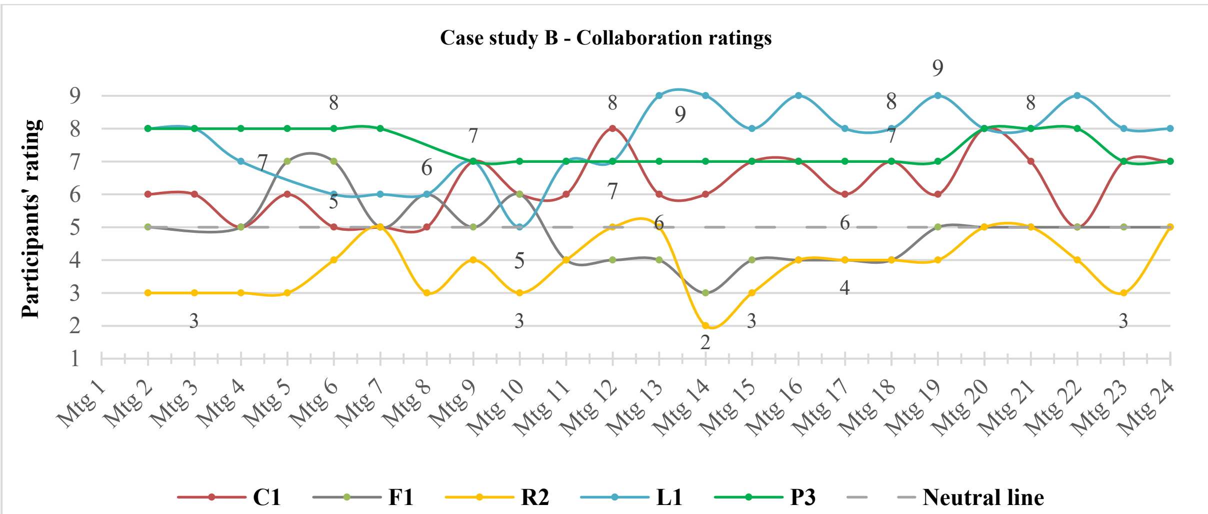

Figure 2: Case study B – Collaboration ratings by meeting

The observation of no consensus among participants about their collaborative experiences existed also in case study B due to the significant divergence between the ratings. Participants' ratings were widely scattered across the neutral line (rating of 5 points), with the most frequent ratings being 7 (22%), 8 (19%) and 5 (17%). For example, all architect ratings (R2) were below the neutral line, indicating a continuous dissatisfaction with the collaborative experience. In early meetings, the scope of the design was not clear due to the discrepancy in the design documentation, as participants had different versions of the tender documents. Thus, the proposed design solution did not match the design intent, which led to led to confrontation discussions, design changes to match the design intent, and delays in developing the design as quoted in the subsequent interview: *"They (subcontractors) don't seem to be listening to our views, like how many times we explained our view on the lower connection of reading rooms, we removed the louvres and its structure, but they keep asking or acting as if it is still there, it's frustrating" [R2, rating of 3 for meeting 5].*

A slightly different rating pattern is seen in the facade consultant ratings (F1) because the ratings were above the neutral line at the initial meetings and then continue to be below the neutral line (rating of 5 points) indicating dissatisfaction at many meetings. The façade consultant was also confused about the scope of the design due to its impact on the structural system design as quoted in the interview: *"The scope, yea, if everyone was clear on that it would be much simpler; we will know who is doing what… but that's taken us since April basically till now (July) to understand that because no one declared it openly… I keep asking questions and every time I ask a question; I find something new" [F1, rating of 5 for meeting 7].* Furthermore, both the architects and the façade consultant were concerned about the insufficient fundamental information on the structural system given in the meetings, but the subcontractor preferred not to go into detailed engineering calculations before agreeing on the design principles. These conflicting views created confrontation in the design discussions because the designers were trying to work out a practical design solution with the subcontractor as F1 quoted: *"They (subcontractor) don't want to say too much because the more you say the more you get feedback on… once they engaged the steel contractor, they will progress their shop drawings, which means that the steel guy would start his shop drawings and will have a note on his drawing that says need to confirm connection if they didn't tell us what that is beforehand" [F1, rating of 3 for meeting 14].*

The contractor project engineer (C1) had constant positive collaboration scores above the neutral line. However, the scores were closer to the natural line in the first 8 meetings, as he had a different view of the changes in the design scope due to budget limits as quoted: *'It is not as per their [referring to the architects] drawings, but we had to let it be based on something because if we were behind, and we would not have a building" [C1, rating of 5 for meeting 4].'* The process of refining the design continued to occur to investigate other ways to reduce the cost, which required further design changes and consequently more reviews. The main contractor (C1) was dissatisfied with these excessive reviews because the design was not progressing as scheduled as quoted: *"We just got 12 very different façade types that have constantly changed, we should be sticking to the design not just keep changing and changing… we don't know where the beam is and it is still changing, today the wind beam is changed again!" [C1, rating of 5 for meeting 8].*

The client's (L1) ratings were positive in general with all ratings above the neutral line showing an overall satisfaction with the collaborative experience despite the tough discussions between designers and contractors in the meetings as quoted in the subsequent interview: *"I gave a rate of 7 because at the end they [referring to the subcontractor] agreed to look at the design again and that is what matters to me" [L1, rating of 7 for meeting 4].*

Despite the design challenges, the subcontractor's (P3) ratings were also positive throughout the meetings at 7 or 8 indicating continuous satisfaction with the collaboration experience due to the concept of early participation in design decisions and being part of the team, as quoted in the interview: "*Yea, my ratings were much higher because we had a lot of coordination on something like this, where in previous projects many decisions were already made before we got involved so we also do not have a say in deciding how the project progresses" [P3, rating of 8 for meeting 5].*

As negotiations and consistent disagreement between participants continued to occur, an organisational decision involving the client and the main contractor was taken after meeting 8 including changing some of the meetings to be a design workshop as a mitigation plan for the delays encountered. A total of six design-focused workshops were held to replace weekly meetings 9, 11, 12, 16, 18 and 19 to better understand the technical concerns directly from the subcontractor's staff who were documenting the design drawings. The collaboration ratings of the participants began to be somewhat consistent after these workshops because the subcontractor team gave detailed feedback that made architects more informed about design restrictions and offered proper design solutions at the meetings, as quoted by the architect and the principal contractor: *'The workshops definitely are more constructive because it is much easier to get things done and decisions made and to work through details rather than having a formal meeting atmosphere and going through a lot of stuff that is not always super critical to what we are doing at the moment' [R2, rating of 5 for meeting 13]. "The workshops are more collaborative … generally because the group is not as big… plus the actual draftsmen work and try and get this resolved sort of coming with real problems and architects a bit more receptive and get things to work" [C1, rating of 8 for meeting 12].*

DISCUSSION

To address the research question, the study found that participants had different views of their collaboration and focused on different phases of collaboration when explaining their ratings. The client prioritised outcomes, subcontractors focused on antecedents, and the main contractor, architects, and facade consultant focused on processes. In the bespoke design case study, there was a greater variance in ratings, with dissatisfaction expressed by those focused on the collaboration's processes.

The client's delivery manager (L1) rated collaboration based on the outcomes achieved rather than the processes in both case studies. The findings support the study conducted by Tzortzopoulos, Kagioglou & Koskela (2020) which highlighted the client's concerns about preserving value during the handover of design responsibilities from architects to subcontractors. In both case studies, the subcontractors expressed satisfaction with their collaboration experience, albeit for different reasons tied to team formation and early involvement in design decision-making. These results are consistent with the existing lean construction literature, which recommends involving subcontractors early on in the design process to provide constructability feedback, enabling designers to make well-informed decisions regarding proposed solutions (Denerolle 2013; Raviv, Shapira & Sacks 2022). Despite the fact that the subcontractors displayed behaviours associated with providing constructability feedback, both attributed their high collaboration ratings to collaboration antecedents. There could be a couple of potential reasons for such practices. Firstly, it is plausible that the subcontractors may not be accustomed to expressing their views on actual working practices. Secondly, the lack of managerial attention towards cultivating a fair working environment where all participants have an equal opportunity to voice their opinions on working practices could be a contributing factor. (Eynon 2013; Winch 2009).

The interviews revealed that the R2, F1, and C1 scores were more focused on the collaboration processes than the outcomes. The high collaboration scores of the senior architect (R2) were related to elaborate feedback backed up by a breakdown of the cost of the design components. These practices led to adopting of practical design solutions and elevating the sense of mutual accountability where all participants shared the responsibility of meeting the design deliverables timeframe. Aligned with Dietrich et al. (2010), these findings provide insights into the knowledge creation process (interaction activities of feedback, brainstorming, and innovation) that are specific to the design discussions. The findings also support Denerolle's (2013) approach of fostering interdisciplinary collaboration through weekly meetings. Although design refinements are common in construction projects due to the highly iterative nature of the design process (Eynon 2013), they were seen by C1 as unnecessary coordination tasks which align with the well-established lean concept of process waste in the design phase that needs to be minimised (Tzortzopoulos, Kagioglou & Koskela 2020). These findings support the need for a planning management approach that is capable of handling the normal design changes in the detailed design phase (Kalsaas, Rullestad & Thorud 2020).

Practices associated with low ratings emerged in case study B because of the dissatisfaction of the architects (R2) and façade consultant (F1) with the practices of lack of transparency and providing inadequate design information combined with minimal cost justification which resulted in a call for mitigation actions to reduce confrontation. These findings demonstrate how goal misalignment at initial meetings led to unhealthy communication behaviours and poor decision quality (Manata et al. 2020; Suprapto, Bakker & Mooi 2015). Although Suprapto et al. (2015) point to the lack of willingness of senior management to be involved in improving team building and interpersonal relationships between participants at the project level, the findings of this study do not support this view, as the workshop decision was made by the senior representative of the client (L1). The diversity of participants involved in the detailed design meetings resulted in different interpretations or ways to frame the problems that existed in their discussions. The inter-organisational practice-based perspective explains such situations of participants failing to align their views and reaching a frame break stage (Gray 1989) , where the problems at the micro level were amplified in scope and time at the macro level (cross-organisational level) (Gray & Purdy 2018). This led to seeking mitigation actions to ease the tension between participants and reduce confrontation and avoid further problems associated with variations or claims for delay in construction projects (Walker, Davis & Stevenson 2017).

These findings suggest that collaboration needs a more tailored management approach based on understanding collaboration as a process that leads to outcomes, and requires regular monitoring of behavioural actions and differing frames when a problem occurs. Managers could remind participants that different interpretations of a problem do not mean by definition that they are opposing views and that their underlying concerns are initially intertwined and need their interdependence to solve the problem (Gray 1989; Gray & Purdy 2018). These different frames of the same problem can enhance creativity and innovation if well managed. More importantly, if participants began to lose their momentum, interventions can be introduced to address the reasons for collaboration inertia and help participants restore their efforts.

CONCLUSION

This paper examines collaboration as a perception-based phenomenon based on the opinions of participants on their collaboration at design meetings of construction projects. Analysis of the ratings of the participants reveals differences in the ways in which people from different organisations viewed collaboration. Two collaboration paths were identified from the analysis of ratings and interviews. A smooth path was achieved through detailed feedback to raise the awareness of technical constraints and sharing cost information to collectively make informed design decisions. The lack of transparency and inadequate design information led to a disruptive collaboration path. The practices of differing frames for addressing technical problems were resolved by an intervention to improve collaboration performance. Theoretically, the findings contribute to the growing literature on the need for better interdisciplinary collaboration in the construction industry to improve performance and provide useful insights into design management. Adopting the inter-organisational perspective provides a new lens to analyse interdisciplinary collaboration perceptions and reveal the practices that influence collaboration practices in construction projects, which can be further explored in future research.

IMPROVING PRODUCTIVITY IN VENTILATION AND PLUMBING INSTALLATIONS BY DEVELOPING DESIGNS

Tuomas Valkonen[1] and Olli Seppänen[2]

ABSTRACT

Quality of designs is one of the most important factors impacting the productivity of mechanical, electrical, and plumbing work. Previous research does not investigate problems with design in detail. This research aimed to identify design aspects where additional investments in design would increase productivity in installation. For this purpose, we selected three construction sites to identify deviations from designs, and interview installers on identified deviations and buildability in general. Observed deviations were divided into three main categories based on the cause of deviation: insufficient space reservations, missing model components, and buildability. Based on our findings we suggest five methods for developing designing: 1. BIM should be used in designing. 2. BIM coordination should include the assessment of buildability. 3. Better use of BIM requires high level of detail and high accuracy in all design models. 4. Contractors knowledge on buildability, schedule, and order of installation should be utilized in designing. 5. Optimizing material cost should be part of designing.

KEYWORDS

BIM, collaboration, assembly, HVAC, design

INTRODUCTION

The main purpose of designs is to convey the designers' intent to construction and enable fabrication of functioning buildings. Ideal designs for construction would contain everything that needs to be installed and they could be executed precisely, meaning that there would be no need for improvisation on site. Unclear designs lead to improvisation and improvisation leads to low productivity (Johnston and Brennan, 1996). Design quality and coordination was identified as the second most important issue affecting productivity concerning mechanical, electrical, and plumbing (MEP) installations in a study by Seppänen & Görsch (2022). The study estimated the potential production improvement to be 20 % by improving design quality and coordination. Similarly Wu et al. (2022) specified clash detection, network optimization, and construction simulation as methods to improve MEP installation productivity.

Prefabrication requires accurate designs that can be executed exactly and utilised as part of assemblies; designs for prefabrication can be considered examples of ideal designs. A study by Poirier et al. (2015) suggested that using high level of detail in BIM and designing for prefabrication might have significant potential for increasing productivity in MEP work. High level of detail enables effective work planning and is a precursor to using prefabrication (Song et al., 2017; Lavikka et al., 2021). High level of detail also refers to geometric representation

and model accuracy. Lavikka et al. (2021) also found that current design quality in Finland is not sufficient for prefabrication. This is one key reason why prefabrication of MEP has not been widely adopted in the Finnish construction market.

Designing for prefabrication is characterised by buildability of designs. Buildability can be considered as tool or methodology throughout the project. In this study we focus on design and construction phases and define buildability as designers using construction knowledge to draft designs that facilitate efficient building of systems or parts of them (Wimalaratne et al., 2021). Designs where buildability is not considered, such as models with clashes, cause waste and rework in construction.

Building information modelling (BIM) and coordination of design models can be used for ensuring buildability across disciplines. Clashes in MEP design models have been studied to identify their root causes and frameworks for resolving them (Tommelein & Gholami, 2012; Wang & Leite, 2016; Chauhan et al., 2022). Tommelein and Gholami (2012) suggested classifications for three different types of clashes, investigated their root causes, and ultimately concluded that clashes highly relate to buildability of designs. Effective coordination of BIM and using virtual design and construction technologies have been shown to increase productivity significantly (Khanzode et al., 2008). Past studies have been covering widely different frameworks and their productivity in BIM coordination (Lee & Kim, 2014; Seo et al., 2012; Korman et al., 2008; Korman & Tatum, 2006; Korman et al., 2003), but are limited to solving clashes that are visible in the models. Wang et al (2016) suggested a framework for MEP clash detection and resolution, their study reported 51 identified design errors from construction site but did not specify the types of errors or how they could have been avoided in designing.

While studies show that BIM coordination increases productivity (Wu et al., 2022; Khanzode et al., 2008), and BIM is widely used, there are also studies showing that current practices cause waste, and problems in coordination process remain (Seppänen & Görsch, 2022; Chauhan et al., 2022). This raises the question of what causes the need for improvisation and rework in MEP installations regardless of BIM use, clash detection, and coordination. To our knowledge there are no studies documenting reasons for deviating from designs and how these deviations relate to designing. The aim of this study is to identify these remaining problems and to suggest improvements to design process for eliminating these problems. Our aim is related to the key lean principle of minimizing waste, with focus on construction and improving designs. For this purpose we conducted three case studies on construction sites to document problems installers are dealing with.

METHODS

Based on the previous research we know that installers use significant amount of time for designing installations on site. The aim of this study was to document deviations from designs, determine causes for these deviations, and discuss possible solutions for removing these issues. To document issues in MEP designing we studied deviations in installation on three construction sites. The sites were selected to represent different project and building types. Key aspects of studied projects are shown in Table 1. All three projects had different designers, MEP contractors and main contractors. Installations of MEP systems were ongoing and observable in all selected sites.

The research was carried out in spring 2022. The first author was on-site observing installations and interviewing installers. A deviation was defined as any installation that was not identical to designs. Examples of deviations included using different parts or installing in different locations. Deviation in this context does not mean that the systems would not work as intended. Some of the deviations can result in non-functioning systems and others do not. The first author compared installations to designs and reported differences between as-designed and as-built. The identified deviations were documented by photographing the installation and writing notes about the reasons leading to the changes. The reasons were determined by interviewing installers and observing conditions affecting the installation. The installers were also interviewed regarding design issues in general and suggestions for improving designs.

All three case sites were different from one another. Cases 1 and 2 were new constructions where the first case was a school building and the second case was an apartment building. Case 3 was a renovation project in a school building where only the old structure was left untouched. All cases used BIM but there was significant variation in the utility and quality of the models. BIM was best used in Case 2 where design models were most detailed and coordinated to eliminate collisions. Lowest use of BIM was in Case 3 where a design model existed only for ventilation systems and BIM was not used in installation. Case 1 had design models of all disciplines and models were partially coordinated however there were obvious issues left unresolved. Installers of Case 1 used 2D drawings while they had seen the BIM model in meetings. Latest BIM models and 2D designs were used for evaluating installations on site. Prefabrication was not used in any of the studied installations.

Table 1: Characteristics of studied projects.

	Building type	Construction type	BIM used in designing	BIM used in construction
Case 1	Residential building	New Construction	Yes	Partially
Case 2	Educational building	New Construction	Yes	Yes
Case 3	Educational building	Renovation	Partially	No

RESULTS

Differences between design and installation were frequent on the studied construction sites. All studied spaces showed some examples of improvisation by installers. However, there were distinct differences of observed issue types between building and project types. Overall, the use of BIM in designing and installation changed problem types and higher utilisation of BIM decreased the number and severity of problems. Based on the results, BIM practices in case projects were not sufficient to remove all the problems and many issues were still left for installers to solve.

The identified problems can be divided into three main categories: insufficient space reservations, missing model components, and buildability. All these problem types could be found on all three cases. Insufficient space reservations were predominant in Case 3 which can be attributed to renovation project type. Missing model components, such as hangers or structural elements, caused issues in all cases but were most prominent in Case 1. While buildability issues are caused by the two problem types, it can be reviewed as separate aspect of designs. Buildability issues were especially observed in cases 1 and 2.

INSUFFICIENT SPACE RESERVATIONS

Insufficient space reservations can be caused by two mechanisms: built spaces are smaller compared to designs or used equipment are larger compared to designs. These problems can lead to equipment not fitting in their designated places or significantly hindering the maintenance of equipment. Insufficient space reservations were mostly observed in Case 3. Existing structures and accuracy of architectural and structural models are key differences in renovation projects compared to new constructions. In Case 3 most of the documented space reservation issues were related to faulty or non-existent measurements of existing structures.

Due to the lack of measurements, heating, ventilation, and air conditioning (HVAC) designer had to use architectural drawings as a starting point and was forced to rely on their accuracy.

In Case 3 there were many situations where corridor was narrower than assumed in designs and installers had to improvise. Figure 1 shows an example of this, where narrow corridor meant that all the ducts could not fit in the corridor and installer had re-routed one duct to be visible in classrooms which do not have suspended ceilings.

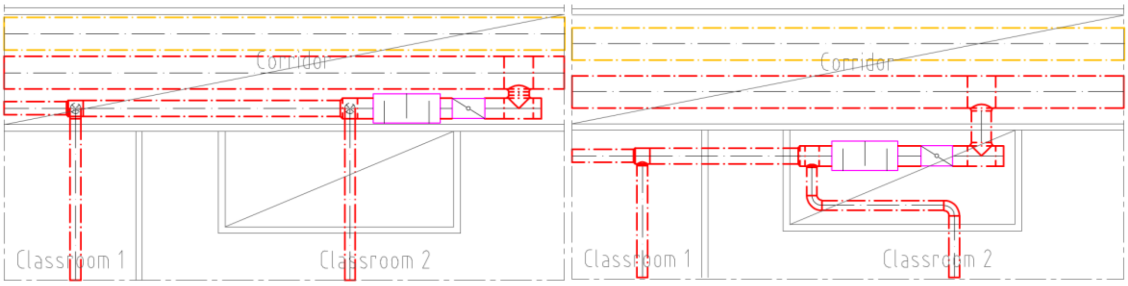

Figure 1: Left (1a) shows designers solution and right (1b) shows the installers solution. Installer had routed the supply air duct visibly in classrooms due to insufficient space in corridor suspended ceiling.

Another deviation was in technical room for ventilation where air handling units (AHU) had been arranged differently to designs, shown in Figure 2. The reason was smaller room compared to designs and as the result one AHU did not fit into its designed location. The installed solution is problematic for maintenance as AHU: s should have free space in front, equalling their depth, for replacing filters and other parts.

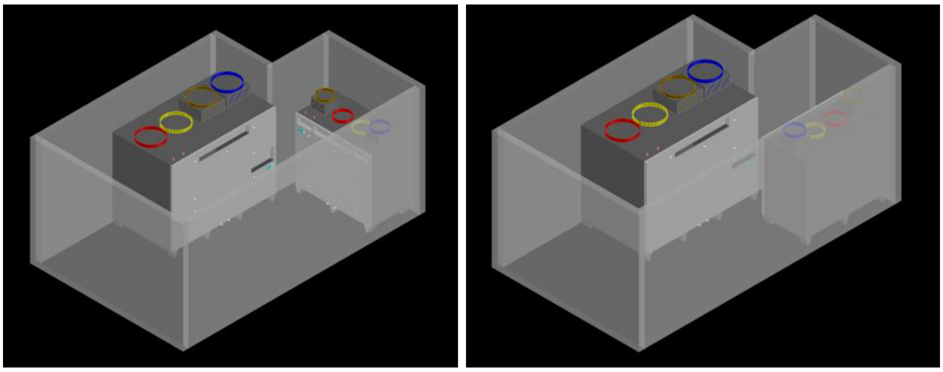

Figure 2: Designed arrangement of air handling units on the left (2a) and installed arrangement on the right (2b).

MISSING MODEL COMPONENTS

BIM coordination is not able to solve issues which cannot be seen in the model. There are many things that affect installation but are not necessarily included in the BIM. These missing model components often include, for example, hangers for MEP systems, small structural elements, and electrical cables. All these objects occupy space and can cause unforeseen problems in installation if not modelled.

In Case 2 there were several examples of walls being modelled to the elevation of suspended ceiling while they should have been modelled and were built to slab height. This leads to penetrations in suspended ceiling space which cannot be seen from the model. According to installers this caused some changes in pipe routing to avoid penetrations of concrete or brick walls. Figure 3 shows an example of re-routing pipes and its effects on the number of penetrations in a toilet group. Blue, red, and magenta lines represent the routes of domestic cold, hot, and circulation pipes. Red dots mark voids that need to be drilled on site. Figure 3a is the design solution for both pipes and walls. Figure 3b illustrates how the walls were built and how the solution affected the number of voids. Figure 3c shows the installers solution with real wall heights. The numbers of voids in the three solutions were 11 for 3a, 23 for 3b, and 18 for 3c. The difference between 3a and 3b shows the number of voids that the designer did not see from the model due to walls not being modelled high enough. The installer was able to eliminate 5 voids compared to the designer's solution.

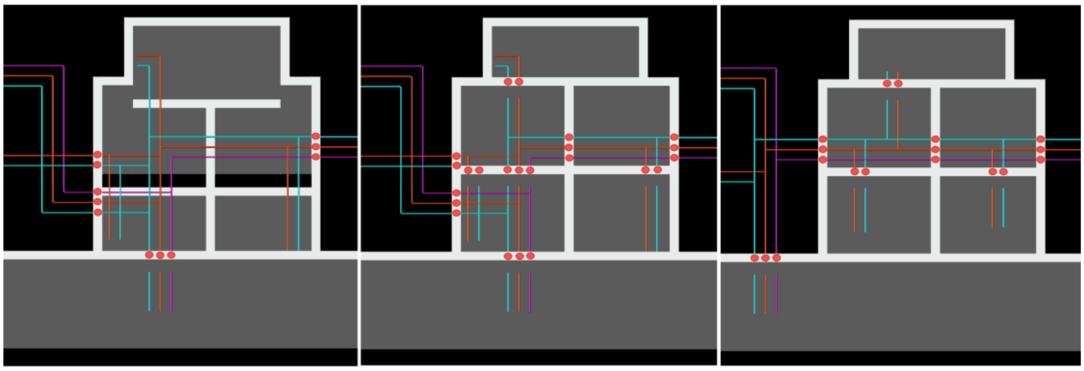

Figure 3: Pipes penetrating wall marked by red dots in three different cases. 3a, situation in BIM model. 3b, designed solution in reality. 3c, installers solution. The cases respectively have 11, 23 and 18 penetrations.

Supporting structures for interior walls and suspended ceilings can similarly cause collisions on site as these structures are not modelled. Figures 4a and 4b show how a supporting structure for suspended ceiling caused the need to lower the ceiling height. Figure 4a shows the design solution where ventilation duct penetrates the vertical surface of suspended ceiling and Figure 4b shows the supporting structure of suspended ceiling as it was built. The designed duct did not fit between the horizontal structures and the ceiling height had to be changed.

Third example of deviation caused by supporting structure can be seen in Figures 5a and 5b. The design model is missing a structure for movable partition wall where the wall can be stacked. Figure 5a shows the designed situation and 5b shows the installers solution. As a result of this structure, the installer had moved the silencers of two ducts away from the wall and re-routed the yellow extract duct to avoid collision with the supporting structure. The larger duct was installed higher compared to design which made it impossible to install the smaller ducts above the larger one. Installed solution is more difficult to install as it requires going through the supporting structure and using more parts for re-routing ducts, and it may result in worse acoustic properties when silencers are not installed beside structures.

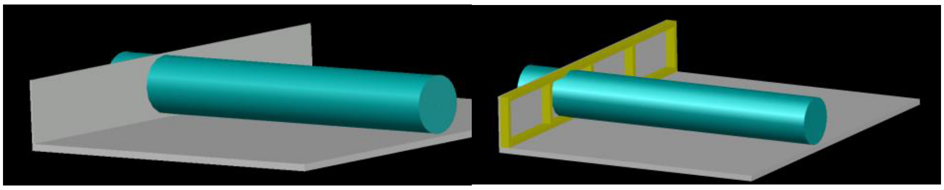

Figure 4: Duct penetrating the vertical wall of a suspended ceiling. 4a shows as-designed solution. 4b shows the supporting structures needed for installing the ceiling. In 4b the duct does not fit between the horizontal structures.

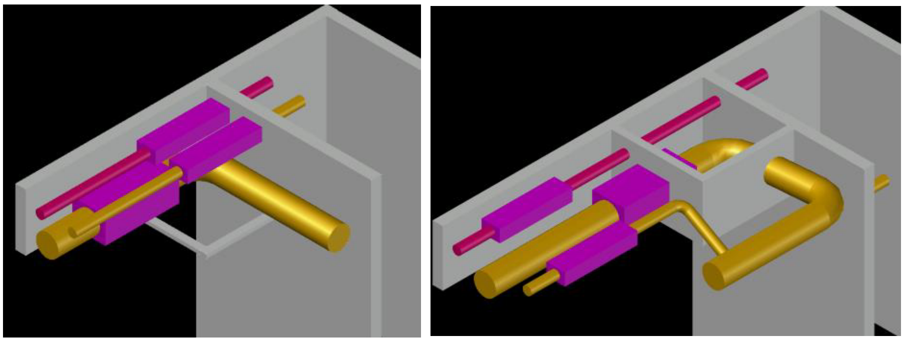

Figure 5: Ventilation ducts and structures as designed (5a, left) and as built (5b, right).

BUILDABILITY

Considering buildability is an important part of BIM coordination and neglecting it can result in clash free models that are impossible to construct. Of all the studied cases, the highest level of coordination was in Case 2 and the lowest in Case 3. In these cases, coordination was focused on eliminating clashes which is reflected in the following examples. Buildability is highly connected to missing model components and insufficient space reservations but it can be considered as individual dimension as well. In this case buildability means for example that there is enough space to make the installations, there is space to use scaffolding for ceiling installations, there is room for using tools, or the order of installation is reflected in designing.

In apartment buildings with decentralized ventilation, bathrooms are typically used for placing the AHU and the suspended ceiling of bathrooms have many ducts in a small space. This can result in difficulties considering buildability. In Case 1 the ventilation installers had made changes to one bathroom type to make more space for installation by re-routing one duct, as seen in Figure 6. The re-routing was possible without changes to other designs as the adjacent room had similar suspended ceiling to bathroom which enabled re-routing the duct. This solution gave more space to the bathroom as the number of ducts decreased and the silencer was installed to the adjacent space.

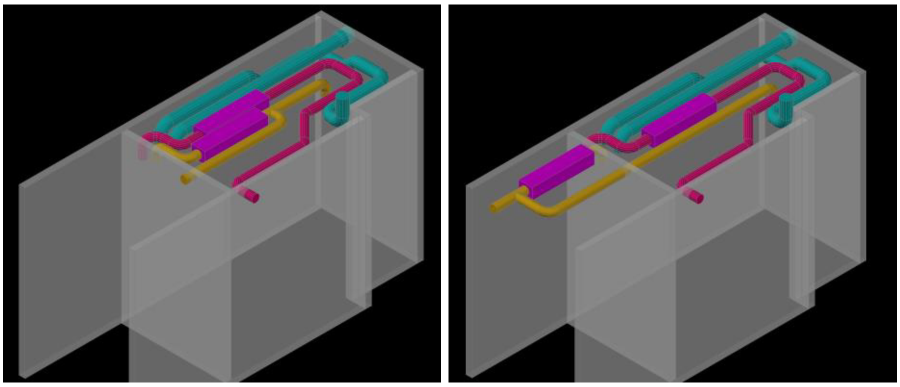

Figure 6: Ventilation ducts in suspended ceiling of bathroom and adjacent hall. Designers solution 6a on the left and installers solution 6b on the right.

Installation sequence should be reflected in designs as changing the sequence in construction phase will lead to clashes that could not be solved in designs. The coordinated models work only if they are followed. Schedule issues can affect the sequence of installations as had happened in Case 3 where plumbing works were changed to be made first. The reason was that the plumbing installations can be made during other dusty stages while ventilation installations require a dust free environment. This resulted in many deviations where pipes were installed above ducts even though ducts were designed to be installed as highest.

Duct crossing takes a significant amount of height and should be avoided or designed to fit into the installation space. In Case 1, there were duct crossings in suspended ceilings that could not fit the reserved space as designed. Figure 7 shows the crossing of two 125 mm ducts with insulation. Left side version is the designed solution and right side version is the installed version. Left hand version does not fit in the space above suspended ceiling. This is clearly shown in the BIM. However, the issue was not solved by either HVAC designer or architect. HVAC designer could have solved the issue by using the same part as the installer had used or a rectangular duct and the architect could have lowered the suspended ceiling or raised the story height. Installer had solved the issue by using a factory made crossing part that enables making the installation in the reserved space. Similar case in Case 3 is shown in Figure 8 where a crossing of two 400 mm diameter round ducts was designed to be done with rectangular duct in the size of 400mm x 200mm, as shown on the left side. Installers solution, where the crossing was made using round duct of 250 mm in diameter, can be seen on the right side. The reason for the change was given by the installer as 250 mm round duct requires the same height as 200 mm rectangular duct with flanges and using a round duct is significantly cheaper and easier to install. Using the round duct causes similar pressure loss compared to the rectangular solution so there is no impact to the functionality of the system.

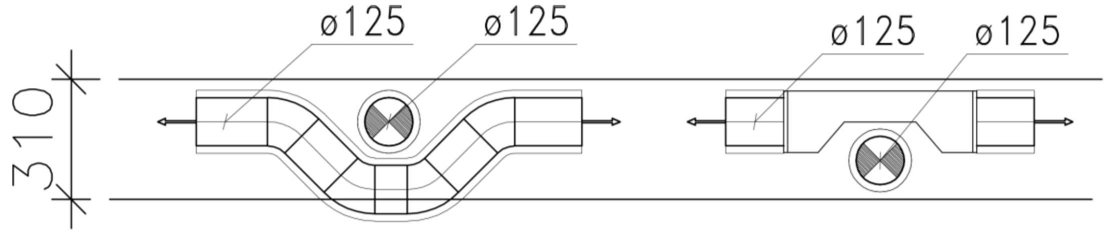

Figure 7: Using special crossing part to fit ducts into suspended ceiling without changing room height.

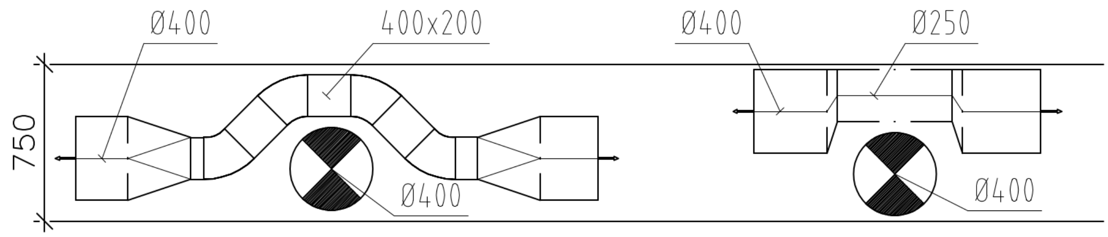

Figure 8: Changing rectangular crossing into round duct for a cheaper and faster installation.

Figure 9 shows a different case of installer changing parts for easier installation. The designer had used 90° elbow in turning a duct from vertical to horizontal under a concrete slab as seen on the left. The installer had changed the bend to a T-branch. This change enabled combining cleaning cover to the T-branch and continuing the horizontal duct in correct elevation and using fewer parts compared to designers solution.

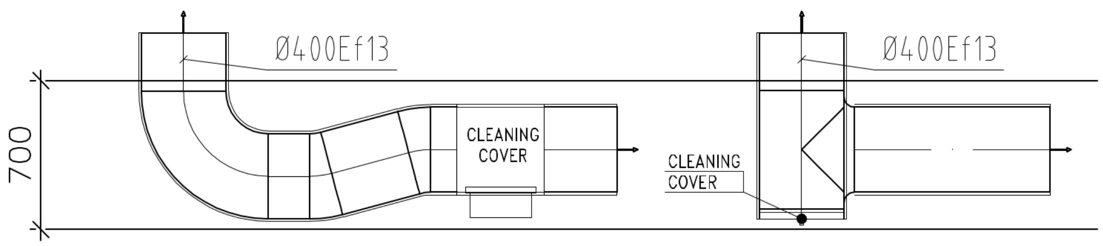

Figure 9: Changing of 90° bend into T-branch to minimize part and space usage.

INTERVIEW OF INSTALLERS

The reasons for deviating from designs are not always obvious and the feedback loop from installation to designing is minimal. For bridging this gap, installers were interviewed on site regarding specific deviations and in general about improving designs to better consider buildability. In addition to the issues described previously the installers identified areas for improvement, these are listed in Table 2.

Table 2: Suggested improvements for MEP designing from installers.

1	Assessment of buildability should be part of BIM coordination.
2	Scheduled order of installation should be reflected in designs.
3	Systems need to be considered on building level as opposed to story level.
4	Unnecessary on-site penetrations of concrete or brick walls should be avoided.
5	Architectural and structural models should be more accurate, especially in renovation projects, to consider existing structures.
6	Unmodelled components such as hangers should be further considered in designing.
7	When defining voids for concrete elements, space for insulation and hangers should be considered.

Many installers mentioned buildability in some form. Their experience was that BIM models always have clashes and buildability is not considered in designing. In addition to the examples given earlier in this paper installers mentioned considering room for using scaffolding. Toilets in Figure 3 were one location where working in the ceiling according to safety requirements using a scaffolding is difficult due to constrained space and the installers were forced to using ladders which is not permitted officially due to safety reasons. In this example they had also minimized the difficult tasks by re-routing pipes.

Scheduled order of installation should be reflected in designs. Systems that will be installed first should be designed as highest since installing will advance from top to bottom. To enable efficient installation constant elevations for systems make installation easier. Frequent changes in installation height means that installers cannot complete their own systems but instead need to wait other systems to be built to continue their own installation.

Especially in large buildings, design tasks can be divided by floors to reduce design time by adding designers. Sometimes this leads to suboptimal solutions which one installer had noticed on site. He suggested that designers should consider systems more on building level and to make sure that the systems are functioning and efficient as a whole.

Penetrations made on site are not desired as the MEP installers often have to drill them by themselves or wait for the main contractor to do it and this decreases the time they can spend making actual installations. These should be avoided if possible by routing pipes and ducts differently.

Existing structures caused many deviations in Case 2. Ventilation installer suggested that available spaces and load bearing structures should be measured in designing to solve problems better in design phase.

Many installers mentioned hangers as an area of development. Hangers were not modelled in any of the studied cases, and it is not customary in Finland. This means that space reservations for hangers are not considered and installers need to coordinate all the clashes caused by hangers. Changing locations of already installed hangers to accommodate other trades is common.

Voids in elements need to be placed so that the pipes or ducts can be installed into them. In some cases, the voids are too close to the ceiling and installing hangers above the parts becomes difficult. Ceilings can also have sound absorbing materials that are not modelled but affect the free space between voids and ceiling.

DISCUSSION AND CONCLUSIONS

The objective to convey designers' intent into installation via designs is not realized fully by using current design practices, even when BIM is used for coordination. In many cases it is not possible to execute the designs exactly as intended. In some cases, it could be said that the designs are used as schematics and routing between two points can be changed as long as the points are connected in correct sequence. The study also showed that improvisation leads to more improvisation and unclear designs lead to waste, as predicted.

Installers have a good understanding regarding buildability and in most cases had good reasons for deviating from designs. In some cases, their changes improved the engineer's solution and in some cases the changes resulted in decreased functionality. Based on the observations and interviews, having contractor comment on design and suggest changes could remove many of the documented deviations and increase productivity in installation phase. Contractors could contribute to solving possible issues in designs phase and optimizing designs based on their experience and typical construction practices. Knowing the building schedule and planned order of installation by early contractor involvement would enable designing for the installers needs.

BIM coordination does not guarantee collision free installation even if models are clash free, as was in Case 2. BIM coordination can only resolve clashes which are visible in the model. Many of the documented deviations were caused by unmodelled objects. These problems could be solved by increasing the LOD of all models. Potential of using BIM was not realized to fullest in any studied case, assessment of buildability was left undone in all cases. Increasing the LOD is a requirement for effective assessment of buildability as only visible issues can be resolved.

Observed deviations from case sites were divided into three categories: insufficient space reservations, missing model components, and buildability. All the problem types could have been solved before installation by more accurate designing. Based on our observations to improve productivity in installation we suggest the following changes to designing. 1. Designing must be done using BIM. 2. Shift from collision free models to buildable models. BIM coordination must be part of designing and it must include resolving clashes and assessment of buildability. 3. Increasing the LOD and accuracy of designs to better enable steps 1 and 2. 4. Contractor should be involved in designing and giving feedback especially on buildability, schedule, and order of installation. 5. Cost optimization based on components should be part of designing.

While positive effects of BIM use in designing have been documented extensively and coordination practices have improved continuously (Tommelein and Gholami, 2012; Jang and Lee, 2018; Khanzode et al., 2008), we found that these practices are not followed in projects in Finland, and likely other countries, where prefabrication of MEP is not yet commonplace. Therefore, we primarily suggest adopting already proven BIM practices in all types of projects. Secondly, we suggest a move from clash free models to buildable models. Projects using modelling and BIM coordination are focused on achieving clash free models but currently neglect assessing buildability in many cases. This is partly due to low level of detail in design models and designers' lack of installation knowledge. Increasing the level of detail in all design models will benefit BIM coordination as more issues can be resolved in designing. Modelling of hangers for example is common practice in markets that use prefabrication and having these additional details will help solving issues in design phase. More research is needed to determine a reasonable level of information need to guarantee that further modelling effort supports assessment of buildability.

We presented prefabrication designs as closest existing example of ideal designs. When studying barriers in adopting prefabrication in the Finnish market Lavikka et al (2021) found designers are lacking capabilities for detailed level design. Our results support this finding with many examples where buildability could have been better considered, while we recognize that contractual issues and tight deadlines may also be factors. Our proposition to solve this issue is involving contractor and installers in design phase and letting them affect designing by analyzing buildability based on their experience. One proven method for incorporating scheduling into designing is 4D BIM (Koo and Fischer, 2000; Buchmann-Slorup and Andersson, 2010), which is not widely used in the Finnish market. Using contractor knowledge in designing and having contractors designing detailed models is commonplace in markets where prefabrication is widely used (Khanzode et al., 2008). Having a feedback loop from construction to designing is critical for identifying and removing problems (Tommelein and Gholami, 2012). Contractors could also help on optimizing designs to decrease material costs. Our results showed that installers are already doing optimization on site to reduce work time and material cost.

ACKNOWLEDGMENTS

This work has been supported by Esivalmistusta tukeva suunnitteluatuomaatio (Design automation to enable prefabrication) project funded by Building 2030 Consortium. Building 2030 consortium is funded by 21 companies from the Finish construction sector.

MANAGING USER REQUIREMENTS IN SOCIAL HOUSING UPGRADING

Samira Awwal[1], Patricia Tzortzopoulos[2], Mike Kagioglou[3], and Joao Soliman-Junior[4]

ABSTRACT

User requirement management is essential to improve value generation in construction projects. Requirements management is also vital in the context of social housing upgrading/retrofit projects, as such projects generally involve a poor consideration of user needs. Design science research is adopted to propose a process model to support the identification of user needs in the social housing upgrade context. Data was gathered through an empirical study carried out in an upgrading project in the UK. The model includes the use of BIM (Building Information Modelling) based tools. The model can help elicit users' needs and values through a participatory approach and the early inclusion of stakeholders in design decision-making. The process model contributes to an improved approach to managing user requirements, which will promote better value generation through retrofit projects.

KEYWORDS

User requirements, social housing upgrading, process model, building information modelling.

INTRODUCTION

Social housing upgrading provides an opportunity to solve housing deficits (Jensen et al., 2018). However, such upgrading/retrofit projects are challenging to manage (Carvalho et al., 2019). These challenges often result in overlooking user needs and consequent poor value generation (Blomsterberg & Pedersen, 2015). User value can be generated through the appropriate identification, processing and communication of requirements to assist design decision-making (Parsanezhad et al., 2016; Koskela, 2000).

Requirements management is essential in Lean. It includes capturing and eliciting client requirements, as well as monitoring the value generated from the user's point of view (Koskela, 2000). The approach involves gathering and processing information, and implementing strategies to support value generation throughout the design and construction phase (Jallow et al., 2014).

In the social housing context, there is a push towards upgrading/retrofitting the existing housing stock to achieve better energy efficiency. Such upgrading projects also can be an opportunity to increase user satisfaction (Kowaltowski & Granja, 2011; Baldauf et al., 2020).

The conflicting interest among stakeholders and end-users highlight the need for a robust method to capture user needs during such projects (Koskela, 2000).

POEs (post-occupancy evaluations), surveys and interviews are often used to elicit user requirements (Miron &Formoso, 2003). BIM can also be used for storing and structuring requirements, and connecting that information to building models for visualising requirements (Parsanezhad et al., 2016; Baldauf et al., 2021). This paper proposes a process model (adapted from Baldauf et al., 2020's paper) to illustrate user requirements management with BIM in the specific social housing upgrading process.

REQUIREMENTS MANAGEMENT

User requirements are often referred to as objectives, needs and expectations of the client/user in a construction project (Jallow et al., 2014; Kamara & Anumba, 2000; Kamara et al., 2002). The requirements management process incorporates initiation, development, adaptation and communication or requirement throughout the project (Barrett et al., 1999; Kamara et al., 2002).

Baldauf et al., (2020) proposed a client requirements management model with the use of BIM tools, which includes the following steps (i) identify-understanding the context and capturing requirements; (ii) analyse-interpretation of requirements; (iii) structure - organising the requirements); (iv) translate - conversion of requirements into product specification; (v) store ; (vi) prioritise - identifying the critical requirements from the categories from the users and stakeholders; (vii) communicate - liaise among stakeholders to facilitate design decisions to avoid conflict; (viii) assess - assessing the product development; to check if all the requirements are met (Baldauf et al., 2020, 2021; Bryde et al., 2013; Jallow et al., 2014; Kamara et al., 2002; Luo et al., 2010; Miron & Formoso, 2003; Pegoraro & Paula, 2017).

