A MESSAGE FROM THE CONFERENCE CHAIR

Welcome to the *31st International Group for Lean Construction Conference (IGLC31)* in Lille, France

Dear Participants attending the 31st International Group for Lean Construction (IGLC31) Conference in Lille (France),

As Chair of the Organizing Committee of (IGLC31) Conference, it is my pleasure to welcome you to this pivotal event. We stand at the cusp of extraordinary transformation within the construction industry, and this conference is a platform for progressive minds to convene, address critical issues, and seek innovative solutions.

The construction sector, a longstanding symbol of human creativity shaping our societies, is in flux. We're amidst a paradigm shift spurred by globalization, digitization, urbanization, and increased sustainability needs. Our focus is on streamlining resources and enhancing quality and work conditions. Given construction's significant contribution to global CO_2 emissions, we must create structures that are resilient, aesthetically pleasing, and eco-friendly. The future belongs to green buildings, low-carbon materials, and high-efficiency technologies.

The rapid adoption of technologies such as artificial intelligence and Building Information Modelling (BIM) brings opportunities and challenges alike. As we employ these innovations, we must ensure our workforce can keep up with this tech revolution. That's where Lean Construction is crucial—no tech transformation can occur without a comprehensively understood Lean approach and social relations.

Rapid urbanization heaps immense pressure on our infrastructure. Our duty is to create inclusive, intelligent, and sustainable cities meeting everyone's needs. Amid these shifts, we must not lose sight of the human element—our construction workers' safety, health, and well-being. Although these challenges are profound, they present opportunities to rethink, reimagine, and reinvent. Our sector thrives on challenges; it's this determination that will shape a sustainable, fair, and innovative future.

The number of contributions this year is exceptional, with numerous topics of great interest to the construction community. I want to take this opportunity to express my gratitude to the external reviewers of the full papers. The organization of this event would not reach the necessary high scientific and technological standards without the skilled work of these reviewers. I would like to extend my warmest thanks to the IGLC31 scientific committee, in particular Zofia Rybkowski, Texas A&M University and the entire committee, who did an outstanding job of steering the conference. I would like to thank the Centrale Lille Institut and the IFCL for their ongoing support in making IGLC31 a great success.

IGLC31 is more than a conference; it is a global assembly of over 250 researchers and practitioners, from all over the world. This program embodies our collective vision of the future of construction. As you read through its pages, you will find articles to bring you ideas that will inspire, knowledge that will empower, and connections that will endure.

We are gathered here to build the future, and there is no task more noble or more necessary. Let's learn, share, collaborate, and transform our industry for the better.

Together, let's build a better future.

Warm Regards,

Prof. Dr. Zoubeir LAFHAJ
Full Professor
Centrale Lille Institut
Chair Holder in Construction 4.0
Founder and President of IFCL (French Institute of Lean Construction)
President of the 31st Annual Conference of the International Group of Lean Construction (IGLC)

FROM THE DESK OF THE SCIENTIFIC CHAIR

Dear Attendee:

Welcome to the *31st International Group for Lean Construction Conference* in Lille, France!

I cannot think of a more exciting place to share this week together with you, my colleagues of the Lean Construction community.

I am guessing your Lean journey is much like my own. I was introduced to the great pioneers of Lean Construction nearly twenty years ago when I embarked on my doctoral research at the University of California at Berkeley in the fall of 2004. Having practiced in the US and overseas as a young architectural designer before returning to academia, I intuitively knew that existing project delivery practices were deeply flawed. For example, why did my colleagues and I find ourselves working late into the night on project details that had already been revised and were now obsolete, while clients were being billed for our irrelevant hours spent? Why weren't we included in meetings so we could contribute in a meaningful way and grow our knowledge base? Like so many of you, I found these practices demoralizing and believed there was a better way to deliver projects. It was simple common sense that is ironically so *un*common (as the late Greg Howell used to say) that drew me toward Lean Construction and its culture of respect.

Since then, I've attended multiple IGLC conferences across the globe: Manchester, Haifa, Lima, San Diego, Fortaleza, Oslo, Boston, Chennai, Dublin, Edmonton—and even Berkeley and Lima (again) as our hosts carried us valiantly through COVID using an online format.

I am grateful for the *international* embrace of the IGLC. Unlike many other annual, mega-conferences that can sometimes seem nearly indistinguishable year-to-year, every IGLC gathering is uniquely defined by its cultural setting, its hosts, and its active participants. When I think about Lean, I think about *inclusivity*. Lean construction principles are informed by the wisdom of multiple disciplines: engineering and project management, to be sure, but also philosophy, psychology, and architecture. The week of a typical IGLC conference includes both academics *and* practitioners. The longer I serve as a former-practitioner-turned-academic, the more amazed I am about how rare the culture of Lean Construction is.

Lean is sometimes described as an inverted pyramid, where project planners are responsible for supporting the efforts and lightening the load of those who do the heavy lifting. Lean leaders are charged to listen well to those with their boots on the ground. One of my favorite sayings was introduced to me by Alan Mossman: "With every pair of hands comes a free brain." In Lean, we live and breathe within a culture of respect. Although not always perfect, the striving to respect is ennobling. It is also, unfortunately, surprisingly rare.

Academic researchers typically report on the number of papers we've published in conference proceedings and journals. So much of academic research requires "checking the boxes," regardless of how read or impactful our research actually is. Lean Construction academics need to check-the-boxes too (universities require it), but our mission above all is to solve the project delivery problem by first identifying and addressing its root causes, working in partnership with members of industry, and then transferring solutions to real projects using action research. Lean academics and practitioners are united by something greater than ourselves, and it is for this spirit that I am incredibly grateful.

Whether this is your first IGLC conference or one of many, I know this week will serve as a unique maker of memories. This is the first *fully* in-person conference held since the coronavirus disrupted our world and challenged our sense of normalcy. Remote conferencing serves a purpose, but as Rafael Sacks once remarked, it is hard to imagine that the Lean Construction community could have coalesced and had the global impact it has had during the past three decades using only online platforms and videos.

Please be sure you take part in as much of the week as you can: Workshop Day, Industry Day, and the Technical Conference, whether at this year's IGLC or next. Don't miss one of my favorite events of all—**the simulation gaming session** on Thursday afternoon that was started by Iris Tommelein four years ago during our first fully on-line IGLC.

Finally, I'd like to send a big shout out to all those who stepped up to the plate to collectively volunteer thousands of hours, delivering the technical segment of this conference. I thank my scientific committee co-chairs: **Min Liu**, of Syracuse University, **Saad Sarhan** of the University of Lincoln, our coordinator **Wassim Al Balkhy** of the Centrale Lille Institut, and **Cynthia Tsao** of NaviLean who stepped in to help in multiple ways. I am extremely grateful to **Thais Alves** from San Diego State University and **Ken Walsh** from George Mason University who used their over 40 years of collective experience in Lean Construction to select papers for plenary presentations that they felt were of greatest interest to the broadest of audiences, crossing multiple tracks. Thank you, too, to **Suryeon Kim** from Texas A&M University and **Chuanni He** from Syracuse University for so diligently shepherding these proceedings.