USE OF BIM IN REQUIREMENTS MANAGEMENT

BIM can facilitate collaboration between stakeholders by providing easy access to information (Jallow et al., 2014; Kamara et al., 2002; Baldauf et al., 2021). Past studies have developed computer tools allowing connections between requirements and product models (Baldauf et al., 2020; Luo et al., 2010). Figure 1 illustrates connections between client requirement management (CRM) steps and BIM.

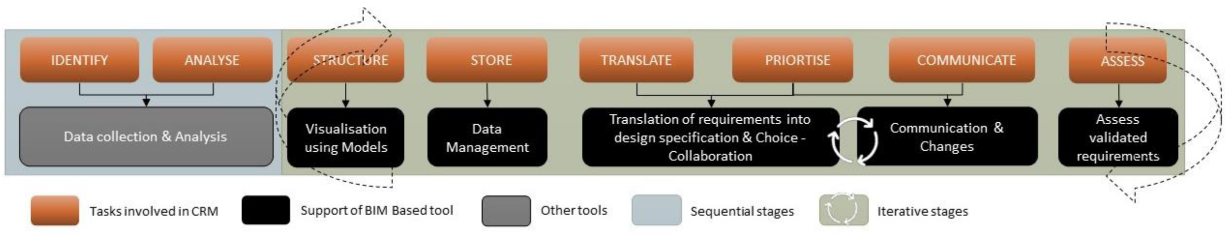

Figure 1: Connection between CRM steps and BIM

Potential BIM benefits in client requirement management are described below for further understanding:

- Data Management - BIM serves as data storage in a single centralised database system and facilitates easy and accessible information to the stakeholders through the 3D model. (Meadati & Irizarry, 2010). BIM allows the storage of requirement information so that the stakeholders' requirements can be accessed and reused at particular points of the project (Baldauf et al., 2021; Jallow et al., 2014; Luo et al., 2010). BIM stores lifecycle data requirements, and operational information that can be used in the requirements management (Jallow et al., 2014; Nørkjaer Gade et al., 2019).
- Visualisation-Visualisation is one of the primary characteristics of BIM and there are potential benefits when implementing 3D/4D BIM in the construction industry to

structure user requirements (Baldauf et al., 2020, 2021; Wang et al., 2014). BIM allows improved client service, using an accurate visualisation (Azhar et al., 2011).

- Collaboration - BIM allows collaboration through a faster and more effective process (Baldauf et al., 2020). All the stakeholders' requirements should be incorporated at the initial stage (e.g., the Briefing stage (Jallow et al., 2014). There should be a connection between the requirements and objects in product development, that will allow value generation in the process (Kiviniemi, 2005).
- Communication & changes- BIM allows changes in product attributes. It contributes to the communication in real-time changes in requirements that can be refined in the model recurrently (Awwal et al., 2022; Luo et al., 2010). BIM provides quicker simulations to simplify the generation of alternative design solutions (Azhar et al., 2011).
- Assess - BIM administers sufficient support for assessing design decisions, depending on validated requirements (Tzortzopoulos et al., 2019; Soliman-Junior, Awwal, Tzortzopoulos, et al., 2022). It can be used to check if the design process of the product considered stakeholders' requirements to ensure value generation (Baldauf et al., 2020).

Requirements management plays a vital role in generating value for users. It is well known that BIM can support the modelling of client requirements (Baldauf et al., 2020). However, there is little evidence in the literature of adaptations needed for its use in the context of social housing upgrades.

RESEARCH METHOD

RESEARCH DESIGN

Design Science Research (DSR) was adopted in this investigation. The products of Design Science Research are (i) constructs; (ii) models; (iii) methods; and (iv)implementations (March & Smith, 1995). This investigation proposes a process model to manage client requirements in the social housing upgrading context (see Figure 2).

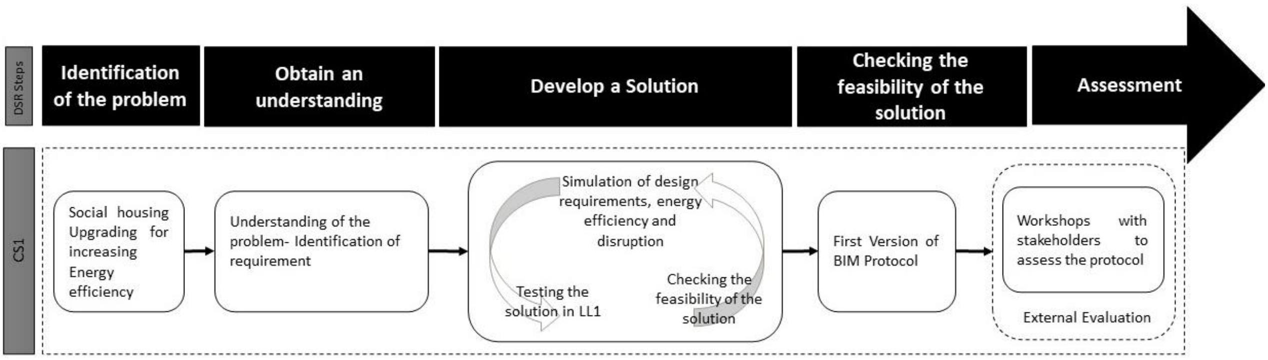

Figure 2: The Research Design

Each research phase consists of five steps based on (Kasanen et al., 1993)'s model : (i) identification of the problem; (ii) obtain an understanding; (iii) develop a solution; (iv) check the feasibility of the solution and (v) assessment.

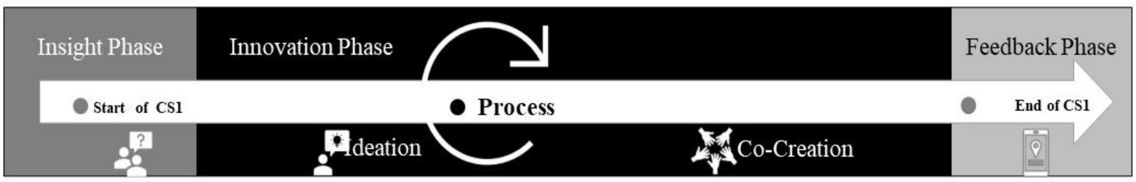

Figure 3: The Phases of the Case Study

The data was collected through the retrofit of 8 social housing dwellings in West Yorkshire, UK. Three workshops were developed to identify user needs and help reduce conflicts between stakeholders, supporting a participatory upgrading process (Keyson and Lockton, 2016). The workshops included: a. Insight; identification and capture of user's requirements; b. Innovation; consisting of ideation and co-creation; and c. Feedback; evaluation (see Figure 3), that follows an iterative process to foster collaboration (Tang & Hämäläinen, 2014).

The workshops were planned to involve the local council, architects, retrofit coordinator, construction company, and tenants/users of the social houses to be upgraded). However, only users and the local council were effectively engaged in the workshops. The council selected 8 houses for retrofit (See Figure 4), mainly aimed at improving their energy efficiency.

Figure 4: Before (left) and After(right) image of the social housing retrofit case study

The retrofit work is now completed (See Figure 4), and the following components were changed/implemented; (i) heat pumps were installed, gas boilers and cookers were removed ending reliance on fossil fuel; (ii) triple glazed windows, loft insulation, cavity wall insulation and external wall insulation were provided, (iii) new roofs were fitted and chimneys closed to remove a possible cold bridge; (iv) Photovoltaic panels and solar thermal panels were installed to create renewable solar energy (v) new entrance doors installed, new bins stall and backyard fences are installed. Figure 5 depicts the timeline of the case studied.

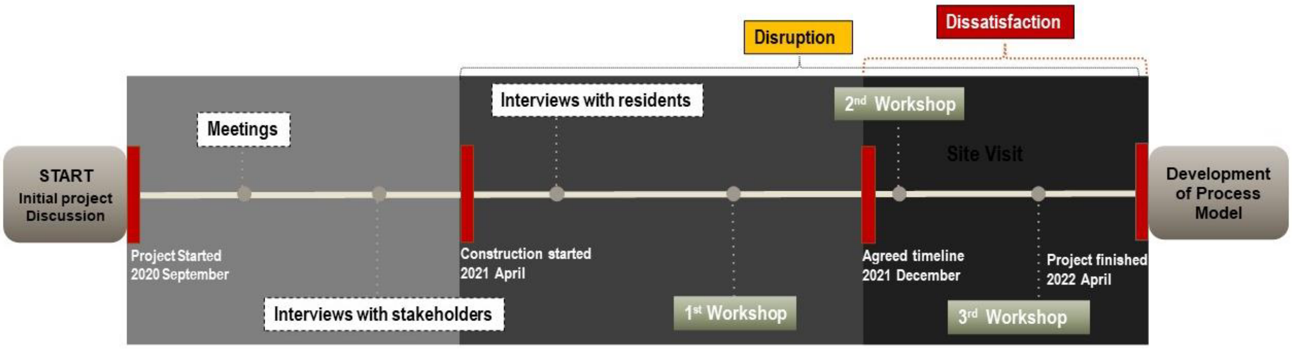

Figure 5: Timeline of the case study

The empirical data was collected from 11 interviews, which included 5 residents from the selected upgrading project and 6 residents from the wider estate. The interview protocol consisted of (i) residents' satisfaction with their homes; (ii) Laddering (what are the three most important things to be upgraded in the house and why); (iii) profile of the residents.

Workshops (see Table 1) were facilitated to capture requirements and to evaluate design versus users' needs. The 1st workshop included four members of the council and four researchers, targeting to better understand how different tools help capture user requirements and help increase end-user participation in the upgrading project. The 2nd and 3rd workshops included three end-users and four researchers, aiming to further understand requirements and experiment with the use of digital models.

Table 1: Sources of Evidence

Source of Evidence	Stakeholders	BIM-Based Tool	Occurrence
Workshop 1 Testing tools to understand requirements and values	• Four Council Members Four Researchers	• BIM: Exiting model, value cards& evaluation of tools	Developed- 11 Jan 2022
Workshops 2 & 3 (i) Testing requirements through BIM immersive experience (ii)Design vs Values	• Four End Users (Tenant) Four Researchers	• BIM: Existing Model & developed design model, value cards and evaluation tools	Developed- 21 Feb 2022

RESULTS

Table 2 presents some interview results, including the highest dissatisfaction elements identified in the existing houses. These indicate focal elements for consideration as part of the upgrade of the houses. Unfortunately, not all requirements were considered in the upgrading process by the council due to financial constraints.

Table 2: Dissatisfaction with product attribute

Key Criteria	Product Attributes	Dissatisfaction Rate
• Dimension and space layouts	• Dining space, Kitchen, Storage	High
• Materials, finishes, equipment	• Doors, windows, wall cladding	Very High
• Acoustics, temperature, privacy	• Winter temperature, privacy, noise	Very High
• Env.quality, safety, accessibility	• Accessibility for the elderly	High
• Consumption, maintenance	• Energy costs/ utility costs, heating system performance	Very High

During the workshops, BIM models were used for (i) Real-time rendering linked to BIM; (ii) BIM models used in a 3-sided Immersive Cave. BIM models of the houses as existing, and the newly designed solution were developed and displayed in the workshops (see Figure 6). Examples of alternative solutions (e.g., colours of windows, fencing materials etc, scaffolding construction) were explored. The tools developed assisted in eliciting user requirements. The tools can, in the future, be used to support generating design options and evaluation through visualisation.

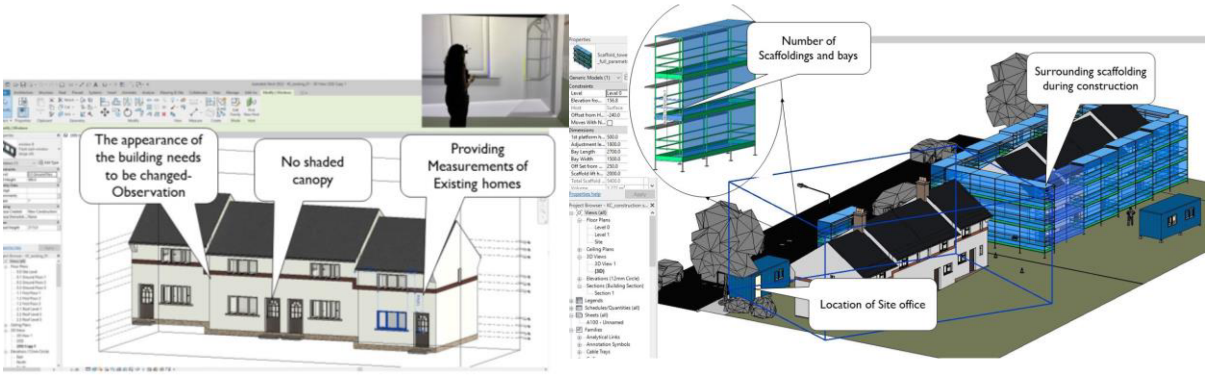

Figure 6: The BIM Model developed in the CS1

The BIM tools foster communication and collaboration by considering multiple stakeholders' needs, aiming to reduce conflicts and misinterpretations, and supporting improved value generation.

THE PROCESS MODEL

The proposed model adopts the stages presented in Baldauf et al. (2021) requirement management model, including the steps displayed in Figure 1. The process consists of sequential and iterative stages. Figure 6 shows the process model to manage user requirements with BIM in social housing upgrading projects.

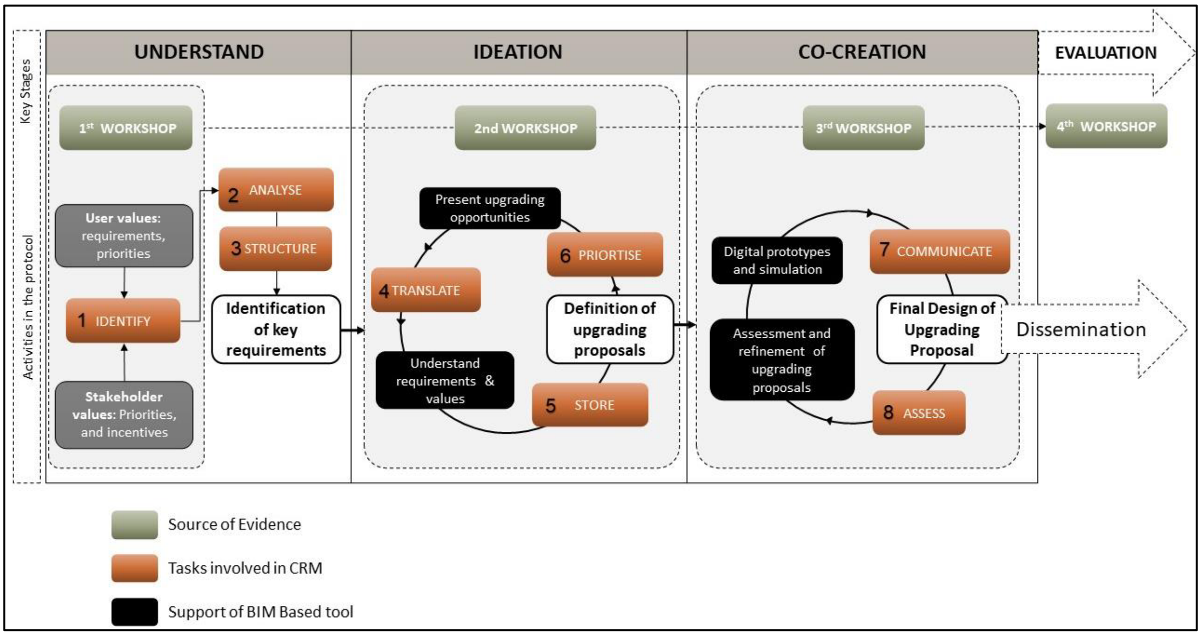

Figure 7: User's requirements management process model for social housing retrofits

The process starts with the identification of stakeholders and their priorities, which need to be analysed and structured in the next phase. The structured requirements need to be embedded in design solutions, and connected in BIM to architectural elements such as building spaces, the colour of the fence etc. BIM (e.g., Autodesk Revit) enables the required data to be stored and reused.

Design alternatives for the upgrade project should be presented visually (through diverse BIM models, i.e., one per alternative to be discussed) and shown to stakeholders. Such joint discussions should enable any conflicting requirements to be identified, and joint decision-making to happen. All information should be accessible to multiple stakeholders at various stages of the design process.

BIM-enabled experimentation through immersive environments, digital prototyping and animation/video rendering allows end-users to directly participate in the design process, which will support the generation of user value in the upgrading process. The last phase involves an evaluation of the process. The main steps are further detailed as follows.

Step 1-Identify: commences with the identification of stakeholders and capturing requirements. These priorities will be based on the purpose of the upgrading project (e.g., energy efficiency upgrading). In the case studied, the initial requirements were limited to energy efficiency, without further consideration of other users' requirements. Hence, mostly product attributes were considered (e.g., energy efficiency, installation of heat pumps), rather than connecting the project users' needs.

Step 2-Analyse: In the analysis phase, multiple sources of information should be considered for capturing and eliciting requirements. For instance, in this investigation, different stakeholders, such as councillors, retrofit co-ordinator, council members, design and construction team and tenants were interviewed. As there are boundaries regarding cost and construction issues, not all initial requirements may be implemented in the upgrade. It is important that these are prioritised accordingly, with input from all stakeholders.

Step 3-Structure: This is based on organising the collected requirements. This can also be based on existing taxonomies (e.g., Baldauf 2020's structure). Structuring the requirements will support the translation of the requirements into design solutions.

Step 4-Translate: Step 4 focuses on translating the requirements into design solutions. For instance, the initial requirements can now be connected to a digital model and presented to the stakeholders.

Step 5-Store: Requirements must be stored in BIM software and can be available to the main stakeholders. For instance, the information stored in the digital model in this investigation has been reused for eliciting client requirements in multiple workshops and meetings.

Step 6-Prioritise: BIM - can support prioritisation through the digital model. These are communicated to the stakeholders through virtual reality and real-time rendering. There are multiple stakeholders in social housing upgrading (e.g., tenants, council members, design, and construction team, retrofit coordinator etc) and their needs need to be considered.

Step 7-Communicate: Communication improves through the use of BIM. During the workshops, users pointed out that the digital models and real-time rendering enabled a much better understanding of the user of changes to be implemented in their homes and enable space for discussions on what would be most appropriate to be implemented, from the users' perspective. As discussed in (Soliman-Junior, Awwal, Tzortzopoulos, et al., 2022), the interviews also reported that BIM-based requirement models would support an improved understanding of the project.

Step 8-Assess: the requirements management process needs to be assessed at the end of the upgrade, so improvements can be implemented in next projects.

The above process aims to provide a better approach to facilitate the design of social housing upgrading projects and enable collaboration to manage requirements.

CLOSING REMARKS

Requirement management explores solutions for managing stakeholders' requirements in construction projects (Jallow et al., 2014). This research highlights the importance of requirement management in social housing upgrading. The discussion highlights that the adoption of the proposed process model can improve the generation of value and the ability of social housing users to co-create design solutions for the upgrade of their homes. End users and stakeholders (council, construction companies, architectural enterprise) are fundamental actors and their requirements should be key drivers in the design and delivery of upgrading solutions (Soliman-Junior et al., 2021).

The process model allows communication through visual management, iteration, and opportunities for feedback in the phases. A summary of how the process model addresses lean principles is presented in Table 3. The findings presented in Table 3 are consistent with some early synergies identified between Living Labs and Lean in (Soliman-Junior et al., 2021)'s paper.

Table 3: Lean principles and CRM Process Model in Social housing upgrading

Lean Principle (Koskela, 1993)	Process Model
Increase Value	• Requirement management focuses on early stakeholder collaboration, that generates value. • Participatory approaches are practised through ideation and co-creation. • The process model aims to support collective decision-making.
Increase process transparency	• Use of BIM to increase transparency and collaboration among stakeholders.
Use visual management	• Using BIM potentially allows for a real-time change in the models, and can be part of visual management processes.
Continuous improvement	• The process is iterative and allows for assessment and refinements in the design process.
Reduce cycle times	• The process allows accelerated feedback loops, minimising errors and thus contributing to the reduction of cycle times.

There are some limitations to this investigation. The artefact suggested (requirements management process model) was developed based on a single and relatively small empirical study. It should also be highlighted that only the researchers developed the BIM models and applied them in the case study to capture and elicit user requirements. This method is not thoroughly applied and tested in another case study; further research is needed to assess the applicability of the artefact. The scope of product attributes to be upgraded was limited due to cost and the council's suggestions. Further empirical data is needed to generalise the artefact's applicability to other upgrading projects.

Despite the limitations, the contribution of this investigation is the introduction of the steps such as identifying and capturing the requirements of end-users, structuring the digital model, storing information, and accessing them at different stages of the project to avoid conflict, and the use of the BIM-based tools in the process to increase collaboration among stakeholders. Also, lean construction practices as described in Table 3 could be further enhanced by using the process model in social housing upgrading. These provide the opportunity to improve understanding of requirements at multiple stages (e.g., preliminary design, development, and construction phase) of the upgrading process, enabling problems to be addressed transparently and facilitating better communication among multiple stakeholders.

ACKNOWLEDGEMENTS

This paper reports on partial results from the u-VITAL project, funded by the Trans-Atlantic Platform for Social Sciences and Humanities and the Economic and Social Research Council (ESRC) (ES/T015160/1). The authors would also like to thank the Innovative Design Lab (IDL) for their financial support.

MANAGING HUMAN-CENTERED INNOVATION WITHIN TVD IN HEALTHCARE PROJECTS

Patricia A Tillmann[1] and Stuart Eckblad[2]

ABSTRACT

Responsible for delivering major healthcare projects, the University of California in San Francisco (UCSF) has devised creative ways of reducing waste and increasing value through project delivery. In a previous paper, we described UCSF Health's journey to rethink project delivery practices. The adoption of Target Value Delivery (TVD) is a core enabler of their success. The University has consistently adopted TVD to deliver complex healthcare projects within or below their allowable costs. Previous papers have provided evidence and insights into why and how such success has been achieved. However, the focus so far has been on collaboration and cost management. This paper describes the strategies utilized to focus on and manage value generation. The term human-centered innovation was chosen to emphasize stakeholder engagement and empathy building as input to idea generation. This approach shaped how TVD is implemented in these case studies. Its analysis provided insights into complementary design and decision-making strategies traditionally used in TVD. In particular, the design strategies observed in this research expand the documentation of TVD best practices to include not only solution development strategies but also participatory and empathic ways of understanding, framing, and reframing design problems.

KEYWORDS

Target Value Design, Value Management, Value Generation, Integrated Project Delivery, and Healthcare Design.

INTRODUCTION

Target Value Design (TVD) is a lean design and construction method that focuses on achieving the target cost of a project while ensuring its quality, performance, and expected outcomes. In TVD, the cost is considered an input throughout the design process. Project teams steer the design process through trade-off decisions to achieve the target cost while maintaining the desired quality and expected performance.

Initially introduced in the manufacturing industry, the first time TVD was successfully adopted in the construction industry was in 2002, in the St. Olaf's College Project in Northfield, Minnesota, by the Boldt Company (Ballard; Reiser, 2004). Since then, the approach has increased in popularity and adoption in the U.S., generating lessons learned and best practices based on its practical application (e.g., Ballard, 2008; 2011).

The name TVD can be traced back to Toyota's Target costing approach. Target costing has been defined as a *"system of profit planning and cost management that is price-led, customer-focused, design-centered, and cross-functional"* (Ansari *et al*., 1997). Macomber et al. (2007) proposed a shift from "target cost" to "target value design" to emphasize that

[1] Senior Manager for Lean Project Development, The Boldt Company, San Francisco, USA. Patricia.tillmann@boldt.com, https://orcid.org/0000-0003-3420-3132

construction projects are not limited to cost and that the delivery of value to customers is paramount.

However, since its successful adoption in the early 2000s, its increased popularity has been associated with its ability to steer projects to meet or exceed financial performance successfully. Thus, its documentation in the literature focuses primarily on describing how those financial goals have been achieved in the different projects. At the same time, the aspects of managing value to customers are less explicit in the literature. Hence, the research question that motivated this study was: How can we improve value management within target value design to focus more on customer value (along with steering a project to a target cost)?

This paper aims to contribute to closing this gap by offering a perspective on managing human-centered innovation to focus on customer value. Such an approach has been successfully adopted within the application of TVD in multiple case studies. The term "human-centered innovation" was chosen to illustrate its focus on stakeholder engagement and participation in the TVD process. Human-centered design is a term often used to describe design philosophies and practices that offer a humanistic perspective on innovation theory and practice (Auernhamme & Roth, 2021).

The research method used in this paper is a multi-case study approach. Figure 1 summarizes the characteristics of all case studies. These case studies were selected because they successfully adopted TVD to deliver projects within their targets for costs, scope and performance, while adopting a unique approach to managing customer value. Data from the case studies started to be collected in 2013 through a research project. Data-gathering techniques changed over the years. From 2013-2016 data were collected by several researchers and graduate students from the UC Berkeley P2SL laboratory through interviews and document analysis. From 2016-2019 one of the researchers joined UCSF's Real Estate Department, changing data collection methods to focus group discussions, document analysis, and participant observation. In 2021, the same person joined one of the analyzed projects under UCSF Health, shifting data collection techniques to participant observation and interviews. This paper reflects on the data collected and insights gained over the years.

Table 1: Summary of Case Studies Characteristics

	Case 1	Case 2	Case 3	Case 4
	2005	2015	2015	2019

Initial Estimate	1.5 bi	275 mi	170 mi	4.5 bi
TVD Savings	200 mi	19 mi	TBD	TBD

A LOOK THROUGH THE LENSES OF HUMAN-CENTRISM

Human-centered design (HCD) is a term often used to describe design philosophies and practices that offer a humanistic perspective on innovation theory and practice (Auernhamme & Roth, 2021). This approach generally implies an active engagement of customers in the product development process (Dell'Era & Landoni, 2014). The concept of HCD is rooted in the belief that the design process should be centered on empathetic thinking and focused on the needs, perspectives, and experiences of the people who will use the design solution.

The empathic design was presented as a process that involved observation, data collection and analysis, and iterative prototyping. Most significantly, it was identified as a way to uncover people's unspoken latent needs and then address them through design (Leonard & Rayport, 1997). It relies heavily on ethnographic research methods to uncover not what people are doing

[3] CMAR – Construction Manager at Risk, DB – Design Build, IFOA – Integrated Form of Agreement

but also the reason behind their actions in an attempt to understand how people make sense of what they do (Diller, Steve; Shedroff, Nathan; Rhea, Darrell, 2005).

Beckman and Barry (2007) explain that HCD belongs to a second generation of design theories and methods that depart from traditional design approaches. On the one hand, the first generation leveraged operations research and optimization techniques, leading designers to think explicitly about how to decompose a complex problem into a set of smaller, well-defined problems, assuming that all these problems can be predicted, well-defined, and made explicit upfront. On the other hand, the second generation focuses on collaboration, co-creation, and leveraging the tacit knowledge of stakeholders, who are deeply engaged in the design process. The design then shifts from a clear-cut problem-solving process to a problem-formulating process in which getting to a collectively acceptable starting point (so that appropriate resources could be committed to solving the problem) is the core of the effort (Beckman & Barry, 2007).

There are several key differences between first and second-generation design theories and methods. Firstly, the designer takes on a facilitative role, guiding and supporting the stakeholders in the design process. Secondly, stakeholders' involvement changes from consultation to active participation in the design process. Thirdly, the design is iterative and flexible, allowing for multiple rounds of feedback and iteration, generally resulting in a solution shaped by the stakeholders' collective perspectives and experiences.

Based on human-centered design literature, Beckman (2022) developed an "innovation cycle," suggesting that human-centered innovation occurs in four quadrants within a learning cycle. This "innovation cycle" was used in this paper to guide empirical data collection and support the understanding of findings. Its four elements are described as follows (Quadrants 1 and 2 represent the "understanding the problem" or "why" portion of idea generation, whereas Quadrants 3 and 4 represent the "solution finding" or "how" portion of idea testing and implementation):

- Reflective observation and empathy building (Observe and notice - Quadrant 1): Fostering empathy for customers by considering their experiences and needs throughout the design process. Ethnographic research methods can help designers understand the emotional, social, and physical aspects of customer experiences.
- Abstract conceptualization (Frame and reframe - Quadrant 2): It is the understanding and synthesis of data gathered. It is the process of integrating different components to create new experiences. Frame and reframe is the process of getting to abstract conceptualization.
- Active experimentation (Imagine and design - Quadrant 3): Generating options and validating ideas through quick experiments. Iterating on the design solution based on feedback from stakeholders to ensure that the design meets their needs and requirements.
- Concrete experience (Make and experiment - Quadrant 4): Getting to the how. Materializing the ideas into artifacts or products. Testing it in the context of use.

Design theory and design methods are not topics covered in papers that describe best practices for TVD (i.e., Ballard 2008; 2011). By bringing this distinction between the first and second generations of design methods, the intent of this brief literature review was to highlight that different design approaches can support the adoption of TVD.

Past research has identified difficulties in applying tools associated with first-generation design methods, i.e., tools that aim to make all requirements explicit upfront (Sahadevan & Varghese, 2018) or to decompose problems into well-defined pieces (Lima et al., 2008). However, their theoretical underpinnings are rarely discussed. Similarly, several studies describe the successful adoption of methods and techniques that support dialogue and the collective understanding of problems-solution space, such as the collaboration that happens in multi-disciplinary design clusters, participatory design processes, set-based design, and Choosing-by-Advantages (CBA) (Ballard, 2011; Bascoul et al., 2018; Parrish & Tommelein, 2009; Arroyo, 2014). Although these approaches align with second-generation design theories, their theoretical underpinnings are rarely discussed. This literature review aimed to bring these distinctions to light so that these approaches and their contributions can be better understood from a theoretical standpoint.

EMPIRICAL FINDINGS

The University of California San Francisco (UCSF) is a public institution dedicated exclusively to health science. It focuses on research, education, and patient care, employing 3,400 faculty and 22,800 staff. UCSF generates nearly 43,000 jobs and has an $8.9 billion economic impact in the Bay Area, California, U.S.

UCSF Health is a department of UCSF focused on the delivery of care. It administers the University's hospitals and clinics: (a) UCSF Medical Center at Parnassus, Mount Zion, and Mission Bay; (b) UCSF Benioff Children's Hospitals in San Francisco and Oakland; and (c) Primary care and specialty clinics throughout Northern California. In addition, the department receives comprehensive project management services from UCSF Real Estate's Health Design & Construction unit, including programming and design, budget development, construction administration, inspection, and move-in assistance.

Since 2006, UCSF Real Estate's Health Design & Construction unit has undertaken a long journey to reshape project delivery practices within the University, introducing mechanisms to design, build and operate cutting-edge care facilities successfully. The University has chosen a very participatory route to deliver projects, which will be described in the following sessions.

1. The owner organization and key stakeholders

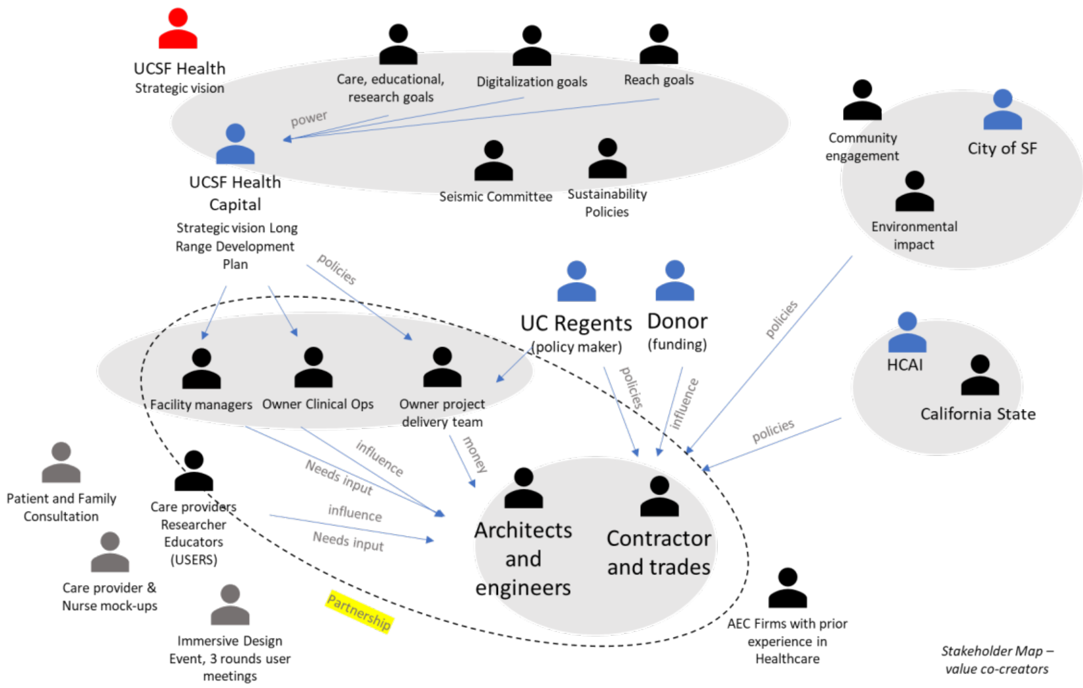

Figure 1: Key stakeholders involved (typical of all case studies)

There is a complex chain of stakeholders that influences the outcomes of a project. In these case studies, we have identified the following owner groups: (a) owner stakeholders who influence through their strategic vision for the organization and goals for the project, (b) owner clinical operations team, user groups, and patient representative groups that have more immediate requirements based on their current practice, (c) owner policy deployment teams, such as sustainability, seismic requirements, health policies compliance, etc. (d) owner technology department; and (e) facilities management group. Outside the owner organization, several key stakeholders also influence the project: (a) the city's community engagement program, (b) the city's environmental requirements committee, (c) the healthcare seismic state agency, and (d) the city's code compliance agency. The type of influence each stakeholder brings is also identified in the picture. The types of influences were characterized by: (a) policymakers, (b) resource control, (c) decision-making power, and (d) required input due to the participatory nature of project delivery.

For each of these stakeholder groups presented in the picture, there are accompanying documents that aim to clarify their requirements and set the parameters for the project. The first type of document applies to several projects within that organization, and examples are seismic and sustainability policies, city codes, university guidelines for new construction, etc. The second type applies to this project and developed in the front end of project development (before the project team was onboard) – business case and programmatic requirements. Finally, the third type is developed by the project team to capture the input of key stakeholders – project charter and conditions of satisfaction, patient and user surveys, user feedback on prototypes, community engagement feedback, etc.

Despite the efforts to make all requirements explicit and documented, this environment is quite dynamic - non-identified stakeholders emerge, new individuals replace existing roles, circumstances surrounding the owner and their business change, and with that, multiple requirements emerge continuously through project delivery. That creates tension between explicit and tacit knowledge with a never-ending need to review and update what has been documented.

To deal with this dynamicity and tackle the tacit knowledge around stakeholder requirements, an integrated project delivery strategy has been adopted to support a participatory process. As portrayed in the picture, a partnership is formed between representatives from the owner organization, builders, and designers. Important to note that in this case, the owner organization is represented not only by the design and construction management team but also by the clinical operations, the information technology, and the facilities management department within the University. In the project directories, about 20% of the individuals are from the owner organization.

2. The project delivery strategy

In previous papers, the authors explained the strategies used in these projects to increase collaboration and integration in project delivery (Melo et al., 2015; Tillmann et al., 2022). Regardless of contract type, all projects benefited from mechanisms to increase relatedness among participants, mitigate diverging interests and align participants with acting as one single team. In this paper, these mechanisms are summarized into three categories (Figure 2):

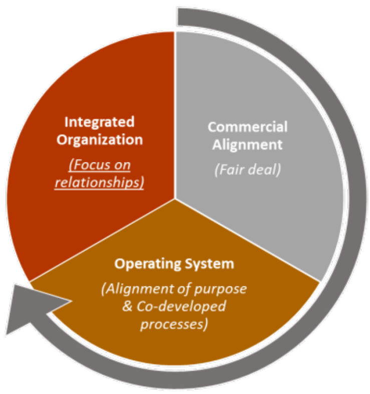

Figure 2: The three critical dimensions of collaborative project delivery

- Integrated organization (the ultimate goal): Co-location, multi-functional teams - the ultimate goal is to make companies behave like a single company with aligned objectives.
- Commercial alignment: sharing risks and rewards (when possible), being open about project finance, expected profit margin, and managing risks collectively.
- Operating system: Agreed upon routine and meeting cadence, Innovation in Design and Construction Center, Use of BIM for progress communication. Lean methods: Target Value Delivery and Last Planner System.

These mechanisms intend to focus on the relationship among parties and create a sense of unity in the purpose and processes of the project. This series of projects has been consistent with the successful application of Target Value Delivery, not only by meeting the target cost but also by meeting or exceeding programmatic and business case expectations.

The focus on value generation and value for customers was an expectation set since the early stages of all projects. In Case Study 1, for instance, the owner set the expectations for the team to *"make decisions by consensus but based on what is best for the project, not individual companies"* on Case 2, the selection process included the expectation that the team *"should work with the ultimate purpose to cure cancer"*; and on Case 4, the expectation set was that *"decisions are made based on what is best for patients."* During interviews, the owner explained that UCSF Health has a very easy-to-remember mission statement: Caring, Healing, Teaching, and Discovering. Those words are always mentioned when the team introduces themselves to potential partners during the selection process: *"This is who we are, and everything we do should always be to support this mission."*

One of the critical elements contributing to this focus on value is the project organizational structure and the owner-stakeholder integration. The projects are organized in Project Innovation Teams, multi-disciplinary cluster groups composed of designers, consultants, owner stakeholders, engineers, and builders. The owner stakeholders may also manage these clusters. In Case 4, for instance, out of the 12 PITs in the project, one is managed by the clinical, operational side of UCSF Health, acting as a liaison to UCSF clinical staff and users. Designers, builders, and consultants are also part of this PIT, gathering customer information, brainstorming design ideas, and developing options to validate with the different stakeholder groups.

In that same project, the other PITs were led by industry partners but also included the active participation of owner representatives, who helped co-design solutions and provided support to capture input from other stakeholder groups. For example, the MEP PIT was led by the general contractor but had the participation of owner representatives that engaged facilities management staff in providing information and feedback on design.

In Case 4, the decision-making structure also represented an integration of the owner's construction management team and the owner's clinical operations team, having seats on the Project Management Team and Senior Management Team and acting as liaisons to the University's leadership group.

An analysis of this team's weekly routine provided insight into how such a structure is operated. During a typical week, the team spent: (a) 50% of the time on Project Innovation meetings - generating ideas, discussing requirements, and resolving interdependencies or conflicts; (b) 25% of time consulting stakeholders and receiving feedback on ideas; (c) 12 % of time coordinating specialty work and solving interdependencies among systems; (d) 10% of the time on meetings to make decisions, and (e) 8% of the time on deploying strategies to improve team's culture. Naturally, these percentages will change depending on the project phase, but this snapshot illustrates how this structure works during the early design development phases.

3. TVD and the adoption of human-centered innovation strategies

All case studies followed a similar TVD process, which is comprehensively described by Melo et al. (2015). In this session, the specific items that refer to managing customer value and customer requirements are described. Beckman's "innovation cycle" described in the literature review was used here to provide a framework to analyze the findings. Below is a list of strategies observed in the projects, categorized according to the four quadrants of the innovation cycle:

a) Reflective observation and empathy building (observe and notice):
   - Hybrid team of owner stakeholders and industry practitioners engaged from early project stages. That allows project participants to build empathy and understand better the why behind requests, preferences, decisions, and also limitations or consequences of their requests;
   - A validation study that is carried out collaboratively by this hybrid team;
   - Owner stakeholders as an integral part of the team – i.e., managing PITs for idea creation, evaluation, and liaison with other stakeholders with a strong message around the expectations to focus on what is best for patients;
   - Active participation of key external stakeholders in idea creation (i.e., permitting agencies, inspector), who are dedicated exclusively to the project and act as an integral part of the team;
   - Extensive stakeholder consultation throughout the different phases of design, which in this case includes patients, users, donors, owner leadership, city community, regulatory agencies, etc.; and
   - ICDC Academy, a series of presentations by UCSF clinical staff and other critical stakeholders in the big room, allows the team to engage with them and ask questions about their work and expectations regarding the project. The academy generally starts at the end of validation and runs throughout the construction phase, allowing for empathy building by those working in the field. Interviewees have expressed that this emphasis supports team building as it creates a unified culture driven by a greater purpose.

b) Abstract conceptualization (a collective effort of framing and reframing the problem)
   - Multidisciplinary Project Innovation Teams with owner stakeholders' involvement, where most of the ideation process happens. Here ideas are discussed, often leading to a co-designed solution;
   - Multi-disciplinary innovation, which is (temporary) workshops set up anytime the team needs to extend the time spent on PITs to further frame and reframe the problem and solutions with a specific scope (these meetings can be initiated by any team member – including owner stakeholders); and
   - Some strategies help the team to set the boundaries for problem framing and reframing. Examples are: (a) cost modeling methods, (b) design constraints to support pre-fabrication and easiness of logistics and installation, (c) project priorities represented in the project Conditions of Satisfaction; and (d) defined priorities for the decision-making process that is collectively defined by the integrated team (or discussion of factors to be considered during CBA processes).

c) Active experimentation and validation (imagine and co-design)
   - Cloud-based Innovation Log, this is a tank of ideas that all team members have access to and can contribute with ideas;
   - Set-based design, used to mature certain areas where the team sees multiple options could bring similar benefits to the project;

- Immersive Design Events are examples of workshops held to dive deeper into the needs and preferences of clinical staff and validate some of the designer's early assumptions. Also in that category are patient surveys built around design options and virtual mock-ups built early to validate some operational workflows with staff;
- CBAs and A3s are used as methods for presenting and discussing ideas; and
- Physical mock-ups, virtual mock-ups, and virtual reality are used to validate ideas and assumptions.

d) Concrete experimentation (make and experiment)[4]

- Value engineering here means design options that were validated and decided on but had to be revisited as saving opportunities emerged, indicating that the team learned something new. Based on this new information, that design should be revisited.
- Continuous estimating was placed here to illustrate a similar point. Options are sometimes drawn first and only later sent to estimators for cost input, who provide feedback. The team then learns about new cost implications and revisits the design seeking alternative solutions.

The picture below represents the observed initiatives displayed in the four quadrants of the innovation cycle (adapted from Beckman, 2022). This picture also distinguishes between the strategies observed in these case studies and typical strategies used in the application of TVD.

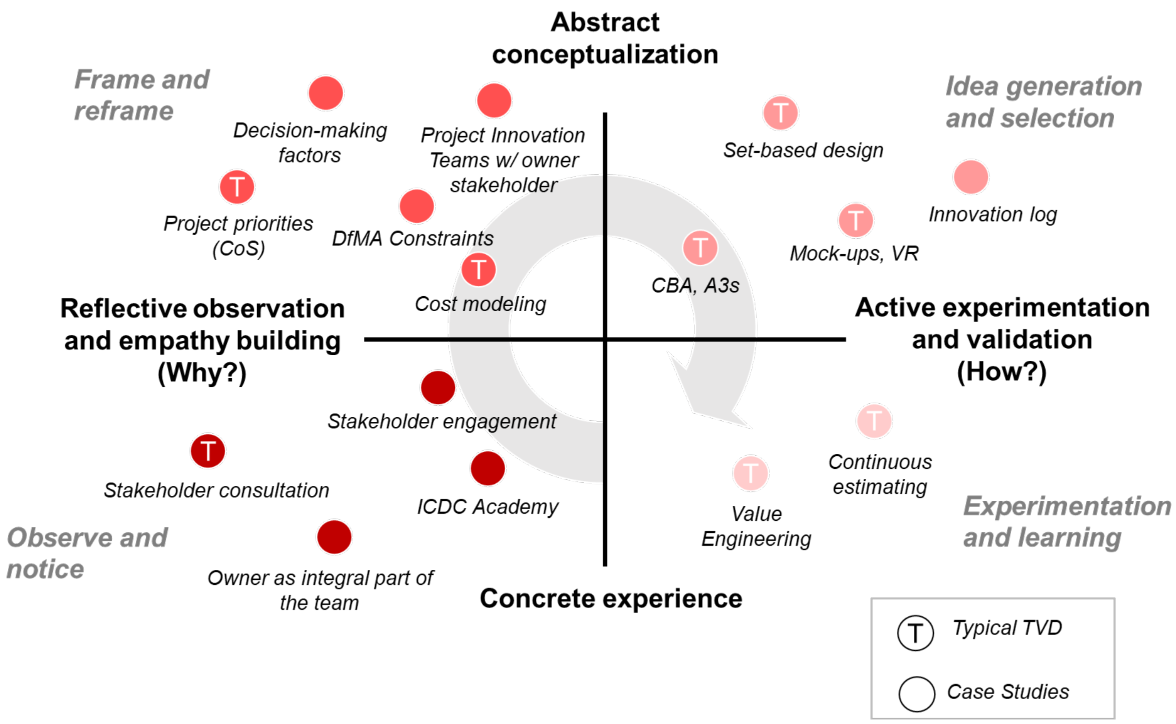

Figure 3: Human-centered innovation strategies used within TVD (Adapted from Beckman 2022)

DISCUSSION

Based on a human-centered approach to innovation proposed by Beckman (2022), the strategies to focus on and manage customer value were analyzed in the case studies. These cases illustrated mechanisms to engage customers in the crucial stages of the human-centered approach: (a) solution development (Quadrants 3 and 4) and (b) problem definition (Quadrants

[4] Concrete experimentation should be understood in this study as the crystallization of a design solution and subsequent documentation on the final set of drawings.

1 and 2). The examples ranged from typical approaches to more unique approaches. Some of the unique approaches include the ICDC academy, with the ultimate purpose of connecting people for empathy building. Another unique approach was the participation of owner team members in the day-to-day management of requirements capturing, idea generation, evaluation, and selection (as opposed to only participating in the evaluation and selection of ideas). In addition, other unique mechanisms were identified during the problem framing and reframing stage. For example, constraints that are discussed on a conceptual level, such as parameters for pre-fabrication, the project's agreed conditions of satisfaction, or even a high-level discussion about the factors to be considered during decision-making. Those serve as guardrails to support problem framing and reframing.

More traditional techniques and methods used on TVD were also observed. This study categorized continuous cost estimating and value engineering as steps pertaining to the fourth quadrant. The reason for that is because they often happen when there was a need to revisit a solution that was already generated or solve emerging issues based on new learnings before setting the final decision. Displaying these mechanisms on the innovation cycle enabled the realization that current best practices for TVD generally fall into the *"idea generation and selection"* and *"experimentation and learning"* categories of the innovation cycle, whereas the unique ones observed in this research can be placed in the *"observe and notice"* and *"frame and reframe"* categories of the cycle. This finding indicates that these unique ideas might bring a complementary perspective to the current best practices of TVD. Also, due to their focus on the "Why" and a deep understanding of customer needs, they represent a greater emphasis on value generation and provide evidence that these approaches can be successfully implemented within TVD while also achieving financial targets.

From a theoretical perspective, this research also corroborates with findings from many previous studies (Ballard, 2011; Bascoul et al., 2018; Parrish & Tommelein, 2009; Arroyo, 2014) that describe the benefits of adopting methods and techniques that support dialogue and the collective understanding of problems-solution space. Thus, building on previous research findings, this paper provides insights on how TVD adoption can be enhanced from the perspective of managing customer value, specifically in what relates to the use of methods and techniques that fall in the second generation of design theories.

CONCLUSIONS AND FUTURE RESEARCH

The research question that motivated this study was: How can we improve value management within target value design to focus more on customer value (along with steering a project to a target cost)? This paper aimed to answer that question by offering a perspective on managing human-centered innovation to focus on customer value during the application of TVD. The journey of UCSF Health to rethink its project delivery methods to focus on value included adopting several strategies related to a humanistic approach to design. This approach shaped how TVD is implemented in these case studies. Its analysis provided insights into complementary design and decision-making strategies traditionally used in TVD. In particular, the design strategies observed in this research expand TVD best practices to include participatory and empathic ways of understanding, framing, and reframing design problems. This research also provided evidence that these approaches can be successfully implemented within TVD to improve customer value without compromising the achievement of financial targets. Finally, this research shows that human aspects of design theories may bring underlying contributions to the construction management discipline, which might not be fully understood and deserves further investigation.

SET-BASED DESIGN IN CONSTRUCTION PROJECTS: BENEFITS, DIFFICULTIES AND TRENDS

Karen Castañeda[1], Rodrigo F. Herrera[2], Omar Sánchez[3], and Guillermo Mejía[4]

ABSTRACT

Design processes generate inputs to plan and control the development of project construction processes. There is a growing interest in implementing design techniques involving various options to reach a systemic overview and select the best proposal. One such technique is Set-Based Design (SBD) which identifies and explores multiple design options simultaneously. Although several studies have been carried out focused on the SBD implementation in construction projects, there need to be more studies that synthesize the main findings to facilitate a proper implementation according to the different contexts. Considering this gap, this paper focuses on presenting a synthesis of SBD's benefits, difficulties, and trends in construction projects. The research method corresponds to a systematic literature review of a sample of 281 documents initially drawn from Scopus database and finally, with 32 documents screened, this study undertook the following stages. The research method has five stages: 1) scope definition; 2) searching of relevant documents; 3) document selection; 4) evidence collection, analysis, and synthesis; and 5) results report. The findings show a trend towards adopting the SBD technique for the design of structural elements of buildings and bridges. The three most frequently reported benefits of SBD adoption are: 1) transparent decision-making processes, 2) better collaboration in decision-making, and 3) better communication among designers. The three most frequently reported difficulties 1) inadequate organizational structure for the adoption of SBD, 2) lack of staff experience, 3) resistance to change in organizations.

KEYWORDS

Set-based design, point-based design, benefits, difficulties, trends, systematic review.

INTRODUCTION

The adoption of Lean Construction tools in the architecture, engineering and construction sector has increased considerably in recent years (Wong et al., 2009). Several studies show that the inclusion of Lean Construction tools in design processes increases product quality, because it promotes compliance with project requirements and increases the value expected by the client (Rischmoller et al., 2006). Nonetheless, if the project design fails, it can compromise the success and continuity of the project. The strong influence of design on construction projects is due to waiting times, rework, accidents, and other events that can result from design defects,

which are identified only at the construction stage (Koskela et al., 2012). If a contractor identifies a design failure, he should request an adjustment or clarification from the designer and wait for a response. The designer can take a significant period to generate a response, which can result in deviations from planned schedules, budgets, and scope; phenomena that have been observed in construction projects around the world (Herrera et al., 2020). Therefore, it is necessary to study methodological and technological approaches that can contribute to improve the design processes. The design process of a construction project involves the interaction of professionals from different disciplines and various analyses to define the characteristics of the project components that meet the requirements and needs of project stakeholders (Herrera et al., 2021). The multidisciplinary nature of design and the associated volume of information generate complex systems to organize and manage (Hannapel & Vlahopoulos, 2014). Nonetheless, in most projects, design processes are based on linear methods that focus on the development of a single design alternative, which limits the possibility of achieving efficiency and generating value for the client.

Several studies have shown benefits of implementing SBD in design processes. For example, Chuquín et al. (2021b) applied a survey at the end of a design process with SBD, the findings showed that 72% believed that the quality of their work had increased, and rework had decreased. Besides, Chuquín et al. (2021a) conducted a survey of the usefulness of SBD among the participants of a case study of a high-rise building. The results showed that 70% of the respondents highlighted the usefulness of SBD and expressed their intention to adopt SBD in future projects. Additionally, Kerga et al. (2016) performed a systems dynamics model to simulate five design alternatives. The findings showed that SBD can contribute to reduce the average project duration by 25%, the total cost by 40%, and significantly improve the return on investment. As in the construction industry, SBD has shown benefits in design processes in other industries. Also, Yamada et al. (2016) performed SBD implementation to generate sustainable design alternatives of a laser printer. The results showed that the total price can be reduced by 18.7% to 36.8% compared to a conventional product, and the total amount of CO_2 emissions of the product can be reduced by 21.9% to 18.8%.

The potential of SBD to improve various design issues has generated interest among industry practitioners and researchers, which has been observed with the publication of several papers addressing the topic (Lee et al., 2012; Shallcross et al., 2020; Singer & Doerry, 2009). However, there is a lack of studies focused on compiling and synthesizing the main findings of SBD implementation in the design activities of construction projects. Therefore, this study has two aims: 1) to identify the benefits and difficulties of SBD adoption in construction projects, and 2) to synthesize the trends of SBD in the construction industry.

TRADITIONAL DESIGN BACKGROUND

Point-Based Design (PBD) has been characterized in the AEC industry as the traditional way of design. PBD is based on an initial design proposal that is progressively detailed. The degree of detail increases as design disciplines become more involved, a characteristic that can be considered ideal (Lee et al., 2012). However, on the one hand, the linearity of PBD compromises the efficiency of the process when a new design requirement arises. A scenario in which designers must perform extensive rework processes to adjust designs to the new requirement. On the other hand, the linear character leads to assume aspects of the design that can lead to issues of incompatibility, inconsistency, and inefficiency in the integration of project elements.

The limitations of the PBD approach have led industry practitioners and researchers to make efforts to adapt and improve techniques that involve the analysis of various design alternatives. In the design of construction projects, one of the techniques that has shown remarkable benefits is Set-Based Design (SBD), which can be assumed as a design management methodology of Lean thinking (Singer & Doerry, 2009). SBD is based on a set of alternatives that when properly combined lead to an efficient design solution, which is aligned with the client's requirements and project constraints (Toche et al., 2020). In the design of a building project based on SBD, the team of architects proposes a set of alternatives for the distribution of spaces and finishes that meet the client's requirements. The structural engineering team generates a set of structural system alternatives in accordance with the general characteristics of the project. Similarly, other design teams propose a set of alternatives, such as sanitary engineering, electrical engineering, sustainability, and others as required. The initial design alternatives are formulated at a low level of detail in order to promote efficiency in the process.

For the selection of the appropriate combination of alternatives, the SBD technique involves a set of objective-based tests that are related to the project requirements (Singer & Doerry, 2009; Toche et al., 2020). Therefore, some of the tests can be focused on objectives related to budgets, schedules, emissions, functionality, construction processes, and materials, among others. Thus, SBD may be adopted for the formulation and evaluation of design alternatives generated by one or more design disciplines of a project. The analysis of various alternatives leads to the adoption of methods to support decision-making processes. SBD integrates criteria evaluation factors for the selection of alternatives based on project requirements (Shallcross et al., 2020). These characteristics generate the need to integrate SBD with computational and methodological tools that support the generation and evaluation of design alternatives. Therefore, several studies have been carried out focused on the joint implementation of SBD and technological and methodological approaches, such as: building information modeling, value stream mapping, choosing by advantages, multi-criteria decision analysis, among others (Lee et al., 2012).

RESEARCH METHOD

For literature review, there are several methodologies, among which bibliometric analysis, meta-analysis and systematic review stand out. According to Donthu et al. (2021), the systematic review is recommended for samples up to 300 documents. Thus, the research method adopted corresponds to a systematic literature review, which focuses on identifying existing knowledge based on systematic procedures to answer a research question. Compared to other review methods, systematic review reduces subjectivity in the extraction of information and analysis of results, which is achieved through the evaluation of a set of inclusion/exclusion criteria for the selection of the sample documents. This study uses systematic review to identify benefits, difficulties, and trends of SBD in construction projects. Therefore, the research method was divided into five main stages: 1) scope definition; 2) searching of relevant documents; 3) document selection; 4) evidence collection, analysis, and synthesis; and 5) results' report. The scope definition was based on the research aims mentioned in the introduction section.

The search and selection of the sample focused on documents that offered the reliability of having undergone peer review processes, this reliability being a relevant factor for the selection of the search engine. Scopus provides this reliability and is considered a search engine that addresses a large number of areas of study in the field of research, so the use of other search engines in addition to Scopus can be considered as a complementary and equally important search. Thus, the search and collection of relevant documents was performed in the Scopus search engine using the following search equation: ("set-based design" OR "set based design" OR "set-based-design" OR "set based-design"). An initial sample of 273 documents was collected, including conference papers, articles, conference reviews, and reviews published between 1994 and 2022. In addition, considering the focus of the research, documents related to the research topic that are available in the IGLC database were included, with the same search equation. A second sample of 16 documents was collected, from which 8 documents repeated from Scopus were discarded, leaving a total of 281 documents.

The final document selection was carried out by applying two inclusion/exclusion criteria: 1) the paper addresses topics related to SBD methodology, and 2) the paper addresses topics related to SBD adoption in the construction industry. The criteria were evaluated by three researchers with knowledge of the topic studied and experience in the systematic review methodology. Each researcher evaluated the criteria individually, thus, for each document and criterion, "yes" was assigned if the document meets the criterion, and "no" if it does not. At the end of the evaluation, it was observed that in 10 of the 281 documents analyzed there was a difference in the evaluation results. Therefore, a meeting was held between the three researchers, and a consensus was reached. By applying the first criterion, 60 documents were discarded. Thus, a total of 221 documents were analyzed with the second criterion, of which 32 documents were selected, and 191 documents were discarded. Therefore, the evidence collection, analysis, and synthesis were performed by reading the resulting 32 documents selected on the basis of the two criteria. The information was collected and organized in an Excel table.

To collect and analyze the information from the selected sample, a detailed reading of each of the documents was carried out. Thus, benefits, difficulties and trends of SBD implementation in construction projects were identified. The information gathered was analyzed by three experts in the research topic. In addition, as part of the discussion of results, four categories were identified for the classification of complementary SBD tools. These categories are part of the added value provided by the group of experts (professionals in the construction industry with a doctorate degree and more than 10 years of experience) who, based on the approach of SBD complementary tools in the documents and the analysis of Lean tools vs. Lean objectives performed by Aslam et al. (2022), made the proposal of categories. Each expert related the SBD complementary tools to the categories, based on affinity and grouping exercises. As part of the classification exercise, the expert group held consensus meetings to discuss and eliminate variations between the complementary SBD tools and the categories. Finally, a frequency analysis has been carried out as part of the exploratory study and identification of the most adopted SBD complementary tools in the AEC industry.

RESULTS

This section presents the benefits, difficulties and trends of SBD adoption in construction projects, according to the analyzed sample. As a result of the research, 23 benefits, 22 difficulties and trends of SBD adoption were identified. The benefits and difficulties of adoption are presented through an absolute and relative frequency analysis. This frequency analysis provides a summary statistic, with which it is possible to compare the benefits and difficulties most frequently evidenced in the literature, as well as the weight of each benefit and difficulty within the set. This analysis could provide an impetus for SBD research in the AEC sector by presenting the results of research within the industry. Finally, a subsection of research trends and complementary approaches to SBD implementation in construction projects is presented. The approaches have been categorized according to their affinity by a group of experts in the research field.

BENEFITS OF SET-BASED DESIGN ADOPTION

Table 1 shows the top-10 most frequently reported SBD benefits in construction projects. The adoption of SBD promotes transparent decision-making processes, based on the selection of design alternatives that focus on satisfying project requirements. This feature helps to prevent decisions from being affected by the particular interests of the designers (Mathern et al., 2019; Parrish & Tommelein, 2009; Sahadevan & Varghese, 2019). Therefore, one of the most frequently reported benefit is 'transparent decision-making processes' (B_1). With the same frequency, the benefit 'better collaboration in decision-making' (B_2) was identified, which is obtained from the collaborative process of analysis and proposal of design alternatives involved in the SBD adoption (Lee & Cho, 2012; Lee et al., 2010). A process that requires the joint participation of the professionals involved, on the one hand, to verify the compatibility and coherence between the options analyzed. On the other hand, to select the combination of alternatives that best meets the requirements of the project.

Table 1. Benefits of SBD adoption in the construction industry.

Id	Benefits	Absolute frequency	Relative frequency (n=32)	References*
B_1	Transparent decision-making processes	10	31.3%	10, 11, 12, 13, 15, 16, 18, 22, 26, 30
B_2	Better collaboration in decision-making	9	28.1%	7, 8, 10, 14, 18, 19, 20, 25, 26
B_3	Better communication among designers	7	21.9%	7, 13, 19, 21, 22, 23, 26
B_4	Improvement of the design solution	7	21.9%	1, 5, 11, 14, 23, 25, 26
B_5	Analysis of various design alternatives	6	18.8%	7, 8, 10, 13, 21, 22
B_6	Increased design solution functionality	6	18.8%	4, 9, 10, 21, 26, 28
B_7	Reuse of design knowledge	6	18.8%	10, 12, 14, 15, 26, 28
B_8	Reduction of rework	6	18.8%	5, 15, 20, 24, 26, 27
B_9	Increased design solution efficiency	5	15.6%	7, 8, 20, 23, 28
B_{10}	Promotes sustainability in the projects	4	12.5%	3, 10, 16, 17

*1. (Chuquín et al., 2021b), 2. (Chuquín et al., 2021a), 3. (Gomez & Rameson, 2019), 4. (Inoue, Takahashi, et al., 2013), 5. (Zoya Kpamma & Adjei-Kumi, 2011), 6. (Kim & Lee, 2010), 7. (Lee & Cho, 2012), 8. (Lee et al., 2012), 9. (Inoue, Nahm, et al., 2013), 10. (Mathern et al., 2019), 11. (Padala & Maheswari, 2017), 12. (Parrish & Tommelein, 2009), 13. (Parrish et al., 2008b), 14. (Parrish et al., 2007), 15. (Parrish et al., 2008a), 16. (Mathern et al., 2018), 17. (Rempling et al., 2019), 18. (Sahadevan & Varghese, 2019), 19. (Tauriainen et al., 2016), 20. (Tuholski & Tommelein, 2010), 21. (Unal, Eeri, et al., 2017), 22. (Wong et al., 2009), 23. (Wong et al., 2007), 24. (Lee et al., 2012), 25. (Lee et al., 2010), 26. (Arroyo & Long, 2018), 27. (Ballard, 2000), 28. (Haymaker et al., 2013), 29. (Knotten et al., 2014), and 30. (Nguyen et al., 2008).

The third most frequent benefit is 'analysis of various design alternatives' (B_3). Some characteristics of construction projects, such as unique and multidisciplinary character, complexity and uncertainty, and required financial capital make the analysis of various design options indispensable during the early stages of the projects (Chuquín et al., 2021a; Rempling et al., 2019). Therefore, benefit B_3 has a positive effect on ensuring that the design solution generates the value desired by the client and satisfies the requirements that gave rise to the project. The fourth benefit is 'better communication among designers' (B_3), which is integrated with benefits B_1, B_2, and B_5 considering that communication is transversal to the decision making and collaboration processes among design teams (Tauriainen et al., 2016; Unal, Eeri, et al., 2017; Wong et al., 2009). Thus, communication favors the proposal and analysis of various design options. The fifth benefit is 'improvement of the design solution' which is obtained by exploring a space of possible design solutions, from which the team has the possibility to choose the alternative that best aligns with the project requirements.

DIFFICULTIES OF SET-BASED DESIGN ADOPTION

Table 2 shows the top-10 most frequently reported SBD adoption difficulties. The 'inadequate organizational structure for the adoption of SBD' (C_1) is the most reported difficulty, which is related to the staffing requirements and organizational structure in the design disciplines of a construction project (Chuquín et al., 2021b; Gomez & Rameson, 2019). C_1 has a major impact on some organizations because it is common to subcontract some of the design disciplines with specialized firms (Hassan & Le, 2021). Subcontracting means that two or more firms must adapt their workflows to integrate design teams according to SBD principles. The second difficulties is 'lack of staff experience' (C_2) which is based on the knowledge and experience needed to adopt SBD by the professionals involved in the design of a construction project (Lee et al., 2010; Zoya Kpamma & Adjei-Kumi, 2011). The emerging nature of SBD in the construction industry leads to a lack of human talent with experience and knowledge in the adoption of SBD. In addition, there is a lack of efforts focused on including SBD in education programs related to the training of professionals in charge of the design of construction projects.

Table 2. Difficulties of SBD adoption in the construction industry.

Id	Difficulties	Absolute frequency	Relative frequency (n=32)	References*
C_1	Inadequate organizational structure for the adoption of SBD	7	21.9%	1, 3, 4, 11, 15, 18, 19
C_2	Lack of staff experience	6	18.8%	1, 4, 9, 11, 21, 26
C_3	Resistance to change in organizations	6	18.8%	1, 3, 4, 26, 27, 29
C_4	Lack of information compatibility between design disciplines	5	15.6%	3, 12, 15, 19, 28
C_5	Limited information to propose design alternatives	4	12.5%	2, 6, 12, 17
C_6	Greater design effort	4	12.5%	7, 12, 13, 16
C_7	Difficulty in managing design processes	4	12.5%	4, 7, 19, 31
C_8	Barriers related to the legal framework	3	9.4%	4, 7, 11
C_9	High dependence on designer's judgment in decision making	3	9.4%	7, 8, 9
C_{10}	Increased design time due to more alternatives	3	9.4%	7, 9, 26

*1. Notation according to Table 1.

'Limited information to propose design alternatives' (C_3) is the third most frequently reported difficulty. The adoption of SBD requires the availability of the information required for the proposal and analysis of design alternatives (Parrish et al., 2008a; Unal, Eeri, et al., 2017). The complexity of the interactions between design disciplines and the multidisciplinary nature of the teams make it difficult to provide, at the right time, the necessary information to propose design alternatives. 'Greater design effort' (C_6) has the same frequency as C_5. Proposing and analyzing several alternatives instead of a single design alternative requires more effort from the design team (Mathern et al., 2018, 2019). However, the consideration of a greater number of design options contributes to the 'reduction of rework' (B_8) and the 'reduction in design times' (B_{12}). Therefore, investment in increased effort by designers could generate positive return on investment (ROI) rates.

Despite the fact that 'Lack of information compatibility between design disciplines' (C_4) does not have the same frequency as C_5 and C_6. The various engineering processes carried out in the design stage of a construction project lead designers to use different tools for the information capture, processing and analysis (Gomez & Rameson, 2019; W. Lee et al., 2010). The diversity of tools and methods has generated difficulties in the integration of information due to the difficulty in making information compatible between design disciplines. Despite the efforts for the adoption of methodologies such as Builiding Information Modeling (BIM) with information exchanges based on Industry Foundation Classes (IFC), difficulties are observed in the exchange of information between design disciplines, which affects the efficient adoption of SBD (Lee et al., 2012)

DISCUSSION

COMPLEMENTARY APPROACHES TO SET-BASED DESIGN

This study found that the SBD is boosted when complementary design management techniques are used. This section summarizes these techniques in four categories: 1) information and process management, 2) decision making, 3) analysis tools, and 4) design (see Table 3).

Table 3. Complementary approaches of SBD adoption in the construction industry.

ID	Category	Complementary SBD		Fr.	Relative frequency (n=32)
1	Information and process management	Building Information Modeling	BIM	6	18.8%
2		Value Stream Mapping	VSM	2	6.3%
3		Design Structure Matrix	DSM	3	9.4%
4		Big Room	Big room	1	3.1%
5		Activity Cycle Diagrams	ACD	1	3.1%
6		Lean Project Delivery	LPD	1	3.1%
7		Lean Project Delivery System	LPDS	1	3.2%
8		Last Planner System	LPS	1	3.2%
9	Decision making	Multi-Criteria Decision Analysis	MCDA	6	21.9%
10		Choosing by Advantages	CBA	6	18.8%
11		Analytic Hierarchy Process	AHP	3	9.4%
12		Group Decision Making	GDM	1	3.1%
13		Sequential Decision Process	SDP	1	3.1%
14		Design by Shopping	DBS	1	3.1%
15		Knotworking	knotworking	1	3.1%
16		A3 reports	A3 reports	1	3.1%
17		Belief Propagation	BP	1	3.1%
18	Analysis tools	Finite Element Method	FEM	3	9.4%
19		Artificial Intelligence	IA	1	3.1%
20		Monte Carlo Analysis	MC	1	3.1%
21		Genetic Algorithm	NSGA	1	3.1%
22		Space Syntax Analysis	SSA	1	3.1%
23		Simulation	Simulation	1	3.1%
24	Design	Target Value Design	TVD	5	15.6%
25		Parametric Design	PD	2	6.3%
26		Depthmap	Depthmap	1	3.1%
27		Set-Based Parametric Design	SBPD	1	3.1%
28		SetPlan	SetPlan	1	3.1%
29		Tekla Structures 14.0	TS 14.0	1	3.1%
30		Lean design	LD	1	3.1%

The SBD technique can be integrated with various complementary approaches to improve the information management processes of the design of construction projects. Therefore, there is a growing interest in integrating SBD with approaches to improve information management processes, such as: Building Information Modeling, Value Stream Mapping, Design Structure Matrix, and others (see Table 3). It is observed that BIM is one of the complementary approaches to SBD that has a higher frequency within the Information and process management category. Studies that have addressed the integration of BIM and SBD have focused on the development of improvement tools for the creation of alternatives in various fields, such as constructability, structural safety, economic feasibility, design management, and shared understanding, among others (Lee & Cho, 2012; Tauriainen et al., 2016; Tuholski & Tommelein, 2010; Wong et al., 2009). Integrating BIM and SBD makes it possible to improve information flows and communication during design activities that are developed by professionals from different disciplines during the early stages of projects. Improving information management processes has a positive impact on the development of construction projects considering that projects involve considerable volumes of information during the design stage.

MCDA is the most commonly adopted complementary tool to SBD in decision-making processes. Evidence of MCDA adoption was identified mainly in the development of road infrastructure projects. Some of the approaches, on the one hand, are oriented to support the selection of strategies for the development of facilities in road projects, evaluate design processes, support decision making, analyze constructability concepts and sustainability criteria, in the structural design of bridges. On the other hand, MCDA has adopted to optimize the structural design of buildings based on sustainability criteria and design alternatives among others (Mathern et al., 2018, 2019; Padala & Maheswari, 2017). Thus, the evaluation of various design alternatives using the SBD tool leads to the need to integrate tools to support the decision-making processes that focus on the evaluation and selection of design alternatives. Hence, there is a trend towards the joint adoption of SBD with techniques that support the decision-making processes during the analysis of alternatives, such as: Multi-Criteria Decision Analysis, Choosing by Advantages, Analytic Hierarchy Process, and others.

The multidisciplinary nature of a construction project means that the design process integrates various engineering analyses that require specialized techniques to carry out the design of the components of a construction project. Hence, there is a trend towards the integration of SBD with tools that can improve and automate the design processes, such as: Finite Element Method, Artificial Intelligence, Monte Carlo Analysis, and others (see Table 3). In turn, these tools can be complemented with design techniques, such as: Target Value Design, Parametric Design, and others. It is noteworthy that in the design category, the TVD approach is the one with the highest frequency, which is related to the complementary nature of the two tools. On the one hand, SBD focuses on the proposal and selection of alternatives, and on the other hand, TVD focuses on the development of the design from a set of budgetary requirements. Therefore, integrating TVD and SBD has a high potential to promote the generation of value for the client from the analysis of several design alternatives that are framed in a budgetary requirement. The findings show that the joint adoption of SBS and TVD has been focused on building, road infrastructure, and bridge projects (Arroyo & Long, 2018; Gomez & Rameson, 2019; Kim & Lee, 2010). Despite the existing studies, it is evident that there are several knowledge gaps, which can be analyzed from the moderate number of documents and the few fields of knowledge that have been focused on: sustainable development, design and evaluation of spaces, and others. Furthermore, there is a lack of studies focused on design and information workflows that facilitate the joint adoption of SBD with complementary tools by the design disciplines that interact in a construction project. Thus, it is expected that in the coming years there will be a growing interest in the development of computational tools based on the integration of SBD principles and complementary approaches specialized in the design of building components.

The adoption of SBD can significantly contribute to improve various aspects of the design of construction projects. Therefore, in the construction industry, it is crucial that researchers and practitioners undertake actions focused on the development of works that make possible the implementation of SBD in the different design disciplines that interact in a construction project. The integration of SBD with emerging tools and methodologies such as: BIM, Multi-Criteria Decision Analysis, Target Value Design, and others (see Table 3) can contribute to improve the decision-making processes that are carried out during the design activities of a construction project. Despite its potential, the findings of this study show that there are several knowledge gaps in the characterization of SBD integration with various complementary approaches. Therefore, it is expected that the coming years will see an increasing number of studies focused on characterizing SBD integration with methodological and technological approaches that can be conducive to leveraging SBD principles, which is focused on the requirements of construction projects.

KNOWLEDGE GAPS AND TRENDS OF SET-BASED DESIGN

There are knowledge gaps of SBD adoption in different types of construction projects. From the set of documents analyzed (n=32; 100%), the types of construction projects identified with SBD adoption were: buildings (n=18; 56.3%), bridges (n=5; 15.6%), road infrastructure (n=3; 9.4%), and other projects (n=6; 18.8%). Hence, there is evidence of a gap in the adoption of SDB in horizontal projects, in which the characteristics of SBD can contribute to obtaining more efficient and sustainable projects. In road projects, SBD can contribute to the analysis and selection of road alignment alternatives based on a set of requirements and limitations defined for the project. Once the alignment is selected, SDB can be adopted to analyze and define a space of possible design configurations, from which designers can select the one that best aligns with the needs of the project. Although there has been a greater adoption of SBD in vertical projects, it has focused mainly on the design of structural elements. Therefore, there are gaps in the adoption of SBD in other design disciplines that are crucial, such as: utility service networks, geotechnics, architecture, HVAC, and sustainability, among others. In addition, there is a lack of studies focused on the analysis and selection of vertical project design alternatives with a multidisciplinary and multi-criteria approach.

Efforts are being made to integrate SBD with various methodological and technological approaches to support the design processes of construction projects (see Table 3). However, the results show gaps in the joint adoption of SBD with systems based on artificial intelligence and cloud computing. A situation that is similar to the joint adoption of SBD with workflows based on virtual reality, internet of things, big-data, machine learning, and others. Therefore, it is expected that in the coming years industry practitioners and researchers will make efforts to integrate SBD principles with construction 4.0 approaches. An integration that has a high potential to automate and improve the efficiency of design processes for construction projects.

CONCLUSIONS

The theoretical contribution of this study is the identification of benefits, difficulties, and trends of the adoption of SDB in construction projects. The research method was based on a systematic literature review of an initial sample of 281 documents. The five most frequently reported benefits of SBD adoption are: 1) transparent decision-making processes (B_1), 2) better collaboration in decision-making (B_2), 3) better communication among designers (B_3), 4) improvement of the design solution (B_4), and 5) analysis of various design alternatives (B_5) (see Table 1). The results show a wide potential of SBD to improve various construction project design issues, however, there are some difficulties that have limited the adoption of SBD in the construction industry. The five most frequently reported SBD adoption difficulties are: 1) inadequate organizational structure for the adoption of SBD (C_1), 2) lack of staff experience (C_2), 3) resistance to change in organizations (C_3), 4) lack of information compatibility between design disciplines (C_4), and 5) limited information to propose design alternatives (C_5) (see Table 3). It should be noted that the contributions of this study are based on a structured review of the literature rather than data obtained through the adoption of SBD in any activity of the life cycle of construction projects. Thus, it is expected that with the emergence of new studies, modifications in benefits, difficulties and trends will occur.

Several of the identified difficulties can be addressed by integrating SBD with approaches that encourage the automation of design processes based on various alternatives. Therefore, there is a trend towards the integration of SBD with complementary technological and methodological approaches to support the processes of proposal and analysis of design alternatives. Among the complementary approaches identified, the following stand out: building information modeling, multi-criteria decision analysis, choosing by advantages, target value design, and finite element method, among others. Therefore, it is expected that in the coming years SBD adoption research will focus on proposing, adopting, and improving design process workflows from the integration of both the complementary tools identified (see Table 3) as well as emerging approaches related to construction 4.0.

The main limitations of this study are: 1) the review's focus on the adoption of SBD in the construction industry without including other industries; 2) the lack of documents from databases other than Scopus; 3) the scope of the review focused on the benefits, difficulties, and trends of SBD, leaving aside other topics of interest; 4) the method of analysis is based on a frequency analysis due to the moderate number of documents that address the adoption of SBD in construction projects, therefore, this study can be classified as exploratory; and 5) all the analyzed documents are assumed to be on equal conditions, which is motivated by the exploratory nature of most of the existing studies that address the adoption of SBD in construction projects. Therefore, future work could focus on 1) review and analyze SDB developments in other industries, 2) update the review presented with documents published in other databases, 3) review SBD developments in the construction industry with complementary approaches to the one presented in this study (see Table 3); 4) adopt more sophisticated analysis methods to study the adoption of SBD in construction projects; and 5) propose approaches that integrate SBD theoretical principles and tools based on artificial intelligence to facilitate the proposal and analysis of design alternatives.

PLANNED PERCENTAGE COMPLETED IN CONSTRUCTION – A QUANTITATIVE REVIEW OF LITERATURE

Eelon Lappalainen[1], Ana Reinbold[2], and Olli Seppänen[3]

ABSTRACT

Although several systematic literature reviews have focused on the Last Planner® system (LPS) and lean construction, few reviews have focused solely on the planned percentage completed (PPC) value. In this light, the present quantitative literature review aims to synthesize individual PPC-related studies from around the world. The research data consisted of 36 peer-reviewed research articles and conference papers published between 1998 and 2021; in these, PPC values were presented such that they could be collected and analyzed quantitatively. As a main finding, a statistically significant difference was observed between the mean PPC values presented in studies published in lean-focused journals and other peer-reviewed journals. The mean PPC values published in lean-focused journals were lower than those published in other peer-reviewed journals. This may indicate that results with higher PPCs are selected for other peer-reviewed publications; therefore, a potential publication bias should be investigated further. The study also revealed mean PPC values over time and geography, thereby enabling an evaluation of the construction industry's global progress by using PPC values as a benchmark.

KEYWORDS

lean construction, last planner, planned percentage completed (PPC), literature review.

INTRODUCTION

The Last Planner® system (LPS) is a planning system that has been developed in lean construction. Unlike in traditional scheduling, LPS emphasizes the role of the "last planner," namely, the foreman (or last person before task execution) who is as close as possible to the task, in production planning (Ballard, 2000). According to Ballard (2000), the key to the production planning system is a good definition of the task, selection of the right work order and workload, and reasonableness of the work task chosen to be implemented (i.e., can it and should it be done?). Planned percentage completed (PPC) is a quantitative measure calculated as the number of planned activities executed divided by the total number of planned activities. According to Ballard and Tommelein (2016), the PPC value used in the LPS is considered a measure of workflow reliability, a measure that correlates with productivity and project progress, and a measure of a team's ability to reliably plan and execute work. PPC is also often considered a visual illustration of the reliability of the promises made by the project parties to each other (Koskela *et al*., 2010).

Researchers broadly agree that the key to measuring the PPC in LPS is the measurement of the reliability of the parties' promises (Howell *et al*., 2004; Fauchier & Alves, 2013). The PPC value is often used in research and practice related to LPS and lean construction, although a holistic examination of PPC values in individual studies is limited. Aslam *et al*. (2020) conducted an extensive literature review of LPS-related studies between 1992 and 2019 and presented mean PPC values from 16 cases. Based on these case studies, they estimated that the average PPC value is approximately 68%, and they stated that this was below their expectations. Accordingly, they proposed that finding and removing the main barriers in LPS would improve the PPC. Singh and Kumar (2020) reviewed literature from 2008 to 2018 focusing on tools and methods of lean construction but collected no PPC information. Babalola *et al*. (2019) reviewed lean construction literature from 1930 to 2018 with a focus on lean construction practices and identified PPC, although they did not collect any related evidence. Fernandez-Solis *et al*. (2013) conducted a systematic literature review of 26 case studies from 2000 to 2009 that focused on how practitioners have used LPS methods, although they did not collect any PPC values.

Although some studies have focused only on the PPC, this systematic literature review of LPS and PPC shows that a more comprehensive sample of research papers that present the PPC value is possible. This study differs from previous ones in that it analyzed PPC from a larger set of articles and over a longer period. In addition, it aimed to take a meta-view by comparing PPC between journals focused on lean and other peer-reviewed journals. We also assessed the geographical differences in PPC in our study. Most similar studies, such as that by Aslam *et al.* (2020), focused on the project-specific PPC as a single value but not on its variation over the course of the study; the present study highlights this point more explicitly than previous studies did. Because the PPC is a fundamental metric in the use of LPS, this study systematically explores a substantial number of studies that presented PPC values and presents a broad view of PPC values recorded worldwide and over time.

METHODS

The heterogeneity of the published research and the prominence of case studies in LPS research hinder the use of statistical analysis, such as meta-analysis. Instead of using statistical analysis, a quantitative literature review that is applicable to incoherent research data was chosen as the research method (Pickering & Byrne, 2014). In this method, the results of individual studies are combined to focus on finding similarities, differences, or other interesting findings that are not visible in individual studies but are observable from the combined set of several studies. However, because the PPC is a number, these differences are analyzed and discussed in this study mainly from a quantitative viewpoint.

The search strategy was primarily aimed at LPS-related studies, because information related to the PPC, which is the focus of this study, was assumed to be found in these studies. Therefore, the Last Planner System alone was used as a search term. Notably, the term "PPC" is also used in cancer research and is a common abbreviation for "production planning and control"; therefore, PPC as a search term would have produced many incorrect and unnecessary search results. In this light, first, the search term "Last Planner System" was used, and then, papers with the PPC values of the method were screened. The researchers searched for LPS-related studies in two research databases: Scopus and Google Scholar. Information was collected between 2020 and 2022, first as separate targeted search events and later using the continuous alert functionality of the Scopus database. Data were collected using the search term "Last Planner" and 551 research articles, review papers, books chapters, and books were identified. The researchers downloaded the papers to which they had either open access or access through the university's library service (including paywall journals). The literature search strategy is presented in Figure 1.

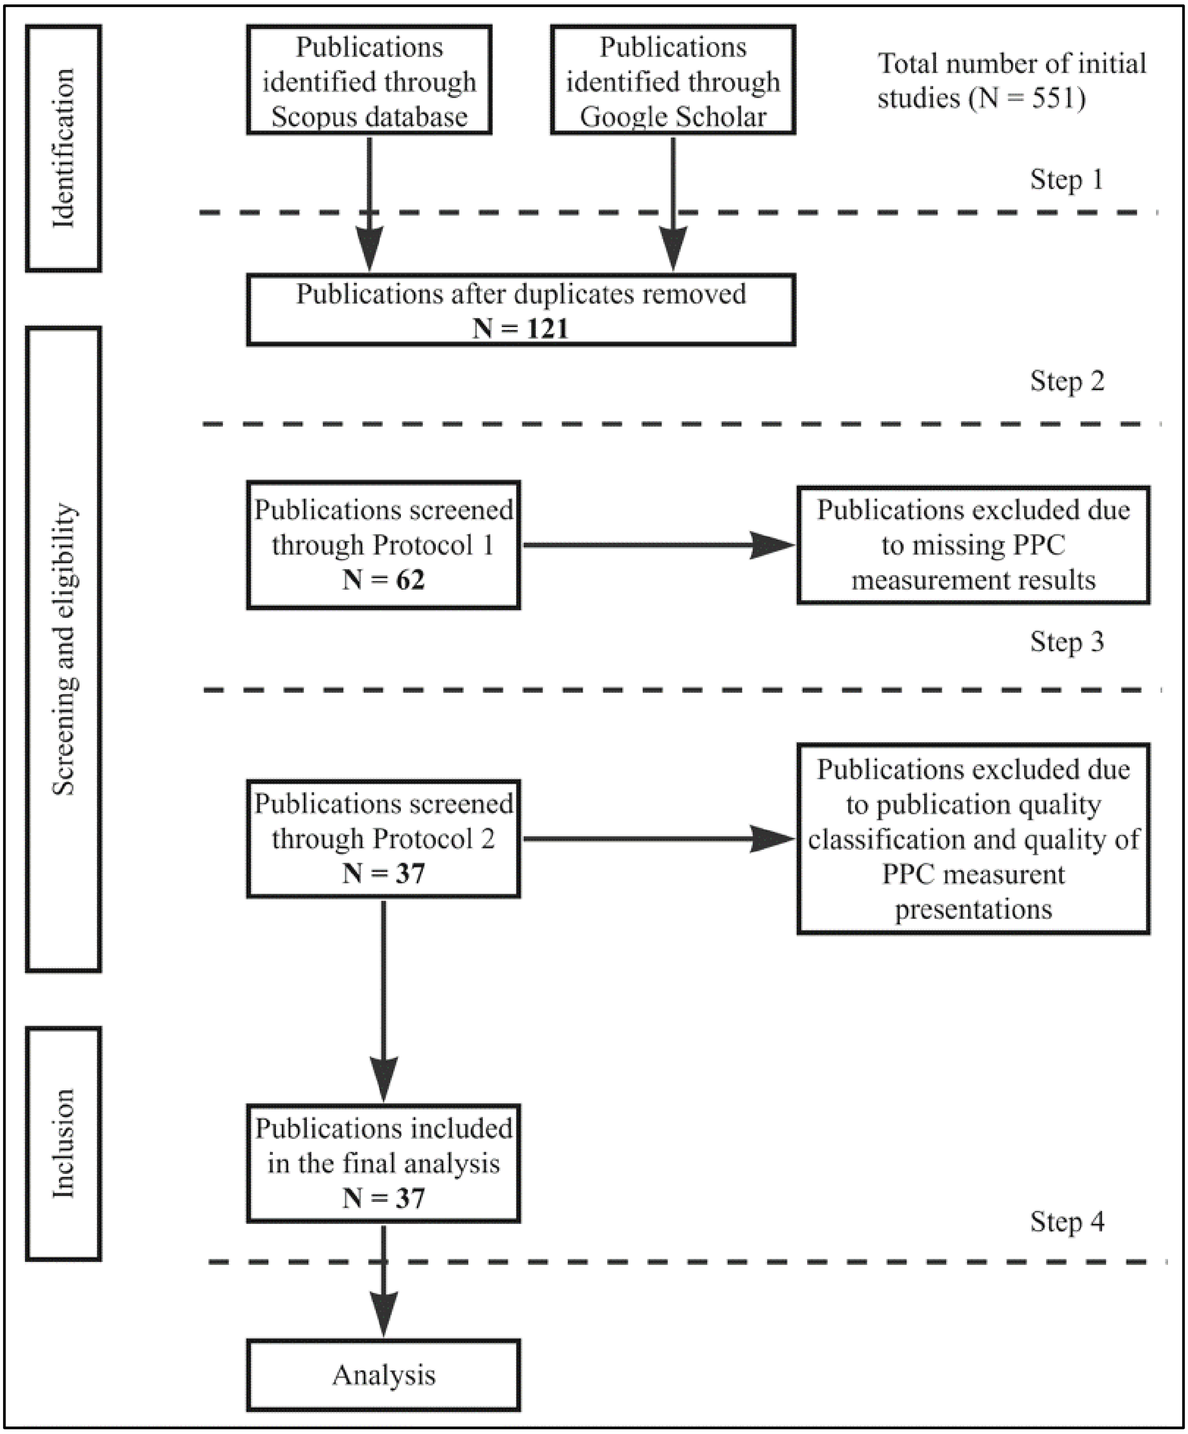

Figure 1: Literature search strategy.

In the first screening step, the researchers included only research articles and conference papers while also removing possible duplicates from different databases. Therefore, no book, part of a book, guidebooks, or industry reports about LPS were included. In the first step, 121 articles were processed. In the second step, the researchers scanned the research articles and searched for articles in which PPC values were presented in text, tables, or graphs; 62 such articles were found. In the third step, the researchers focused on the quality of the research and determined whether the research results were genuine results from actual case studies, action research, or runs from various project databases. All simulations, theoretical modelling, and design-related articles that included PPC results were also excluded. The quality of the study results was screened in this context, from which factors such as low-quality figures and tables or insufficient data were unclear. At this stage, articles that had been published in predatory journals were also excluded. After these screening steps, 37 peer-reviewed research articles and scientific conference papers were included in the final analysis.

In the analysis phase, basic information was collected from the research articles, such as the names of the authors, journal, and publisher; year of publication; country in which research data were collected; research method; and category to which the publication belonged. Two categories were defined: articles published in lean-specific scientific journals or peer-reviewed conferences and articles published in other peer-reviewed journals in the construction industry. Numerical data related to PPC were also collected from the articles, such as the mean, maximum, and minimum PPC values and their standard deviation. Regarding the duration of measurements of PPC values, we collected the number of PPC data points and the duration of the data collection process (in weeks). Information was collected from the text, tables, and figures of the articles. Data were stored and analyzed using Excel spreadsheets and Minitab 19 statistical software.

FINDINGS

The articles selected for the study are presented in Table 1. For each study, this table lists the mean (MeanPPC), maximum (MaxPPC), and minimum (MinPPC) PPC values and their standard deviation (StdPPC) as collected in the original study or calculated by the authors of the present study. For each study, the research method, geographic location, and information source were also collected (i.e., whether the PPC value was obtained from the text, tables, or figures of the study). In the table, the studies are presented in chronological order, and whether the study belongs to lean-focused publications ("LFB") or other peer-reviewed publications ("Other") is shown on the left-hand side next to the code. The code is a unique identification number (e.g., "33") assigned to a single study at the beginning of the study, and it contains subnumbers (e.g., "51.1") if the study has several cases in which a PPC value is presented. The abbreviation "Dat" implies the number of data points in the table (i.e., number of PPC measurements presented in the study), and the abbreviation "Dur" implies the duration of the study in weeks.