I especially thank the **chairs of our twelve tracks** and the **216 reviewers** from around the world who volunteered for the substantial task of ensuring that conference papers met the quality standards required by the IGLC. Their names are listed in the proceedings. If you were an author who submitted a paper and have a chance to meet your track chair either in Lille or elsewhere, please reach out to thank them for their efforts in helping to improve the quality of our papers.

Finally, a big "merci" goes out to **Zoubeir Lafhaj** from the Centrale Lille Institute and his enthusiastic organizational team for hosting the IGLC31 and meeting with the Scientific Committee on a regular basis, ensuring we were aligned in our efforts to create a week of exciting presentations and meaningful discussions. I know these conversations will impact our industry in positive ways during the years to come, as the IGLC already has during the past three decades.

--

Chair, Scientific Committee
IGLC31, Lille France

FOREWORD

A total of 172 papers were received, and following a double-blind review, 151 papers were accepted for publication. The accepted papers were organized into twelve tracks: BIM and Enabling Lean with Innovative Technology; Contract and Cost Management; Health, Safety and Quality; Lean and Green; Lean Theory; Learning and Teaching Lean; Modular and Off-site Construction; People, Culture and Change; Product Development, Value and Design Management; Production Planning and Control; Production System Design; and Supply Chain Management. A summary of the submitted and accepted papers by track is shown in Table 1.

Table 1: Papers Accepted to IGLC31 by Theme

Theme	Received	Accepted
BIM and Enabling Lean with Innovative Technology	25	24
Contract and Cost Management	9	8
Health, Safety and Quality	10	7
Lean and Green	11	11
Lean Theory	9	6
Learning and Teaching Lean	7	7
Modular and Off-Site Construction	14	14
People, Culture and Change	16	13
Product Development, Value and Design Management	13	8
Production Planning and Control	33	29
Production System Design	14	14
Supply Chain Management	11	10
Total	**172**	**151**

The accepted papers (Table 2) represent twenty-eight countries including (in alphabetical order, per the first author's affiliation): Australia, Brazil, Canada, Chile, China, Colombia, Denmark, Finland, France, Germany, India, Indonesia, Ireland, Israel, Italy, Japan, Lebanon, Luxembourg, New Zealand, Nigeria, Norway, Peru, Portugal, Qatar, South Africa, Switzerland, United Kingdom, and the United States.

Table 2: Papers Accepted to IGLC31 by Country of First Author's Institution

Countries	Papers Accepted	Countries	Papers Accepted
USA	17	Ireland	4
Canada	17	Japan	3
Brazil	13	Peru	3
Norway	11	New Zealand	3
UK	10	Nigeria	2
Germany	9	Lebanon	2
Finland	8	Colombia	2
Chile	8	Luxembourg	2
France	6	Portugal	2
Australia	5	Italy	2
South Africa	4	Indonesia	1
India	5	Qatar	1
Israel	5	China	1
Denmark	4	Switzerland	1
	Total	**151**	

The high quality of the submissions led us to choose 12 plenary papers worthy of presentation to the entire IGLC audience. The plenary papers are listed in Table 3.

Table 3: Selected Plenary Papers of IGLC31

Plenary paper title	**Presenter**
Using Low-code and Artificial Intelligence to Support Continuous Improvement in the Construction Industry	Eder Martinez University of Applied Sciences and Arts Northwestern Switzerland (FHNW), Switzerland
Integrated Project Delivery (IPD) for Healthcare Projects: A Company-Specific Analysis	Awad Hanna University of Wisconsin-Madison Department of Civil and Environmental Engineering, USA
Creating Co-location Concepts Under Consideration of Hybrid Approaches in Construction Projects	Leonie Szyperski Yukon Projects GmbH, Karlsruhe, Germany
Role of Work Flow in Reducing Life Cycle Energy Consumption in Construction	Musab Jamal Maraqa Technion-Israel Institute of Technology, Israel
Exploration of Educational Backgrounds, Personality Traits, and Gender on Tendencies to Collaborate Among Owners, Architects, Engineers, and Contractors	Zofia Rybkowski Texas A&M University, USA
Improving Premanufacturing Phases in Off-Site Construction Through a Digitalization Approach	Claudio Mourgues Pontificia Universidad Católica de Chile, Chile
Perception of Project Management among Construction Workers: A Survey in Denmark	Søren Wandahl Aarhus University, Denmark
Managing User Requirements in Social Housing Upgrading	Samira Awwal University of Huddersfield, UK
Analyzing the Lean Principles in Integrated Planning and Scheduling Methods	Moslem Sheikhkhoshkar Université de Lorraine, CNRS, CRAN, Epinal, France
Analysing the Impact of Construction Flow on Productivity	Asitha Rathnayake University of Cambridge, UK
Managing Human-Centered Innovation within Target Value Design	Patricia Tillman The Boldt Company, USA
Waste: Why Economics Got It So Wrong, and What Could Be the Remedy?	Lauri Koskela University of Huddersfield, UK

Listed in Table 4 are the invaluable conference track chairs who orchestrated the double-blind review process for the technical conference. We are grateful for their substantial behind-the-scenes efforts.

Table 4: IGLC31 Conference Track Chairs

Track	**Track chair name and affiliation**
BIM and Enabling Lean with Innovative Technology	Wassim Al Balkhy Centrale Lille, France
Contract and Cost Management	Sean Mulholland United States of Air Force Academy, USA
Health, Safety and Quality	Fidelis Emuze Central University of Technology, Free State, South Africa
Lean and Green	Kristen Parrish Arizona State University, USA

Lean Theory	Olli Seppänen Aalto University School of Engineering, Finland
Learning and Teaching Lean	James Smith Brigham Young University, USA
Modular and Off-Site Construction	Mohamed Al-Hussein; Ghulam Muhammad University of Alberta, Canada
People, Culture and Change	Paz Arroyo DPR Construction, USA
Product Development, Value and Design Management	Frode Drevland Department of Civil and Transportation Engineering, Norway
Production Planning and Control	Farook Hamzeh University of Alberta, Canada
Production System Design	Mani Poshdar Auckland University of Technology, New Zealand
Supply Chain Management	Emmanuel Daniel University of Wolverhampton, UK

We would also like to acknowledge the efforts of those who voluntarily committed their time and expertise to review papers. The double-blind review process was made possible by 216 reviewers from 35 countries. The reviewers listed in Table 5 worked diligently to ensure that accepted papers represented the high standard traditionally expected of an IGLC conference.

Finally, we would like to recognize the efforts of the authors too, for rigorously addressing the reviewers' comments and improving the quality of their final submissions.

As with most construction projects, an international conference represents an enormous collaborative undertaking that engages multiple moving parts. It is nice to know that members of the IGLC community practice what we profess.

Speaking on behalf of my co-editors and assistants for these proceedings, it has been an honor and a privilege to be part of this exciting and intellectually vigorous, collaborative effort. --ZKR

TECHNICAL PAPERS

[INVITED PAPER]

Waste: why economics got is so wrong, and what could be the remedy? 1
Lauri Koskela, Glenn Ballard and Trond Bølviken

[BIM AND ENABLING LEAN WITH INNOVATIVE TECHNOLOGY]

Examining the gap between construction software modules and lean contractor practices 13
Matt Stevens and Kola Olayiwola

Strategies for the implementation of greenBIM in a developing country 24
Samuel A. Adekunle, Clinton Aigbavboa, Obuks Ejohwomu, Matthew Ikuabe, and Tunde Aregbesola

Building information modelling (BIM) for project planning: measures to improve its adoption 32
Opeoluwa Akinradewo, Olusegun Oguntona, Babatunde Ogunbayo, Clinton Aigbavboa, and Gilbert Chimbadzwa

Barriers to the adoption of building information modeling in quantity surveying practice in South Africa 41
Kenneth Otasowie, Clinton Aigbavboa, Matthew Ikuabe, Peter Adekunle, Ayodeji Oke, and Samuel Adekunle

Application of big data and internet of things in the built environment: a bibliometric review 50
Peter Adekunle, Cliton Aigbavboa, Ayodeji Oke, Opeoluwa Akinradewo, and Osamudiamen Otasowie

Process analysis with an automatic mapping of performance factors using natural language processing 59
Svenja Lauble, Philipp Zielke, Hongrui Chen, and Shervin Haghsheno

Promoting the IPD delivery method in construction projects: a BIM-based smart contract approach 69
Mohamed Assaf, Lena Salami, Diana Salhab, and Ahmed Hammad

Lean supporting a framework for the construction innovation process 81
Bernardo Martim Beck da Silva Etges and Carla Schwengber tem Caten

Zooming into workers' psychology and physiology through a Lean construction lens 92
Lynn Shehab and Farook Hamzeh

A construction information system as a Lean information management enabler – case study 104
Yanh Ribeiro, Jorge Teixeira, Pedro Mêda, Joaquim Moreira, Rui Sousa, and Hipólito Sousa

Leveraging BIM and mixed reality to actualize lean construction 116
Alessandro Carbonari, Massimiliano Pirani, and Alberto Giretti

Barriers to BIM implementation in bridge construction: a case study 128
Eric Forcael, Alonso Castro, Francisco Bedwell, Euro Casanova, Francisco Orozco, and Francisco Moreno

The role of lean in digital project delivery 140
Kevin McHugh, Bhargav Dave and Marzia Bolpagni

Development of an immersive virtual reality prototype to explore the social mechanisms of the Last Planner® System 151
Canlong Liu, Vicente A. González, Gaang Lee, and Roy Davies

Lean construction waste reduction through the autonomous vehicle technology 162
Omar A. Owais, Mani Poshdar, Ali GhaffarianHoseini, and Amirhosein Ghaffarianhoseini

Efficient pavement distress detection and visual management in lean construction based on BIM and deep learning 173
Ting Deng and Yi Tan

Construction productivity graph: a structured framework to enhance productivity and safety on construction sites 185
Francesco Livio Rossini and Gabriele Novembri

Using low-code and artificial intelligence to support continuous improvement in the construction industry 196
Eder Martinez and Diego Cisterna

Unleashing the power of ChatGPT for lean construction: an early outlook 208
Makram Bou Hatoum and Hala Nassereddine

Lean construction and building information modeling (BIM) in design management: survey results from French companies 220
Wassim AlBalkhy, Eva Chaize, Vincent Morael, Zoubeir Lafhaj, and Ivanka Iordanova

Lean and industry 4.0 in brick manufacturing: a digital twin-based value stream mapping proposed framework 230
Dorra Karmaoui, Wassim AlBalkhy, Zoubeir Lafhaj, and Christophe Chapiseau

Cost reduction in construction through project compatibility in a virtual prototype 242
Joseph Hakkinen Alves Santos and Camila Campos Goméz Famá

Evaluating the usability of the Leanbuild software application after the design stage 254
Muktari M. Musa, Emmanuel I. Daniel, Namadi S. Ahmed, and Ifeatu C. Enedah

Environmental improvements for renovation work using laser scraping 266
Kaori Nagai, Motoki Imazeki, Yasuaki Kaneko, and Yuuki Kawai

[CONTRACT AND COST MANAGEMENT]

A fuzzy framework for contractor selection on IPD projects 276
Zeina Malaeb, Mohamed ElMenshawy, Anas Badreddine, Omar Azakir, and Farook Hamzeh

Life cycle cost and value of Norwegian sports facilities 285
Johan C. Ørke, Tobias O. Malvik, Olav Torp, and Terje K. Fossheim

IPD en France: is it legal? 297
Emna Attouri, Alan Mossman, Laetitia Fehlmann, Ian Heptinstall, and Laure Ducoulombier

Strategic partnerships – best practice across Norway and Denmark 309
Sigurd B. Paulsen, Atle Engebø, Morten S. Jensen, Rolf Simonsen, and Ola Lædre

Integrated project delivery (IPD) for healthcare projects: a company-specific analysis 321
A.S. Hanna, Z. Zhu, and J.T. Morrison

Collaborative dialogue during the pre-tendering phase to maximize project value generation 333
Valeria Vecchio, Abbey Dale Abellanosa, Bernadette Konwat, Yu Wei, and Farook Hamzeh

Towards a flow-based disruption metric: a case study 344
Eran Haronian and Shmuel Korb

Procurement of collaborative project teams – a literature study 353
Trond Bølviken, Una Obiose Kriston Nwajei, and Magnus Mikael Hellström

[HEALTH, SAFETY AND QUALITY]

Safety culture in construction industry of Nepal 365
Prajwol Neupane and Farook Hamzeh

SAFETY-I and SAFETY-II: contributions of UAS safety monitoring on construction sites 377
Roseneia Rodrigues Santos de Melo and Dayana Bastos Costa

Potential application of deep learning and UAS for guardrail safety inspection 387
Hugo S. Peinado, Roseneia R. S. Melo, Mírian C. F. Santos, and Dayana B. Costa

Features of a behavior-based quality system (BBQS) 399
Sulyn Gomez, Semich Chousein, Iris D. Tommelein, Glenn Ballard, Ralph Romayor, Michelle Diaz, Paz Arroyo, and Safak Tekin

Assessing quality performance outcomes & the relationship with RFI and PCI processes: a general contractor case study 412

WASTE: WHY ECONOMICS GOT IS SO WRONG, AND WHAT COULD BE THE REMEDY?

Lauri Koskela[1], Glenn Ballard[2] and Trond Bølviken[3]

ABSTRACT

A paradigm shift occurred in economics in the middle of the 20th csentury. According to the old paradigm, economics studies the determinants of wealth. The new paradigm, called neoclassical economics, posits that economics studies behaviour under scarcity of resources. A corollary of the new view is that people and organisations can be assumed to make optimal, best possible, decisions regarding the scarce resources.