Table 1. Reviewed articles and research data.

The reviewed studies were published between 1998 and 2021. The highest number of studies in which PPC values are presented (26 out of 37) were published between 2005 and 2013. Geographically, the reviewed articles containing PPC values were mainly from South and North America and Western Europe. Africa and Asia accounted for three and four studies, respectively. Further, no studies were from large regions such as China, Russia, Australia, Canada, and Central and Eastern Europe. The geographical locations in which the reviewed articles were published are shown in Figure 2.

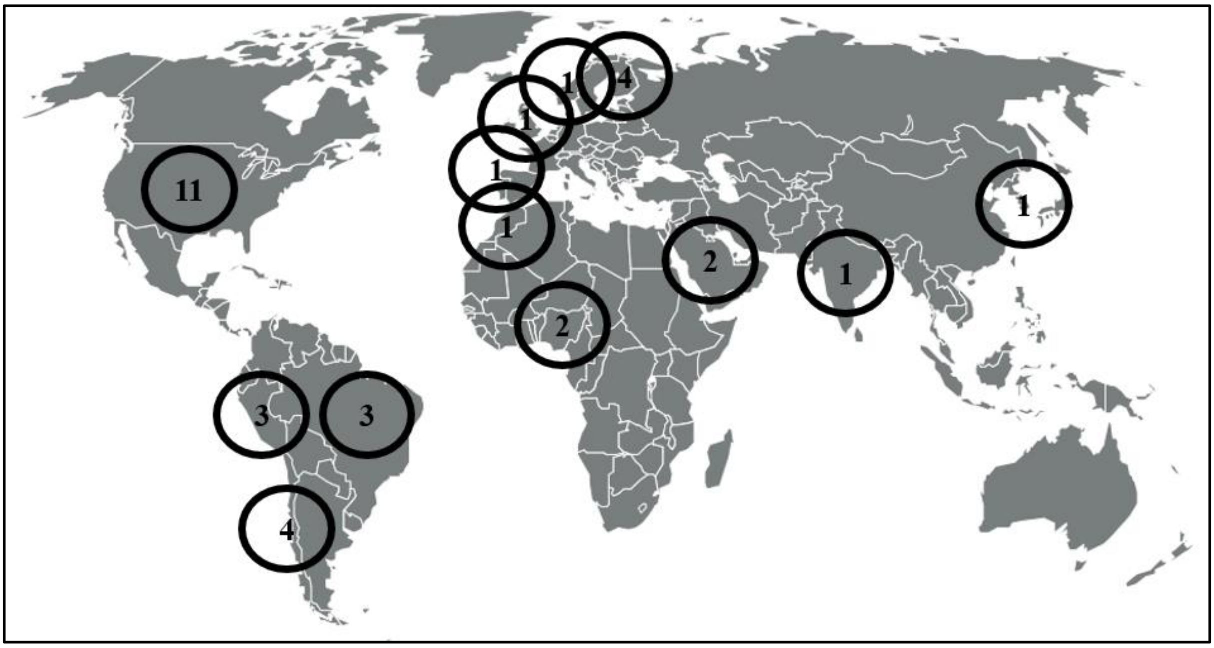

Figure 2: Geographical locations in which reviewed articles were published.

PPC measurements were performed for an average duration of 28 weeks, and the longest study lasted for 113 weeks. The average of all mean PPCs was 71.3%. The average mean PPC was 69.2% in lean-focused journals and 76.2% in other peer-reviewed journals. No significant development trends or patterns were observed in PPC values over time. Figures 3 and 4 show the mean PPC values of articles published in lean construction journals and other peer-reviewed journals, respectively. In these figures, the larger solid black dot indicates the mean PPC of each study, and the smaller dots indicate other measurement results such as the distribution of PPC in each study. Studies showing only a solid black dot only contain mean PPC data and lack other metrics. The horizontal axis of the figure shows the studies identified by code number in chronological order.

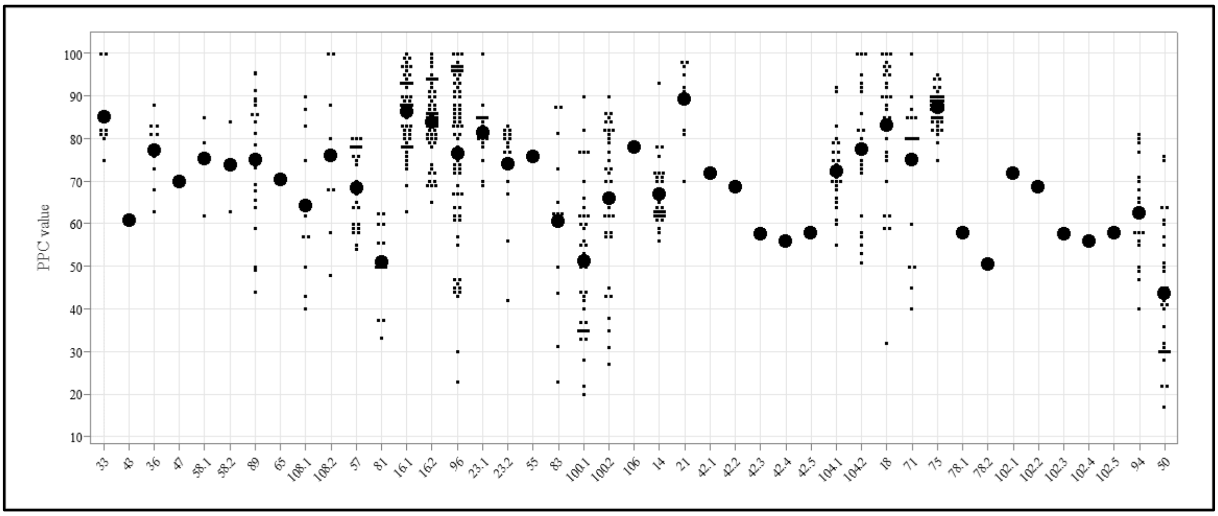

Figure 3: PPC values of articles published in lean construction journals.

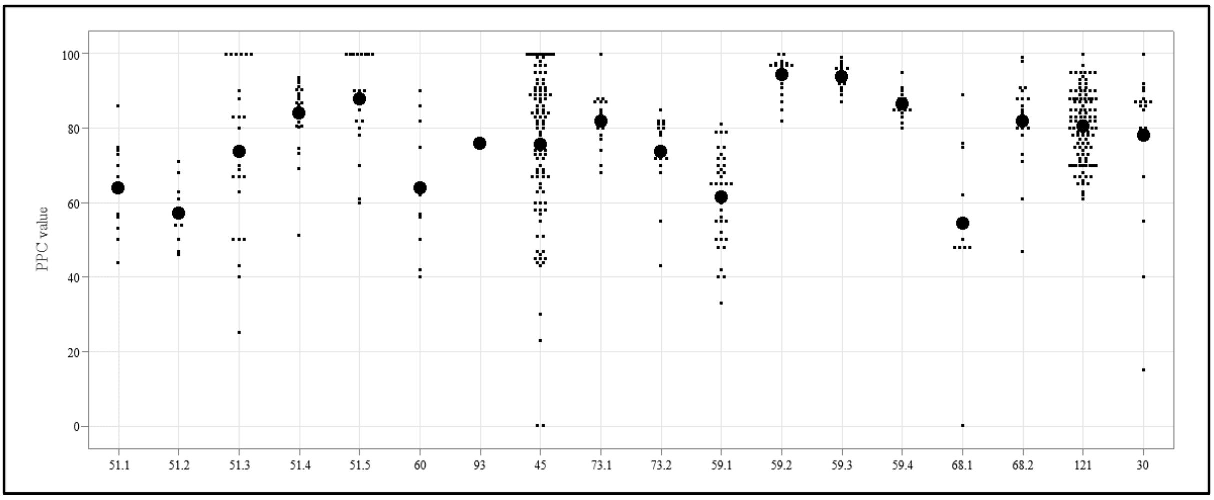

Figure 4: PPC values of articles published in other peer-reviewed journals.

The mean PPC seemingly differed between lean-focused journals and other peer-reviewed journals. Therefore, the researchers first verified that the PPCs of both groups were normally distributed. The fact that they were meant that they could subsequently analyze these two groups using the analysis of variance (ANOVA) method. The ANOVA revealed a statistically significant difference between the groups. The ANOVA results are shown in Table 2.

Table 2: ANOVA results.

Source	DF	Adj SS	Adj MS	F-Value	P-Value
Factor	1	618.7	618.7	4.79	0.033 < 0.05
Error	59	7627.0	129.3		
Total	60	8245.7			

Factor	N	Mean	StDev	95 % CI
PPC Mean of lean-focused journals	43	69.20	11.16	(65.73; 72.67)
PPC Mean of other peer-reviewed journals	18	76.18	11.86	(70.82; 81.54)

Pooled StDev = 11.3697

Source = source of the variation in the data, DF = degrees of freedom, Adj SS = adjusted sum of squares, Adj MS = adjusted mean sum of squares, N = total number of PPC observations per group, StDev = standard deviation, CI = confidence interval.

One-way ANOVA revealed a statistically significant difference in PPC between the two publication groups, with an F-value of 4.19 and a p-value of 0.033 ($p < 0.05$).

Figure 5 shows the mean PPC values of the research articles by continent. The larger solid black dot indicates the average of the mean PPC of all results for a continent, and the smaller dots indicate the mean PPCs of individual studies.

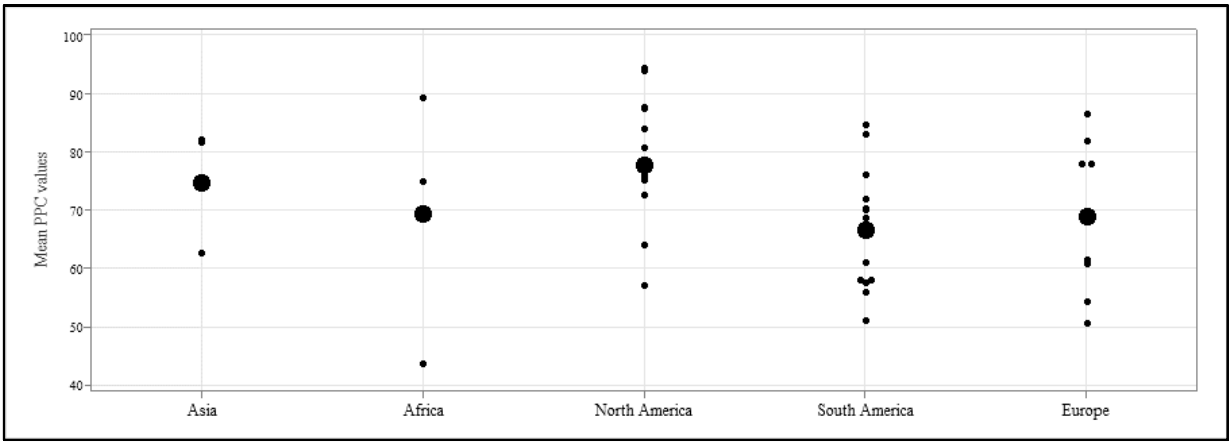

Figure 5: Mean PPC values presented in the reviewed journals by continent.

When compared geographically, the highest mean PPC average was in North America (77.7%, N = 16) and the second-highest one was in Asia (74.9%, N = 7). Europe (69.0%, N = 8) and Africa (69.4%, N = 3) were almost at the same level, and South America (66.7%, N = 14) had the lowest value. Most studies presenting PPC values were in North and South America, followed by Europe, Asia, and Africa.

DISCUSSION AND CONCLUSIONS

With the PPC value constantly at or below 50% on average, the foreman's job is essentially a roll of the dice (Ballard & Tommelein, 2016). Our findings from a large sample of studies in which PPC values have been presented show that the published PPC values are approximately 71% (±5%), although they differ by case and continent. This finding agrees with the findings by Aslam *et al*. (2020) of a mean PPC of 68% (N = 16). Further, no developing (or declining) trend was observed in the data, even though the studies were analyzed between 1998 and 2021. Howell and Macomber (2002) argued that a PPC value of 80% is "good" and one less than 60% is "poor," and very mature teams can maintain a daily PPC of 85%. These findings suggest that the case studies in which the PPC value is close to the "good" level are published in peer-reviewed journals, and a wider range of cases, including some in which the PPC value is "poor," are published in lean-focused journals. At the same time, among case studies presenting PPC that were published in other peer-reviewed journals, only three had PPCs that remained above the 80% level throughout the monitoring period. By contrast, none of the studies published in lean-focused journals had PPCs that maintained this "mature" level of 80% throughout the monitoring period. This might indicate that the PPC level of 80% is too high to be consistently reached and maintained or that construction planning still lacks an understanding of feasibility and that the promises made during LPS meetings continue to ignore and stress all the barriers that might impact task execution. From a learning and development perspective, future research should focus on starting levels of PPC from the cases and evaluate the PPC changes during the studies.

Another study finding was the statistically significant difference between the results of articles published in lean-focused journals and those published in other peer-reviewed articles. The fact that research results showing higher PPC values are published in non-lean focused journals may indicate a publication bias (Thornton & Lee, 2000). These findings raise the questions of whether articles presenting low PPC values remain unpublished in peer-reviewed journals and if so, the effect it has on LPS-related research. However, the findings indicates that studies with lower PPC values are compiled in lean-focused journals and conference publications, possibly indicating that the publishers are trying to prevent publication bias. The findings also raise the questions of whether journals focusing on lean will not publish even lower PPC values or whether the lowest samples of PPC values will be published. This finding requires further qualitative research, because the PPC value itself is not necessarily relevant in the published research. What has been studied is how the results have been interpreted based on PPC and what conclusions have been drawn.

The third finding is the geographical differences in published PPC values, which raises several interesting questions for further research. First, are the geographical differences in PPC due to the more extensive and long-term use of LPS, different ways of applying LPS, or different cultures and societies in the continents? For example, cultural differences can affect how low values can be presented in different cultures. There is evidence of differences in the use of LPS; however, the connection to variations in PPC has not yet been investigated (Power *et al*., 2021). Similarly, in relation to takt production, researchers have observed three different geographically distributed schools in the implementation of the method (Lehtovaara *et al*., 2021); this observation may indicate similarities in the use of LPS as well. Further research into the questions arising from these observations is recommended.

The research is limited by the heterogeneity of the material and the variation in the quality of images and tables. Consequently, the researchers had to perform visual evaluations and manual work, especially on the figures; this could affect the accuracy of the individual PPC values. However, no significant loss in reliability occurred because articles with low-quality figures and tables were excluded. Another limitation is the that the majority of the research data contained individual studies that had combined databases containing several projects, implying that they were an "average of averages" and not individual measurement periods. The third limitation is the meta-nature of the study, in which values are averaged; therefore, the reader should exercise care when interpreting the findings. Averages always conceal variations and other valuable information that may exist in the individual studies considered in this study, and the authors recommend familiarizing oneself with not only the results of these studies but also the original research articles. The fourth limitation is that PPC values can vary depending on the type of project, tasks included in the weekly plan, project constraints, uncertainties and risks, and several other variables that make a project a unique achievement. PPC evaluation is flawed if these variables are not considered, and further research should also assess the impact of these variables and how they appear in different academic publications. In further research on PPC, it is essential to expand toward qualitative methods that will provide deeper insights into the statistics and phenomena.

ENHANCING EARNED VALUE ANALYSIS WITH INTRINSIC SCHEDULE PERFORMANCE METRICS

Frédéric Bosché[1] and Kat Larabi-Tchalaia[2]

ABSTRACT

The Earned Value Analysis (EVA) is a well-known, widely taught and used project monitoring method in both public and private sectors. It nonetheless has some limitations that have led to the emergence of complementary methods like the Earned Schedule (ES) or the Earned Duration Method (EDM). In this paper, another method is proposed that aims to address the limitations of EVA in terms of schedule performance assessment. This method introduces intrinsic schedule performance metrics that (1) ensure that the schedule performance of the overall project and that of individual work packages (WPs) can be measured reliably and independently from the performance of preceding WPs; and (2) do not converge to neutral values at the end of the project or WP (e.g. schedule variance converging to zero). This means that not only are project managers provided with reliable data throughout the entire project, but it also allows to record the real schedule performance of past projects for benchmarking and future planning. The proposed metrics and their application are demonstrated using simulations illustrating their benefits, or complementarity with current EVA metrics.

KEYWORDS

Earned value analysis, project, schedule, performance, monitoring.

INTRODUCTION

Earned Value Management (EVM) is one of the most long-lasting project management methods to this day. Detailed in the international standard ISO 21508:2018 (ISO, 2018), it is now well-known and used in both public and private sectors. Countries like the USA, Australia, Canada, Japan, the UK and Sweden now use the method extensively and participate in the progression of EVM in the field through the International Performance Management Council (De Marco & Narbaev, 2013).

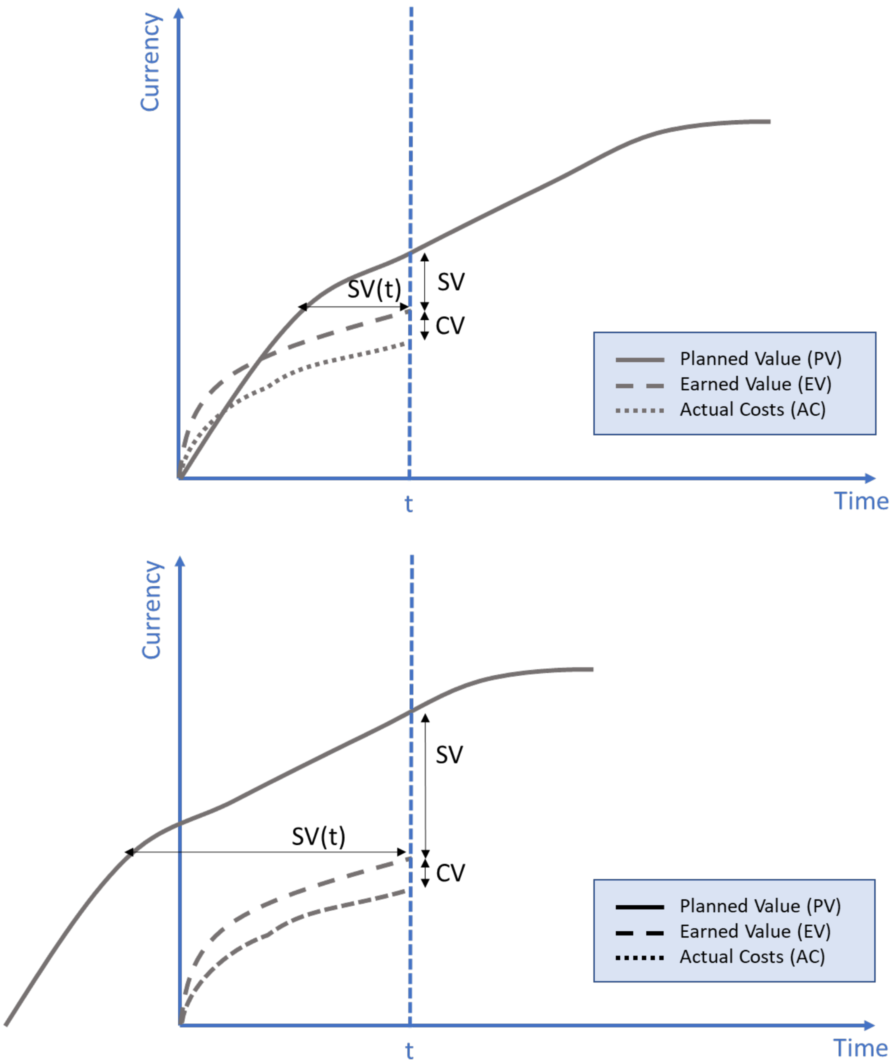
The Earned Value Analysis is the quantitative technique used as part of EVM to evaluate project performance in terms of time and cost. One of the selling points of EVA is that it calculates metrics that measure cost and time performance independently from one another. However, some limitations of the EVA have also long been highlighted. In particular, the EVA's Schedule Performance Index (SPI) and Schedule Variance (SV) metrics are known to lose interpretative meaning once two thirds of a work package (WP) (or project) is completed (Corovic, 2006), at which point they converge to "perfect" schedule performance (i.e. SPI=1.0 and SV=0.0).

[1] Reader, School of Engineering, The University of Edinburgh, Edinburgh, UK, f.bosche@ed.ac.uk, orcid.org/0000-0002-4064-8982

[2] Civil Engineer, Assystem UK Ltd, Bristol UK, kat-externe.larabi-tchalaia@edvance.fr, orcid.org/0000-0002-8078-4743

The Earned Schedule (ES) method has been developed by Walt Lipke in the USA and Kym Henderson in Australia (Lipke, 2003; APM, 2013) in order to express the schedule performance in units of time instead of cost (EVA expresses schedule in units of cost), and to address the convergence of the EVA SV and SPI metrics. Its simplicity and compatibility with the existing EVA technique have led to its widespread adoption and it is presented in ISO 21508:2018 (ISO, 2018). Figure 1 (a) shows a typical diagram used to illustrate the EVA and ES methods and how their metrics are calculated on the graph. The formulas for calculating their corresponding performance metrics are summarised in Table 1 (Lipke, 2003; ISO, 2018).

More recently, the Earned Duration Management (EDM) method was proposed by Khamooshi and Golafshani (2014) as a third alternative that distinguishes micro and macro level performance assessment and computes performance (and forecasts) with more direct relation to schedule-related information. Further extensions to EVM and EDM have also been published recently that focus on introducing new fine-tuned metrics (e.g. (Ballesteros-Pérez et al., 2019)), introducing stochastic measures (e.g. (Zohoori et al., 2019; Hendiani et al., 2020)) and improving the forecasting methods (e.g. (Vandevoorde and Vanhoucke, 2006; André de Andrada et al., 2019)).



(a)

(b)

Figure 1: (a) Illustration of the EVA metrics (SV and CV) and the ES metric SV(t): (a) when the actual start date equals the planned start date; and (b) when the actual start date is delayed.

Table 1: Formulas for the calculation of the main performance metrics calculated in the EVA and ES techniques. In this table, AC is the Actual Cost and PV is the Planned Value.

Technique	Metric Name	Metric Acronym	Formula
EVA	Cost Variance	CV	CV = EV - AC
	Cost Performance Index	CPI	CPI = EV / AC
	Schedule Variance	SV	SV = EV - PV
	Schedule Performance Index	SPI	SPI = EV / PV
ES	Schedule Variance [time]	SV(t)	SV(t) = t' - t with t' the time at which PV(t') = EV(t)
	Schedule Performance Index [time]	SPI(t)	SPI(t) = t' / t

Despite the improvements provided by the ES method, some challenges remain. First of all, it must be highlighted that the EVA method does not require the cumulative PV curve to calculate any of its metrics. These are only calculated based on PV, EV and AC values at the performance measurement time t. In contrast, the calculation of EV(t) requires computing the time t' when PV(t') = EV(t). Besides, this requires the PV and EV curves to be aligned to start on the same date. If that is not the case, then SV(t) loses meaning, as shown in Figure 1 (b). It is interesting to note that this requirement is rarely explicitly stated, even in the ISO standard. This is likely because project managers will typically assess schedule performance at the overall project level, at which the start dates of the EV and PV curves will naturally match. However, this is not necessarily true for the Work Packages (WPs) making up the project, due to precedence relationships which can cause the delay in one WP to generate delays in following WPs. In such situations, any following WP will show poor schedule performance from the start, even if they are delivered as planned. These observations also apply to the EDM method.

This paper attempts to provide a solution to the following research problem: can the EVA technique be refined, or extended, to give schedule performance metrics that remain meaningful throughout the delivery of a WP (and the overall project) and do not require the processing of cumulative data for their calculation?

The next section "Method" presents the proposed intrinsic Schedule Performance metrics, with full details on their calculations. The benefits of these new metrics in comparison to existing EVA metrics, and the ES method, are illustrated in the section "Demonstration" with an example, that is kept as simple as possible but perfectly highlights the weaknesses of existing EVA schedule performance metrics (and ES method) and benefits of the proposed new ones. Finally, the section "Conclusion" summarises the results obtained and discusses future works.

METHOD

INTRINSIC SCHEDULE PERFORMANCE

The comparison between Figure 1 (a) and Figure 1 (b) shows how the start date of a WP does not affect the cost performance metric CV (and similarly CPI). In other words, the cost performance metrics (CV and CPI) rightly capture the *intrinsic* cost performance of the WP. In contrast, the figures also show that the start date does have an impact on the schedule performance metrics SV and SPI. In fact, even if a WP is delivered as planned in terms of intrinsic schedule performance, if its start is delayed, then its schedule performance metric SV is negative (and CPI < 1.0) from the outset and for its entire duration up until its completion (due to SV systematically converging to SV = 0.0). This shows that SV and SPI, as calculated in the EVA method, do not capture the *intrinsic* schedule performance of the WP – and should thus be interpreted with great care. It is important to note that these observations also apply to the ES and EDM methods.

In order to determine the *intrinsic schedule performance* of a WP, the PV curve must be (re-)aligned with the EV curve, by setting the planned start date to be the same as the actual start date of the WP. In other words, a separate, *intrinsic* schedule performance baseline (*intPV*) needs to be created for each WP in the WBS and that is set to start on the WP's actual start date. This second baseline, illustrated in Figure 2, is in effect *intrinsic* to the WP, because not impacted by the performance of preceding WPs. Note that an intPV curve needs to be created for each WP at each level in the WBS.

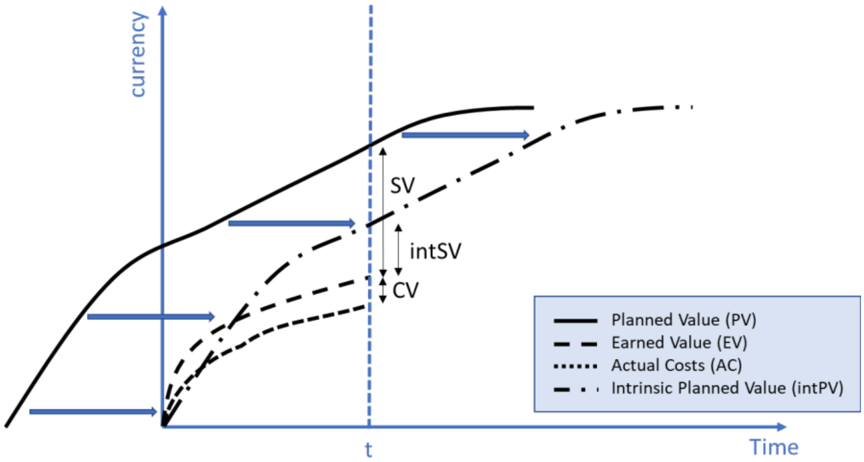


Figure 2: Illustration of the EVA and ES metrics when the intPV curve is added that is the result of (re-)aligning the PV curve with the EV curve (and AC curve).

If PV(t) is the original planned schedule performance baseline of a WP, then the intrinsic baseline intPV(t) can be obtained using the formula:

$$\begin{aligned} intPV(t) &= PV(t-d) \\ &= P\%C(t-d) \times BCWS \end{aligned}$$

where BCWS is the *Budgeted Cost of Work Scheduled*, $P\%C(t-d)$ is percentage of work complete at time (t – d), and:

$$d = S^{actual} - S^{planned}$$

is the difference between the original planned start date $S^{planned}$ and the actual state date S^{actual} of the WP (d is negative if the WP starts earlier than planned).

For completeness, we define *intP%C(t)*, the *intrinsic planned percentage complete* curve calculated as:

$$intP\%C(t) = P\%C(t-d)$$

The formula for intPV(t) then becomes:

$$intPV(t) = intP\%C(t) \times BCWS$$

intPV can now be used to calculate *intrinsic schedule performance metrics*, *intSV* and *intSPI* as:

$$
\begin{aligned}
intSV &= EV - intPV \\
&= (A\%C - intP\%C) \times BAC
\end{aligned}
$$

$$
\begin{aligned}
intSPI &= \frac{EV}{intPV} \\
&= \frac{A\%C}{intP\%C}
\end{aligned}
$$

where $A\%C$ is the *actual percentage of work complete*.

We note that the creation of an intrinsic baseline PV curve, intPV(t), may already be implemented by some practitioners, but such practice is not explicitly suggested in existing standards and most guidance documents, in relation to the ES or EDM methods.

Schedule Performance Convergence Behaviour

While intPV, as introduced above, factors out the impact of the schedule performance of preceding activities on the schedule performance of the activity of interest, intSV and intSPI still converge to 0.0 and 1.0 respectively. This behaviour is illustrated in Figure 3 with the same example where a WP takes longer to complete than planned. The bottom chart shows the evolution of the intSV value as the WP was being completed. The purple part shows the intSV conversion to 0.0, which in that case occurs once the planned duration is passed. Note that the same behaviour occurs if the WP is completed faster than planned. The only difference is that the role of the intPV and EV curves is inverted, i.e. the conversion occurs from when the WP is actually completed until its planned completion date.

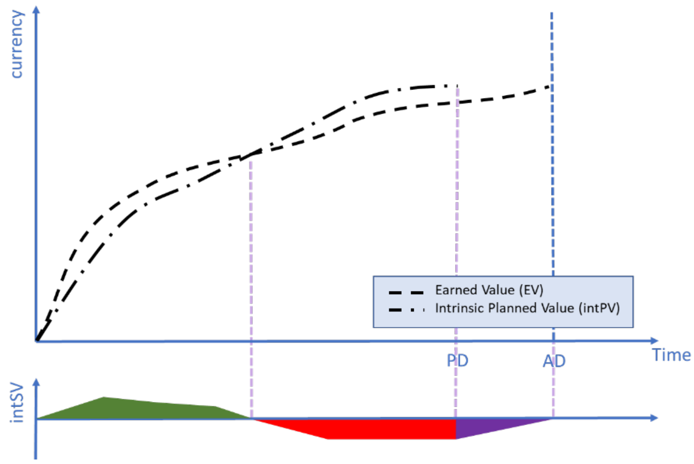

Figure 3: EVA graph for a WP concluding later than intrinsically planned. PD and AD are the planned and actual durations of the WP. The bottom plot shows the evolution of intSV.

To address this limitation, let's start with the case illustrated in Figure 3, of a WP concluding later than planned. In that case, to prevent the conversion, the intPV curve must be artificially extended. This artificial extension of the $intPV$ curve can follow various principles, depending on what may be considered the "financial impact of the difference in completion duration (e.g. delay)". Three approaches are proposed here (illustrated in Figure 4):

a) intPV continues to increase at the same average rate as planned, i.e. for t > PD:

$$intPV_{proj}(t) = \frac{BAC}{PD} \times t$$

b) intPV continues to increase at a rate that maintains intSV at the same value as it was at the time PD (in other words intSV is maintained constant from PD onwards), i.e. for t > PD:

$$intPV_{proj}(t) = EV(t) + intSV(PD)$$

c) intPV continues to increase at a rate that maintains intSPI at the same value as it was at the time PD (in other words intSPI is maintained constant from PD onwards), i.e. for t > PD:

$$intPV_{proj}(t) = EV(t)/intSPI(PD)$$

Note that these options, in particular (b) and (c), follow similar ideas as those proposed for calculating the *Independent Estimate at Completion (IEAC(t))*, i.e. forecasted duration at completion based on various metrics of past performance and assumptions for future performance, in the context of the EVA method (ISO, 2018), the ES method, or the EDM method (Corovic, 2006; Vandevoorde and Vanhoucke, 2006; Jacob and Kane, 2004).

intSV and intSPI are then calculated as normal, i.e. for t > PD:

$$intSV(t) = EV(t) - intPV_{proj}(t)$$

$$intSPI(t) = \frac{EV(t)}{intPV_{proj}(t)}$$

The second case is when a WP is completed earlier than planned. This is illustrated in Figure 5. To prevent the conversion in this case and maintain meaningful intSV and intSPI values, to prevent the conversion of intSV to 0.0 and intSPI to 1.0, intSV and intSPI should simply maintain their values obtained at t = AD, i.e. for t > AD:

$$intSV(t) = intSV(AD)$$

$$intSPI(t) = intSPI(AD)$$

In summary, the proposed strategy to prevent the conversion of intSV and intSPI to 0.0 and 1.0 respectively, is in effect to accrue intPV up to t = AD. In the case of a WP completing earlier than planned, accrual of intPV is simply stopped after t= AD; and in the case of a WP completing later than planned, intPV is accrued artificially after t=PD, until t= AD.

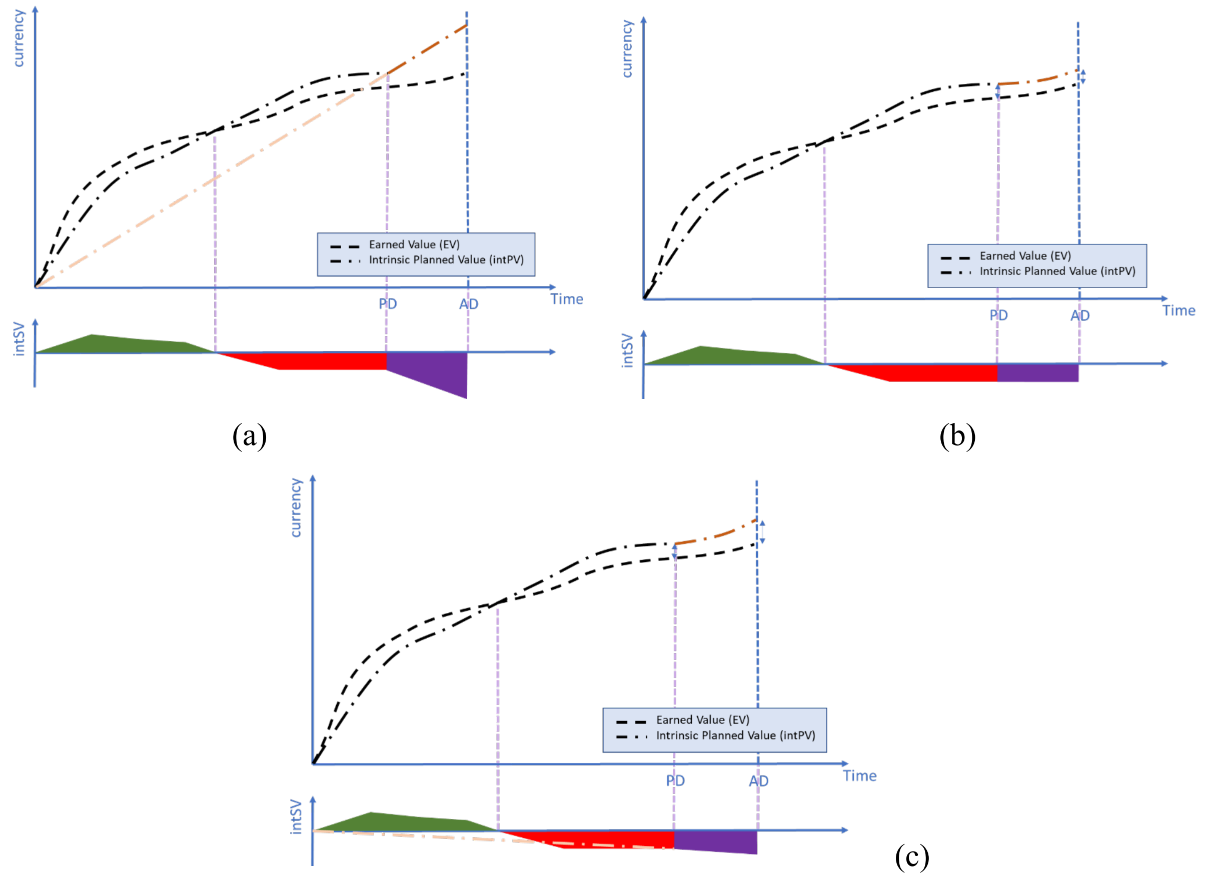

Figure 4: The same EVA graph as in Figure , but where the intPV curve is extended from the PD to AD following three alternative strategies: (a) intPV increases at the same rate as planned; (b) intPV continues to increase at a rate that maintains intSV constant; and (c) intPV increases at a rate that maintains intSPI constant.

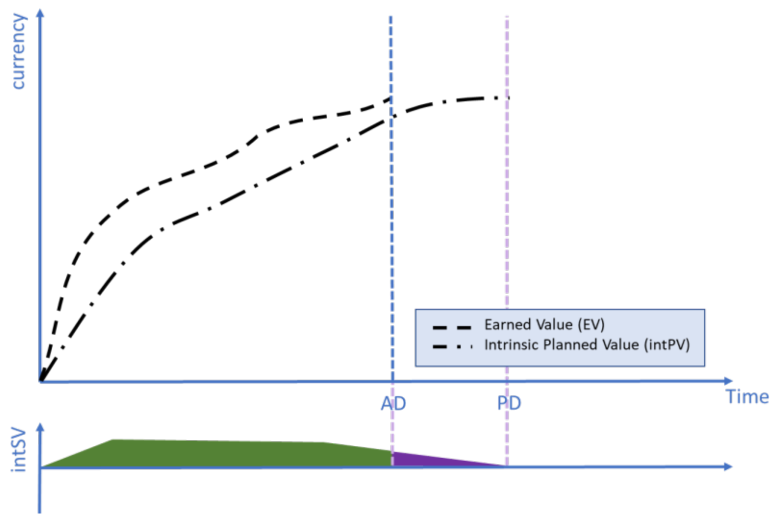

Figure 5: EVA graphs for a WP concluding earlier than planned. PD and AD are the planned and actual durations of the WP, respectively. The bottom plot shows the evolution of the intSV value as the WP was being completed.

SUMMARY

In summary, the proposed method to calculate schedule performance metrics that are intrinsic to the WP (i.e. not influenced by the schedule performance of preceding activities) and that do not converge to 0.0 (SV) and 1.0 (SPI) entails the calculation of: (1) a new curve intPV intrinsic to that WP, no matter its level in the WBS; and then (2) the proposed intrinsic schedule performance metrics intSV or intSPI.

First, the curve intPV is simply a re-baselining of the PV curve so that the planned start date equates the actual start date. Then, intSV and intSPI are calculated as follows:

$$intSV(t) = \begin{cases} EV(t) - intPV(t), & \text{if } t \leq PD \text{ and } t \leq AD \quad \text{[Case 1]} \\ EV(t) - intPV_{proj}(t), & \text{if } t > PD \text{ and } t < AD \quad \text{[Case 2]} \\ intSV(AD), & \text{if } t \leq PD \text{ and } t > AD \quad \text{[Case 3]} \end{cases}$$

$$intSPI(t) = \begin{cases} \frac{EV(t)}{intPV(t)}, & \text{if } t \leq PD \text{ and } t \leq AD \quad \text{[Case 1]} \\ \frac{EV(t)}{intPV_{proj}(t)}, & \text{if } t > PD \text{ and } t < AD \quad \text{[Case 2]} \\ intSPI(AD), & \text{if } t > AD \text{ (including for } t \leq PD) \quad \text{[Case 3]} \end{cases}$$

In the above formulas, the three cases correspond to the following contexts:

d) Case 1: WP is on-going, and its PD and AD are not reached yet.

e) Case 2: WP is on-going, and the PD has been passed (i.e. it is taking longer than planned).

f) Case 3: WP is completed but the PD has not been passed yet (i.e. it took less time than planned).

For Case 2, $intPV_{proj}$ can be calculated using either of the three formulas below depending on the expected schedule performance from the measurement point to completion (other formulas may also be considered):

$$intPV_{proj}(t) = \begin{cases} \frac{BAC}{PD} \times t, & \text{if projection is based on planned performance} \\ EV(t) + intSV(PD), & \text{if projection maintains } intSV \text{ measured at time } PD \\ EV(t) \;/\; intSPI(PD), & \text{if projection maintains } intSPI \text{ measured at time } PD \end{cases}$$

It must be highlighted that the method can be applied for any WP in the WBS, which includes the project overall as well.

DEMONSTRATION

To illustrate the method, Figure 6 shows a simple sequence of two WPs (1.a and 1.b) that are part of a WP higher in the WBS (1). In this diagram, the green bars represent the WPs according to the planned schedule, and the red bars represent the WPs according to the actual schedule. The green bars with the hash represent the WPs according to the intrinsic planned schedule, i.e. planned schedule baseline shifted so that the planned start date is aligned with the actual start date and (artificially) extended up until AD, if needed. We assume that the start of the overall WP was delayed due to some preceding WP having been completed late.

The intrinsic schedule performance metrics and current EVA schedule performance metrics for the two WPs and the overall WP at the end of days 2, 4, 6 and 8 are summarised in Table 2. For simplicity, but without loss of generality, all schedule performance metrics are calculated with the assumption that the PV, intPV and EV progress linearly through the WP durations. In this example, intPV is projected beyond PD using the second projection option defined above, i.e. by assuming that the intSV will remain constant until completion.

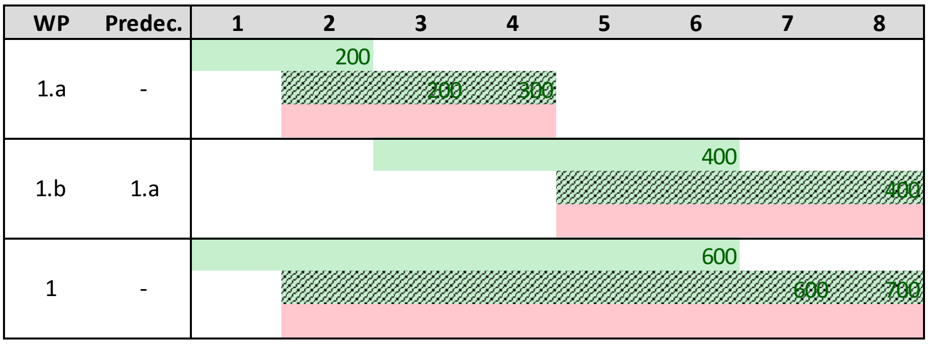

Figure 6: Gantt chart of two sequential WPs. In green: planned delivery. In red: actual delivery. In green with hash: intrinsic planned (i.e. planned baseline aligned to actual start). The numbers indicate the costs (planned and actual) of each WP.

Table 2: The intrinsic schedule performance KPIs and current EVA schedule performance KPI for the two WPs and the overall WP at the end of days 2, 4, 6 and 8.

Day	WP	intSV	intSPI	SV	SPI	intPV	PV	EV
2	1.a	-33	0.67	-133	0.33	100	200	67
	1.b	0	n/a	0	n/a	0	0	0
	1	-33	0.67	-133	0.33	100	200	67
4	1.a	-100	0.67	0	1.00	300	200	200
	1.b	0	n/a	-200	0.00	0	200	0
	1	-100	0.67	-200	0.50	300	400	200
6	1.a	-100	0.67	0	1.00	300	200	200
	1.b	0	1.00	-200	0.50	200	400	200
	1	-100	0.80	-200	0.67	500	600	400
8	1.a	-100	0.67	0	1.00	300	200	200
	1.b	0	1.00	0	1.00	400	400	400
	1	-100	0.86	0	1.00	700	600	600

The intrinsic performance metrics correctly reflect the fact that WP 1.a took 50% more time than planned and that, schedule-wise, WP 1.b is intrinsically performing as planned. In contrast, the SPI and SV values as defined in the EVA technique suggest a completely different picture with 1.a overestimating the delay at day 2 and then converging to 1.0 at day 4 when the activity is actually completed. Similarly, for WP 1.b, SV reports that the activity is behind schedule, but this is only due to the delay of WP 1.a, and not intrinsically due to WP 1.b itself. Then, at day 4, SV and SPI continue to suggest the activity is behind schedule, while it is in fact intrinsically proceeding as planned. And, again, at day 8 the SV and SPI converge to 1.0, thereby losing interpretation meaning. Looking at the overall WP 1, the SPI values suggest at day 2 that the WP is significantly behind schedule (0.33) and then delays are recovered throughout the completion of the WP until the SPI value converges to 1.0 at the end. But, in reality, WP1 does get behind schedule at the beginning due to WP 1.a, but later maintains performance with WP 1.b. This is rightly captured by intSPI that gives a 0.67 value up to day 4, and then 0.8 and 0.86 at days 6 and 8 respectively. The final value is logical since it ultimately took 7 days to deliver the WP which was initially planned for 6 days (6 / 7 = 0.86).

Because the proposed intrinsic schedule performance metrics do not systematically converge to 0.0 (SV) or 1.0 (SPI), they retain intrinsic performance which enables project management teams to more easily trace back the origins of performance deviations. These would also be very useful for organisations to store historical records of the schedule performance of common types of works, which could then be used for benchmarking and enhance the quality of planning for future projects.