The old paradigm of economics recognized waste as a factor influencing wealth. The new paradigm, focusing on optimal allocation of resources, did not apply the notion of waste. The Nobel laureate economist Stigler went in 1976 even further and claimed that waste is not a useful concept in economic theory, though he admitted the occurrence of waste, which he narrowly defined as a foregone product that can be obtained for less than its cost.

The 1976 paper of Stigler is critically assessed. Three major shortcomings are found. First, waste is ubiquitous in economic activities, whereas Stigler downplayed its significance. Second, waste can occur irrespective of the context, whereas Stigler insisted that waste occurs in the context of market exchange. Third, decision usually needs to be implemented in the material world, and waste often emerges in this implementation. Stigler considered decisions without taking implementation into account.

To rectify the shortcomings in the economic conception of behaviour under scarcity, a new conception is offered. It is based on the recognition of three different types of waste in relation to a decision: background waste, non-optimality of the decision, and foreground waste. There should be an attempt to reduce or to eliminate all three types of waste. The new conception implies that the starting point of neoclassical economics has been seriously wrong.

KEYWORDS

Economics, waste, optimum, scarcity, Stigler

INTRODUCTION

The neoclassical economic theory assumes that firms make optimal decisions under scarcity. Thus, in their production, the maximum possible output from given amounts of inputs is gained. Firms are thus operating on their production frontier, determined by their production function and representing the maximal production opportunities. Obviously, firms differ regarding their efficiency; this is explained by assuming each firm to have its own production frontier.

[1] Professor, School of Arts and Humanities, University of Huddersfield, UK, l.koskela@hud.ac.uk, orcid.org/0000-0003-4449-2281

[3] Professor, Faculty of Engineering and Science, Department of Engineering Sciences, University of Agder, N-4846 Grimstad, Norway, trond.bolviken@outlook.com, orcid.org/0000-0003-4834-2408

However, firms can move their production frontier by deciding to invest into new technology (this concept includes also knowledge). (Stigler 1976).

In the discipline of production management, there has been another conceptualisation of production, where the concept of waste is used. Waste refers here to avoidable costs of production (or any other activity in the firm), for example costs which can be attributed to poor quality. The efficiency differences between firms using the same technology may be explained by different levels of waste. These waste costs can be avoided or at least reduced by appropriate training, management, etc. However, first the root causes of waste need to be investigated, for selecting appropriate countermeasures. Thus, problem-solving is emphasised as a key activity. All in all, the key significance of waste is that it represents unexploited potential for improvement.

These two conceptions of production are starkly contradictory: one assumes that firms continuously make optimal decisions and gain maximal output, the other views that there always exists, more or less, waste in operations, representing avoidable costs. This contradiction has attracted surprisingly little scholarly attention. However, in a recent call for economics of climate change and related change in economics (Stern 2022), a new research area for economics is proposed: "There are all kinds of inefficiencies that exist in our economies and we must try to to understand their nature and origins and how to overcome them."

This paper endeavours to respond to Stern's call. The treatment of inefficiency, waste, in economics is critically reviewed and its serious errors and weaknesses are pinpointed. Based on this, a new conception of behaviour under scarcity is proposed. This conception deals with decisions and waste in the same framework, and in so doing, offers itself as one new starting point for economics for understanding inefficiencies. This may sound recklessly and unrealistically ambitious. However, as Attenborough states (2021): "Economics is a discipline that shapes decisions of the utmost consequence, and so matters to us all."

The paper is structured as follows. The following section gives a historical account on the understanding of waste in economics. Then, the most influential, and also most detailed theoretical concept of waste in economics, originated by Stigler, is critically evaluated. Next, the current understanding of the notion of waste in the context of economic practice is explored. To rectify the found shortcomings of the concept of waste of neoclassical economics, and to remove the current confusion around this notion, a new conception of behaviour under scarcity is then devised.

WASTE IN ECONOMICS

WASTE IN ECONOMICS UP TO MID 20TH CENTURY

Up to the 1930's, the common definition of economics stated that it deals with the causes of material welfare, especially production and distribution (Robbins 1932). In this framework, waste was acknowledged as a worthy topic of the economic science, but there was little theoretical work on it.

A new paradigm of economics, now called neoclassical economics, did a breakthrough in the period 1935 – 1950. One leading idea was that economics is a science addressing behaviour under scarcity – production was excluded from the subject-matter of economics. In an influential essay, Robbins (1932) states: "But when time and the means for achieving ends are limited and capable of being distinguished in order of importance, then behaviour necessarily assumes the form of choice." It is of course prudent to assume that economic agents try to make the best decisions (choices) they can, given their circumstances. However, another branch of the economic theory gave even further support to the idea of optimal decisions. In analyses of perfect competition, assumptions closely related to optimal decisions were made from early on. Such assumptions included the following (Knight 1921):

Economic agents act with complete rationality

They know what they want

They know absolutely the consequences of their acts when they are performed, and perform them in the light of the consequences

The mathematization of the neoclassical economic theory gave a further boost to the idea of optimal decisions. Especially, Samuelson's (1947) influential synthesis of the neoclassical theory contained the axiomatic assumption of economic agents making optimal decisions, for maximizing profit or utility under the ubiquitous scarcity. The concept of waste does not fit into this conception; waste implies that decision-making has not necessarily been optimal.

The production management-based conception was dominant in the first part of the 20th century: waste was discussed in writings on economics, management, production and policies. However, the neoclassical economic theory started to be propagated in the 1930s and diffused in the next decades. Along with this, the usage of the notion of waste diminished; it was simply not needed in discussions focusing on optimal production. Along with the proliferation of neoclassical economics, the usage of the term waste declined both in economic literature and economic policy. It is illustrative that when President Johnson in 1964 launched a war against waste in administration, the Time magazine commented that he felt "folksy pride" when describing efforts to eliminate waste (Time 1964). The term of waste started to be positioned as a word used only in colloquial contexts.

COMPETING VIEWS IN ECONOMICS ON OPTIMAL DECISIONS AND WASTE

Nevertheless, the everyday observations on less than optimal decisions and inefficiencies of course continued in the context of business, households, etc., and there were attempts to incorporate such findings into economic theory.

An early example is provided by Simon (1955), who argued that people do not search for the absolute optimum, but rather satisfice, that is, stop the search when a sufficient and satisfactory option has been found. Especially, Simon pinpointed that the concept of rational behaviour should be compatible with the access to information and the computational capacities actually possessed by the "economic man". Based on this seminal contribution, a new branch of economics, namely behavioural economics, emerged. However, behavioural economics has not been able shake the dominance of the neoclassical theory.

Among the many modes of behavioural economics, one has been directly focused on waste, namely Leibenstein's (1966) theory of X-efficiency, which explains the formation of waste mainly through motivational factors. According to Leibenstein, "where the motivation is weak, firm managements will permit a considerable degree of slack in their operations and will not seek cost-improving methods".