In addition, as indicated earlier, because WP 1 starts later than planned, the ES metric SV(t), if calculated with the PV curve as opposed to the intPV curve, is negative from Day 1 and increases subsequently. While it would correctly capture the delay of WP 1 in the context of the broader project (SV(t) = - 2 days at t=8), this would not correspond to the intrinsic schedule performance of the WP that has a delay of only 1 day.

CONCLUSION

In this paper a new set of schedule performance metrics are proposed to complement and strengthen the existing EVA technique. The benefits of the method are that:

- It captures the intrinsic schedule performance of any WP at any level of the project WBS (including the overall project) independently from the performance of preceding activities.
- It ensures that intSPI does not systematically converge to 1, and similarly intSV does not systematically converge to 0. Instead, both continuously and correctly measure the intrinsic schedule performance throughout the duration of WP. This property is useful (1) for project management teams to be able to trace back the source of any performance deviation; and (2) for organisations to keep historical records of past schedule performance to support the planning and monitoring for future projects (e.g. a certain type of work might be more likely to cause delays).
- It does not require any additional input from that needed for the traditional EVA. It can thus easily be added to existing software solutions.
- It provides schedule performance metrics without needing to conduct any look up in the PV curve, as needed by the ES and EDM methods. But, in contrast to those methods, it reports schedule performance in units of cost as opposed to units of time. With regard to the ES and EDM methods, this paper also shows how, although never explicitly discussed in the literature, they should be applied with the intPV curve, not the PV curve.

While the experimental results positively illustrate these benefits, further validation will naturally be pursued with more complex data – ideally from real projects – in order to identify potential challenges or barriers to implementation in practice. Besides, more formal and detailed comparisons of the proposed approach with the ES and EDM methods should be conducted.

ABSTRACT

Monitoring and evaluation (M&E) practices in construction projects are valuable for managing the execution and ensuring quality project delivery. However, implementing the lean-guided M&E practice in construction projects faces different issues and challenges. The study considered issues and challenges in lean-guided monitoring and evaluation practices for construction projects in South Africa. A field survey was carried out among construction professionals in Mpumalanga province, South Africa, to identify issues and challenges they faced in lean-guided M&E practices on construction project activities. A random sampling method was used to collect data, and 36 questionnaires were retrieved from the construction professionals within the study area. Data collected were computed using a descriptive statistical approach. The valid mean item score was determined in this study by utilizing a statistical data equation (mathematical equation). The study's findings showed that lack of dedicated management staff, proper documentation, and construction project goals were the highest-ranked challenges facing lean-guided M&E practices in construction projects. The study concluded that construction professionals should be trained on lean principles and their application in different aspects of construction management and planning to improve the M&E practices on construction sites to achieve set project goals.

INTRODUCTION

The procedure for controlling and examining the construction project process to ensure that professionals involved meet the project objectives is M&E (Ogunbayo et al., 2022). Tengan and Aigbavboa (2019) state that M&E is a tool that aids effective project performance. It is also a valuable tool for managing the execution and successful project delivery (Kissi et al., 2019; Ogunbayo & Aigbavboa, 2019).

M&E is a project management function aimed at sequentially collecting information on construction projects to inform stakeholders involved on the progress on cost, quality, and time triangle towards promoting organizational learning and management decision (Otieno, 2000; Tengan and Aigbavboa 2016; Kusek and Rist 2004). However, M&E, aided by the lean principle for construction projects, will define a clear set of objectives for the delivery process of construction projects. Effective use of the Lean construction principle in guiding the M&E system in construction projects will improve production control throughout the project's life (Locatelli et al., 2013).

Construction professionals and other stakeholders benefit from effective M&E by avoiding unforeseeable issues (Ogolla & Moronge, 2016; Ogunbayo & Mhlanga,2021). In project appraisal for construction work, M&E needs to be complete and ready for projects to be sustainable and relevant (Muiga, 2015). M&E practices in construction projects make it simpler for the construction professional to execute the construction program for an effective production process. Tengan and Aigbavboa (2016) postulated that M&E practices in construction projects are management functions for effective project resource organisation. Hence, M&E is significant to construction industry performance by facilitating strategic decision-making for successful project implementation (Otieno,2000). Nonetheless, Thomas et al. (2003) noted that the main effort of lean thinking in M&E practice in a project is to reduce the high variability that affects it through a more reliable workflow of information, materials, and equipment carried out mainly through the last planner system. Further, Howell et al. (2004) sustain that lean construction and principle is not only about project activity optimization by activity but overall project optimization with bases for consideration on how every single activity affects the next.

Despite efforts made by construction professionals to achieve lean-guided M&E practice in the construction industry, the process faced different issues and challenges. Also, fewer studies have established the issues and challenges affecting lean-guided M&E practices within the construction industry, especially in developing economies (Ogolla & Moronge, 2016; Tengan & Aigbavboa, 2019). Hence, this study uses the South African construction industry as a case study to assess issues and challenges in lean-guided M&E practices in construction projects.

LITERATURE REVIEW

Developing economies' inability to deliver construction projects successfully is based on poor implementation of M&E and practice (Otieno, 2000; Ogunbayo et al., 2018). Construction projects in these countries faced different issues and challenges hindering the lean-guided M&E practice within their construction industry (Bohn & Teizer, 2010). These issues and challenges affected developing economies' construction industry, including South Africa, in meeting their construction target leading to abandonment and delays in construction delivery (Tengan &Aigbavboa, 2016; Ogunbayo et al., 2021).

Bhagavan (2004) states that in the construction industry of developing economies, lean-guided M&E practices are affected by weak government policies, political conflict, corruption among policymakers (government), and a lack of standard M&E guidelines. Similarly, weak government institutions have made the M&E practice in the construction industry face issues and challenges (Oloo, 2011). This has caused corruption among stakeholders (government and construction professionals) involved in the tendering process for construction projects and impacts the lean-guided M&E practice and its implementation (Crawford & Bryce, 2003).

Chaplowe and Cousins (2015) state that lean-guided M&E practice needs a combined effect of good planning, budgeting, and construction targets to achieve all stages in the construction project cycle. However, Prennushi, Rubio, and Subbarao (2002) assert that the lack of construction project goals, objectives, and standard guides or planning for the construction industry are issues and challenges affecting the lean-guided M&E practice in developing economies. Waithera and Wanyoike (2015) noted that insufficient data gathering, poor construction methodology, and construction documentation were issues and challenges affecting lean-guided M&E practice in construction operations and processes. This clearly shows that the weak link between construction project goals, objectives, standard guides or planning, and M&E practice will lead to issues and challenges affecting construction activities (Prennushi et al., 2002; Ogunbayo et al., 2021).

Badom (2016) postulated that in ensuring effective lean-guided M&E practice in construction projects, stakeholders must be dedicated to its implementation, especially by working with appropriate construction documents and lean principles. Zhou and Hardlife (2013) assert that this process can be difficult due largely to a lack of a dedicated management team, poor construction documentation, and a shortage of skilled construction professionals. Similarly, Tengan and Aigbavboa (2016) noted that lean-guided M&E practice is a process that can improve construction proceedings, but its implementation within the construction industry is hindered by insufficient funding allocation by the government, lack of resources and knowledge on lean principle for M&E implementation for construction projects.

Kusek and Rist (2004) posit that a corrupt-free system within a country has a multiplying impact on national economic development, including the construction industry. However, Masoetsa et al. (2022) postulated that the construction industry's economic expansion problem without adequate planning for bureaucracy to cater for lean-guided M&E practice toward a healthy construction industry has led to issues and challenges affecting project executions. Also, the lean-guided M&E practice faces implementation problems in construction projects due to corruption and unethical behaviour of construction workers on sites (Kamau & Mohamed, 2015).

Further, Issa (2013) reveals that Lean construction techniques and principles can potentially reduce the effects of risk factors (issues and challenges) on cost, quality, and time objectives during the M&E process for construction projects. On this note, studies on the significance of using lean construction in construction projects have been conducted in different countries (Adamu & Hamid, 2012; Akinradewo et al., 2018; Fiallo & Revelo, 2002). Further attempts have been made to apply lean principles and techniques to construction project management processes, including the M&E aspect of the construction projects, production control, design, project delivery system, and supply. Koskela et al. (1996) studied a fast-track office building project, and the study's findings showed how the building process could be made leaner and speedier. The study of Tsao et al. (2000) indicated how lean thinking and work structuring helped improve the construction process's design and installation. The finding of the study by Ballard et al. (2002) illustrated the power of lean concepts and techniques and their applicability to construction project processes and operations.

Table 1: Issues and challenges affecting M&E practices.

		Waithera and Wanyoike (2015)	Kenya
18	Insufficient construction funding	Kusek and Rist (2004)	USA
		Tengan and Aigbavboa (2016)	Ghana

However, the application of the lean principles in the M&E process still faces issues and challenges that need to be identified as it affects the construction project processes and operations (Badom, 2016; Kusek & Rist, 2004; Tengan & Aigbavboa, 2016). Additionally, it is critical to identify issues and challenges as it affects the lean-guided M&E practice in construction projects. This is because the political climate around construction projects (on and off the project site) might make it difficult to have effective and efficient lean-guided M&E practices within the project (Masoetsa et al., 2022). These issues and challenges, as highlighted in Table 1, have deprived M & E practitioners within the developing economies' construction industry of meeting the demand for effective construction project flow, budgeting, execution, and delivery (Oloo, 2011; Kamau and Mohamed, 2015; Tengan & Aigbavboa, 2016; Masoetsa et al., 2022). This study aims to affirm these issues and challenges in M&E practice as it affects construction project operations and processes in developing countries using the South African construction industry as a case study.

METHODOLOGY

This study was carried out within Mpumalanga province in South Africa among construction professionals working on construction projects within the construction industry. Respondents for this study were selected based on their involvement and experience with the M&E process in construction projects. Mpumalanga province was chosen for this study because it has many ongoing construction projects (government and private projects) with M&E units established within their construction process. Through the systematic random sampling method, 50 (fifty) questionnaires were administered to the respondents, and 36 (thirty-six) were retrieved. This study used the systematic random sampling method because it is easier and more direct and eliminates the possibility of clustering when adopted than cluster sampling, which breaks the population into different clusters and takes a simple random sample from each cluster. (Rea & Parker, 2014). It also tends to cover all the elements evenly (Ogunbayo et al., 2022). The questionnaire was designed on a 5-point Likert scale and recorded a 72% response rate, using Strongly Disagreeing=1, Disagreeing=2, Neutral=3, Agreeing=4, and Strongly Agree=5.

The respondents were asked questions about their genders, years of experience, profession, and type of construction projects they were involved in the construction industry. Through the questionnaire, respondents were further asked about eighteen issues and challenges facing M&E practices in construction projects identified from the literature. After computation, the issues and challenges identified were sorted from the highest to lowest in terms of their mean item score (MIS). This helped this study assess issues and challenges affecting lean-guided M&E practices in construction projects within the study area. The study adopted descriptive statistical tools using MIS to analyse how participants rated various questions in the survey questionnaire. According to Pallant (2020), means are significant in descriptive research since they reveal average participant scores on a given measure.

RESULTS

Figure 1 reveals the respondents' gender. The result shows that 69.44% (25) of respondents are male, while 30.56% (11) are female construction professionals within the study area.

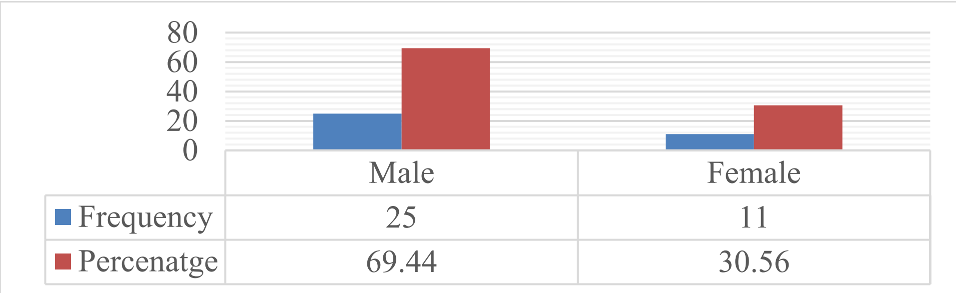

Figure 1: Respondent’s gender

Figure 2 reveals the respondents' years of experience in M&E within the construction industry. The result reveals that 25% (9) of respondents have 0-5years of experience, 41.67% (15) have 6-10 years of experience, 19.44% (7) have 11-15 years of experience, while 13.89% (5) of the respondents have above 16 years of experience.

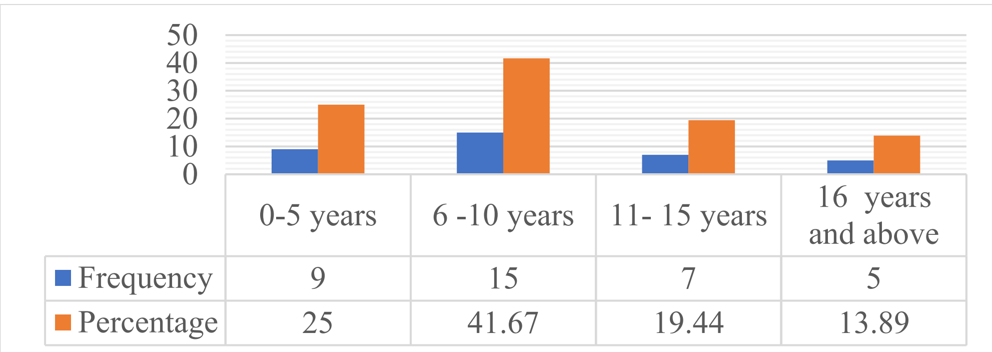

Figure 2: Respondents’ years of experience

Figure 3 shows the respondent's profession in the construction industry. As shown in Figure 3, 22.22% (8) of the respondent are civil engineers,27.78 % (10) of the respondents are construction managers, 19.44% (7) are construction project managers, 25% (9) are quantity surveyors, while 5.56% (2) are other comprises of an architect and a consultant.

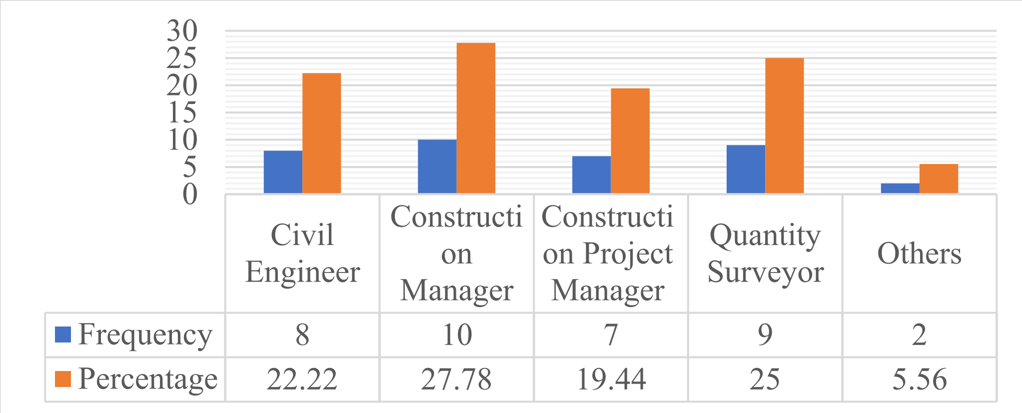

Figure 3: Respondents' professions

Figure 4. reveals the type of construction projects where respondents carried out their M&E practices within the construction industry. The outcomes indicate that 22.22% (8) of the respondents carried out their M&E practices in residential buildings projects, 16.67% (6) of the respondents are involved in civil and road projects,33.33% (12) of the respondents are engaged in private and commercial projects, while 27.78% (10) are involved in government projects within the construction industry.

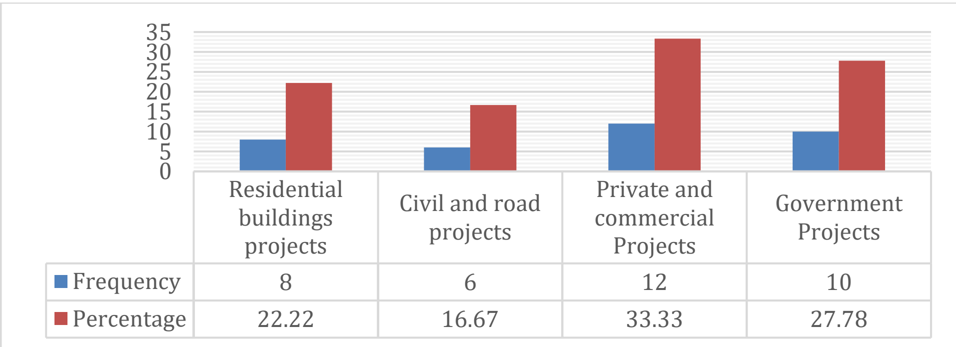

Figure 4: Type of construction projects respondents carried out their M&E practices.

Table 2: Ranking of issues and challenges facing lean-guided M&E practices by respondents

s/n	Issues and Challenges	$\bar{x}$	σX	R
1	Lack of dedicated management staff	4.44	0.773	1
2	Lack of proper construction documentation	4.25	0.937	2
3	Lack of construction project goals	4.19	1.009	3
4	Corruption in construction projects tender process	4.11	0.854	4
5	Lack construction objectives	4.08	0.874	5
6	Problem of economic expansion of the construction industry	4.03	0.774	6
7	Lack of M&E policy by the government	4.00	0.828	7
8	Corruption among government personnel	3.89	1.008	8
9	Corruption among construction workers	3.83	1.000	9
10	Lack of standard guide for the construction industry	3.83	0.845	9
11	Unethical behaviour of construction workers	3.81	0.951	11
12	Shortage of skilled M&E team	3.75	1.317	12
13	Lack of knowledge of implementing M&E	3.75	1.052	12
14	Political conflicts	3.75	0.967	12
15	Lack of construction resources	3.72	1.031	15

16	Insufficient data gathering	3.69	1.238	16
17	Lack of proper construction methodology	3.64	0.990	17
18	Insufficient construction funding	3.61	1.128	18

Mean of the values = $\overline{x}$; Standard Deviation (SD)= σX; Rank = R

Table 2 illustrates the respondent ranking of issues and challenges facing lean-guided M&E practice within South African construction projects. The outcomes show the top and low ranked issues and challenges facing lean guided M&E practice within construction projects delivery and they include; lack of dedicated management staff ranked first with a $\overline{x}$ of 4.44 and a σX of 0.773; ranked second was lack of proper construction documentation with a $\overline{x}$ of 4. 25 and a σX of 0.937; while lack of construction project goals was ranked third with a $\overline{x}$ of 4.19 and a σX of 1.009; corruption in construction projects tender process was ranked fourth with a $\overline{x}$ 4.11 and σX of 0,854; lack of construction objectives was ranked fifth with a $\overline{x}$ of 4.08 and a σX of 0.874; ranked sixth was problem of economic expansion of the construction industry with a $\overline{x}$ of 4.03 and a σX of 0.774; while lack of M&E policy by the government was ranked seventh with a $\overline{x}$ of 4.00 and a σX of 0.828; corruption among government personnel was ranked eighth with a $\overline{x}$ of 3.89 and a σX of 1.008; while corruption among construction workers with a $\overline{x}$ of 3.83 and a σX of 1,000 was ranked ninth; lack of standard guide for the construction industry was also ranked ninth with a $\overline{x}$ of 3.83 and a σX of 0.845. In addition, unethical behaviour of construction workers was ranked eleventh with a $\overline{x}$ of 3.81 and a σX of 0.951; shortage of skilled M&E team was ranked twelfth with a $\overline{x}$ of 3.75 and a σX of 1.317; lack of knowledge of implementing M&E was also ranked twelfth with a $\overline{x}$ of 3,75 and a σX of 1,052; ranked twelfth was political conflicts with a $\overline{x}$ of 3,75 and a σX of 0,967; lack of construction resources was ranked fifteenth with a $\overline{x}$ of 3,72 and a σX of 1,031; while insufficient data gathering was ranked sixteenth with a $\overline{x}$ of 3,69 and a σX of 1,238, ranked seventeenth was lack of proper construction methodology with a $\overline{x}$ of 3,64 and a σX of 0,990; and insufficient construction funding was ranked lastly with a $\overline{x}$ 3,61 and a σX of 1,128.

DISCUSSION OF FINDINGS

The study assessed the issues and challenges in construction project M&E practices in construction project delivery within the South African construction industry. The result of the study indicated that lack of dedicated management staff, lack of proper construction documentation, lack of construction project goals, corruption in the construction project tender process, lack of construction objectives, and the problem of economic expansion of the construction industry were the highest-ranked (1st - 6th) issues and challenges facing lean guided M&E practice. The finding aligns with Prennushi et al. (2002) and Crawford and Bryce (2003) that lack of project goals, corruption in the tender process of projects, and absence of objectives for construction projects were challenges facing lean-guided M&E practices in construction work. Similarly, the finding agrees with Kusek and Rist (2004), Waithera and Wanyoike (2015), Badom (2016), and Masoetsa et al. (2022) that improper construction documentation, economic expansion of the construction industry, and lack of dedicated management staff were issues affecting lean-guided M&E practices in the construction industry. The study's findings imply that poor management processes in contract documents, such as bills of quantity, construction agreements, general conditions, special conditions, and drawings, affect M&E practices for construction projects if not well guided by lean principles.

The findings also showed that lack of M&E policy by the government, corruption among government personnel, corruption among construction workers, lack of standard guide for the construction industry, unethical behaviour of construction workers, shortage of skilled M&E team, lack of knowledge of implementing M&E and political conflicts were mediumly ranked (7th – 12th) issues and challenges facing the M&E practice in the construction industry. The study affirmed Bhagavan (2004), Oloo (2011), and Masoetsa et al. (2022) that issues and challenges facing M&E practices in the construction projects were poor government policy on M&E, corruption among government officials in the M&E documentation process, corruption among construction workers in the production process, absent of M&E specialist, and poor knowledge on the implementation of M&E procedures. This study findings also agree with Crawford and Bryce (2003) and Zhou and Hardlife (2013) that the lack of a standard guide for the construction industry, unethical behaviour of construction workers, and political conflicts and instability were issues and challenges facing M&E practices in construction projects. The study findings imply that M& E of construction projects guided by lean principles will not be effective in the construction projects if issues such as corruption in the construction process and operation are not deterred. This can also lead to substandard work caused by unethical behaviour among construction workers and poor understanding of the lean principle.

Further, the findings indicated that lack of construction resources, insufficient data gathering, lack of proper construction methodology, and insufficient construction funding was the least ranked (15th -18th) issues and challenges facing the M&E practice in construction projects. This supports Kusek and Rist (2004), Waithera and Wanyoike (2015), and Tengan and Aigbavboa (2019) that poor funding of the construction industry, scarce construction resources, inadequate data gathering, and dearth of proper construction methodology were issues and challenges facing the M&E practices in the construction projects. The study findings imply that poor understanding of the lean principles in the M&E practices can lead to poor handling of the construction methods and resources. This might affect the use of digital tools, especially in gathering enough data information for the construction process and operation. Moreover, lack of understanding and usage of the lean construction principle among M&E practitioners in construction projects might discourage clients or project sponsors, especially in mega construction projects, from being conscious of providing projects funding because of the poor establishment of the lean principle on M&E practice for the construction projects.

CONCLUSIONS

The study assessed issues and challenges facing lean-guided M&E practice in construction projects in the South African construction industry. The study identified a lack of dedicated management staff, lack of proper construction documentation, lack of construction project goals, corruption in the construction project tender process, lack of construction objectives, and the problem of economic expansion of the construction industry as major issues and challenges facing M&E practice in construction project delivery. These issues and challenges were caused by the construction professionals' poor understanding of lean construction principles. The study suggested that to avoid issues and challenges in lean-guided M&E practices in construction project delivery, government personnel and construction professionals involved in construction M&E should be trained on lean construction principles and their application to different aspects of construction management planning. The study concluded that construction project M&E practice should be guided by proper government policy enacted through the Act of the parliament. Government agencies such as the Construction Industry Development Board (CIDB) and other construction professional bodies in South Africa and other developing countries should establish monitoring and enforcement units guided by lean construction principles to monitor the implementation of M&E practices on construction projects. The study contributes to the body of knowledge by making the professionals and government agencies involved in construction project delivery identify issues and challenges anticipated in lean-guided M&E practices and the need to understand the importance of lean construction principles toward achieving efficient construction production and control.

ABSTRACT

Optimized Cycle-Time Flow (OCF) is a comprehensive lean construction approach to portfolio, process, and operations management of design, demolition, and tool installation projects. It comprises seven principles which teams can implement in sequence to align resources across a portfolio of projects, remove constraints, and plan for continuous uninterrupted execution of each project once it has started. Beginning in 2018, it has been applied to increasingly larger portfolios of projects in an expanding set of Intel facilities, generating consistently reliable results with up to 50% reductions in project cycle-time. A plethora of quantitative data collected through action research over five years indicate that the characteristics of OCF make it more resilient and persistent than many lean construction interventions, overcoming the various barriers to implementation discussed in the literature. The results indicate that OCF principles, vertical integration, leadership, and education make OCF repeatable and scalable. Applying these features to lean construction implementations may help practitioners achieve better results.

KEYWORDS

Action Research, Constraint Management, Last Planner® System, Optimized Cycle-Time Flow (OCF), Production Control, Strategic Integration & Planning

INTRODUCTION

Optimized Cycle-Time Flow (OCF) is a comprehensive approach to portfolio, process, and operations management of projects developed and tested within Intel Corporation at several worldwide fabs. Tool installations are short-term construction projects with very high product and process complexity. A typical semiconductor fab tool has tens, sometimes hundreds, of connections to infrastructure and material supply systems.

OCF is an improved version of the original Optimized Installation Flow (OIF). OIF achieved a 48% average cycle time reduction on a portfolio of 75 projects and 42% on 33 projects (Gabai and Sacks 2020). Gabai sought to explore whether cycle-time reduction could be scaled from the Project Implementation Team (PIT) level to the program level to learn how to better improve the system and its application through action research (Azhar et al. 2010; Lewin 1946). As is common in action research, Gabai was immersed in repeated cycles of

devising the system, applying it in practice, evaluating the outcomes of the action, and improving it according to learning. The objectives of the research were to determine the degree of OCF impact to which it might contribute to reducing project cycle-times and to identify which aspects that make it resilient and scalable in implementation.

To date, OCF and OIF have been implemented on more than 1,700 projects at Intel fabs, in portfolios of ~300 at Kiryat Gat in Israel and ~1,400 at Intel's fab in Arizona, supporting a unique longitudinal action research effort. The wealth of experience and data collected enabled analysis of the mechanisms behind its success manifested primarily in a reduction of cycle-time of some 50% across the portfolio with significant productivity gains for trade crews. In this paper, we describe the challenges faced and review data to highlight ways in which this lean construction innovation was scaled and implemented without loss of focus, degradation of the practice, or the results over time.

OIF/OCF ORIGINS

In 2018, Doron Gabai (the lead author) was assigned to lead a subprogram with Intel Corporation construction teams. He managed three project managers, ten construction coordinators, and five hundred subcontractor trade personnel - from process-mechanical, dry-mechanical, electrical, and architectural disciplines. Although Gabai ostensibly had mature teams that previously worked together and well-defined project scopes consisting of repetitive tasks with the latest tools and techniques - his projects continued to finish late with abound excuses and unpredictable results. He was forced to request and apply acceleration actions. In retrospect, most of the mishaps could have been avoided if strategic planning had been in place to enable PIT members to catch them in a timely manner. Repeated production failures became stressors to Gabai's teams and blighted his professional track record. Gabai's mission to empower his teams to achieve their best was failing. He disliked reporting weekly failures and sought a better way - a new strategy that would:

- Benefit both project stakeholders and PIT
- Resolve constraints prior to production
- Start a project only when ready
- Not allow late production
- Not allow stopping after a project has started
- Consistently produce success and optimize flow

Gabai and his PIT began experimenting with planning strategies derived from the Last Planner® System (Ballard 2000; Ballard and Tommelein 2016), Strategic Project Leadership (Shenhar 2015), the Theory of Constraints (Goldratt and Cox 2016) and the Portfolio, Process and Operations (PPO) model (Sacks 2016) depicted in Figure . OIF integrated two project management principles (*strategic integration planning* and *target tactical planning*)**,** two LPS steps (*collaborative planning* and *constraint management*)**,** two measures design to ensure project flow at the portfolio level (*control installation start* and *ensure continuous installation*) and an emphasis on *prefabrication* (Gabai and Sacks 2020). OIF was tested on a set of 199 projects over a period of 18 months from July 2018 through December 2019. Intel teams successfully reduced installation cycle-times by 42% to 48% without adding additional resources or acceleration. This was measured as actual installation project start-to-end durations divided by planned durations, as recorded in Primavera P6. The name changed from OIF to OCF when the system operated on a portfolio level and reliably reduced cycle times when portfolios of multiple projects of a variety of types were planned in concert.

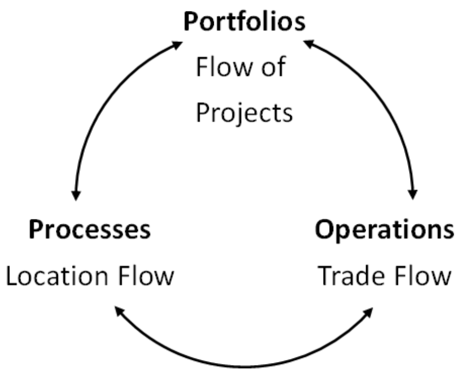

Figure 1: PPO Model - cyclical view of the relationship between project portfolios, processes and operations (Sacks 2016).

WHAT IS OPTIMIZED CYCLE-TIME FLOW (OCF)?

OCF applies seven principles to optimize flow of projects within an organization's portfolio while simultaneously reducing cycle-times and resources. It reduces the number of work-in-process (WIP) through a combination of prefabrication and constraint clearance filtering. This optimizes process flow through sound structuring of resources, task allocations, and multi-trade collaboration. OCF also applies organizational learning to maintain and repeat practices of this workflow for future projects. The Flywheel in Figure 2 depicts the seven principles. Six out of the seven principles emphasize deliberate serve as overarching strategic integration and planning that propel the flywheel. The arrows in the middle of the flywheel – trust, value, innovation and knowledge – help build and maintain flow. Achieving a reliable flow of projects and processes is one of the explicit goals of OCF and enables predictable project delivery. The principles collectively implement strategic integration and planning to enable a thorough production start in principle seven.

OCF Principles:

1. Plan & Integrate Strategically
2. Plan Tactical Targets
3. Collaborate
4. Resolve Constraints
5. Restructure Resources
6. Control Project Start
7. Ensure Project Flow

Figure 2: Optimized Cycle-Time Flow Strategy for management of projects

The sequential order of OCF principles establishes the planning and control of workflow for all stakeholders involved, from executive-level teams to production teams. Each principle requires an immediate action and builds upon the prior principle onward into the start of production in Principle VII. Table outlines the intended outcomes of applying principles within an OCF batch in a project to enhance the flow of a program portfolio. Six of the seven apply to the planning phase, which emphasizes the importance of deliberate planning.

Table 1: OCF Principles and intended outcomes.

Principle No.	Principle name	Intended outcome	Project phase
I	Plan & Integrate Strategically	Align project strategy with organizational strategy, establish 50% reduction of both cycle-time and resources	Initiation & Planning
II	Plan Tactical Targets	Written plan with percentage duration reduction target	Planning
III	Collaborate	Stakeholders' commit to OCF targets	Planning
IV	Resolve constraints	Proactively identify and resolve resource, information, procedure, material, labor, and space constraints	Planning
V	Restructure Resources	Shift skills/activities off critical path/project	Planning
VI	Control Project Start	Start only when ready by re-evaluating checklists	Planning
VII	Ensure Project Flow	Execute and maintain flow using one dedicated team "Touch the Project Once"	Execution & monitoring

OCF was developed in response to numerous problems observed in prevailing project management practices. Like many other lean construction interventions, it conflicts with existing behavioral patterns that are deeply ingrained in the traditional culture of construction. This requires paying careful attention to hearts and minds, as workforce and managers need to reset deeply-rooted ideas about production planning and control. The problems that were observed and ways in which OCF principles address them are detailed in Table .

Table 2: Production problems observed during 2018-2022 in two sites and the OCF approach to ameliorating them. Relevant OCF principles are listed in parentheses.

Problem	Description	OCF strategy
Multi-Projecting (project WIP)	Teams often struggled to work simultaneously on up to eight different tool installation projects in different locations	OCF assigns one project per team at a time. Allowing a team to focus on one project reduces distractions and overworking the PIT (*Strategic Integration & Planning, Project Flow*)
Optimism Bias and Parkinson's Law	Much time is wasted and/or unreasonable deadlines are set. Targets are set, but not discussed with the teams who are performing the work.	OCF requires ongoing collaboration between the PIT and stakeholders during strategic integration and planning; input from the PIT is solicited, valued, and shared with stakeholders (*Target Tactical Plan, Collaboration*).
Wasted Work	Teams do not finish what they started without changes and/or multiple interruptions (e.g., waiting for materials, waiting for crews, waiting for approvals)	The PIT's skill and expertise are respected and applied for constraint filtering. Projects start only when make-ready checklists are complete. OCF's six planning principles are preventative discussions that enable uninterrupted project execution and prevent rework (*Constraint management, Project start*).
Competing Priorities	Every task in a project is considered "high priority". This leads to provision of resources to complete the tasks, which denies resources from other tasks.	Knowing true priorities reduces stress on the PIT. OCF applies readiness tools to label priorities: OCF batching matches resources demonstrated capabilities with the right priorities (*Strategic Integration & Planning*).

Problem	Description	OCF strategy
Constant Change	Change in project scope is prevalent due to market demands (the need to keep ahead of competition). Most often change is introduced during a project surprising and disrupting teams' performance	OCF enables a competitive edge by reducing cycle-time. This allows freeze of scope: when a PIT starts project *i*, the scope of project *i+1* is frozen. Changes can still be made only in OCF batch *i+2* subject to thorough application of make-ready checklists. Thus, OCF establishes a stable and predictable way to introduce innovations and changes for the PIT (*Strategic Integration & Planning, Project Start*).
Inefficiency	Project 'acceleration' actions lead to inefficiency because they force trade crews to move resources from project to project, interrupting other projects in unpredictable ways.	OCF avoids accelerated work schedules that overwork the PIT and establishes consistent and ongoing work for the PIT to complete (*Strategic Integration & Planning, Project Flow, Throughput formula*).
Task Force Mode	Priority projects are assigned exclusive resources, disrupting PITs.	The OCF batching team proactively removes constraints with PIT and stakeholders' assistance, eliminating the need for 'Task Force Mode' (*Project Flow, Strategic Integration & Planning*).
Lack of Incentive	No incentive to finish projects early; we typically have not acknowledged PITs for finishing a project early	Finishing projects early and reliably give PIT time for a break and helps avoid stress. Early finishes are recognized and rewarded (*Project Flow, Strategic Integration & Planning*).
PAS Start valued more than PAS Finish	Start Progress (or Performance) Against Schedule (PAS) was prioritized. Teams were frequently successful at starting, but less frequently succeeded in finishing on time.	OCF does not allow projects to start unless ready and enables successful completion. PIT can be assured that once they start, they will finish (*Project Start, Project Flow*).
Multi-Tasking	PIT trade crews work on multiple tasks simultaneously and priorities often change. Often when welding or bending pipes, for example, teams are sent to work on different tasks (fetching materials, for example).	OCF does not allow changes to task assignments during production and enforcing make-ready conditions means the PIT can consistently complete tasks with repeatable results. This also reduces safety risks and improves quality (*Strategic Integration & Planning, Restructure Resources*).

Extensive data obtained from OCF implementations (Freeman 2022a; Miera et al. 2021) indicate the following measurable and quantifiable benefits of OCF:

1. **Increased Organizational Throughput:** Reduced project cycle-time improves project throughput in accordance with Little's Law, allowing control of work in progress (WIP). Overall, schedule execution is reduced by eliminating constraints and idle times in the strategy. This is achieved without acceleration.
2. **Predictable Delivery Performance and Execution:** OCF provides a visual representation of current projects and prioritizes OCF batches based on customers' needs through predictable delivery performance.
3. **Improved Cost Control & Cash Flow:** Reduction of the cost of resources due to reduced waiting and continuous work, thanks to strategic planning of project batches and improved schedule predictability and reliability. Resource demand is leveled, avoiding peaks that degrade productivity.

4. **Change Control:** Rather than apply innovations via short-term project scope changes. Innovations are introduced in i+2 OCF batches. This prevents interruption and disturbance to the workflow of the majority of projects.
5. **Efficient Decision Making:** OCF batching decisions are made in collaboration with project customers and support stakeholders, freezing and prioritizing per customer needs.
6. **Shorter time to market:** The overall value of the strategy when applied broadly is to reduce the time needed to bring new products to market.

The associated qualitative benefits to the company and different stakeholders include enhanced competitive advantage, operational excellence, improved communication and increased internal customer satisfaction.

EXPANDING IMPLEMENTATION

Expanding and implementing OCF required overcoming barriers identified in the literature (Bølviken and Koskela 2016). A recent study highlighted a lack of support and commitment from top management as a barrier (Moradi and Sormunen 2023). Gabai faced multiple challenges when scaling and expanding OCF beyond Israel to Arizona. However, working with co-authors Miera and Cloyd, Gabai and his team were able to demonstrate production results with sufficient throughput improvement to convince top management that OCF succeeds in engendering vertical integration. They were guided by Kotter's eight steps for leading change (Kotter 2012, Fig. 2-2 p. 23). In the OCF context, this involved:

1. Emphasizing the urgency of implementing tool installations effectively to provide a competitive edge in semiconductor fabrication.
2. Convincing management that the OCF strategy was an effective solution and explaining the benefits to PITs through their lenses.
3. Formalizing the OCF strategy and documenting it clearly.
4. Identifying and equipping OCF Champions to lead teams.
5. Convincing PIT members, both employees and subcontracted trade crews, to take the risk necessary to change their patterns of work.
6. Generating and celebrating early wins – work with the most promising candidates in each PIT, experiment with OCF to gradually optimize 50% cycle-time reduction.
7. Promoting ongoing learning and education of OCF goals per project through team collaboration, measuring results and assessing production flow for improvement.

Nevertheless, finding willing partners among project managers and production teams proved exceedingly difficult. Gabai leveraged the experience of five fearless early adopters (Montoya, Yalung, Bambauer, Miller and Lempert) – all project managers with whom he worked previously (Freeman 2022b). He met with trades and other subject matter experts (SMEs) within their PIT to engage them. This resulted in an initial set of 48 projects with an average of 48% reduction in cycle-times.

Gabai devised a strategy for the broad implementation of OCF, answering such questions as: What would the throughput look like? What are the cycle-time benefits for the program? A careful analysis of implementation barriers across teams served as possible solutions to guide this effort. The analysis is detailed in Table .

Table 3: Barriers to OCF implementation in Arizona and solutions applied.

Barriers to OCF implementation in Arizona	Strategic OCF Solutions
Contracts from previous projects set the tone for doing things the same way. Convincing trades that OCF was different to current practice, where only Last Planner® was used, was challenging	Help people understand the current reality and see the future, building a shared vision, making incremental improvements, and asking what needed to be done to make this successful. The small wins when the team hit 25% (crawl) and 33% (walk) aiming toward 50% (run) targets were celebrated – building trust.
Culture of the project ecosystem. Each team believed that others were the constraints.	Formed a coalition of the willing – following Kotter's 8th step. This is the foundation of vertical integration. We established an OCF Program Batching team that met daily to continually communicate the vision, remove obstacles.
Threading various groups together. Lack of cohesiveness, multiple teams working in silos. Focus on local optimization.	Team leaders understood that OCF was unlike other strategies. They learned that OCF is not simply tactics or objectives, and they may have recognized parts of OCF in previous initiatives such as IPD or Last Planner® System. They learned to avoid selective implementation and implement all seven principles to yield disruptive change.

OCF was performed with four PITs in 2020, and this grew to eight Arizona PITs that included design teams during 2021 and 2022. The Arizona team developed a strategy to halve the project durations using a crawl, walk, run, methodology. As each new group of trade partners was introduced to OCF, they initially set a target of a 25% reduction in duration. This allowed gradual onboarding of new trades to experiment with the owner and develop trust over time while applying the new strategy with a less demanding target. As project managers and PITs learned and grew in confidence applying OCF, targets were adjusted to a 33% reduction of duration for their next set. Finally, a set of 378 projects was given a 50% target reduction rate. Figure shows the distribution of outcomes. The 57 projects with targets of 25% achieved an average of 26% schedule reduction in practice. The 139 projects with 33% targets achieved 34% and the 139 projects with 50% targets achieved 48%. Table shows the expanding number of projects.

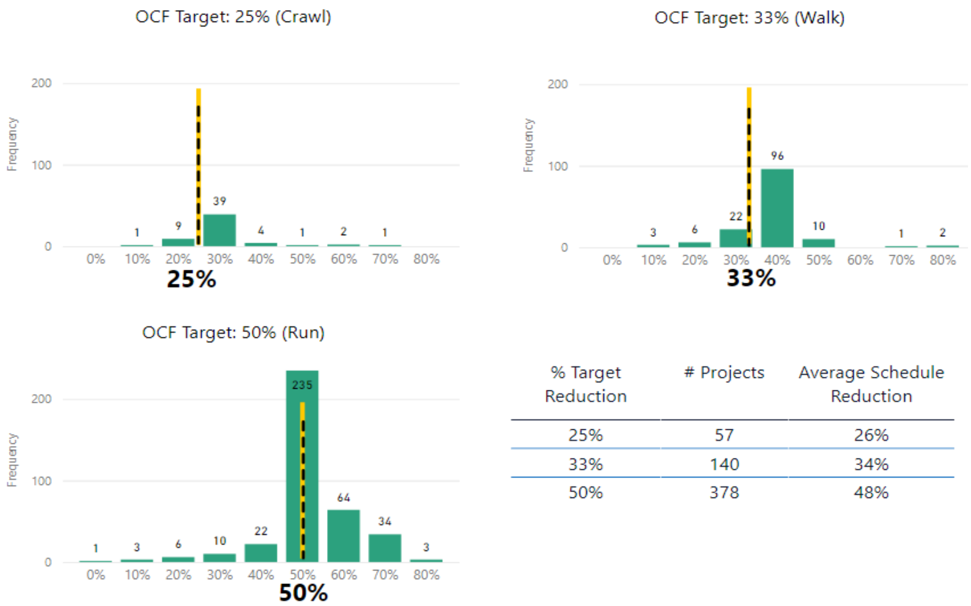

Figure 3: Distribution of duration outcomes for crawl (25% target reduction in duration), walk (33%) and run (50%) projects sets.

Table 4: Expansion of OCF to Intel's Arizona PITs (quantity of discrete projects).

Project type	2020	2021	2022
Demolition	-	281	220
Design	-	230	105
Tool Installation	48	307	268
Total	48	818	593

Over time, the Arizona OCF program yielded five times as many projects as Israel and demonstrated a 233% throughput improvement compared to non-OCF projects for Intel Corporation. Table lists the cumulative total project durations over five years. This was made possible thanks to vertical leadership and upper management changing the ecosystem culture from the top down in the organization in terms of planning and executing OCF projects. At the time of writing, the company has completed more than nineteen batches of OCF projects reducing costs and substantially enhancing revenue for Intel benefitting subcontracted trades and third-party teams. We have annotated three anecdotal comments from PIT trade members below saying the following:

- "This [OCF] program definitely shows a nice level even flow of work without the spike in manpower…that's what I got out of it."
- "All of us trade partners – the majority of us were doing well on the performance side but, every once in a while, there was a supplier or equipment delay. That's where we found our biggest challenge because then it's a domino effect on batching. So, everyone has to perform 100% for the batching to be 100% successful. I definitely felt like this last ramp that we went through was smoother."
- "Schedule wise it was successfully compared to previous ramps for sure and the profitability side you know…we did not lose money overall, the teams definitely liked the [OCF] batching program – the "get it done before we start a new task." They definitely preferred, enjoyed and liked that method of scheduling. So we're on board with this, this OCF concept for sure."

Table 5: Cumulative total project durations in days for OCF implementations of tool installation and demolition projects - baseline plan, OCF target and OCF actual days.

Baseline Plan, Target, Actual	2018 ISR	2019 ISR	2020 ISR & AZ	2021 ISR & AZ	2022 ISR & AZ
Baseline Plan project days	1,057	3,996	3,969	16,231	11,321
OCF Target project days	826	2,753	2,422	8,357	6,572
OCF Actual project days	502	2,288	2,129	8,775	6,674
% Reduction (Actual vs. Baseline)	53%	43%	46%	46%	41%

DISCUSSION

Organizations must adapt to be innovative to meet current and future demands. These innovations require projects to be better optimized for them to deliver new products or services. Hence, many organizations run portfolios of numerous projects and programs in parallel. To yield outcomes that lead the market, an organization's ecosystem should enable setting the right priorities for compatible resource allocation so that the goal of the projects can be done in shorter and more predictable cycle-times ahead of competition.

Considering the barriers to the implementation of lean construction innovations and Kotter's steps for organizational change, the OCF team at Intel focused on preparing leadership by highlighting and publicizing potential benefits to educate PIT teams - taking proactive steps to remove barriers to lean construction implementation.

LEADERSHIP AND EDUCATION

OCF has garnered engagement from top management because of active participation mandated beginning with principle number one to completion to strategically plan with a commitment to the schedule and needed resources to optimize 50%. OCF is not deployed successfully without vertical leadership support and recognition of mutual benefits for both the organizational and PIT ecosystems. Thus addressing Moradi and Sormunen's (2023) findings on lean barriers. OCF Champions, stakeholders, etc. must fully understand the organizational benefits of OCF in conjunction with the benefits of OCF for the PIT prior to attempting strategic integration and planning discussions. This helps everyone understand the "why" and the need for such a holistic production strategy.

Collaboration and the component of mutual benefits for everyone (i.e., the customer, production, and organizational teams) were focal points for reiterating the crawl, walk, run optimizations of OCF cycle-times. Miera, Cloyd and Gabai coached PMs to keep crawl, walk, run in mind as they developed target pull plans for their OCF batches. PMs had to adapt to new targets based on the OCF batch; applying Principles I and II which helped to identify OCF Champions – team members who fully grasped and accepted the strategy. Next, an OCF batching team of leaders from Intel, internal customers, and PITs worked side by side to devise an inclusive strategy at all levels of program implementation to address:

- Why are we doing this?
- What is the shared vision that will inspire and challenge our teams?
- Are we freezing the scope?
- Do we have an up-to-date target tactical plan?
- How do you turn common field constraints into a pre-defined constraint checklist?
- Are we really ready to start?
- Can we start and not stop?

BARRIERS TO LEAN IMPLEMENTATION

Many publications point out the difficulties that implementers of Lean Construction face (Bølviken and Koskela 2016; Moradi and Sormunen 2023). Lack of definition of what constitutes Lean Construction hinders both adoption and sustainable implementation from managers and crews often not having a clear idea of what is expected of them (Leong et al. 2015; Pasquire 2012). Mano et al. (2020) provide a useful meta-analysis of the literature. From some 400 causes identified, they isolated eight key barriers to Lean Construction implementation: (1) lack of commitment in the team, (2) difficulty in obtaining support and commitment from upper management, (3) resistance to change from leaders, (4) difficulty in centralizing the focus of the client's business, (5) resistance to change from employees, (6) inability to measure the progress of the Lean project, (7) decision centralization, and (8) lack of preparation by the managers to conduct the change. Six of the eight relate to leadership, and three highlight the need for a solid base amongst company leaders prior to deployment. Reflecting on our action research taken to expand implementation of OCF and subsequently to other Intel sites in the US, Far East, and Europe, one can identify how OCF defused barriers. Appendix A outlines the barriers identified and discusses how the comprehensive strategy ameliorated those barriers.

CONCLUSION

OCF implementation started with Doron Gabai attempting to bring predictability and order to the project portfolio of one Intel PIT. In doing so, he created added value for the team, for Intel stakeholders and for subcontracted suppliers. The OCF journey continues, with expansion of adoption within Intel and beyond. At the time of this writing there are three OCF sites (Israel, Arizona, and Oregon), each at a different point in their OCF journey, applying OCF to four different project types (tool install, demolition, design, and progressive build). More than 1,700 projects have been successfully delivered ahead of schedule without adding resources, funds, or time.

The barriers authors encountered mirror those identified in the literature, with leadership ranking as the top barrier. We propose the OCF strategy as a means to overcome barriers and deploy Lean Construction to project portfolios reliably, consistently, and predictably. Among the key aspects that enable OCF to achieve changed beahviours reliably are a) a set of formally defined and standardised steps that must precede the start of any project, all aimed at ensuring continuous execution without stoppages; b) a conscious effort to level resource allocations across the portfolio of projects, avoiding overloading of any critical resources; c) setting of aggressive targets for cycle-time reduction up to 50% in full implementation when compared with accepted practice, which preventing reliance on incremental adaptation in favour of the thorough fundamental realignment of the project execution strategies of PITs.

The findings of this action research may contribute to researchers and practitioners seeking a formal framework to support scalable and reliable Lean Construction implementation.

APPENDIX A: BARRIERS TO IMPLEMENTATION

Table 6: Aspects of OCF that address barriers to implementation of Lean Construction.

#	Barriers to Lean Construction	OCF Strategic Solutions	Main OCF Principle #
1	Lack of commitment in the team	All stakeholders commit to reviewing pre-OCF results and assessing the need for changes to implement OCF strategy	I & III
2	Difficulty obtaining support and commitment from upper management	Collaboration and vertical integration commitments	I & III
3	Resistance to change from leaders	Organizations are made aware of resistance from any stakeholder as being a direct constraint	III & IV
4	Difficulty in centralizing the focus of the client's business	A clear picture of the throughput formula (Little's Law) along with strategic integration and planning of the OCF visual batches, enables consistent workflow toward the target	I, IV, VII, & Little's Law
5	Resistance to change from employees	Resistance is a form of constraint. OCF depends on collaboration and creates transparency amongst teams to effectively assess use of skills and resources to collectively remove constraints. We identified ten benefits to the PIT, mainly reducing the workload and respecting and ensuring constraint-free project implementation through Go/No Go; start only when ready checklists	III, IV, V & VI
6	Inability to measure the progress of the Lean project	OCF offers a clear percentage target of 50% optimization of cycle-time in the strategic integration and planning principle and builds the target tactical plan from Little's Law, enabling successful project control of the project prior to starting	I, II, VI & Little's Law
7	Decision centralization	The OCF batching team governs the implementation and does not rely exclusively on a single authority, thus enabling flow while simultaneously meeting targets with key leaders across the trade disciplines	II, III, VI, VII & Little's Law
8	Lack of preparation by managers to conduct the change	OCF cannot happen without all teams on board. Crawl, walk, run is a proven approach to help PITs become familiar with the new culture.	I & III

WHAT IS THE COMPLEXITY OF PRODUCTION PLANNING AND CONTROL?

Omar Zegarra[1] and Luis Fernando Alarcón[2]

ABSTRACT

Questionable project performance is a common issue in the Architecture, Engineering and Construction industry, with one contributing factor being the degree of difficulty or complexity of the project. One effective approach to address this issue is to improve the system of production planning and control (PP&C). This strategy, as per the literature, had evolved to include up to four different types of PP&C mechanisms that are related to ´business´, ´production´, ´virtual´, and ´complex´ aspects. Nonetheless, despite the progress, PP&C still disregards various complexity-related aspects. To address this issue, we analyzed the concept of the *´Complexity of PP&C´*. This paper discusses its definition, elements, and role. It was found PP&C complexity involves three aspects: project complexity, outcomes complexity, and structural complexity. Thus, we conceptualized PP&C complexity as a feature of the behaviour of outcomes that emerge to answer project stimulus driven by the interaction between the elements of the structure of PP&C, a feature that is both a risk and an opportunity for performance improvement. This perspective offers new insights for PP&C evolution and improvement, although further work is still required.

Production planning and control, complexity.

INTRODUCTION

Projects in the architecture, engineering, and construction industry frequently demonstrate poor performance. For example, Flyvbjerg et al., (2003, 2004) studied a sample of 258 infrastructure projects worth US$90 billion and found persistent cost escalations of between 20% and 45% that were strongly correlated with the duration of the project implementation.

In this regard, one significant factor that contributes to project duration is complexity. It influences negatively performance, as noted by Baccarini (1996), Floricel et al. (2016), Luo et al. (2017), and Williams (1999). For instance, complexity is often understood as the level of difficulty encountered during project implementation, although terms such as challenging, unstable, or unpredictable are also used to characterize it (Brockmann & Girmscheid, 2007; Gidado, 1996; Jarkas, 2017; PMI, 2013).

On the other side, one effective strategy to face the poor performance of projects relies on improving the system of Production planning and control (PP&C). The PP&C is a system which aims to transform ´intended´ into ´realized´ outcomes during the project(Ballard & Howell, 1998; Mintzberg, 1978). According to Burbidge, (1990) it *"... plans, directs, and controls the material supply and processing activities*". To do so, the PP&C relies on the use of a mechanism implemented using a set of managerial processes (e.g., planning procedures, meetings,

[1] Doctor of Engineering Science, Department of Construction Management Pontificia Universidad Católica de Chile, E-mail: ozegarra@uc.cl, orcid.org/0000-0001-7811-7637

[2] PhD, Professor, Dep. of Construction Management Pontificia Universidad Católica de Chile, E-mail: lalarcon@ing.puc.cl, (56 2) 354-4201, (56 2) 354 4244, orcid.org/0000-0002-9277-2272

etc.)(Marks et al., 2001). In turn, these managerial processes relate the strategic and operational activities while trying to create conditions to deploy and drive the construction operations, where consistent work of PP&C improves operational productivity and project performance (Ballard & Tommelein, 2021; Liu et al., 2011).

Figure 1 depicts the causation of a generic model for PP&C. This model involves two main parts: outcomes and system. The PP&C outcomes refer to the production aspect, which includes the final physical product or deliverable, the construction operations and its features (e.g., labour productivity, the propagation of variability, etc.). In turn, the PP&C system describes the managerial aspect which drives the PP&C outcomes. The system receives the stimuli from the project context, inputs (e.g., information on resources, labour, tools, methods, etc.) and feedback from the performance details of operations and progress. The structure of this system involves the use of an internal mechanism(s) which is set by the use of a particular model for PP&C (e.g., the Last Planner System, Critical chain, etc). Finally, the PP&C system generates an output (which involves streams of orders, weekly assignations, etc.) that drives the outcomes and could be considered part of them.

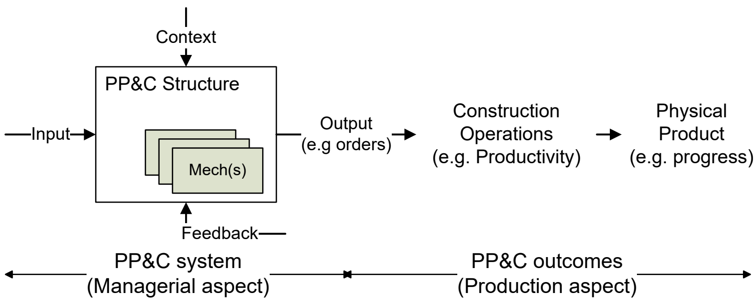

Figure 1: General causation of PP&C (for the construction stage of projects) (Zegarra 2021)

The literature suggests that PP&C use could be categorized into four types of mechanisms. The classification is based on the features and emphasis of the managerial processes used to implement the PP&C system and includes the following categories: business, production, virtual, and complex, which are complementary rather than optative(Zegarra, 2021). The business category emphasizes the use of economic/contractual processes, the production category focuses on processes for handling the workflow, the virtual category emphasizes processes for the use of virtual construction, BIM, Digital twins, etc., and finally, the complex category highlights the existence of processes for handling the interdependences between the elements of PP&C (Ibid). Thus, these categories suggest an evolution effort to improve the capabilities of PP&C and in consequence the performance of projects.

Nonetheless, despite the progress observed, the evolution of PP&C still disregards various aspects related to complexity. Where complexity is understood as a feature of the mechanism of PP&C, which emerges from its outcomes and structure. The complexity of the outcomes refers to behaviour features observed in the inputs, such as the propagation of variability (Pereira et al., 2013; Zegarra & Alarcón, 2017). Whereas structural complexity refers to the organization of a set of interdependent elements from social and process domains and their related emergent featuresover time (e.g., Zegarra & Alarcón, 2015, 2019).

In the face of an evolving AEC industry where the complexity of projects is ever-growing, the cost of doing nothing about the complexity of PP&C implies accepting both a risk and a missing improvement opportunity. For instance, Flyvbjerg, (2014)suggested that projects have moved into the TERA projects era due to the scale of their costs far beyond mega projects. Thus, this condition raises the following question:

What is the complexity of PP&C?

Thus, this study´s goals are: (1) To develop a PP&C complexity model (for the construction stage). (2) To provide a baseline theory useful for analytic generalization.

This article is organized as follows: First, the background section reviews key concepts on PP&C and Project Complexity. Then some relevant insights on the methodology are presented. After, the results section presents two models which help to describe the concept of complexity of PP&C. Finally, the main implications of the concept are discussed and conclusions are drawn.

BACKGROUND

DEFINITION OF PP&C

The PP&C plays a crucial role during project delivery, it is the system that governs the deployment of construction operations and the attainment of project goals. According to Ballard & Howell (1998) in the AEC industry, the PP&C system often is depicted as the preparation and control of schedules and their related budgets at the project level. For instance, the creation of as-planned schedules and their comparison against as-built schedules. Modern PP&C systems have been redefining this view, by describing it as a hierarchical and collaborative planning system, which involves several stakeholders and spans various levels, from operational to strategical (Ibid) or as a system enabled by the use of BIM (Schimanski et al., 2020).

According to Zegarra (2021), the literature suggests the existence of four approaches to the definition of PP&C, as the examples in Table 1 shown

Table 1: Selected definitions of PP&C (Zegarra, 2021)

View	Definition
Business	"*Project planning and control have as its broad and overall objective the prescribing and field attainment of an orderly progression within budget and time, toward the completion of project facilities."*(Halpin & Woodhead,1980 p293)
Production	*"Construction production and control can be usefully conceived and represented as consisting of three hierarchical levels roughly corresponding to … (1) aggregate production planning; (2) material coordination and work-load capacity; and (3) work order release and production unit control … the levels are (1) "initial planning"… (2) "lookahead planning", " … and (3) "Commitment planning"… "* (Ballard & Howell, 1998 p11)
Virtual	"*BIM-based production management system … is characterized by a theoretical integration model for BIM and existing construction management techniques …"* Schimanski et al., 2020 p1*)*
Complex	*"[Project control feedback structures] are managerial decisions and actions to correct poor project performance during project execution. Project controls can include process improvement, adjusting performance targets, change management, and resources management"(* Taylor et al., 2007 p1*)*

In this context, this work uses the following definition of PP&C, which is a synthesis of the definitions found in the literature:

> *´the PP&C is a Project´s function which aims to transform intended into implemented outcomes, to do so, it uses a system that interacts with the project and which relies on a particular causal mechanism(s) (e.g, a set of managerial processes), to transform strategy into operational actions through the interaction*

of persons, information, decisions, actions, processes, and technical resources while generating managerial throughput (e.g., weekly instructions)and emergent features (e.g. variability), which in turn drives and influences the deployment of construction operations over the project course´ (Zegarra 2021 p 17).

PROJECT COMPLEXITY

Complexity is a critical characteristic which influences the performance of projects. Over time its ever-growing magnitude has exposed the weakness and limitations of the managerial methods used for project delivery (Baccarini, 1996; Floricel et al., 2016; Luo et al., 2017; Williams, 1999). For instance, it influences the required levels of planning, coordination, and control, where higher complexity levels impact negatively, time, cost and quality performance (e.g., Baccarini, 1996; Floricel et al., 2016)

The definition of complexity Involves the existence of various aspects. In this work, complexity is understood as a "*property according to which, aspects such as the interactions between elements within a system structure, dynamical trends in the behaviour of its outcomes, emergent and unexpected features …., and uncertainty play a crucial role in the behaviour of the system* (e.g., Boisot & McKelvey, 2011; Dooley & van de Ven, 1999)" (Zegarra 2021 p2).

In this context, emerges the definition of *project complexity.* Although there is a lack of consensus, the concept can be described using the selected terms in Table 2:

Table 2: Project Complexity (Zegarra, 2021)

Definitions
"*The degree of difficulty faced during the execution and fulfilment of work activities and objectives over the project course* (Brockmann & Girmscheid, 2007; Gidado, 1996; Jarkas, 2017)*"* (Zegarra 2021 p3)
" A project´s feature ´… "consisting of many variated interrelated parts" and can be operationalized in terms of differentiation [of elements] and interdependency´ (Baccarini, 1996; Luo et al., 2017)*"* (Ibid)
" A feature characterized by two aspects ´… [i] structural complexity, [i.e.] the number and interdependence of elements (following a paper by Baccarini) … and [ii] uncertainty in goals and means (following a paper by Turner and Cochrane)´(Williams, 1999 p269)*, where interaction and emergence drives a structural complexity which includes uncertainty* (Cristóbal, 2017)*"* (Ibid)

The interest in project complexity has grown during the last two decades, nonetheless, its use as part of the regular arsenal of methods available in projects is under development. According to the literature (Baccarini, 1996; Cristóbal, 2017; Floricel et al., 2016; Luo et al., 2017; PMI, 2013), among the aspects currently studied, are its importance, the awareness of its role, its elements, measurement, impact, and management, where the main findings include:

- Key drivers: team and technological complexity
- Measurement: Based on conceptual frameworks (e.g., surveys) but it still lacks robust approaches (e.g. using interactions, dynamics, etc.)
- Impact: It affects negatively project performance
- Approaches currently used to face it: risk management, style of management, and capacity for adaptation.

METHODOLOGY

This study aims to provide *a preliminary theory* for future study of PP&C. To do so, it builds a mechanistic explanation (Hedström & Ylikoski, 2010) that uses a set of models and theoretical propositions to address the features of PP&C complexity. This reasoning uses the findings of (Zegarra & Alarcón, 2017, 2019) and Zegarra (2021) and concepts from a Language Action Perspective (LAP)(e.g.,Winograd & Flores, 1986), Lean Management (e.g., Koskela et al., 2002), and Complex Adaptive Systems (CAS) (Boisot & McKelvey, 2011).

The methodology follows the case study logic to state the role of the theory it aims to develop. Thus, following Yin, (1994 Chp 2), this work builds a baseline theory useful for guiding future inquiry on the complexity of PP&C (Figure 2a, step 1). The baseline, in turn, will be tested later throughout future empirical data analysis (Ibid).

The baseline theory provides a mechanistic explanation. In this regard, it focuses on building models to depict the "*cogs and wheels of the causal process through which the outcome to be explained was brought about*" (Hedström & Ylikoski, 2010 p50). Thus, the explanation integrates observations on the PP&C work, previous studies, LAP, Lean, and CAS concepts to build two models. Figure 2b describes the reasoning process used to develop the explanation (Pauwels and Di Mascio 2009).

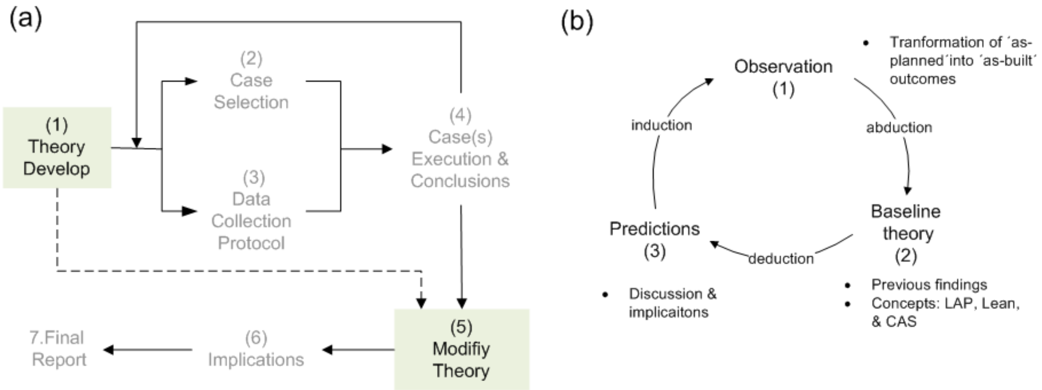

Figure 2: Research methodology: (a) Baseline theory role; (b) theory-building approach (After Pauwel and Di Mascio 2009 p13)

The following assumptions on the mechanistic explanation must be noted: First, it conceptualizes human action using LAP. Then, it uses a Lean view to model the value stream of PP&C. Finally, using CAS tools and concepts it describes the behaviour of outcomes. The CAS tools and concepts include the "Ashby Space" (Boisot & McKelvey, 2011), the *´law of requisite complexity´* (Ashby, 1957; Boisot & McKelvey, 2011), variability propagation concepts (Zegarra & Alarcón, 2017) and complex adaptive ideas about PP&C modelling (Zegarra & Alarcón, 2019).

PP&C COMPLEXITY MODEL

The following models describe the different aspects of PP&C complexity. The first model (Figure 3) describes a general view of the causation enabled by the PP&C, highlighting its complexity-related elements (e.g. emergent features, feedback linkages, etc.). The second model (Figure 4) describes the behaviour aspects of the relationship between the complexity of the project and the complexity of the PP&C system and outcomes.

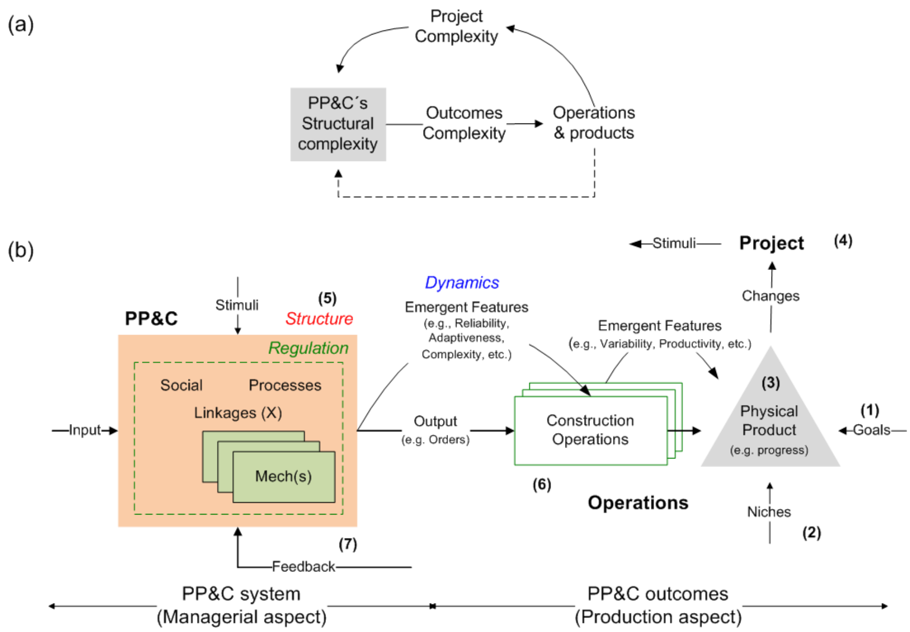

Figure 3: General causation of PP&C and its complexity features (After Zegarra 2021)

GENERAL CAUSATION MODEL

The model in Figure 3 describes the relationship between PP&C, Operations and Project. The model considers them as three coupled and hierarchical systems. The Project level is the most external, while PP&C is the most internal. At the Operations level, the outcomes of PP&C answer project stimuli. In this way, the complexity of PP&C can be divided into three related categories, project complexity, structural complexity, and outcomes complexity (Figure 3a). Figure 3b details the different aspects of the relationship, explained as follows:

Project complexity describes any element located beyond the construction operations level but within the project´s boundary. For instance, engineering, procurement, etc. or any other aspect carried out as part of the project

Structural complexity describes an attribute of the PP&C system´s structure. It includes elements from social and process domains, the linkages between elements, emergent features, and mechanisms used to provide managerial causation. The handling of the structure during the project involves a regulatory effort.

The outcomes complexity describes the behaviour attributes of the PP&C outcomes. These include managerial output (e.g., the emission of orders, weekly assignations, etc.) and its associated emergent features (e.g. the assignations´ reliability), the deployment of construction operations and their related emergent features (e.g., their productivity, variability, etc.), and finally the generation of physical products. The model names the managerial output and the emergent features as dynamics

Finally, the model depicts a progressive adaptation process of PP&C, operations, and projects. Thus, following Ellis (2008), to attain a certain goal (1) (e.g., an as-planned goal), the PP&C outcome fulfils a certain behaviour niche (2), through the generation (6) of a physical product (3) (e.g. an as-built result), all of these steps generate feedback (7) on the structure of PP&C. Step 3 introduces a change in the project´s conditions (4), which in turn generates a new stimulus that influences the operational level and the PP&C structure (5). Given the hierarchical and coupled nature of the model, the adaptation process suggests a double-loop interaction (Sterman, 2000). The internal loop involves PP&C and operations, whereas, the external loop involves the operational and project levels. This mechanism may drive the co-evolution of PP&C, Operation, and Project over time.

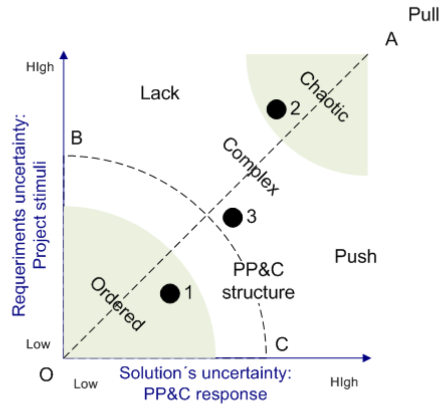

Figure 4: Relationship between Project and PP&C (after Zegarra and Alarcón 2019)

BEHAVIOUR MODEL

Figure 4 presents a behaviour model for PP&C complexity. It relates project complexity and PP&C complexity aspects (Figure 4). The model also provides insight from a lean perspective, based on a comparative ratio between stimuli and response.

Figure 4a describes the relationship between the complexities of the project and its PP&C system. Thus, following Boisot & McKelvey (2011): The X and Y axes describe the project stimuli and the PP&C responses respectively (e.g., in practical terms, these axes could use as stimuli data from as-planned schedules and as response as-built schedules data); The curve BC describes the boundary of the PP&C structure; The line OA describes a state of equilibrium between stimuli (Y) and response (X); Each black dots describe a pair of values x,y over X and Y axes; Finally the space also depicts three potential states of behaviour: ordered (i.e., linear and regular), chaotic (i.e, random) and complex (i.e., a transition between the previous two states and which mix their features), where for instance the relationship x,y for the dot 2 exhibits chaotic behaviour.

In addition, the model in Figure 4 also provides a behaviour insight from a Lean perspective. Thus, following Zegarra & Alarcón (2017, 2019): OA reveals an ideal pull relationship between Project stimuli and PP&C response (i.e, response/stimuli = 1), whereas the areas OAX (below OA) and OAY (above OA) respectively depict "push" (i.e., response > stimuli) and "lack" (i.e., response < stimuli) behaviours for each pair of x,y values. This interpretation is based on the behaviour of a divisive ratio used to express the nature of the activity between stimuli and response, for an x,y point over a two-dimensional diagram (Lindemann et al., 2009 p202). Finally, as a summary, it can be said for instance, that dot 3 is located beyond the structure of PP&C, and exhibits a complex behaviour, with a push relationship between stimuli and responses.

DISCUSSION

This study aims to provide an answer to the question, what is the complexity of PP&C? To do so, it presents a model that depicts and explains the nature of this concept. The complexity of PP&C is understood as a characteristic that influences performance and that involves three aspects: ´outcomes complexity´, ´structural complexity´ and ´project complexity´. The model developed in this study depicts the complexity of PP&C as a relationship between project complexity (stimuli) and the complexity of PP&C outcomes (responses), a condition which in turn is regulated by the structural complexity of PP&C. This relationship may behave exhibiting an ordered, chaotic or complex regime. The complexity of PP&C reveals both, a risk and an opportunity for PP&C performance and improvement.

The complexity of PP&C is a behaviour feature. In this regard, it could be observed in ´*the behaviour of outcomes that emerge to answer Project stimulus, outcomes which in turn emerge driven by the interaction pattern between the elements of the structure of PP&C*´(Zegarra 2021 p17). This understanding involves the presence of three aspects: ´*project complexity*´ (i.e., the behaviour beyond the boundary of PP&C), ´*outcomes complexity*´ (i.e., the behaviour pattern observed in the PP&C outcomes), and ´*structural complexity*´ (i.e, the hierarchical organization of interdependent elements which configure the PP&C system). The complexity of the outcomes and structure are behaviour features of the mechanism used to provide PP&C in the project. This mechanism relies on the implementation of a managerial system which in turn drives the generation and deployment of various types of outcomes. This causation generates an interaction with the project through a progressive adaptation.

Project complexity describes the behaviour beyond the boundary of PP&C. It includes a set of interacting elements, which in turn, can be understood as complex adaptive systems (Choi et al., 2001). These elements interact with the PP&C over the project.

Structural complexity is an emergent attribute of PP&C. Where the structure refers to the set of interrelated elements used to implement the system driving the outcomes. Thus, the complexity of the structure describes a hierarchical organization of interrelated elements from social and process domains (e.g., team members, managerial processes, meetings, etc.) and emergent features organized to provide the PP&C.

Outcomes complexity is a behaviour pattern in the outcomes of PP&C. These outcomes may include managerial throughput, construction operations deployment, physical products or deliverables, and emergent features. The complexity of outcomes is a feature observable over the dynamic behaviour of these elements. For instance, if the managerial throughput (e.g. the set of weekly assignations) is understood as a stream of conversations used to guide the deployment of the operation, the behaviour of this stream may exhibit ordered, chaotic or complex behaviour features.

The complexity of PP&C involves an interaction between the project and PP&C. Figure 4 represents different degrees of the state of this interaction using black dots. The stimuli (Y-axis) on PP&C represent the project complexity, whereas the response from PP&C represents its outcomes complexity (X-axis). The relationship between response and stimuli is constrained by the structure of PP&C. This relationship exhibits different degrees of behaviour which span from an ordered regime, up to a chaotic one, passing through a complex state.

The model also provides insight into the behaviour of PP&C using a lean perspective. According to Lindeman (2010), over a two-dimensional diagram, a divisive ratio expresses the level of activity between stimuli and response.

The ideal behaviour for the complexity of PP&C may emerge within its structure boundary when this is located in the complexity zone close to the edge of the chaotic zone. The following reasoning elaborates on Boisot and McKelvey (2011) to explain the behaviour of PP&C: The regulation of the system structure is dynamic and involves a change of form and position. For the PP&C complexity model, this means a change of position of BC, where it can move closer to the ordered or chaotic estate driven by a change of capability in the structure (e.g. by the addition of resources). The behaviour located beyond this boundary could be problematic and difficult to sustain because it overcomes the available PP&C system capability. Also during this process, the boundary BC has the potential to change its shape (i.e. $OB \neq OC$), as the PP&C structure becomes better suited to face more stimuli with less use of resources (i.e., $OB > OC$). Thus, in the case of PP&C, the optimum level of behaviour arises when the boundary of the system is located in the complexity zone, while its structure closes to the edge of chaos, along with a response/stimuli relationship prone to pull behaviour.

A practical target for the behaviour model may be located within a band over the equilibrium line and around the boundary of the PP&C structure. According to Boisot and Mckelvey (2011), this behaviour in Ashby´s space involves a mixture of exploration (i.e., in the lack area) and exploitation (i.e., in the push area). The behaviour of PP&C is dynamic and evolves as the project progress, thus it seems unlikely that every single dot will be located within the boundary, instead some exploration may be needed to improve exploitation. The findings of Zegarra and Alarcón (2019) suggest a behaviour in this way.

The complexity of PP&C is both, a threat and an opportunity for improving PP&C performance. To survive a system must adapt to its environment. Thus, following Ashby´s (1957) law of requisite variety, restated by McKelvey & Boisot (2009) "*... to be efficaciously adaptive, the internal complexity of a system must match the external complexity it confronts*" (Boisot & McKelvey, 2011). During this process, managing the use of resources to answer stimuli may involve a *stimuli simplification* (i.e., using fewer resources) or a *response complexification (i.e., using more resources)*. In this way, a productive PP&C (i.e., both, effective and efficient), which properly adapts and co-evolves with the project´s requirements proper handling of complexity is critical.

Paying attention to complexity is an opportunity to improve the performance of PP&C. Interaction is responsible for the emergence of features such as variability, self-organization, and scalability, features have the potential to generate negative or positive outcomes (Boisot & McKelvey, 2011). Proper handling of interactions could be used to provide a positive impulse or to control a negative effect of these features on the system's behaviour (Choi et al., 2001)

The main limitations of this work include: The study´s scope of work focuses on the construction stage of AEC projects. The studies on which this work is based were conducted on high-rise buildings and housing construction projects which used the LPS.

CONCLUSIONS

In the AEC industry, one effective strategy used to face the poor performance of projects is to improve the PP&C system. In this context, the complexity of PP&C is a characteristic which influences the performance of this system. This concept involves three aspects: project complexity, outcomes complexity, and structural complexity. The relationship between them helps to describe the behaviour of PP&C in terms of ordered, chaotic, and complex states. Complexity represents a risk and an opportunity for the improvement and evolution of PP&C. The PP&C complexity concept suggests a route to expand the theory of Lean Project Management (based on the joint use of lean and complexity science concepts), especially to explain and guide the building of new PP&C mechanisms to face the different challenges of Construction 4.0.

LOCATION-BASED WORK SAMPLING: FIELD TESTING AND UTILITY EVALUATION

Cristina T. Pérez[1], Stephanie T. Salling[2], and Søren Wandahl[3]

ABSTRACT

Visual management has been developed and used by Lean practitioners to enhance communication and control operations and processes. Lean construction, as a process-focused approach, and emerging IT tools have the potential to transform and facilitate construction operations. The authors of this paper have previously presented a prototype adaption of the work sampling technique, called location-based work sampling, based on the results of a case study. However, the utility of this visual management tool has not yet been tested. Thus, this research aims to assess how the tool can provide managers with helpful information for decision-making. The paper presents the second learning cycle of a research project that adopted the Design Science Research strategy. The second cycle includes five steps. The first four steps consist of the application of LBWS, and the last step represents the evaluation: (1) clarifying work activities & workspaces; (2) data collection; (3) data visualization; (4) data analysis; (5) tool evaluation. The assessment results show that the tool, to a high degree, fulfills the six requirements of a digital visual management practice. However, the assessment also concludes that further development is needed to fully understand user needs and integrate the tool into daily management routines and processes.

KEYWORDS

Location-based management, visual management, waste, work sampling, geographic location observations.

INTRODUCTION

Visual Management (VM) can be defined as a set of practices that support visual communication by adopting different visual devices (Tezel et al., 2016). Lean practitioners have developed and used VM and its tools to enhance communication and control operations and processes in real time (Parry & Turner, 2006). Among the benefits of VM is that it directly supports other management efforts, such as production management, safety management, performance management, and workplace management (Tezel et al., 2016). Moreover, the use of VM tools reduces feedback time for action taking (Alvarez & Antunes Jr., 2001). Tezel et al. (2015) have investigated the advantages of VM as a managerial strategy that can benefit a project in aspects such as transparency, ease of information flow, and minimizing complications in communication.

Although VM tools have been used in the construction industry for a while as signs, color coding, and hazard elements, there is a significant potential for implementation at managerial

[3] Professor, Department of Civil & Architectural Engineering, Aarhus University, Denmark, swa@cae.au.dk, https://orcid.org/0000-0001-8708-6035

levels in combination with Information Communication Technologies (ICT) (Tezel et al., 2016). Some researchers have integrated IT and tools with VM to improve efficiency and communication in construction projects. Some examples of these approaches are: (1) Integration with Building Information Modeling (BIM), named KanBIM (Sacks et al., 2009); (2) Integration with BIM-based sheet (Matta et al., 2018); (3) Digital Last Planner System (Conte et al., 2022; McHugh et al., 2022; Pikas et al., 2022); (4) Visual Management to support design planning and control (Pedó et al., 2022); and (5) Construction progress monitoring (Álvares & Costa, 2019).

Some of those VM tools have been converted into successful IT-based prototypes. In the prototypes, information visualization interfaces (often BIM models) are displayed on large touch-screens in the field and supported by a Lean construction engine (e.g., a virtual Kanban system linked to the Last Planner System by Ballard (2000)) connected to the existing main-servers and Enterprise resource planning (ERP) systems. Although useful, those prototypes do not fully illustrate the extensive potential of the combined use of Lean construction techniques and emerging IT systems (Tezel & Aziz, 2017).

As a new approach, "the present authors" (year) adapted the traditional Work Sampling (WS) technique by adding geographic information collected using mobile computing to the random observation, creating the VM tool named Location-based Work Sampling (LBWS).

"The authors" (year) defined LBWS as a visual, graphical approach that facilitates sharing information obtained during the WS application, based on adding geographic location information to the random observations, named geo-located observations. The visual technique shows the observations made on construction trades and work categories in the foreground and job site spaces in the background.

The authors of this paper previously presented the prototype adaptation of the WS technique based on the results of a case study. However, the utility of this VM tool using IT has not yet been tested. Thus, this paper aims to assess how the tool can provide job site managers with useful information for decision-making. This is an ongoing research project, so the evaluation of this new WS adaptation was exclusively performed after the field testing in one construction project.

RESEARCH METHODOLOGY

The present authors adopted the Design Science Research (DSR) strategy (Lukka, 2003) for conducting the research project. DSR aims to produce innovative constructions, called artifacts, to solve real-world problems and to contribute to the theory of the discipline in which it is applied (Lukka, 2003). This project's artifact consists of the adaptation of the WS technique, called LBWS, previously defined in the introduction section.

The research process of designing the artifact is being developed during the realization of three learning cycles, named Cycles 1, 2, and 3 (Figure). During each cycle, the four main phases that categorize this DSR were conducted. The four phases are: (1) understanding; (2) construction; (3) analysis; and (4) evaluation. The four DSR phases organize different approaches carried out by the research team in various rounds of visits in the same construction site. For that purpose, the authors used the Case Study (Yin, 2003) as the primary research method, as case studies offer flexibility for explorative and theory-building research in real-life contexts.

During the first learning cycle, the first version of LBWS was developed (Authors, year). The case study's findings led the authors to identify the utility of adding geographical location to the WS technique. The present paper focuses exclusively on presenting the results of the second learning cycle, comprising the second field test and its evaluation (see text in the rectangle highlighted in Figure 1).

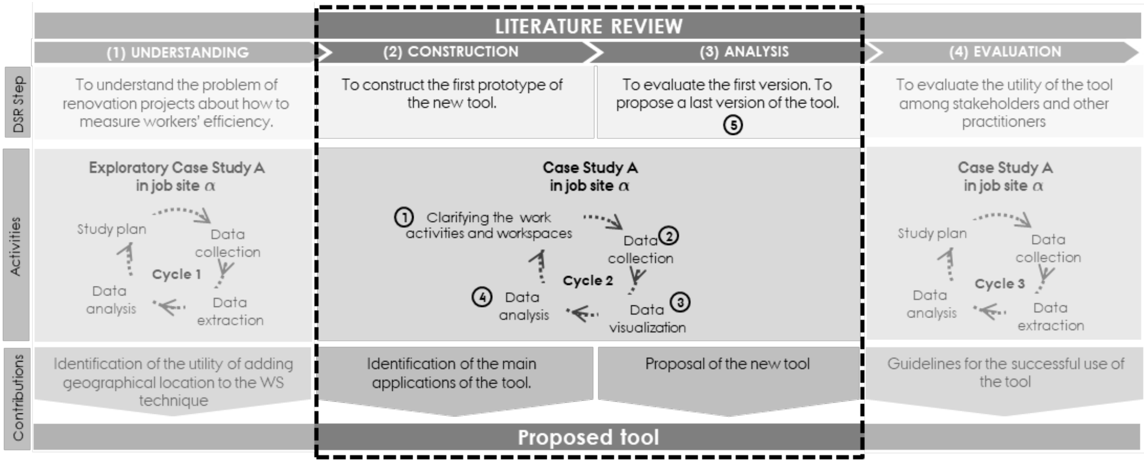

Figure 1: Research Design

CASE STUDY DESCRIPTION

The case study consists of a renovation project of 24 five-story housing buildings, a total of 597 housing units, originally constructed from 1950 to 1970 in Roskilde, Denmark. The case organization is one of the main contractors in the building sector in Denmark.

The contractor rented a façade scaffolding with plastic covering the entire temporary structure for each building under renovation. The scaffolding of some buildings is interconnected to facilitate workers' movement among the buildings. The scaffoldings included a cabin as the primary lift solution for material transport. Moreover, a mobile crane was used for lifting windows using hooks for installation and pallet lifts for transportation.

The main renovation tasks were conducted outside the buildings from the façade scaffolding and were mainly related to carpentry work, such as replacing windows and roofs, and painting work. Installing new ventilation and electricity systems represented the only two inside renovation activities. The contractor company placed modular containers within the job site for storage, administration, and changing rooms. The main material storage area, destined for inventory deliveries, is located next to the administration containers. Several work tents were installed at ground level next to the buildings under construction for conducting support activities, such as painting wood panels before installation, cutting steel profiles, cutting wood panels, etc.

RESEARCH DESIGN

Cycle 2: Application of the LBWS and Evaluation

The second cycle presents five steps (see numbers in Figure 1). The first four steps consist of the application of LBWS (Figure 2), and the last step represents the evaluation: (1) clarifying the work activities and workspaces; (2) data collection; (3) data visualization; (4) data analysis; and (5) tool evaluation.

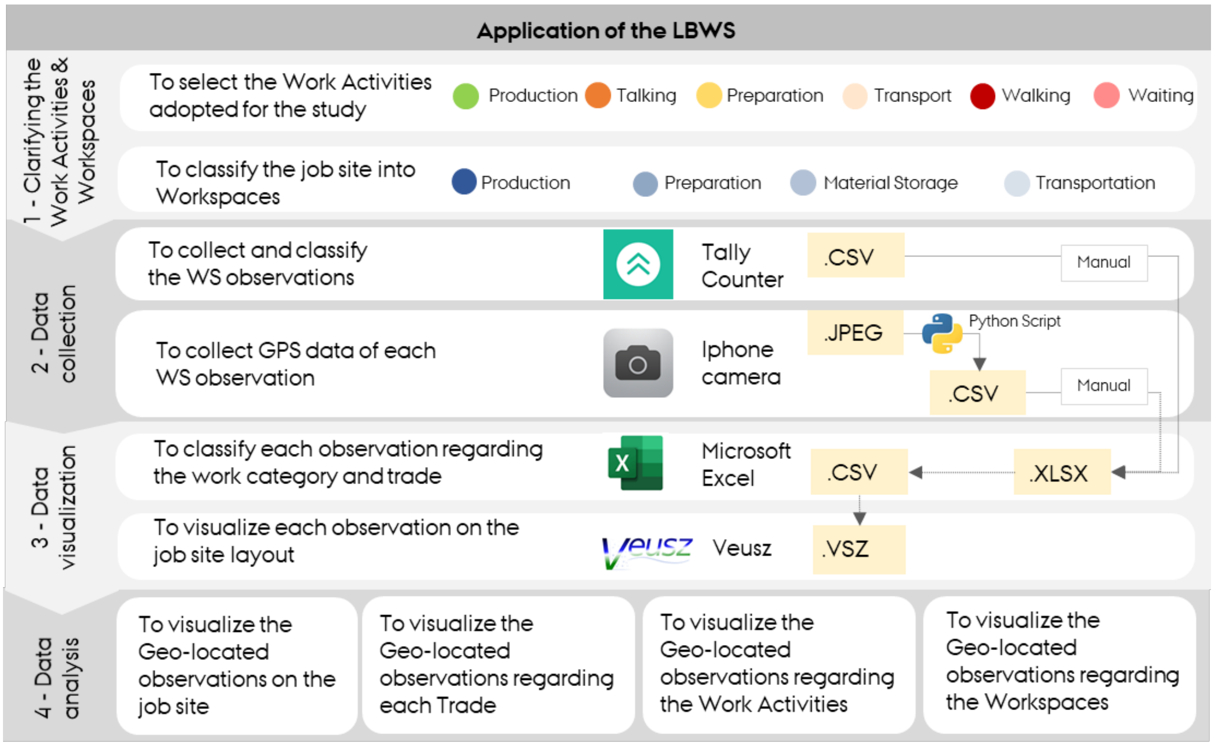

Figure 2: Application of the LBWS

Step 1: Clarifying the work activities and workspaces

The authors classified the activities of each trade observed on the job site during the first day of job site visits, named Day 0. In this study, a six-work categories classification was adopted to keep consistent with previous WS studies carried out by the research team as part of a long-term research project. The six categories are: (1) production, e.g., installing gypsum boards on the roof; (2) talking, e.g., discussing the installation process; (3) preparation, e.g., measuring with a ruler the gypsum boards; (4) transportation, e.g., carrying tools and materials; (5) walking, e.g., moving empty-handed; and (6) waiting, e.g., delaying action until receiving material.