Triggered by Leibenstein's theory, which challenged the neoclassical orthodoxy, the noted economist and Nobel laureate Stigler published an article that defined waste from the neoclassical viewpoint as error, and then claimed, in essence, that waste is not a useful economic concept (Stigler 1976). Next Kirzner (1978) presented his concept of waste, also based on the idea of waste as error in decision; however he rejected Stigler's view that the amount of waste is negligible. Somewhat later, Williamson (1991) forwarded the claim that failures of alignment of transactions and their governance structures create waste.

These competing conceptions of waste in economics are summarised in Table 1. Out of the four conceptions, only Stigler's contribution, which closely relates to the dominant neoclassical doctrine, has had long term influence. Therefore, it is focused on in the remainder of the paper.

Table 1: Competing conceptions of waste in economics

Originator	Cause of waste	Prevalence of waste	Reduction/elimination	Conceptual framework
Leibenstein, 1966	Lacking motivation or incentives (and a variety of factors influencing these)	Considerable: "…people and organizations normally work neither as hard nor as effectively as they could."	Competitive pressure, adversity, force of example	Neoclassical economics, psychology
Stigler, 1976	Error in decision; non-optimal behaviour	Negligible: can be abstracted away	Costs and prices incite to correct decisions	Neoclassical economics
Kirzner, 1978	Error in decision	Very common: "enormous scope for improvement exists"	Through entrepreneurship	Austrian economics
Williamson, 1991	Failures of alignment of transactions with governance structures	The assumption of firms working on their production function and maximizing profits is an egregious oversimplification.	"…better organizational form; better internal incentives and controls; better alignment of the contractual (interfirm and intrafirm) interfaces"	Institutional economics, especially transaction cost economics

STIGLER'S ATTACK ON WASTE IN 1976

In his much cited and influential[4] paper, Stigler (1976) seems to want to explicitly push waste out of economics. In doing so, he comes to define waste from the economic viewpoint in a useful detail. In the following, this attack on waste is presented and critically analysed.

DEFINITION OF WASTE

According to Stigler (1976), "waste is a foregone product that could be obtained for less than its cost". This definition is somewhat cryptic[5] as well as vague and deserves to be clarified through an example.

The grocery shop that is frequently used by the first author has an oven where bread, rolls, etc., are daily baked from frozen dough. For example, a multigrain roll has the price of 85 pence. However, if there are rolls still available after 19.00 o'clock or so, the price is reduced to 5 pence. Most probably this is below the cost of the roll. Thus, the question is about waste, in Stigler's sense.

It can be observed that Stigler wants to define waste in connection to a possible or realised market exchange. However, in doing so, he excludes waste that occurs in organisations not offering products for market, such as governmental organisations or households. Also, because

[4] Perelman (2011) writes: "Realizing that Leibenstein's idea of X-efficiency represented a serious threat to abstract price theory, Stigler (1976) rose to the occasion, pulling out all the stops. In terms of rhetorical success, Stigler's combination of brilliance and bluster mostly carried the day."

[5] The word "foregone" requires interpretation. The probably most common meaning of a "foregone product" refers to a product that was not purchased although seriously considered. However, here the question is about another meaning of "foregone", namely previous or past. Thus "foregone product" refers to a product that has been (previously) produced, and is available after a time lag for less than its cost. Namely, a producer will not knowingly create a wasteful product; time is needed after the act of production for realising that a reduced price is appropriate.

waste, as defined by Stigler, must be visible in a product, wastes (in the generic sense of the word) occurring inside the productive processes may not get visible[6].

Moreover, alone from our example, questions that challenge the logic of Stigler's definition of waste arise: Is it waste if the shop would not reduce the price in the evening, and a roll does not get sold? If a customer buys a roll, but just forgets to eat it in time, and has to put it into the garbage can or feed to birds, is that waste[7]?

Stigler does not explain why he has selected this definition for waste. However, a possible inspiration is the purpose given to production in the economic theory. According to Frisch (1965), production in the economic sense means an attempt to create a product which is more highly valued than the original input elements. Obviously, this purpose is not fulfilled if a foregone product could be obtained for less than its cost.

CAUSES OF WASTE

Stigler recognises two causes of waste: (1) Plans rested upon erroneous predictions; (2) The economic agent is not engaged in maximizing behavior.

Even if the word is missing in these two causes, the question is about decisions; regarding the first cause, assumptions of a decision that turn out to be wrong, and regarding the second cause, decisions that are not made in an optimal manner.

In our illustrative example, waste arises if the predicted daily demand for rolls turns out to be wrong (erroneous prediction), or if the number of rolls produced is not based on empirical patterns of demand (that is, the behaviour is not optimising).

The second cause, of course, represents the ideas of Simon (1955), Leibenstein (1966) and others who have claimed that economic agents are not making optimal decisions.

In critical analysis, a significant oversight is that Stigler sees waste causation only in terms of decisions, belonging to the world of ideas. Waste will emerge when a decision is implemented in the material world – this is not covered by Stigler at all. An implication is that Stigler fails to see a number of important causes of waste in the material world, such as variability of productive processes (as studied in Hopp & Spearman's Factory Physics (2011)).

AMOUNT OF WASTE

Stigler comments the amount of waste regarding the first cause above, decisions being based on erroneous assumptions. According to him, "its magnitude is subject to control". He does not justify this claim. He does not present empirical evidence on the amount of waste. Nevertheless, he seems to conclude that the amount of waste is negligible and can be abstracted away.

PLACE OF WASTE IN THE ECONOMIC THEORY

Regarding the first cause of waste, Stigler states: "Waste is error within the framework of modern economic analysis, and it will not become a useful concept until we have a theory of error".

Regarding his second cause, he says: "Until one is prepared to take the mighty methodological leap into the unknown that a nonmaximizing theory requires, waste is not a useful economic concept."

Thus, in either case, "waste is not a useful economic concept". The message is clear: the occupation with waste should thus stop in economics.

---

[6] An analogous situation has been noted by Koskela and Tommelein (2009), who claim that opportunities for sustainability improvements may be invisible when production is looked at from the economic viewpoint, as a black box transformation.

[7] This example also illustrates that "waste" is an abstract man made construct rather than a phenomenon. What is waste depends on the subject observing the setting.

REDUCING OR ELIMINATING WASTE

Nevertheless, Stigler gives, in passing, one direction that, besides solving the original problem of Leibenstein, namely productivity differences between firms, could be used for reducing or eliminating waste. He writes: "No attention has been paid by economists to the analysis of the optimal amount of technological knowledge that a firm should possess." He illustrates this through a dense sketch concerning two farmers with different productivity: "In neoclassical economics, the producer is always at a production frontier, but his frontier may be above or below that of other producers. The procedure allocates the foregone product to some factor, so in turn the owner of that factor will be incited to allocate it correctly".