Regarding the job site locations, this study adopted the following workspace classification: (1) production workspace, this being the buildings under renovation and the scaffolding area; (2) preparation workspace, represented by the area surrounding the production workspace; (3) material storage workspace, consisting of the container's area; and (4) transportation workspace, consisting of the area 1 and the material storage area.

Step 2: Data collection

Data was gathered in two rounds of visits, Round 1 and Round 2 (see Table 1). The data collection lasted seven days in Round 1 and five days in Round 2 (8.5 hours/each) from 07:00 to 15:30, excluding breaks: coffee break (09:00 to 09:15), lunch break (11:30 to 12:00), and coffee break (13:30 to 13:45). The observers used a smartwatch to track the position during the random tours to guarantee that all the workspaces were observed. Although the time spent in each workspace was not the same during each tour, the results presented a relatively homogeneous sample.

The scope of the observations was limited to the trades that conducted their activities outdoors (N) during the period of visits. Those trades were: (1) Carpenter (N_1); (2) Mason (N_2); Electrician (N_3); (4) Ventilation (N_4); (5) Scaffolding (N_5); (6) Painter (N_6); and (7) Demolish (N_7). The research team made the observations from the scaffolding (from the façade and roof level) as interior tours were not possible due to the presence of the tenants.

Table 1: Data collection characterization

Description	Period	Visits	Geo-located samples	Con. Interval	Sample (N)
Round 1	Weeks 45 & 46, 2021	7 visit days 8.5h/visit	n = 993 samples 142 average per day 39.8 std. deviation per day	95% ± 2%.	N =40 workers N_1=13 carpenters
Round 2	Week 20, 2022	4 visit days 8.5h/visit	n = 689 samples 172 average per day 41.2 std. deviation per day	95% ± 2%.	N ≈ 40workers N_1=13 carpenters

The research team used several digital devices to collect data during the random tours. A tablet was employed for separating the observations according to the six-work categories classification using the application "Counter – Tally Counter" by Tevfik Yucek (Apple, n.d.). A tally counter is a digital number clicker used to count something incrementally. The Counter application allowed the researchers to digitally record each observation with an exact time and export this data in a Comma-Separated-Values (CSV) format.

A mobile phone was used for taking pictures of each observation. The purpose of the photo was to collect the geographic coordinates from each observation. Despite the fact that the coordinates represent the location of the observer instead of the task observed, this difference does not impact the results since the photos were taken as close as possible to the worker. At no time were individuals' faces or other identifiers registered; The authors extracted locations and additional metadata (timestamp and file name) stored using the Exchangeable Image File Format (EXIF) Phyton library. EXIF is a standard that specifies the formats for images for recording technical details associated with digital photography (EXIF.org, n.d.). Thus, each geo-located observation contained the following associated information (Table 2): (1) photo; (2) timestamp; (3) trade observed; (4) work category; and (5) geographic coordinates, consequently, workspace category.

Table 2: Example of information associated with each geo-located observation

Photo	Time Stamp	Trade observed	Work category	Geographic coordinates	Workspace category
IMG-5548.JPG	2021.11.18; 13:33:05	Carpenter	Production	Lat 56.089999; Lon 12.309999; Alt 58.930754	Production workspace

Step 3: Data visualization

The data extracted from the devices during the random tours was visualized using the Veusz program. Veusz is a free scientific plotting and graphing program for producing 2D and 3D plots (Veusz, n.d.). This allowed the researchers to plot each geo-located observation using a graphical 2D user interface. The authors collected the coordinates of the job site facilities and buildings using a smartwatch and converted them to a visual layout using the RouteConverter program. RouteConverter is a free Global Positioning System (GPS) tool to display, edit, and convert routes from several different file formats (RouteConverter, n.d.). The list of job site coordinates was exported into a Microsoft Excel Open XML Spreadsheet (XLSX), converted into a CSV format, and then imported to Veusz. Hence, Veusz allowed visualizing the position of each observation on the job site layout. In this study, the analysis aimed to identify how and where the workers spent their time.

Step 4: Data analysis

The research team conducted the following four types of data analysis: (1) Visualization of the geo-located observations on the job site layout; (2) Distribution of the geo-located observations per trade; (3) Distribution of the geo-located observations per work activities; and (4) Distribution of the geo-located observations per workspaces.

Step 5: Evaluation of the LBWS

The utility of the LBWS was assessed according to its ability to accomplish its objectives. The objectives of this adaptation of the WS techniques are: (1) to facilitate the sharing of information of the WS technique; and (3) to support decision-making. The assessment is based exclusively on the empirical study presented in this paper. The set of six requirements that a VM should contain proposed by (Pedó et al., 2022) was used to assess the first version of the tool by the present authors.

Table 3: Set of six VM requirements (Pedó et al., 2022)

VM requirements	Definition
(R1) Simplicity	It is concerned with how easy it is to use a VM practice based on a clear understanding of its objective or function.
(R2) Standardization	It is related to whether there is repetition in using devices, i.e., regularity of information units, which can support accurate information delivery.
(R3) Availability	It is related to making updated information available at the right time and in the right amount, making it easy to prioritize information.
(R4) Accessibility	It considers how easy it is to access the information, i.e., if the information is located in the right place.
(R5) Flexibility	It is related to: (i) how easy it is to make changes, i.e., the possibility of adapting devices and practices according to the users' needs over time; (ii) how easy it is to update the information, i.e., changes can be quickly displayed in the device
(R6) Traceability	It is associated with easy storage of information and tracking its origin.

RESULTS

LBWS RESULTS

The LBWS results focus on the discussion of the use of the tool for the four sorts of data analysis previously presented.

Visualization of the geo-located observations on the job site

Figure 3Figure 3illustrates the distribution of the geo-located observations from one day of data collection from Round 1 and Round 2. There are 140 data points from Round 1 and 224 data points from Round 2. In Round 1, the carpenter trade constitutes a larger part of the observations than in Round 2.

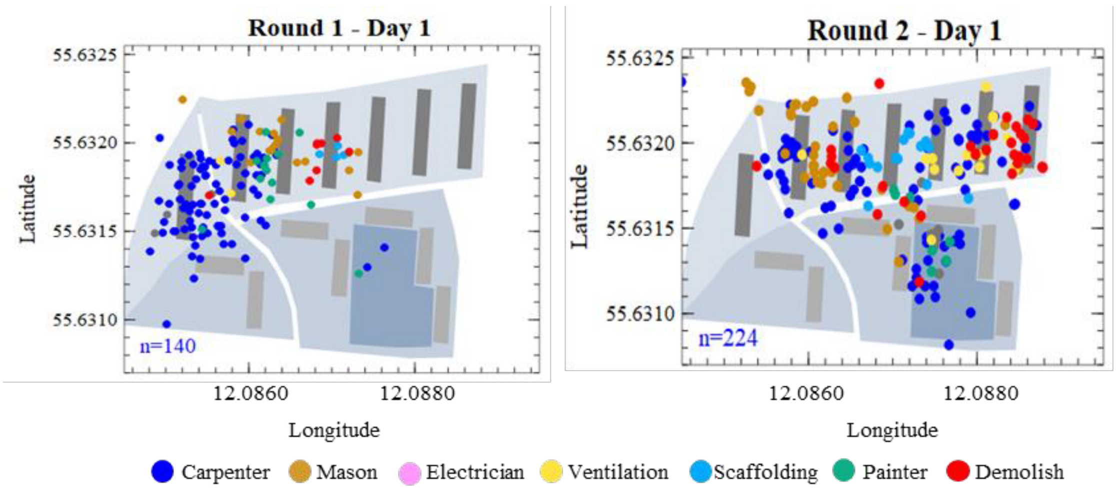

Figure 3: Geo-located observations of all trades during Day 1 of Rounds 1 and 2.

The visualization shows that there are not many similarities between the data from the two visits. During Round 1, most of the observations were concentrated on and around four of the apartment buildings, especially the building furthest to the left on the job site. Some observations were obtained in the transportation area south of the four buildings, and a few were recorded in the storage area. During Round 2, the observations were scattered across a larger part of the job site. The workers were seen on the scaffolding of almost all of the buildings as well as in the preparation workspaces between buildings, and a significantly higher number of observations were recorded in the material storage area compared to during Round 1.

Distribution of geo-located observations per trade

The geographic distribution of observations can be analyzed for each trade individually. In Figure 4, only the observations of the carpenter trade are included. As for the distribution of observations for all trades, the observations of carpenters are highly concentrated in one area during Round 1 as opposed to Round 2, where the observations are distributed across most of the job site. This means the carpenters were working in many different places during the visits of Round 2, both in the buildings and in the material storage area. The many workplaces also led to more observations in the transportation areas, as the carpenters needed to move between buildings more often.

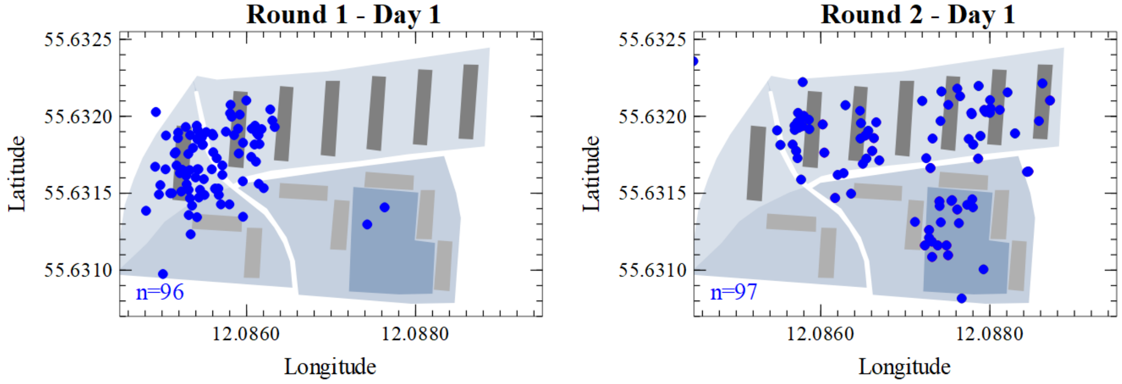

Figure 4: Geo-located observations of carpenters during Day 1 of Rounds 1 and 2.

Distribution of geo-located observations per work activities

In Figure 5, the observations of the carpenter trade have been categorized according to the work activity observed. The overall distribution of observations of the six work categories is shown in the pie charts.

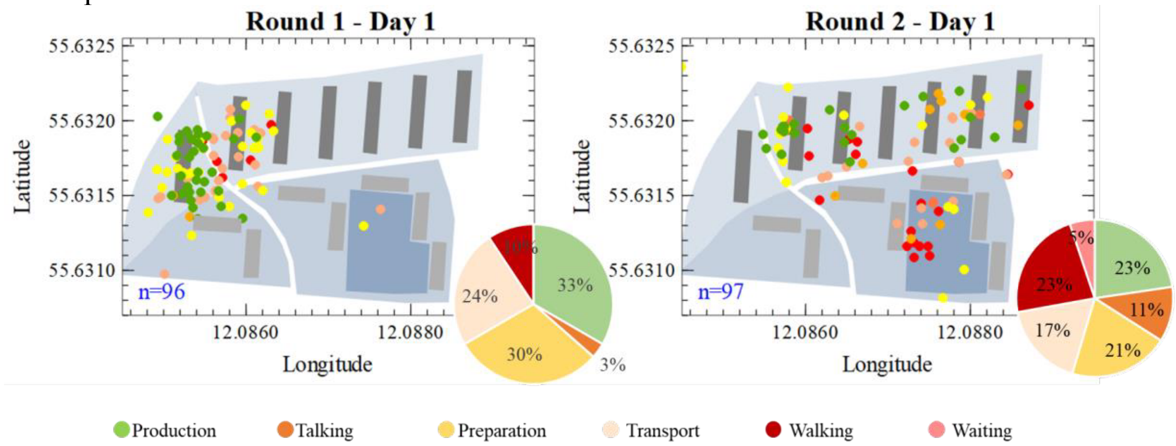

Figure 5: Positions of the carpenters' WS categories during Day 1 of Rounds 1 and 2

As seen in the figure and explained above, there were more observations in the transportation and preparation areas during Round 2 than during Round 1. The work being done in these areas is mostly non-value-adding activities such as walking and transportation, thus, the share of time spent on value-adding activities is significantly lower for Round 2 than for Round 1.

Distribution of geo-located observations per location

In Figure 6 (left), the positions of the carpenter trade observations for observation days 1 to 4 of Round 2 are illustrated. The coordinates of each observation are based on the geo-location of the photo taken of each work sampling observation. As the geo-location of each photo also includes a precise altitude value, the WS observation can also be distributed per level of each building, cf. Figure 6 (right). This visual information can serve multiple purposes, e.g., compliance checking of the location-based schedule and checking if carpenters were working on the location that was planned.

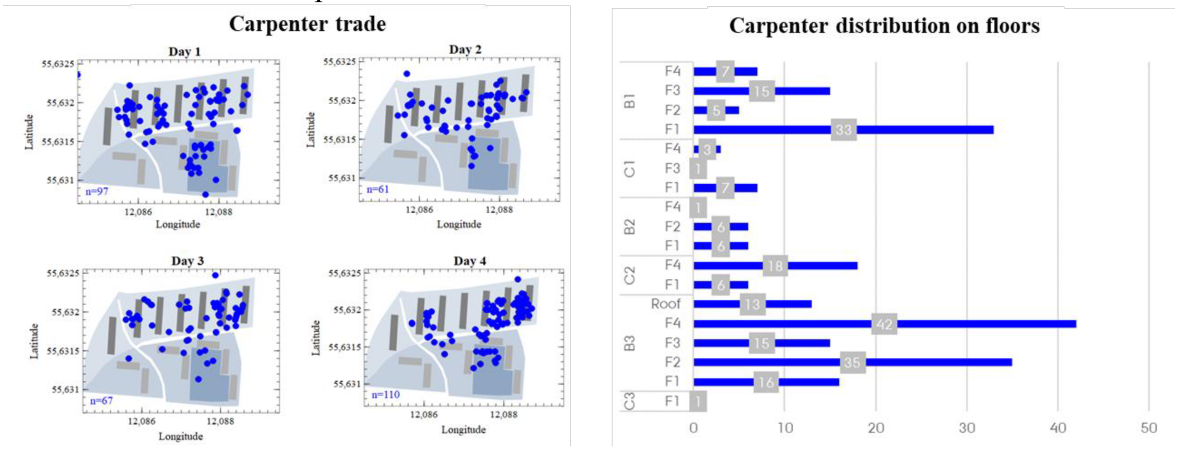

Figure 6: Longitude and latitude positions (left) and altitude (right) of WS observations for the carpenter trade per for round 2

In combination, these four types of visual data analysis of the location-based work sampling data can be used for many different purposes, such as documentation and analysis of plan and production system efficiency. This visual data can feed the production planning and control system and serve as VM to further improve the production system.

LBWS EVALUATION

The first requirement was simplicity, which is defined as how easy it is to use a VM practice based on a clear understanding of its objective and function. The objective of LBWS is to provide information obtained during the WS application based on adding geographic location information. The visual technique shows the observations made on construction trades and work categories in the foreground and job site spaces in the background. A number of different functions of LBWS have been demonstrated in this paper, and the visual representation of these functions is considered easy to comprehend.

The second requirement is standardization, which is related to whether there is repetition in using devices, i.e., regularity of information units, which can support accurate information delivery. This is very important for the operational level, as team members must be guided on how to use the practice correctly, allowing autonomy and valid data simultaneously. As the practice is still novel, standardization is ongoing. However, the data lakes are standard, i.e., geo-location, WS categories, site layout, etc. Thus, applied in repetition, the information provided to users holds a large degree of standardization.

Availability is the third requirement and focuses on making updated information available at the right time and in the right amount, making it easy to prioritize information. For all the four functions described in LBWS, it is easy to update the data file and produce new visual outputs. Both Work Sampling data and Location data are based on .csv files, cf. Figure 2. However, the update process currently includes some manual steps. Filtering the information is easy in the Veusz program.

Accessibility is the fourth requirement and is defined as how easy it is to access the information, i.e., if the information is located in the right place. The main users of the LBWS practice are likely also those who orchestrate the data collection and carry out the data analytics. Thus, the main users have very good accessibility to the information provided by LBWS.

The fifth requirement is flexibility, which is related to how easy it is to make changes and adapt to the user's needs. As described, the four functions of LBWS are the practice's main utility. Other functions and analyses might surface, and it should be easy to amend to such user requests, as the process of data acquisition and data analytics is simple and standardized, cf. Figure 2. However, some of the steps of converting data require insight and knowledge of the data collection and are also quite time-consuming.

Traceability is the sixth and final requirement. It is associated with easy storage of information and easy tracking of the origin of the information. The system has full transparency, i.e., every graphic representation is directly linked to one or more data sets that correspond with time, place, trade, etc. The practice does, however, not have a versioning system, meaning old versions cannot be accessed if the users have not saved these deliberately. In Table 4, a summary of the evaluation of the six requirements' fit with LBWS is presented, based on a high/medium/low assessment.

Table 4: Assessment of the six VM requirements on LBWS

VM requirements	High/Medium/Low evaluation of LBWS
Simplicity	Evaluated as high. A clear objective of LBWS is present. Several different functions with a clear visual representation.
Standardization	Evaluated as medium. Data lakes are standardized, and processes for harvesting data lakes are described.
Availability	Evaluated as medium to high. Some of the data processing is manual, however easy and standardized.
Accessibility	Evaluated as high. Information is likely generated by the main user who also organizes the data collection and analytics.
Flexibility	Evaluated as medium. The practice is adaptable to new user requests, however some of the processes of data conversion requires insight and time.
Traceability	Evaluated as high. There is a clear link from the graphical output down to the data source. This is very transparent.

DISCUSSION

The main contribution of this study is the adaptation of the widespread WS technique, named LBWS. This new adaptation can be seen as a VM practice combined with digital technologies. As pointed out by (Tezel & Aziz, 2017), the combination of VM and ICT contributes to an increase in the degree of automation in project control, increasing efficiency in data collection and processing, and reducing the feedback time.

LBWS has also been assessed in relation to requirements of VM with focus on digital VM practices (Pedó et al., 2022). Overall, it is assessed that most of the requirements, to a high degree, are fulfilled in LBWS. As the development of LBWS as a VM practice is still ongoing, the next paragraph will discuss future steps, particularly how LBWS can be implemented and integrated into daily managerial routines and processes.

Implementing VM in construction projects poses additional challenges in comparison to manufacturing due to the complex and project-based nature of construction (Valente et al., 2019). In construction, VM should increase the involvement of workers in continuous improvement efforts (Bernstein, 2012) because it allows for rapid understanding of and response to problems (Bateman et al., 2016). Valente et al. (2019) advise a 4-step model for devising digital VM practices for production management in construction. The first step is an observation phase, where the problem itself is investigated. This step has already been documented for LBWS, cf., the DSR cycle. The second step is to identify the user and user needs to identify the level of visual literacy, which information is required, types of data, etc. The user needs have partially been described in the results of LBWS, showcasing four different functions the practice can offer. However, a future step would be to conduct focus group workshops with industrial experts to elaborate further on user needs. This focus group workshop would also be useful for the fourth and final step, namely defining the final visual attributes. These four steps to implement a digital VM practice complies with the VM typology presented by Brandalise et al. (2022). The final level in their typology is the integration into daily managerial routines. This needs to be further formalized for LBWS, as it currently offers a number of functions, i.e., visual information analysis types, that can be used to identify problems and potentials of the production system.

CONCLUSION

The LBWS is, to the authors' knowledge, one of the first adaptations of the WS technique with ICT application. It brings together the workers' distribution of time into work activities, as the traditional technique, and the geographical location of the WS observations. It presents visual information, i.e., WS data on a map or site layout drawing. Four different types of information and analysis useful for project and site management have been showcased. For this presentation purpose, data from a case study was applied. Although different data like WS categories and location data were collected, the duration of the field tests and the depth of integration in company information systems are insufficient to provide conclusive results of the utility of LBWS.

The utility was assessed by evaluating LBWS with respect to six requirements of digital VM. Overall, the assessment was positive, however, it was recognized that additional implementation steps are needed, in particular with respect to further analyzing user needs and how to integrate into process routines. Several recommendations were made for improving the tool, among them to conduct focus group workshops with industrial experts. While the results are positive and indicate the value of LBWS-enabled process control, further development and testing are needed.

Another significant limitation of the tools is the manual data collection process, which can be laborious and error-prone. Moreover, the accuracy of the locations of the workers collected from the photos could have impacted the results. Other tools for gathering workers' coordinates (e.g., GPS trackers) should be tested in future studies. Lastly, the tool provides delayed information, not contributing to conducting real-time analysis.

ANALYSING THE VALUE ADDING ACTIVITIES IN THE BRAZILIAN CONSTRUCTION COMPANIES

Lucas B. Bizarro[1], Luís C. Staudt[2], Bernardo M. B. S. Etges[3], and Marcus C. T. Fireman[4]

ABSTRACT

This paper presents an update of a study carried out by Etges (2018) in which an approach to answer the question about the level of value adding activities in Brazilian companies is presented. Taking into consideration the concepts of Lean Construction, adding value and wastes, and Value Stream Mapping (VSM) allied to the perspective of Operational Excellence, the study was conducted in 26 different companies divided into 7 categories of construction works, namely: airports, buildings, renewable energies, highways, Intracity, pipelines and railways.

The analysis of the methodology consisted of characterizing the concepts of wastes and of the Value Stream of processes, and this was added to field analyses using the Work Sampling Method (WSM), which consists of measuring and identifying the level of wastage and adding value to the operation at the place of execution. The results show a low level of activities that add value in the sectors analyzed, representing, in the general analysis, 28% of the total time in manhours available. The results are also categorized by the predominant wastes in each category of construction works, and, in the general analysis, 48% of the wastes are related to Waiting.

This analysis makes it possible to identify great opportunities for reducing waste and it is extremely important for the construction industry to promote critical actions aimed at leaner construction management.

KEY-WORDS

Lean Construction, Value-adding activities, Value Stream Mapping, Work Sampling Method.

INTRODUCTION

One of the main problems of the construction industry is the lack of improvement in its productivity over time (Abdel-Wahab and Vogl, 2011; Fulford and Standing, 2014). The study carried out by Barbosa et al (2017) identified that in the last two decades, the growth rate in productivity in the construction industry was only 1%, a figure well below the average of the world economy, which is 2.8%, and almost 4 times smaller when compared to industries such as manufacturing. The reflection of low productivity can also be identified in the most recent

study presented by the Brazilian Chamber of the Construction Industry (CBIC, 2022), which pointed out that 45% of projects exceed budget and 27% are completed after the expected deadline.

In this context, one of the alternatives that companies have adopted are the principles and concepts of Lean philosophy (Fabro et al., 2020). Coming from the automotive sector, Lean strengthens the culture of continuous improvement in companies by systematically reducing losses and waste (Shinohara, 1988; Pheng et al., 2016; Salgin, 2016). Under the lens of Lean, companies in the construction sector are starting to see the everyday existence of activities that do not add value and that result in low productivity. Such activities consume resources, time or space and do not add value to the product (Neve et al., 2020).

Hence, the use of concepts and tools that help the construction industry to reduce this waste is of fundamental importance for the survival of companies in the sector and for the conservation of the vast quantity of material resources consumed by the construction industry (Cardoso et al., 2005). This search by the construction industry to improve its productivity has been identified by Etges (2018), and this paper sets out to update the work already carried out. Still according to Etges (2018), to understand the level of value adding activities on the sites under study, three main concepts need to be integrated, namely: waste identification, value stream mapping and Gemba routines. In the latter, the Work Sampling Method (WSM) will be applied to enable the volume of activities that add value and their wastes to be monitored.

This study aims to update the analysis carried out by Etges (2018) by identifying opportunities and create a reference to allow academics ans professionals in the sector to be aware of the amount of waste in the sector, allowing insights to improve productivity in the construction industry. Thus, this diagnosis aims to illustrate the state of added value in construction industry during execution of activities based on using value stream mapping and observing wastes by using Gemba. Analyses were undertaken in 26 Brazilian companies in two specific periods, between 2013 to 2016 which was carried out by Etges (2018) and the second period between 2018 to 2022 which aims to update the analyzes in the first study.

The article is divided into three phases. The first phase consists of exploring the conceptual references in the literature on adding value, wastes, value chain and value stream mapping, and on how to identify value by seeking to understand the production process. The second stage will address the methodology used to identify activities that add value to the production process and, finally, the results and discussions of the analyses will be presented.

REVIEW OF THE LITERATURE

This section will address the literary review of the three main concepts and tools used to build this paper. They are: (a) definitions of activities that add value and waste; (b) Value Stream Mapping and (c) the Work Sampling Method.

VALUE-ADDING ACTIVITIES AND WASTES

The activities within a production process can be classified as follows according to Hines and Taylor (2000): Activities that add value, these being the activities that make the product or service more valuable to the customer; Necessary activities that do not add value are activities that the customer does not consider valuable but which are necessary; and finally, Activities that do not add value, which are activities that are not valuable to the customer and are not necessary in the current circumstances (Pothen and Ramalingam, 2018). Koskela (1992) also argued that activities that do not add value have three main causes, namely: design, ignorance and the intrinsic nature of production. This definition is in line with the discussion proposed by Koskela et al, (2013) in which the seven classic wastes are in fact in a specific context and that, for the construction context, the crucial wastes must be identified and defined from the characteristics of this type of production. Koskela (2000) defined that in order to apply these concepts in civil construction, what must be understood is what the main wastes to be eliminated in construction are. Thus, the seven wastes defined by Ohno (1988) are: excess production, time on hand, transportation of products, processing itself, stock on hand, motion and the manufacture of defective products.

In this scenario, to analyze the list of construction-related wastes, three main requirements stand out, namely: the list of wastes must be conceptually compatible with the construction industry, empirically justified, i.e., the focus is on the most relevant wastes, and is persuasive and motivating for improvement actions (Koskela et al., 2013). For this reason, Value Stream Mapping is a key tool for understanding wastes in each project, considering the seven losses being considered as possible references.

It is sought to increase the share of work that adds value by eliminating wastes, thereby progressively reducing activities that do not add value (Ghinato, 1996). Thus, the complete understanding of the production process is fundamental for identifying what to eliminate, since, very often, the activities that do not add value are not easily visible. Hence, opportunities to reduce these losses and real improvements arise (Ohno, 1997).

VALUE STREAM MAPPING (VSM)

According to Womack (2004) value stream mapping is the identification of all specific activities that occur along a flow referring to a product or family of products. It is a simple but effective approach to understanding the flow of material and information as value is added to a product or service throughout its processing (Slack, 2002). Thus, to map the value stream, the production trail from the beginning to the end of the process, from the consumer to the supplier, and then a map of the current state of its material and information flows should be drawn up. Following on from this, one should draw up the map of the future state of how its value should flow, and thereby improve the current flows (Rother and Shook, 1999; Rentes et al., 2004).

By doing so, the main function of the VSM becomes to identify when and where the value starts to be triggered and where there is waste, since the team members become more objective in eliminating losses with the use of this tool (Menezes, 2003; Tapping et al., 2002). Recently, new studies, such as Covarrubias et al (2016), have been carried out focusing on the construction industry, in which VSM was used to improve administrative processes in construction. Another study demonstrated that the use of VSM and the Work Sampling Method are two important tools for the Lean philosophy, which have the objective of reducing and minimizing waste in the life cycle of a process and, consequently, of increasing productivity (Pothen and Ramalingam, 2018).

WORK SAMPLING METHOD (WSM)

One of the ways to monitor the number of activities that do not add value which are performed by laborers is to apply the Work Sampling Method. This method, initially applied in industry by the British engineer Leonardo Tippett in 1927, aimed to observe and quantify the time spent on different tasks in order to deeply understand the factors that increase or decrease their efficiency (Neve et al., 2020). Introduced in the civil construction sector around the 60s (Thomas and Guevara, 1984), the tool has enabled the effectiveness of using manual labor to be measured, thereby indicating the portion of time allocated to non-productive activities and exposing the soundness of the planning of the work fronts.

The WSM consists of making a series of snapshot observations, such as photos, of work in progress over a period of time to measure workers' productivity (Jenkins and Orth, 2003). This method, therefore, enables moments of low productivity to be identified, which in turn, can generate enough information to carry out the necessary corrective actions (Thomas and Napolitan, 1999). Despite criticisms regarding the reliability of the method, Wandahl et al (2022) monitored data through nine days of continuous WSM application considering Direct Work, Indirect Work and Wastes. They concluded that the WS Method is robust, considering the three types of testing involved in the Research (Wandahl et al., 2022; SALLING et al., 2022).

A study conducted by Perez et al (2015) used the WSM to measure the amount of productive and non-productive work regarding transport waste in physical flows of construction processes, and thus demonstrated activities that are necessary, avoidable and unnecessary. Another study carried out by Pothen & Ramalingam (2018) obtained positive results when using the VSM tools and the WSM to understand the current productivity scenario in a construction project and to identify and reduce the non-productive time spent by workers, thereby increasing the productivity of the process. Recently, digitization has been used as a way to capture samples of workers' behavior and the respective value adding activities. Perez et al. (2022) added the geographic location for each WSM observation in order to be able to better understand the workers' behavior when carrying out their activities, thus analyzing, jointly, the workplace.

METHODOLOGY

With the objective of supporting the understanding of the productivity scenario in civil construction in Brazil, this research carried out by a consulting company applied the WSM in two different periods, from 2013 to 2016 and from 2018 to February 2022. Data were collected in 26 different companies divided into 7 categories of construction works, namely: airports, buildings, renewable energies, highways, Intracity, pipelines and railways. The activities in each category was selected based in two criteria, (a) the activities that was in execution during the construction on VSM current state; and (b) activities that was identify as bottlenecks during the construction routines.

The WSM was used to measure the number of activities that add value and activities that do not add value (Perez et al., 2015). The traditional definition for adding value to activities set by Koskela (1992) states that activities that add value are activities that transform materials or information into what is requested by the customer; Activities that do not add value, also called waste(s), can be considered as activities that consume time, resources or space, but do not add value.

Applying the WSM in the present research consisted of direct observations and data collection construction sites. The laborers acting in a certain activity were the object of analysis. At each fraction of time, (approximately 5 min), a sample of the work was analyzed and the activities that the laborers performed were classified into macro categories in accordance with Hines and Taylor (2000) which is represented in Table 1.

Table 1: Macro classification of the activities

Category	Description	Value Category
Value-adding activities	Activities which transform material or information into what the client is looking for	Adds value
Activities with hidden wastes	Activities which do not add value, but are necessary to support activities that add value (e.g., motion, transport)	Auxiliary
Activities with evident wastes	When the activity does not add value (e.g., waiting, rework, etc.)	Does not add value

The macro classification of activities facilitates the visualization of process inefficiencies, thus enabling an understanding of the potential for reducing waste in the system. In order to better understand waste, during each analysis, the activities performed by the laborers were classified into 11 subcategories that enabled the work to be understood. This classification was based on the definitions of Ohno (1988) and these are represented in Table 2.

Table 2: Classification of wastes

Category	Description	Value category
Area	When the excessive use of area occurs	Does not add value
Delays	When a time challenge occurs in carrying out the activity	Does not add value
Loading and Unloading	When the need to load and unload materials occurs	Auxiliary
Defects/ Rework	When production errors occur resulting in the need for repairs	Does not add value
Waiting	When the work front is paralyzed and the worker is kept waiting	Does not add value
Inventory	When the presence of materials and products in excess occurs in the production chain or in the storage areas	Does not add value
Excess production	When processing occurs beyond that requested by the client	Does not add value
Motion	When the employee needs to undertake more movements and displacements to carry out the activity	Does not add value
Preparation	When preparing to conduct the activity occurs	Auxiliary
Quality	When the conduct of the activities is checked	Auxiliary
Transport	When the materials or products are moved	Auxiliary

RESULTS

The data presented in this study correspond to the collection of 4374 samples, totaling more than 218 hours of observation. The analyses were collected by consultants and the general public, trained by specialists. The collection time in each macro category of work is detailed in Figure 1.

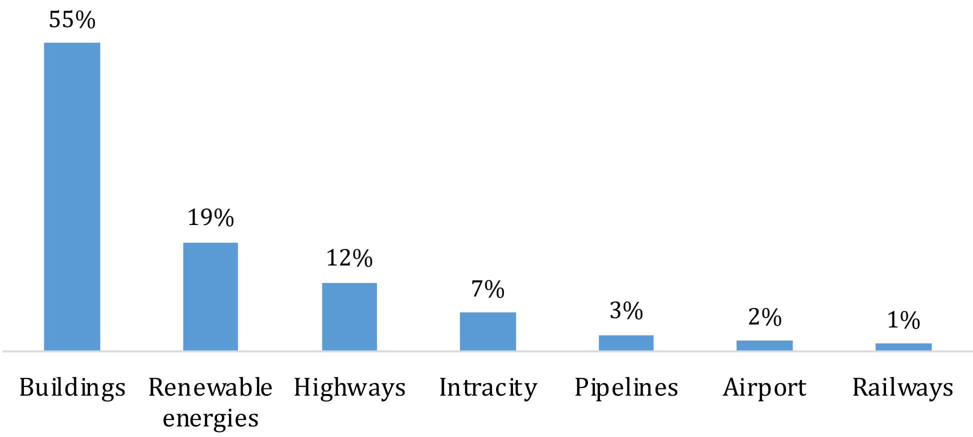

Figure 1: Collection time by category of construction work

From the data collected and analyses carried out under the WSM, a significant level of 72% of the efforts of manual labor dedicated to activities with some type of waste was identified. That is, of the 218 hours of work analyzed, transformation processes that add value to the customer were occurring in only 28% of this time. The results presented below show the relationship between the activities that add value and the wastes observed in civil construction, related to auxiliary activities (hidden waste) and activities that do not add value (evident waste) to the product. Figure 2 presents the absolute data referring to the addition of value in the activities carried out by the laborers.

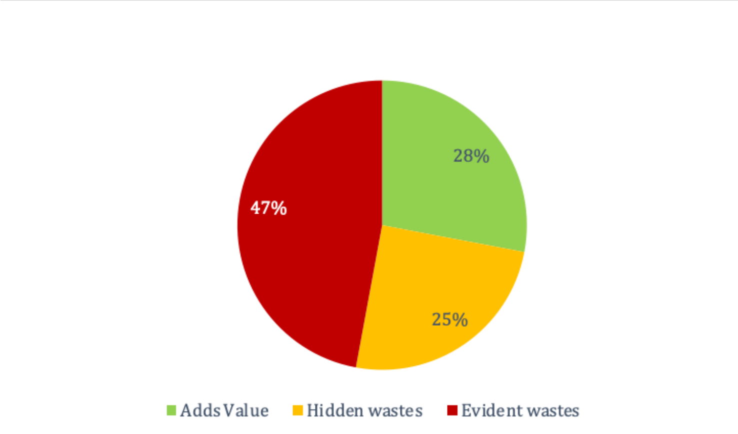

Figure 2: Analysis of added value

On stratifying the results obtained in the main civil construction segments, we can observe that the best results in terms of value adding activities are linked to works with high repetitiveness, as is the case of railways (37%) and buildings (34%) (Figure 3). In the case of buildings, this category of work was the one with the lowest percentage of activities that did not add value (30%). Even considering that building construction have high variety of typologies, one may say that the repetitiveness and flow of activities is objective for a more productivity performance, which is associated with a more consolidated construction system, in which the composition of teams and the division of tasks are mostly standardized.

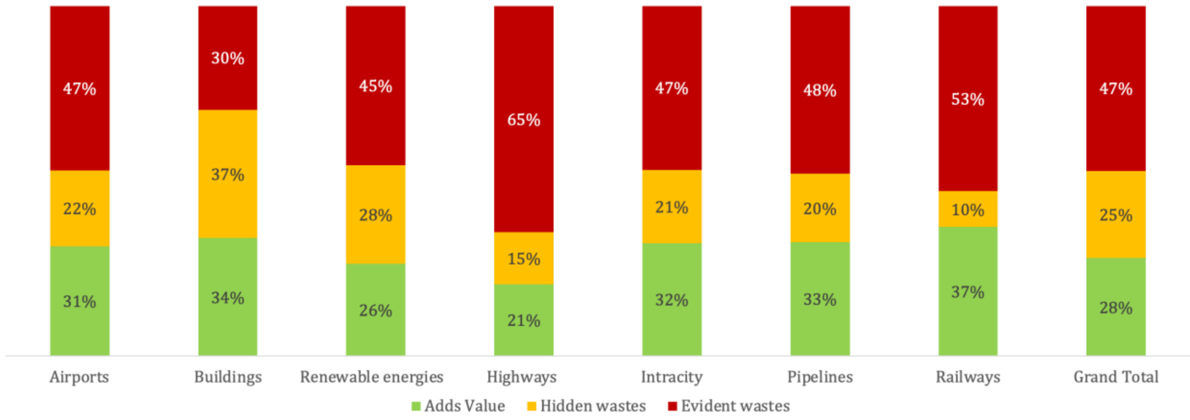

Figure 3: Analysis of value adding activities by type of construction works

On the other hand, the segments of Renewable Energies and Highways presented a lower value adding activities (26% and 21%). The two segments have the following characteristics in common: (a) long longitudinal distances that demand efficient planning and logistics; (b) characteristic complexity related to relief and vegetation; (c) strong dependence on heavy equipment that requires more attention to response time for maintenance.

TYPES OF WASTE

From the work sample analyzed, the types of waste that make up each activity were mapped and it was identified that three categories represents the major wastes: Waiting – 48%; Transport/Motion 19%; and Preparation – 18%, which are represented in Figure 4.

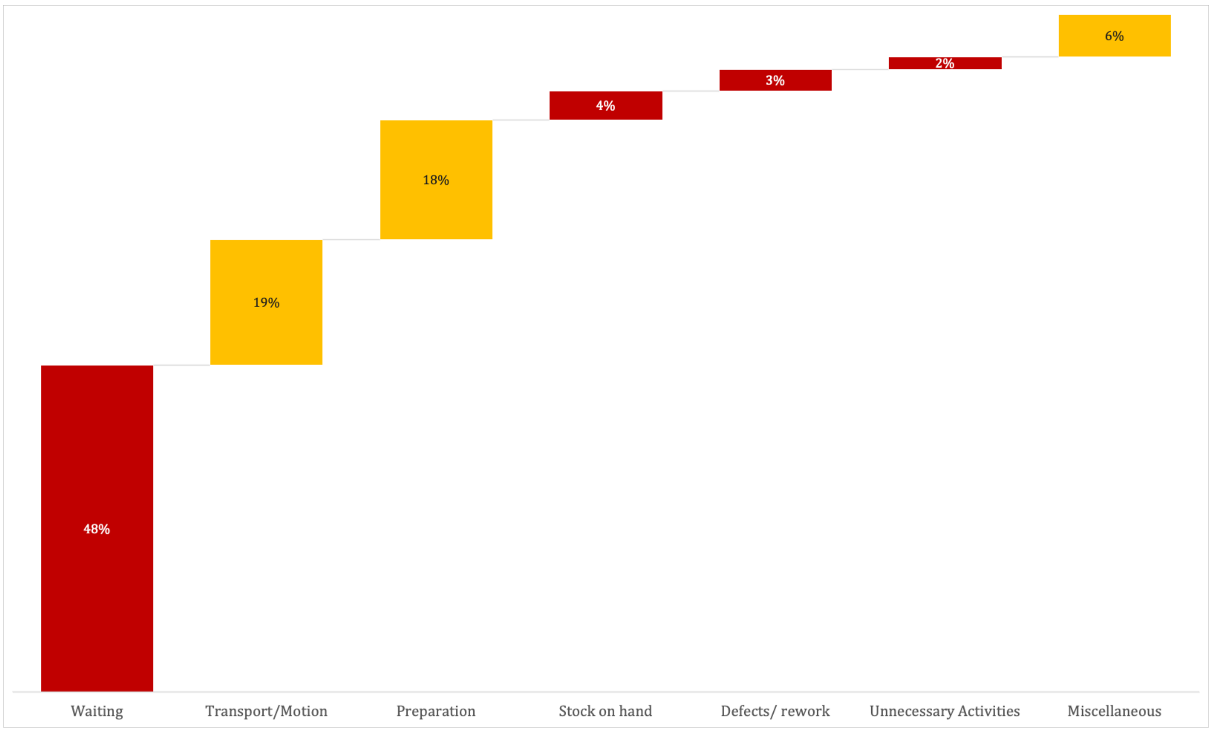

Figure 4: Percentage of wastes per category

Waiting (48%) was the mains waste identified, often perceived in civil construction due to idle workers, waiting on a availability of materials, equipment or even information. This can be reduced by adopting an assertive planning of the work stages, aiming to predict which materials and equipment will be needed in each work stage and ensure that they are available at the right time. In addition, constant monitoring of the production process is essential to identify problems and bottlenecks in production and to be able to act quickly and agilely in solving problems. The use of lean routines and tools, such as the Last Planner System, significantly reduced this waste and led to more efficient work management.

Transport and handling waste (18%) can be reduced with efficient logistical planning in civil construction. For this, collaboration between work sectors, especially between planning and logistics teams, is essential to ensure efficiency. The definition of routes and routines must also be guaranteed in order to minimize excessive movement and transport at peak times and minimize the distances traveled by employees and materials. In addition, the adoption of tracking systems can help control and monitor equipment and work materials, allowing managers to identify bottlenecks and opportunities for improvement.

Another important set of data shown in Figure 4 is the number of defects/reworks in the sector, which corresponds to 3% of the waste analyzed. Despite the low number, given the reality of the sector, it is important to make it clear that the analyses were mostly carried out under the main execution of the services, i.e., the traditional reworks or repairs that are normally carried out in a more advanced phase of the projects were not contemplated in the analysis.

Performing a focal analysis on the three types of construction work with the highest volume of samples collected (Buildings, Renewable Energy and Road), what can be identified is that the three main wastes are the same. They only differ in proportion (Figure 5):

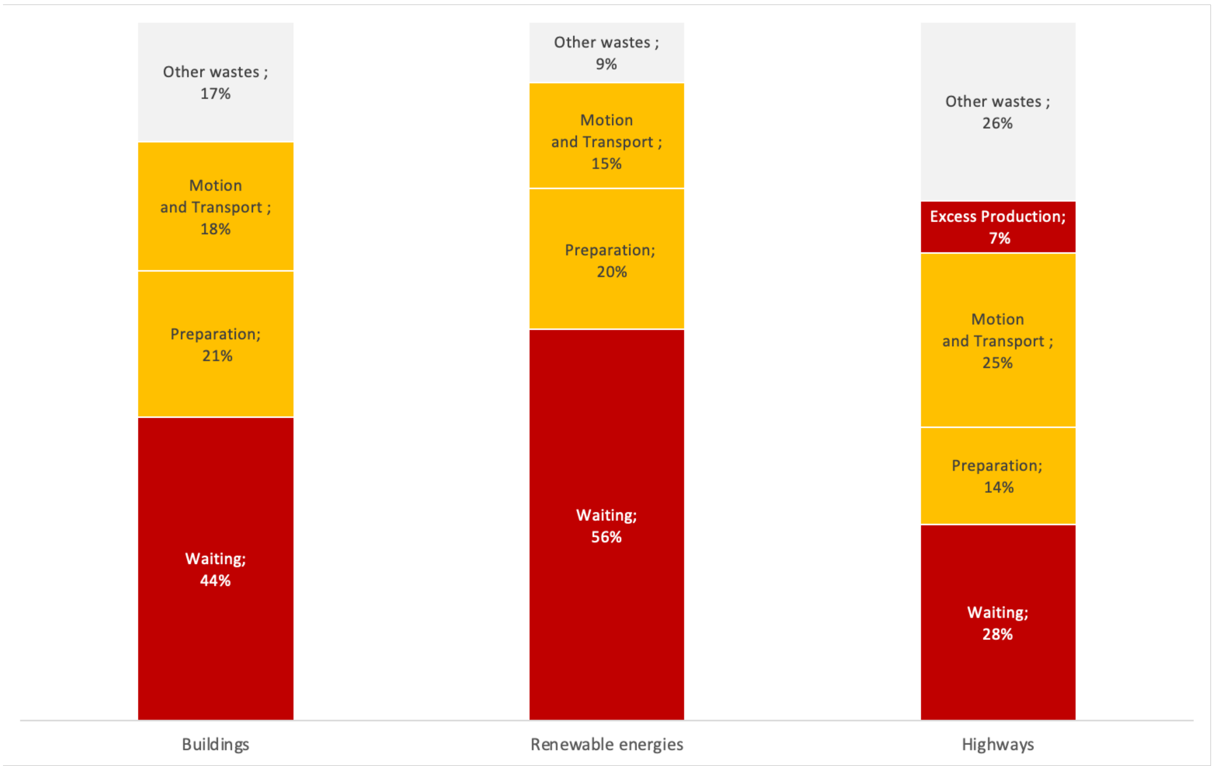

Figure 5: Percentage of wastes by category

Analyzing the proportion of waste presented in each sector, it is possible to infer that:

- The building sector has characteristics that allow greater efficiency (reduced size of construction sites, standardization of the product such as houses or building floors, greater specialization of manual labor) in relation to other types of works. However, it presented a high percentage of waiting (44%) and of motion and transport (18%) in the observations due to factors such as sharing logistics equipment (elevator rack, manipulator), poor sizing of auxiliary teams (laborers) or even errors in the distribution of activities between teams.