The procedure outlined by Stigler seems to be based on three principles. Firstly, the starting point here is the "foregone product", which for whatever reason has been observed as problematic. For example, the company can get the products sold only by having a lower price than the main competitor, or there is waste (in Stigler's sense) associated to the product. Either way, for the particular foregone product, the problematic feature is identified.

Secondly, then, that problematic feature is "allocated" to some factor of production. These include, manpower, land (raw materials), capital (machinery) and technology. In neoclassical economics, production is a black box, meaning that only inputs (factors) and outputs (foregone products) are visible. Thus, remarkably, the problematic feature of a product is associated, through the black box, to a factor. Obviously, some kind of an inference backwards (regression) is carried out.

Thirdly, the owner of that factor will then make a "correct" decision. It can be assumed that this is the optimal decision.

This Stigler's procedure is closely based on the doctrine of neoclassical economics: production gets managed, through optimal decisions, by prices and costs. However, there is one exception: as far as we know, regressive inferences from outcome to cause are not part of the conceptual framework of economics. Looking at the proposed framework from a practical viewpoint, the central question is how the right factor can be identified when production is seen as a black box. Say, quality problems are identified in the products: it may be impossible to determine whether the cause lies with materials, manpower, equipment or knowledge without opening the black box and investigating the process (flow) of production.

OVERALL ASSESSMENT OF STIGLER'S CONCEPT OF WASTE

Above, features of Stigler's conception of waste have already been critically assessed; here the conception is assessed as a whole.

Stigler, as a leading proponent of the neoclassical economic theory, defines and discusses the notion of waste and finds that is is not a useful concept for economic theory. Unfortunately, Stigler's conception of waste is distorted and biased, and his conclusions are wrong. Three major shortcomings in his conception can be identified:

- Stigler's narrowly defined waste is unavoidable, however it's magnitude can be subject to control so that it can be abstracted away; we argue that waste is ubiquitous and of such magnitude that it cannot be abstracted away.
- Stigler defines waste in the context of decisions and market exchange; we argue that waste can occur irrespective whether the context is decisions and market exchange or not.
- Stigler does not take into consideration that decisions often, if not usually, need to be implemented in the material world; we claim that it is also here that waste can occur.

These arguments lead us to contend that waste, inefficiency, should be fully incorporated into economic theory.

CURRENT PRACTICAL IMPACT OF ECONOMIC TREATMENTS OF WASTE

Above, the treatment of waste in the neoclassical economic theory has been discussed. It is also of interest how waste is currently dealt with. In the following, three cases of current treatment of waste in the practice (or practice-oriented teaching) of economics are discussed. Although the sample is small, the cases give a cogent picture of the situation.

WASTE IN HEALTHCARE

In 2017, the the Organisation for Economic Co-operation and Development (OECD) published a report on healthcare waste. In that report, two principles for reducing waste are highlighted:

"• Stop spending on things that do not improve health – for example, unnecessary surgeries and clinical procedures.

• Swap inputs and change approaches when less pricy alternatives of equal value exist."

The first principle would seem to suggest deciding to eliminate waste. In turn, the second principle interestingly recommends making optimal decisions.

The suggested implementation of waste reduction is summarised as follows: "…recognizing the existence of the problem, developing tools to assess its scale, convincing and incentivizing stakeholders to change their behaviour are all part of the solution."

Thus, waste is seen to be caused by stakeholders' decisions and behaviour, in compliance with economic theory. However, in contradiction to that theory, it is implicitly admitted that decisions are not necessarily optimal, causing waste.

FOOD WASTE

The attention given to food waste has triggered recent research in economics, given that "there exists no foundational economic model of food loss and waste for consumers, processors, intermediaries and farmers based on first principles" (Drabik, de Gorter and Reynolds 2019). This lack of a foundational model for food waste is of course related to situation that there is no foundational economic model of the emergence of waste in general. Given this, economists try to use existing economic theory. For example, Lusk and Ellison (2020) consider it self-evident that food waste is an economic phenomenon, related to consumer decisions:

> In fact, many analyses of food waste seem to conceptualize food waste as a mistake or inefficiency, and in some popular writings a sinful behaviour, rather than an economic phenomenon that arises from preferences, incentives and constraints.

In their view, "it is imperative to view the waste decision like any other decision – one with costs and benefits". However, the insistence of seeing food waste because of consumer decisions unavoidably leads to the contradiction mentioned above: the assumption of optimal decision-making does not leave room for waste. Lusk and Ellison (2017) are at a loss to explain this:

> A challenge with the studies that model waste as an outcome of consumer maximization decisions, insofar as informing public policy, is that the decision to waste, at least from the perspective of the consumer, is optimal. If so, it is unclear what role there is for public policy or public education aimed at reducing food waste. If "waste" is a result of an optimal decision, forcing a lower level of waste would necessarily harm consumers.

WASTE AS DISCUSSED IN A TEXTBOOK FOR CONSTRUCTION ECONOMICS

In his popular textbook on construction economics, Myers (2004) says:

> In any free market economy businesses will never waste inputs. A business will not use 10 units of capital, 10 units of labour and 10 units of land when it could produce the same amount of output with only 8 units of capital, 7 units of labour and 9 units of land.

This of course contrasts to empirical observations stating that waste is omnipresent in construction (Arbulu & Tommelein 2002).

CONCLUSIONS

An overview on the approaches to waste in the three cases considered is given in Table 2.

Table 2: Conceptualisation of waste in the considered three cases.

Context of waste	What is the cause of waste?	Are decisions optimal?	How can waste be reduced or eliminated?	Is waste prevalent?
Healthcare	Decisions	No	Decisions	Yes
Food	Decisions	Yes	Decisions (?)	Yes
Construction management	Decisions (but only in principle)	Yes	No need	No

In all three cases, waste is seen to be caused by decisions, and correspondingly decisions are held as the means for waste reduction (if this is needed). In two cases, decisions are seen to be optimal, whereas in one case, this is denied. In turn, waste is seen to be prevalent in two cases, whereas in one case, the occurrence of waste is denied. Thus, beyond the idea that waste is caused and reduced by decisions, there is a major confusion regarding the existence and causes of waste.

The analysis of these three cases shows that the topic of waste has been left fallow in economics: "…economists have mainly assumed the problems of waste away…" (Williamson 1991). Arguably, Stigler's paper which concluded that waste is not a useful concept has contributed to this situation. All in all, this analysis of current economic application of the notion of waste supports the view that a clarification of this notion is badly needed.

BEHAVIOUR UNDER SCARCITY: A NEW CONCEPTION

CONSTRUCTING THE NEW CONCEPTION

Above, three major shortcomings in Stigler's conception of waste were identified as well as correctives, which include:

- waste is ubiquitous and of such a magnitude that it cannot be abstracted away but rather one should continuously act on it
- waste due to a decision can occur irrespective whether the context is market exchange or not.
- decisions often, if not usually, need to be implemented in the material world; it is also here that waste can occur.