- In the Renewable Energies sector, we highlight as reasons for 56% waiting, the high frequency of moments of teams being idle at workstations waiting for formal clearance to start activities, such as: work safety clearance, clearance to work in a given environment, clearances from the previous work front.
- In the highways sector, we draw attention to the waste of excess production (7%), which was sometimes noticed due to the fragility of the control of executing the service. For this reason, the work carried out on the road section is greater than what would be necessary - for example in a base or sub-base compaction, or in precast production centers used in the construction of highways, which can lead to wasted resources and increased costs. In short, due to the difficulties of following up on execution, excess becomes the default. In addition, Transport and Motion (25%) also have great opportunities for reduction, commonly caused by lack of material delivery schedule, excessive stock of materials, difficulties in accessing roads with remote areas and excessive movement of materials due to lack of organization on construction site. To reduce this waste, the adoption of collaboration and visual management tools through the Last Planner System practices is an efficient alternative to reduce these problems, in addition, the use of technologies such as drones and monitoring systems, it can help to optimize the production process, allowing a more efficient management of resources and a reduction significant waste.

DISCUSSION AND CONCLUSIONS

By determining the current status of companies in the construction industry regarding adding value to their processes, it can be stated that the study achieved its objective. The study also enabled the construction companies, by using tools, to perceive the possibilities and needs for improvements applicable to their respective processes. The samples analyzed demonstrate that the Work Sampling Method was an efficient tool for identifying value-adding activities in construction projects.

The results analyzed in this study showed that 72% of the construction activities observed do not add value to the process, a slightly better number compared to Etges (2018) who presented 74% of time spent on wasteful activities. Recognizing these data is of paramount importance for the construction industry to promote critical actions aimed at improving performance, reducing waste and costs, and mainly, achieving leaner construction management. Experiences similar to those of Thomas et al. (1991) were perceived. They suggested that the results can stimulate discussions between managers and, in this way, serve as support to stimulate the search for improvement. Analyses are fundamental to demonstrate to managers the time spent on activities that do not add value.

The building sector has shown great opportunities for reducing waiting and movement and transport waste. In view of this, implementing practices that optimize performance related to layout improvement, in terms of reducing waste, improving the movement of material, storage organization and the use of technology, such as BIM-4D for planning layouts and work phases, can facilitate and reduce losses in the operation, which are fundamental for companies to obtain a competitive advantage in the current scenario.

The logistical issue is also essential to reduce waiting and wastes in movement and transportation in works that have long distances to be covered, such as road works, wind farm works, transmission lines works and photovoltaic plants. In these cases, the supply of materials is one of the issues that can be taken into account in terms of travel time. In road works, intermediate points for stocking equipment and materials can be considered. In addition, using technologies such as digital systems to control their equipment can help companies to carry out a more robust data analysis in order to eliminate this waste.

Due to the large number of companies that were analyzed, one of the limitations of the work is the availability of access to customer data, therefore, as suggestions for future work, it is interesting to analyze it by type of activities. Besides, it would be interesting to apply improvements in a process and to compare value adding activities after implementation. Case studies applying technological solutions aimed at reducing waste in an infrastructure company can help make it more competitive, which can contribute to the answer of the question: how many infrastructure companies use a real sampling of their equipment?

Furthermore, it would be interesting to expand the data sample and increase the number of projects analyzed. Different regions, branches of construction, with different types of technology can be relevant for the comparison between sectors and projects aiming at the continuous improvement of the industry. The main gain from the study was the perception that the Brazilian construction industry is susceptible to changes and that this is fundamental for building a more competitive and efficient sector.

ACKNOWLEDGEMENTS

We thank all the Construction Companies team involved in the projects and we are also grateful to Climb Consulting for the theoretical support and methodological tools used.

ACHIEVING A 4-HOUR TAKT TIME – AND DRIVING CHANGE WITH IT

Jaakko Riekki[1], Jukka Rannisto[2], Joonas Lehtovaara[3], Olli Seppänen[4], and Antti Peltokorpi[5]

ABSTRACT

This study seeks to validate the hypothesis that takt production can be used as a driver for implementing several lean construction concepts together and for making them work as a system. This is done by studying a single case project where takt production with a 4-hour takt time was a core element of the operating system. In studying the case, a set of lean construction concepts found present in the project are extracted and analysed. It is concluded that takt production and in particular the short takt time worked to integrate the stakeholders and enabled the individual lean construction concepts to work in a tight relationship. Future case studies could be more explicitly designed to further validate the hypothesis.

KEYWORDS

takt production, daily management, logistics, continuous improvement, collaboration

INTRODUCTION

According to Koskela et al. (2002) in their description of a Lean Project Delivery System (LPDS) there are two differing interpretations of lean construction: (1) application of lean production methods to construction and (2) a new theory-based methodology for construction that draws inspiration from lean production. In practice the approach of the first interpretation has demonstrated good results yet advancing towards the second would be desirable.

As methodologies akin to the second interpretation, we have The Last Planner System (LPS) (Ballard & Tommelein 2021) that is an important component of lean construction and has gained wide acceptance, and the Location-Based Management System (LBMS) (Kenley & Seppänen 2009) that attempted to bring construction planning together with design scheduling, procurement planning and production control. These systems however have not yet been able to bring to practice the transition from lean construction as a kit of methods to a holistic theory-based system. On the other hand, applications of lean production methods have demonstrated performance gains in individual case projects but there seems to be a knowledge threshold at the point where we are looking for ground up methods that can be used as the underlying drivers

from a set of separated elements towards a system of interrelated concepts. By ground up we mean that it can be applied in practice even in the absence of a theory-based methodology.

Takt production has been suggested as one such underlying driver. Lehtovaara et al. (2020) developed a maturity level model that describes how the development of an organization's takt production capability can be used to connect and implement many other lean construction concepts. Peltokorpi et al. (2021) identified takt production as one key driver for systemic change and suggested a conceptual framework of integrating a set of sub-systems present in construction, that need to be developed together in order to achieve sustainable development. From a more single project-based viewpoint Tommelein & Emdanat (2022) described takt planning as an enabler for bringing together and as a starting point for continuous improvement using lean principles. Studies involving takt production have also highlighted the need to connect with other lean production concepts. For example, Lehtovaara et al. (2021) presented how takt production contributes to construction production flow but with the requirement of significantly increased effort in terms of planning, control and continuous improvement.

Building on this idea we suggest that one way of gaining more knowledge about how to make progress in the transition from applying a set of tools towards applying a management system is to study a successful takt production case project where a scattered set of other lean construction concepts were identified, analyse the effects of the individual efforts, look at how they worked together and, specifically, how they related to the takt. By doing this we can seek to validate or refute the hypothesis that takt production can function as a ground up driver towards a more holistic approach for future lean construction implementation. To this end, this study aims to explore a case project where a short takt time of four hours is highlighted as a novel concept for driving production flow and where many other lean construction concepts were found to be present.

Among these concepts are collaboration, as argued useful by Koskela (2022), integration of design and procurement, an interesting avenue for furthering collaboration as explored for example by Uusitalo et al. (2019), and the core lean principle of continuous improvement. Top management support is required because an implementation of lean tools and methods by themselves often leads to failure without a cultural change in the organization (Walter et al. 2020). Similarly, Hackler et al. (2019) shares efforts towards developing lean leadership and disseminating lean through a larger scale training program. These views are supported by a questionnaire sent out to LCI members that propose barriers for lean implementation (Demirkesen et al. 2019). Emphasis on planning effort is another common lean production idea and has been demonstrated as a rewarding experience for example by Ghio et al. (1997).

Binninger et al. (2018a) showed the power of small batch-sizes, which came together with intensive daily management and the idea of andon pulls i.e., to stop to fix problems as they arise. Also, relating specifically to takt production, several control adjustment mechanisms have been compiled (Binninger et al. 2017) and the daily management activities of construction managers have been analysed (Binninger et al. 2018b).

Tetik et al. (2019) describe industrialized logistics to better serve the needs of construction. Visual management has as well been experimented with on construction sites with promising results for example by Grönvall et al. (2021). First-run studies (Ballard & Tommelein 2021) may also be considered. Digitalization (Sacks et al. 2020) is a tool that opens possibilities for implementing many of the other lean concepts.

In the next section, the method of analysis of this study is described, including a brief summary of the project general information. After that, the findings of the analysis are presented, and finally, implications of the study are discussed.

METHOD

In the following, we first explain the method of this study and then give a brief general description of the case project and how it was managed.

STUDY METHOD

Because we examine a single interesting project noticed by the authors, the method used is a single case study. We gathered data from the project by gaining access to the project databases and conducting interviews. We then searched the data to extract a set of lean construction concepts evident in the project. After that we analyzed how the concepts worked in the project and finally, we report on the findings of the analysis.

The data used in the study consisted of

- documents such as schedules, production plans, process descriptions, contracts, project presentations, photographs and design documents,
- digital data platforms that were used for process planning (Miro), quality control and issue tracking (Congrid) and material management (NPL),
- 4d video animations that were created to visualize the takt phase,
- unstructured interviews with the project participants who were involved in planning, managing and leading the project and
- site observations by the first two authors that consisted of general site walks, site personnel interviews on the spot and included observation of the daily huddles.

The extraction of the concepts to be analysed was achieved through discussions between the authors that followed a preparation made by the first author's study of the data. It was noted that the set of concepts could be grouped and renamed in many ways, but the aim was to settle on a set that is representative of what was learned from the data, does not have excessive overlap between the concepts and would look familiar to most lean construction professionals.

An analysis on how the concepts were used, what, if any, were their benefits or drawbacks and what could be concluded from the experience of implementing them was carried out by asking the following questions for each of the identified concepts:

- (Q1) How were the lean and takt concepts present in the case project?
- (Q2) What were the apparent benefits or drawbacks in implementing the concepts?
- (Q3) What can be concluded from the experience of having implemented the concept?

The answers to these questions and their data sources are presented in the findings section. A deeper reflection on the analysis and the research hypothesis is presented in the discussion section.

CASE PROJECT DESCRIPTION

The case was a renovation project where an office building was turned into a hotel. The site's location was a crowded city center with limited space, posing a challenge for logistics. The building was constructed in several phases from 1920 to 1952 and had since been transformed through other renovation and new construction projects. Through these transformations the building has a varied history of use from industrial to office before being turned into a hotel.

The project consisted of around 29 000 gross m^2 which included 352 hotel rooms with their corridors and other hotel facilities such as restaurants, spas, reception areas and technical spaces. The project started in January 2020 with the demolition phase and was finished and handed over to the client in June 2022.

The construction of the hotel rooms and corridors starting from interior walls were managed by takt production while the other construction phases were managed by a combination of

LBMS flowlines and a modification of the Last Planner System. We will call the phase of production where takt production was used the *takt phase* which is also the focus of this study. Separated from the takt phase, a preparation phase of demolition, structural changes, concrete casting and floor levelling was managed by the other means before the takt phase started. The takt phase started in January 2021 and was finished in April 2022, with total duration of about 16 months.

The project was managed by a project management organization (PMO) who was involved early in the project by the client from goal setting to design process management, procurement preparation and finally to being responsible for the construction site management. In the construction phase the PMO was responsible for the planning and coordination of operations including design, the trade partners and the logistics. However, the designers, trade partners and the logistics contractor were in direct contractual relationship with the project client as part contractors and not with the PMO, who acted only as a project management consultant and a supervisor. By the PMO's requirement, the part contracts of the trade partners were included with a takt appendix that described the takt principles to be used in the takt phase and required the trade partners to take part in takt planning, daily huddles during the takt phase, preparation of work in the takt plan and quality assurance of the finished takt areas.

In the project management role, the PMO took strong leadership in planning, facilitating collaboration and implementing several lean construction concepts in the project. Specifically, the enforcement of takt production was due to the PMO's leadership.

The project was described as successful by the PMO and the client from the schedule point of view. The PMO also reported that in their view specifically the use of takt production in this project eliminated several sources of waste compared to both the other phases of the same project and other similar projects without takt production.

FINDINGS

Figure 1 depicts the set of lean construction concepts that were found present in the case project arranged into four groups. The concepts to be analysed by answering the three questions are in the white boxes.

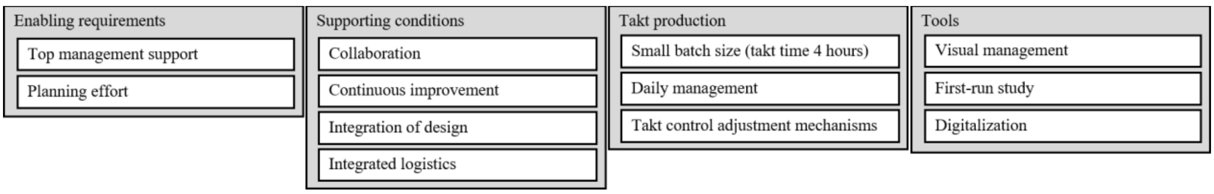

Figure 1: Lean construction concepts found in the case project arranged into groups.

Top management support: The site visits and interviews indicate that the top management of the PMO at the site put a lot of pressure on the management team, the logistics operator and the trade partners to make efforts in new ways of working along the lines of lean construction concepts. The highest-ranking manager at the site had knowledge and experience about lean construction concepts and made efforts to put them into practice through frequent coaching of the management team. In addition to putting pressure, the top management expressed an explicit recognition of the need to allocate an uncommonly high number of resources to the planning phase in order to enable a thorough preparation. (Q1)

These observations make clear the benefit that most of the lean efforts would not have been realized without the pressure and commitment from the top management. There was however no formal lean leadership initiative present, and some members of the management team were observed in a few situations as having been somewhat at a loss in the middle of several new methods pushed by the leadership all at once. (Q2) This was taken to be evidence for the proposition that, in addition to support from top management, getting a good grasp of lean construction concepts requires proper training and coaching. (Q3)

Planning effort: As hinted above, the planning documents and interviews indicate that an exceptional effort was put in planning the takt phase from early on. Evidence of this was also an initial two-day workshop with a large group of the PMO company's production management staff, that began identifying the work steps in the production process along with their quantities and performance rates. This workshop was held around six months before starting production, was led by an external consultant and acted simultaneously as a training session for the participants into takt production principles. In the workshop the knowledge base of around 15 experienced construction professionals was leveraged to gain insights into the details of the production process. Afterwards a group of 2-4 people was assigned to develop the plan further. Around three months prior to the start of the takt phase, two core members of the group worked full-time in fine-tuning the plan. Similarly, around six months before production start, the logistics contractor was tasked with defining the supporting material management processes required by the takt plan. The materials required by the takt work packages were quantified in detail and the methods of transportation as well as lay-down areas on site was planned for each type of material. Closer to production, a preparation meeting was held with each trade partner where a short training of takt principles was given and their input into the takt plan's details and feasibility was solicited. (Q1)

According to the interviews the production management team along with the logistics contractor gained benefits from the planning effort by being well versed in the plan ahead of production which gave them confidence in controlling the takt phase and dealing with the trade partners. Good understanding of the required material and worker resources enabled the production management to tackle surfaced problems quickly by being able to refer to the already gained knowledge. In short, the interviews indicate the sentiment of the management team that putting this exceptional effort in planning and preparation helped in creating and controlling a good production process. (Q2)

It is difficult to discern the economic impact of the decision on the amount of planning and preparation. The case project can however be taken as anecdotal evidence for the hypothesis that the line after which more effort on planning does not gain a net benefit anymore has not yet been reached. It should also be noted that the management team of the takt phase had no prior experience or knowledge of takt production. The careful preparation was used simultaneously as a training opportunity. (Q3)

Small batch size (takt time 4 hours): From the schedules and planning documents it can be seen that the takt plan was built around the smallest space unit of one hotel room and a corresponding length of corridors as the takt areas, which eventually led to decision on using a takt time of four hours i.e., a half workday. This is illustrated in an excerpt of the takt plan and progress record in Figure 2. The interviews reveal that the target for a short takt time was set early in the planning phase explicitly because of the perceived benefits of a small batch size. During the planning process the target was deemed feasible and incorporated into the plan. (Q1)

As told in the interviews, the short takt time enabled a lot of flexibility in the work step definition, sequencing, buffer management as well as levelled the material flow and drove the tight control efforts during production. As evidenced by the schedules, planning documents and progress records, planning and controlling with a short takt time also made the required work steps and progress tracking highly visible and accurate. The feasibility of controlling such a short takt time was said in the interviews to have been initially questioned due to the perceived increased management burden. However, the short takt time was later not only proven feasible but indeed regarded as the key driver for success. (Q2)

Through interviews it was clear that the management team felt that the burden increased by the short takt time was set off and well paid back by the tightness, flexibility and accuracy of control. These observations are similar to what Binninger et al. (2018b) described in their experiment with a short takt time on a smaller scale project. (Q3)

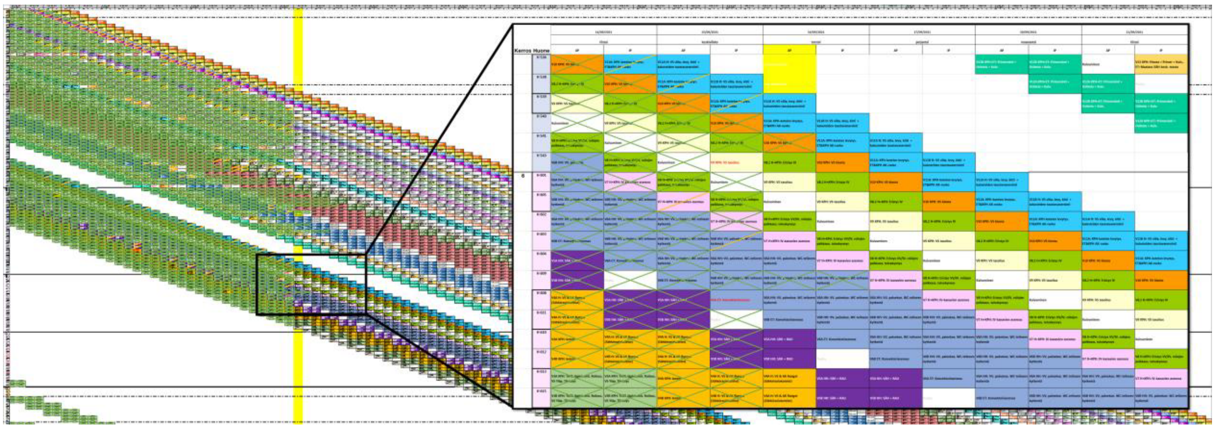

Figure 2: An excerpt of the takt plan and progress record on 16th September 2021 illustrates the plan with a 4-hour takt time. The progress was recorded for every takt in the daily huddles. A green double cross over a wagon stands for done, yellow single cross stands for started but incomplete.

Daily management: The PMO enforced a disciplined daily management process of takt control through worker huddles where all the trade partners were required to be represented every day. In the huddles, observed by the first two authors, the progress in the preceding two takts reported by the trade partners were recorded in a schedule printed out on a large sheet of paper for the purpose of visualization. The progress was simultaneously also recorded in the digital spreadsheet schedule. Figure 3 shows what the daily huddles looked like. Any issues raised during the huddle were also digitally recorded on a separate spreadsheet where in total over 7,000 issues were found having been recorded during the takt phase. Immediately after the huddles, the management team went to solve the surfaced issues with the trade partners. (Q1)

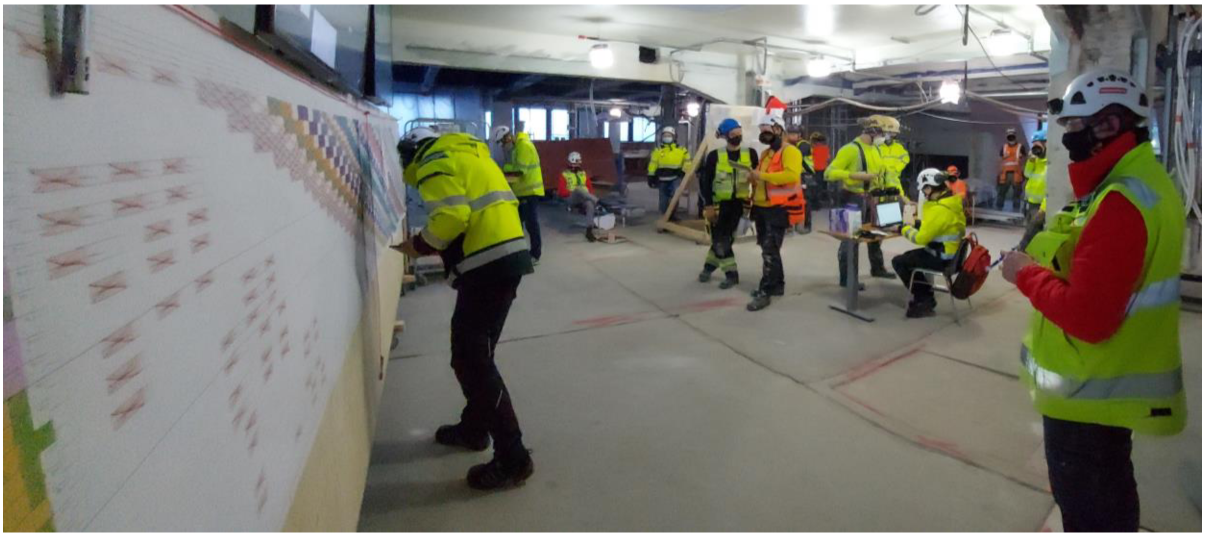

Figure 3: The progress was recorded both digitally and on a visual board in the daily huddles. The raised issues were also recorded in a digital spreadsheet.

The daily huddles served in sharing a common situational awareness of the takt process and enabled the trade partners to get a fast response to issues in their work. At the same time, the progress of planned work was updated and visualized daily. (Q2)

Learned from the interviews, the daily huddles required some enforcement from the PMO. The site observations confirm that some trade partners were reluctant to take part in the huddles, since the huddles took around 30-45 minutes of their workers' time. The PMO held the discipline by referring to the contractual clauses about the huddles. After initial backlash, the huddles became routine and were attended to by almost all trade partners even when they were longer than required in the contract, because they found them useful. After the project was finished, the PMO identified the need to consider breaking the daily huddles apart into several smaller size huddles in order to shorten them in their future projects. (Q3)

Takt control adjustment mechanisms: The studied schedules and interviews reveal that at least the following takt control adjustment mechanisms similar to presented by Binninger et al. (2017) were used during the takt production phase: contents of work steps were modified, the sequence of wagons was changed, new work steps were added, buffer wagons were added and takt areas were omitted in order to protect the train flow. In addition to these the worker resources and material delivery quantities were adjusted as knowledge about their requirements was gained during production. Notably there was one situation where a decision was made to split and stop the trailing part of the train in order to solve problems that had accumulated delays and blockages. The trailing portion of the takt train behind the delayed wagon was stopped for 2 weeks to let the delayed wagon catch up and solve the problem. The leading portion of the train was not affected by the stoppage, and it was kept moving normally. The stoppage time was sufficient for the catchup and the train was restarted with the modifications caused by the stoppage. According to the PMO the decision of stoppage for a specific amount of time was clearly communicated to the affected trade partners, and no major complaints arose. The schedule had enough planned buffer at the end to compensate for the delay caused by the stoppage. (Q1)

Problems that were surfaced during production caused some delays, but the deviations were able to be adjusted for with the major benefit that the plan was kept under control throughout the takt phase. One notable downside to the frequent use of adjustment mechanisms was the effort required to update the modified schedule. The takt plan was drawn on a spreadsheet with a low level of automation and each change took several hours or in some cases even a whole day of work to update and repost on the site. (Q2)

Interviews confirm that the adjustment mechanisms were essential in keeping the takt train flowing. The short takt time along with the upfront effort spent in planning made the takt plan very flexible for adjustments even if they required some effort in replanning. The problem of increased effort required for manual data management can presumably be mitigated by development and adoption of more sophisticated digital tools with a higher level of automation for creating takt schedules. (Q3)

Collaboration: The PMO launched a system of workshops aimed at facilitating collaboration between the site management team, the logistics operator and the trade partners. As described in the interviews, the system was called "three-based-meetings" referring to the usual three stakeholders of the PMO, a trade partner and the logistics operator who all had a stake in most matters relating to the takt phase. In contrast to a prior standard way of sending documents back and forth, the PMO organized workshops together with the other stakeholders where planning and continuous improvement efforts were carried out in collaboration. (Q1)

The top site manager of the PMO described and the management team confirmed an anecdotal example where the planning of materials for a trade partner's work package took several weeks when they first tried it in the documents transfer way and was condensed to a single 1-hour workshop after the launch of the system. (Q2) It was also noted that merely the definition of a process for the purpose of collaboration helped in achieving a collaborative way of working. A high impact was achieved with a small nudge. (Q3)

Integrated logistics: According to the PMO, material flow management was identified early as a key requirement for success in the takt phase because of the small takt areas and the challenges posed by the site's location at a city centre. Study of the planning documents showed that the material quantities were calculated, and a delivery strategy was planned for each work package individually.

The logistics operator used a material management software system to manage all the material flows. The takt schedule was imported to the software, where the bills of materials required by each takt wagon were also added. By doing this an appropriate material package was linked to every work package of the takt plan. The material management process was presented, and the corresponding software was demonstrated by the logistics contractor to the first author.

As per a process map created by the logistics operator, the materials were delivered depending on their type through one of two types of flow: (1) The large and heavy materials such as gypsum boards and bricks were delivered using an off-site warehouse as a buffer to level the flow. The material management system produced a plan for daily picking and delivery from the off-site warehouse to the site and eventually to the corresponding takt area on a just-in-time basis one takt time ahead of the work package. (2) For smaller materials such as water faucets and light switches, an on-site area was provided for the trade partners to be used as a supermarket-like buffer. These materials were delivered directly to the site supermarket and picked by the trade partners as required by the takt schedule. The supermarket area was also used as a one-day buffer against expected delivery failures. (Q1)

Through site observations and interviews it was verified that the material buffers on site were able to be kept small which helped avoid congestions and unnecessary moving. The average material buffer was estimated to have been on average no more than one day's worth for most of the logistically important material types. The site management also felt that the daily delivery plans simplified the daily management of the logistics even if they were not meticulously followed and controlled. (Q2)

Even with such lean material buffers a lack of materials due to supply disruptions was reported as not having been a major problem for the flow of work, which leads to the conclusion that the material management process was reliable enough to enable them. (Q3)

Continuous improvement: The interviews indicated that occasionally during the project, out-of-standard conditions compared to the planned work processes were spotted and meetings to manage the specific issues were held (Q1) and due to the held meetings, several sources of waste were reduced during the project. (Q2) This is in alignment with the general expectation that explicitly defined work processes enable continuous improvement efforts to tackle issues in a formal way. (Q3)

Visual management: As observed during the site visits, the takt plans were printed out on large sheets of paper and put on display in the daily huddle area. Smaller versions of the same sheets were posted on site in common walking areas such as staircases. 4D animations of the takt process and operations flow were created and kept running on displays in the daily huddle area. The hotel room numbers were painted on the floor in the corridors in front of the room entrances. (Q1)

According to the PMO, the workers were frequently found around the posted takt plans either discussing their issues with each other or reminding themselves of which area they were supposed to work in and go to next. Taking note of the room numbers in the takt plan, the painted room numbers made it easy for them to be sure about the correct work location. The 4D animation of the operations flow made the takt train highly visible which presumably helped in gaining common understanding about the direction of the flow. The process flow 4D animation was suspected to be mostly helpful in gaining initial understanding about the sequence of work for newcomers to the project (Q2)

The painted room numbers were unanimously considered as very helpful for orientation at the site and as they were easy to create, the idea was found to be a true low hanging fruit. The

4D animations seemed helpful at the start but updating them to take into account every takt control adjustment was considered too burdensome to do. (Q3)

Integration of design: (Q1) There was a defined documented process for escalating design problems surfaced during production according to the size of the problem and the level of involvement required. A presentation witnessed also by the first author was given to the designers to inform them about the takt process and the urgency of solving problems as they appear. In addition, an interview revealed that in order to make the urgency feel more real, the designers were invited to visit the site shortly after the beginning of the takt phase intentionally to let them see for themselves the hectic nature of the production flow. After this a response time of one takt was sought in order to tackle the problems that can be solved quickly.

The interviews with the management team of the takt phase confirmed that the designers were better prepared to being on call during the takt phase due to at least in part the involvement initiative. Involving the designers personally with the takt phase helped to create clear lines of communication between the site and the designers, and the sense of urgency to solve problems reached the design team. (Q2)

According to the site management, the explicitly defined escalation process was not strictly enforced. This was mostly because solving most issues was too straightforward to warrant any need for a formal process. (Q3)

First-run study: According to interviews and witnessed during a site visit, a mock-up of one typical hotel room was planned and built off-site in order to gain knowledge about the potential problems in the details of the work steps. (Q1) However, because the mock-up was not completely finished before the start of the takt phase its usefulness was limited to the planning phase. (Q2) In order to gain benefits from a first-run study, the process needs to be planned and managed adequately in advance of production. (Q3)

Digitalization: The logistics contractor managed the material flows with a digital materials management system, which was presented to the first author by the logistics contractor. The material management software was also developed for the purposes of the project by the software vendor. Quality control was also managed with a digital cloud platform, to which the first two authors had access. (Q1)

The digital material management system allowed the logistics operator to print out sheets of daily material deliveries for management of picking the materials at the off-site warehouse, packing them into delivery trucks and transporting them to takt areas on site. According to the logistics operator the system reduced manual work in handling the logistics information flows, simplified management and enforced good adherence of the materials flow to the takt plan. The digital quality management system is also generally considered to reduce manual work. (Q2)

The digital footprints of the systems reinforce the view that the materials management system was coupled with a planned workflow that the users were trained in while the quality management system lacked tight coupling with the takt. From this it can be presumed that in order to take full advantage of digital tools, management processes should also be defined and adhered to. (Q3)

DISCUSSION

The decision to use takt production in the project was made early by the project management who had learned about its potential as a lean construction concept. Takt quickly became a dominant theme and emerged as the foundation to link together the treated lean construction concepts in Figure 1. In the planning and preparation phase, takt drove the need for the enabling requirements of top management support and planning effort. The supporting conditions of collaboration, continuous improvement, integration of design and integrated logistics revolved around the takt plan. The takt production concepts of a 4-hour takt-time, daily management and takt control adjustment mechanisms during production were new to most of the management team but worked as an essential part of their operating system. The tools visual management, first-run study and digitalization were all taken in to serve the functioning of the takt phase. All in all, it seems clear that the decision to use takt production was the key to make the parts come together.

More than that, it was evident that the relationship of the individual concepts with the takt and each other leveraged their benefits. For example, visual management techniques and digital tools facilitated collaboration between trade partners, the logistics operator, designers and the site management team, which happened at the level of daily management, which in turn was enabled by thorough planning at the level of a very small batch-size. The short takt time required a lot of attention to details both in planning and operating, which also worked to bring the stakeholders very close together.

It is therefore suggested that this study of the case project validates the hypothesis that takt production can work as a ground up driver towards implementing a system of interrelated lean production ideas in construction. This does not provide nor negate the desire to search for a new theory-based methodology for construction that draws inspiration from lean production as outlined in the introduction but aims to help in bridging the gap.

As an interesting result from the study, it is wondered whether the enabling requirement of top management support could be argued as the even more important concept than takt production for the success of the project. On the one hand, in the absence of the pressure from the site's top manager, the application of takt production and in consequence all the other concepts would most probably have been less stringent and the benefits highly diluted. On the other hand, takt production was the instrument that enabled applying the pressure.

As limitations of this study, it must be noted that the nature of the data was unstructured and did not fit well for a systematic approach. That being the case, the discussion and conclusions in the findings section represent mostly inferences of the authors through heuristics and experience instead of a rigorous analysis. The study relied heavily as a data source on interviews that are anecdotal and therefore of only limited qualitative value. The findings represent only one case project and are therefore not generalizable.

CONCLUSIONS

Returning to the research question of whether takt production can function as a driver for change from an application of lean production methods in a scattered way to a system where the concepts work together, the case project does indeed suggest that the hypothesis may be valid. As described in the discussion section, all the identified lean production methods related in an important way to the takt and would have lost a lot of their benefits in the absence of the takt. Particularly the short takt time created the sense of urgency needed to force the concepts to come together.

However, even if takt was the engine that made the system run, it needed as its fuel the exceptional involvement of the site management team and a constant input from the leadership in the form of coaching and encouragement. It seemed clear that the takt phase would have gone very differently in the absence of these, which lets us conclude that we should not see takt production as a wonder weapon but rather as a solid foundation for a system.

Future research could further validate this suggestion by designing and running an experiment of improvement effort where takt production is explicitly put at the core and other lean construction concepts are built around it as supporting functions.

ANALYZING THE LEAN PRINCIPLES IN INTEGRATED PLANNING AND SCHEDULING METHODS

Moslem Sheikhkhoshkar[1], Hind Bril El-Haouzi[2], Alexis Aubry[3], Farook Hamzeh[4], and Mani Poshdar[5]

ABSTRACT

The shortcomings and limitations of conventional planning and scheduling methods led to a great deal of emphasis on combining them and developing integrated scheduling methods. Also, lean principles and tools are included in the integrated scheduling methods' structure to develop more effective scheduling strategies. This paper implements a multi-step methodology to identify and analyze the lean principles utilized in integrated scheduling methods. The findings show that integrated scheduling methods, Building Information Modelling (BIM)-Last Planner System (LPS)-Kanban, BIM-LPS, Location-based Management System (LBMS)-LPS-CPM, and BIM-LBMS have included a variety of lean principles into their frameworks. Moreover, improving the reliability of the planning, increasing transparency, identifying and eliminating waste, detecting and solving spatiotemporal conflict, enabling the coordination of the look-ahead plans, and continuous flow of work have received the most attention in the integrated scheduling methods. This paper contributes significantly to the body of knowledge by raising project stakeholders' awareness of the lean principles utilized in integrated scheduling methods in construction projects.

KEYWORDS

Lean principles, Integrated Scheduling Methods, SNA, Quantitative Analysis

INTRODUCTION

The construction industry remains still among the lowest productivity rates across all sectors (Turner et al. 2020). Ineffective planning and scheduling (Al Hattab and Hamzeh 2016; Salama et al. 2021), a lack of effective communication and collaboration between stakeholders (Hamzeh et al. 2019; Khanzadi et al. 2020), unrealistic scheduling and inefficient resource management (Hamza et al. 2022) are some reasons for this issue. Thus, it consistently seeks innovative and productive methods for optimizing projects, reducing waste, and increasing efficiency. To overcome the challenges related to ineffective planning and scheduling, using lean principles and tools combined with conventional scheduling methods and developing

integrated scheduling methods is an approach that has received considerable attention in recent years. (Abbasi et al. 2020; Aslam et al. 2020; Boton et al. 2021; Heigermoser et al. 2019). In line with this, several studies integrated the Last Planner System (LPS) with Building Information Modelling (BIM) to improve productivity and efficiency, promote continuous improvement, increase understanding of project stakeholders, and improve the reliability of the planning (Barkokebas et al. 2021; Heigermoser et al. 2019; Sacks et al. 2010; Schimanski et al. 2020; Schimanski et al. 2021). In addition, Abdelmegid et al. (2021) established a framework for adopting simulation modelling in construction by integrating the LPS with simulation modelling approaches. Novinsky et al. (2018) combined the LPS with Earned Value Management (EVM) to improve transparency and control project progress concerning time and cost. Moreover, Ammar (2013) integrated the Critical Path Method (CPM) and Line of Balance (LOB) to consider both logic dependency and resource continuity constraints for repetitive projects. Seppänen et al. (2010) developed an approach that combined the benefits of LPS and Location-based Management System (LBMS) to achieve the lean goals of decreasing waste, increasing productivity, and decreasing variability. Although integrated scheduling methods have primarily addressed the shortcomings of traditional and common scheduling methods, like CPM, and provide the project manager with a wider range of capabilities, a lack of understanding of their underlying concept and incredibly lean principles used make it challenging for the project manager and scheduler to choose the practical and required approach for planning and scheduling.

This study seeks to identify and assess a list of lean principles utilized in integrated scheduling methods in the construction industry. Furthermore, it provides project managers, planners, and schedulers with new insights into the underlying lean principles used in integrated scheduling methods to improve planning and scheduling effectiveness. The following sections provide an overview of the research methodology, analyses and results, a discussion of research findings, and, eventually, recommendations for further research in this field of study.

RESEARCH METHODOLOGY

As shown in Figure 1, a multi-step methodology is employed to achieve this study's objectives.

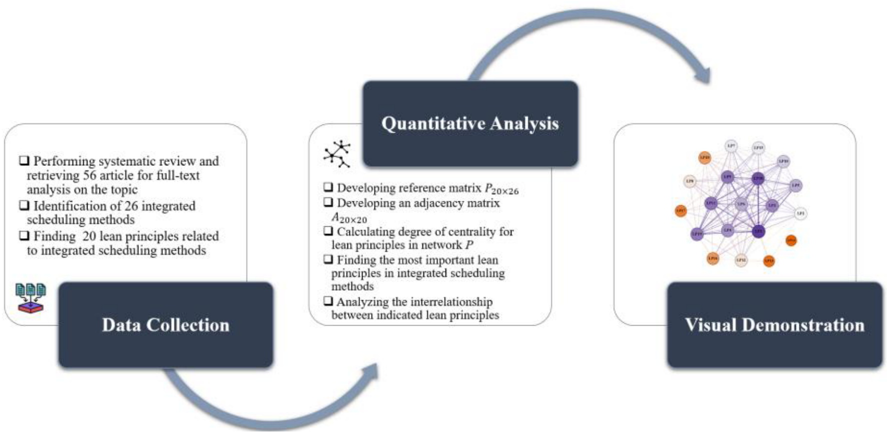

Figure 1: A brief overview of the adopted multi-step research methodology

This study's methodology consists of the following steps: (1) a Systematic Literature Review (SLR) on integrated planning and scheduling methods in the construction industry; (2) identification of lean principles applied in the integrated scheduling methods; and (3) using Social Network Analysis (SNA) to quantify most important lean principles in the integrated scheduling methods. The following sections outline the research methodology's components in more detail.

SYSTEMATIC LITERATURE REVIEW

The applied SLR consists of three components: (1) paper identification, (2) screening; and (3) content analysis conducted by a quantitative literature analysis using SNA. Conference proceedings and peer-reviewed construction journal papers were considered to collect data. As shown in Table 1, the search string was created by combining scheduling methods with "AND" and "OR" in the Web of Science (WoS) database. Title, abstract, and keywords were searched till December 2022, resulting in 1283 publications.

Table 1: Search keywords

Search Query
TS=(("CPM" OR "Critical Path Method" OR "PERT" OR "CCPM" OR "Critical Chain Management system" OR "Critical chain method" OR "LOB" OR "Line of Balance" OR "LPS" OR "Last Planner System" OR "Takt Planning" OR "Takt time planning" OR "LBMS" OR "Location Based Management System" OR "BIM" OR "Building Information Modeling" OR "4D" OR "4DBIM" OR "Linear Scheduling Method" OR "LSM" OR "Simulation" OR " Monte-Carlo") AND ("Project Planning" OR "Project Scheduling" OR "Construction Planning" OR "Construction Scheduling"))

The screening phase is conducted based on several inclusion criteria, such as choosing articles written in English and including at least one combination of scheduling methods (i.e. LPS-LSM). After the screening phase, content analysis was performed on 56 acquired papers to identify the lean principles used in the integrated scheduling methods. To do this, the finalized papers based on 26 identified integrated scheduling methods were analyzed and coded using Nvivo Qualitative Data Analysis software to extract the lean principles associated with each integrated scheduling methods. After that, first, 26 integrated scheduling methods were considered essential and beneficial for the aim of this study. Second, 38 lean principles were extracted from 56 approved papers. The authors tried to aggregate the principles with same concept such as reducing the cycle time with identifying and eliminating of wastes, resulting 20 lean principles for further analysis. It should be mentioned that the codifying and extracting lean principles were applied by this research's first author and evaluated and approved by the other authors of the article.

QUANTITATIVE ANALYSIS OF LEAN PRINCIPLES

The SNA facilitates researchers' efforts to discover systematic literature-related outcomes by connecting concepts, themes, and ideas missed by manual review evaluations due to its quantitative strength and capacity to evaluate interrelationships among numerous factors (Elsayegh and El-adaway 2021). So, same as other studies for quantitative analysis of the collected data from the literature (Assaad and El-Adaway 2020; Elsayegh and El-adaway 2021; Hosseini et al. 2018; Saedi et al. 2022), the authors chose SNA as the best approach for assessing and identifying the most highlighted lean principles in the integrated scheduling methods. A reference matrix P must first be developed to perform SNA on the extracted lean principles. The rows of this matrix reflect recognized lean principles, while the columns indicate integrated scheduling methods. The second step is constructing an adjacency matrix based on the reference matrix P. A weighted adjacency matrix is computed by multiplying the reference matrix P by its transpose and then removing and replacing the values in the diagonal cells of the resulting matrix with zeros. Equation 1 is used to construct this matrix. This matrix represents a network where the rows and columns represent lean principles, and the cell values indicate the co-occurrence frequency of each lean principle.

$$A_{l\times l} = \begin{cases} P_{l\times m} \times P_{l\times m}^{T} & for\ i \neq j \\ 0 & for\ i = j \end{cases} \tag{1}$$

Where $A_{l \times l}$ = weighted adjacency matrix; $P_{l \times m}$= reference matrix; $P_{l \times m}^{T}$= transpose of the reference matrix where i and j are the row and column indexes of the reference matrix, respectively.; l = the number of identified lean principles (i.e., 20); and m = the number of integrated scheduling methods (i.e., 26).

In addition, degree centrality (DC) was utilized to evaluate the significance of a given lean principle based on its frequency and association with other lean principles. The DC for each lean principle is calculated based on Equation 2.

$$DC_i = \sum_{j;j \neq i} P_{i,j} \tag{2}$$

Where DC_i is the degree of centrality for lean principle i and $P_{i,j}$ is the value of the cell in row i and column j of the adjacency matrix. Since the DC calculation depends on the size of the relevant network, it was decided to normalize it. According to Equation 3, the normalized DC of a lean principle i in a network equals the DC of the evaluated lean principle divided by the highest DC of the network.

$$\overline{DC_i} = \frac{DC_i}{max\,\{DC_k\}} \tag{3}$$

Therefore, all lean principles reflect a DC_i normalized between 0 and 1.

RESULTS AND ANALYSIS

The systematic search and screening efforts provided 56 approved journal and conference papers from 1994 to 2021, as indicated in the methodology. By reviewing the contents of the papers, the authors found 20 lean principles in 26 integrated scheduling methods, detailed in Table 2 and Table 3. As shown in Table 3, the 26 integrated scheduling methods were established by merging 14 conventional scheduling methods with lean tools, such as the last planner system, Kanban, six sigma, Just-in-Time (JIT), and takt time. Furthermore, Figure 2 shows the mapping of studied integrated scheduling methods and the identified lean principles. Purple cells indicate that the integrated scheduling methods have attempted to meet lean principles. BIM-LPS-Kanban, BIM-LPS, LBMS-LPS-CPM, and BIM-LBMS have incorporated various lean principles into their frameworks.

Table 2: Identified lean principles

ID	Lean Principles
LP1	Improving the reliability of the planning
LP2	Increasing productivity
LP3	Continuous flow of work
LP4	Decreasing workflow variability
LP5	More efficient constraints analysis
LP6	Visualizing of schedules to understand and communicate content to a variety of stakeholders
LP7	Avoiding omissions and sequencing mistakes
LP8	Schedule constructability analysis
LP9	Identifying and eliminating of waste
LP10	Decreasing meeting durations
LP11	Detecting and solving spatiotemporal conflicts
LP12	Maintaining continuity of resources
LP13	Scheduling of modular and offsite construction
LP14	Eliminating the root causes of variability
LP15	Reducing of production cycle time
LP16	Improving the usability of the 4D BIM for workflow analysis
LP17	Increasing safety on construction sites
LP18	Increasing transparency
LP19	Enabling the coordination of the lookahead plans
LP20	Implementing of pull flow control