A new conception for decision-making behaviour under scarcity is needed where all inefficiencies are covered. Thus, waste before a decision, waste directly originated by that decision, and waste possibly occurring after the decision, as an indirect consequence of it, have to be addressed. It is proposed that these are called background waste, decision related waste and foreground waste. This conception is compared to Stigler's conception in Table 3, and its different elements are discussed in the following.

Table 3: Comparison between the waste types in the new conception for behaviour under scarcity and in Stigler's conception.

Waste type	The new conception	Stigler's conception
Background waste	Waste existing prior to the decision, and affecting that decision (through general resource scarcity or as a factor in the decision)	Not covered
Decision-related waste	Outcome of a non-optimal decision	Foregone product can be obtained for less than its cost
Foreground waste	Waste occurring in the implementation of a decision	Not covered

BACKGROUND WASTE

Background waste consists of the waste "normally" emerging in the activities of an organisation. This occurrence of waste adds to costs, and relatively, adds to the scarcity of resources the organisation is experiencing. Williamson's (1991) first order economising addresses this kind of waste, whereas second order economising is about optimal allocation of resources.

Authors in production management argue that waste should be continually reduced. Especially, the approach of continuous improvement (Imai 1986), *kaizen*, focuses on background waste.

What is then the relation between background waste and a decision? Robbins defined economics in terms of scarce means in view of our limitless ends. First, the accumulated savings from continuous improvement and reduction of background waste diminish the scarcity of means: simply, there is more money for every need considered important. Secondly, background waste is also related to our ends. If our household can reduce the food waste, we would need to buy or otherwise acquire less food. Note that the relation of background waste reduction to a decision is generic in the first case. Instead, in the second case, decision-specific waste reduction (that is, waste related to an end should be reduced) is needed.

DECISION-RELATED WASTE

All non-optimal decisions lead to waste. The question may be about assumptions that turn out to be wrong, calculation error, etc. Surely decisions need to be as good as possible, based on the factors that are known at the time of making that decision. As it is well-known, uncertainty about the future, incomplete information on the current state and deficient understanding of the phenomena dealt with in the decision make it difficult if not impossible to determine the optimal, best possible, decision in practice.

FOREGROUND WASTE

Decisions represent mental commitments – however most decisions need to be implemented in the material world. During this implementation, waste can occur. This is called foreground waste as the room for it is created by the relevant decision. By not acknowledging the implementation of decisions, economics fails to recognise this type of waste.

The mundane example of buying milk on a hot summer day provides an example. When deciding to buy, we need to anticipate how long it would take to have the milk brought to the fridge, to avoid it being spoiled. Another example is offered through the case that a client decides to start a construction project. That decision leads to a multitude of subsequent activities in the material world, as well as to a multitude of subsequent decisions in the world of ideas, and the possibility of waste is lurking everywhere.

ILLUSTRATION

Let us illustrate the new conception through the case of a hospital project.

Background waste

The OECD report (2017) and other literature gives abundant evidence on the prevalence of waste in healthcare settings, including hospitals. The reduction of such background waste is already a reality in some hospitals (Virginia Mason Institute 2021, Reijula & Tommelein 2012). By reducing operational costs, there is more room for capital investment.

On the other hand, some background waste may be directly related to an upcoming decision. Through a new facility design, the daily walking time of the nursing staff may be reduced. By reducing re-admissions, the number of beds needed may be reduced.

Decision-related waste

Decision-related waste is mostly related to the continued need for the facility in question. Thus, the correctness of assumptions and predictions accentuates.

Foreground waste

Hospital design, as such, is a complex endeavour, and proceeds under many uncertainties. The best available approaches need to be used for avoiding waste. Life cycle thinking and future-proofing (Memari et al. 2023) can be mentioned as promising countermeasures regarding issues emanating from the long life of the facility and the uncertainties surrounding it. However, the primary consideration should be given to approaches and methods addressing waste in design and construction, for the sake of continuous improvement during these stages and beyond (Koskela & Ballard 2021). Especially the Target Value Delivery procedure (Ballard 2020) has turned out to be instrumental for reducing avoidable cost. The commonly achieved savings, in the region of 10 – 30 %, give a manifest proof of the existence and magnitude of foreground waste.

CONCLUDING DISCUSSION

The idea of scarcity of resources as a starting point for economising, and indeed, economics, is fundamental. The conclusion drawn from this has been that resources should be allocated to different uses in the best possible way, optimally. However, there is a critical shortcoming in this reasoning: for its part, resources are scarce because we are wasting them. As Williamson (1991) argues, reduction and elimination of waste should be the primary form of economising, only after that come optimal decisions.

However, economics has acknowledged only optimal decisions, and been silent on the need to tackle waste. Because of the immense influence economics has had from the middle of the 20^{th} century onwards, this has had considerable consequences on many fronts. Let us just remind that many of the sustainability problems are waste problems, starting from the considerable food waste to the inefficient use of energy resources.

It is noteworthy that the concept of waste has never been explicitly and convincingly argued to be useless in economising; it has just been incompatible with the theoretical constructions of neoclassical economics, and attempts to import waste into the economic theory have been aggressively shot down, with strong rhetoric but weak justification.

The suppression of the concept of waste in economics is also related to the neglect, in economics, of a phenomenon which shows perhaps the majority of waste: production. Background waste exists in all activities of an organisation, including especially production. Much, if not most foreground waste likewise falls into production. Thus, the exclusion of production from economics, which was strongly propagated by Robbins (1932) and then realised through the proliferation of neoclassical economics, was a grave mistake.

The declared purpose of academic economics is to explain and predict; however, in practice, the economic theory is taken as a description of economic phenomena, and as a normative guideline. The many books of managerial economics are examples of the latter. Waste being absent both in the description and in the normative guidelines has led to a situation where waste reduction is not recognised as a valid and necessary line of practical action. Furthermore, without awareness of the possibility of the emergence of waste, it may be that lines of action based on economics have actually increased waste.

The new conception of behaviour under scarcity, if accepted, arguably leads to the need to reassess the neoclassical economic theory; there is no visibility on all implications now. However, a more immediate and important consequence is that the normative guidance on the part of economics needs to be changed to cover both optimal decision and waste reduction.

ACKOWLEDGEMENTS

The comments of Dr. Ergo Pikas and two anonymous reviewers have improved the paper.

EXAMINING THE GAP BETWEEN CONSTRUCTION SOFTWARE MODULES AND LEAN CONTRACTOR PRACTICES

Matt Stevens[1] and Kola Olayiwola[2]

ABSTRACT

Construction contracting software has existed for over three decades while this industry has suffered many of the same problems, such as disproportionately high bankruptcy rates and stagnant multifactor productivity. This paper reviewed industry software operating manuals and conducted executive interviews to examine a significant blind spot in the Australian construction industry. This gap is the lack of support their products give to the accepted practices of contractors' operations. Software developers appear to have not pursued the clear Lean ideal of "perfection". All their client's needs and wants have not been met. Many small and medium-sized contractors rely on customising computer spreadsheets to calculate supporting information needed to execute some practices. In contrast, others are unaware of the methods or have not taken this additional step. The researcher has identified eight specific processes to research software firms' product literature to discover the extent of the gap. The sources of these issues are many; however, tailoring construction software to enable effective practices while "hardwiring" them into a company's process could lessen industry problems. Lean Construction researchers have asserted that this is the potential of Information and Communication Technology through a "push" approach.

KEYWORDS

Construction software, contractor ICT, built environment technology

INTRODUCTION

The construction industry globally has been slow to adopt Information and Communication Technology (ICT) even though projects generate much information that must be processed timely and securely stored. Additionally, construction contracting is more complicated than any other sector due to one-of-a-kind production (Andújar-Montoya et al. 2020). The industry has many ad-hoc production control methods, most of which are informal, fostering uncertainty that prevents smooth production flow (Dave et al. 2016).

Rapid standardisation and automation are highly improbable without software tools and digitalised business processes (Matt and Rauch 2014). Nevertheless, the transformational potential is apparent to many researchers in the standardisation and automation of processes and workflows in both the planning and execution stages. Moreover, practitioners and scientists have made efforts to improve the current situation (Faghihi et al. 2015).

Researchers and software vendors have provided many reasons for the low implementation of ICT solutions in the industry, such as high acquisition cost, ongoing investment, and mastery time it requires. However, this paper asserts that there may be another reason, it does not possess significant value (total cost versus profit) for contractors over generic software such as spreadsheets. Standardisation and automation can be provided by using accessible spreadsheets.

Approximately 3/4 of contractors physically construct the work (subcontractors or specialty contractors), and more than 95% employ 20 employees or less, qualifying as Small-Medium Enterprises (SME) (ABS 2022). These SMEs deliver significant value to project owners by installing materials in compliance with the specifications. This is where ICT can make the most industry impact. Increasing value-for-money for all more will adopt more information technology; thus, performance in critical areas such as safety, quality and productivity should improve. Technology appears to be the logical solution enabler. Improvement seems highly probable if it can be tailored through construction software recoding, application programming interface or a mobile computing application. Not creating these well-established and accepted practices in the industry standard software will contribute to the continuing malaise.

LITERATURE REVIEW

This literature review examined the nexus between construction contracting accepted practices and construction software modules.

INDUSTRY CONTEXT

Construction is characterised by factors that affect the schedule, forecasting of resources and quality. It is considered complicated and information critical based primarily on the accuracy of interpreting varied issues based on a professional's body of work (Wu et al. 2012). Prior studies have identified the construction industry's unique working methods as the main barrier to implementing an industry improvement (Dubois and Gadde 2002).

Lean Construction researchers have recognised that expected productivity can decline due to conflicting goals between individual trades and the project (Sack et al. 2010). Hartmann et al. (2012) suggest that project teams must align their work processes to the new "collaborative and integrated ways of working" including using ICT to reach these goals. Contractors – main and sub - typically work with constrained resources to complete different projects simultaneously, making portfolio management a critical skill. The organisation enables well-executed projects. They try to optimise these resources, which requires thoughtful planning to execute interdependent tasks well (Lasni and Boton 2022). Best construction practices help manage multiple processes that must work simultaneously to make a construction firm consistently profitable and raise its position on the Risk-Reward Curve (Stevens 2012). Constant planning, as well as careful schedule monitoring, detailed decision-making, proactive problem recognition and, thus, earlier than needed solutions (Ahuja et al. 1994). However, according to the Australian government, multifactor industry productivity in that country has been stagnant for over two decades (Stevens and Smolders 2023)

A recent technological shift, such as Building Information Modelling (BIM), appears to be re-energising the focus on effective practices, including those considered Lean (Sacks et al. 2018); it enables project stakeholders to plan, design, review, program, cost or manage construction projects. This interactive process enhances the design end product (Kuiper & Holzer 2013). In addition, ICT can improve construction industry operational procedures, particularly planning and control (Martins et al. 2020). The most used goals for contractors revolve around time, cost, quality, profitability, customer satisfaction, safety, and sustainability (Fahri et al. 2015).

Construction managers must interpret and process voluminous data for proper up-to-date decision-making in effectively running a project. Therefore, the project's success depends on the increased reliance on technology. However, individuals' readiness to adopt technology has four dimensions: optimism, innovativeness, discomfort and insecurity. The four are independent; optimism and innovativeness encourage people to use and hold a positive attitude to technological products and services, while a lack of comfort and security prevent their adoption (McNamara, Shirowzhan & M.E. Sepasgozar 2022).

The research literature does not contain a rigorous review of ICT Technologies applied in the construction industry, although several have been proposed. There has been a fluctuating decline in articles since 2002, resulting in fewer publications in 2015. (Adwan and Al-Soufi 2016). Additionally, minimal research has been conducted to capture the issues barring technological adoption among small firms (Clermont et al. 2020) to help them identify their real needs and wants, including their challenges. This identification can help companies make changes and better address pressure from competitors (Lasni and Boton 2022).

SOFTWARE DEVELOPMENT AND UPGRADING HURDLES

Today, software development is conducted in a chaotic environment. For example, Holmstrom et al. (2012) found disordered and dynamic markets, complicated and uncertain customer demands, shorter development cycle time pressures, and Moore's Law effects in most software development projects. Notably, nine barriers in the industry dampen construction innovation, Also, this results in suboptimal investment in new ideas, including software development (Stevens and Smolders 2023).

There is no standard software development process due to the differing characteristics of the organisations, products, and projects. The process is contingent on the knowledge and experience of the software Research and Design staff and the organisational guidelines, including the economic ones they must work within (Choi et al. 2017). In many software development firms, product managers struggle to get well-defined customer perceptions, needs and wants. Often, software value and utility validation occur after deployment. Furthermore, learning from customers is neither typically formalised nor continuous. As a result, the selection and prioritisation of utilities become suboptimal, and products are misaligned from what the customers need or want (Fabijan 2015). Literature has established that the lack of programming management commitment has been one of the top reasons for the failure of Software Process Improvement (SPI) (Abrahamson 2000ba). Their framework defines the levels of success achieved in SPI initiatives.

Agile software development is well-known for its focus on the customer. However, while it has succeeded in developing strong programming, there is an urgent need to understand customer use, perceived value, and shortcomings. Continuous deployment is delivering functional software consistently to customers while learning extemporaneously about customer usage. However, the transition towards short-cycle deployment involves several barriers (Holmstrom et al. 2012). Abrahamson (2000b) suggested five dimensions to gauge the success achieved in SPI: (1) project efficiency, (2) impact on the process user, (3) business success, (4) direct operational success and (5) process improvement fit. These were adapted from the project management literature and support Lean Construction principles.

Some existing implementation theories in construction management advocate "technology push" implementations during which current construction practices need to be radically changed to align with software functionality. Others advocate using well-accepted construction management planning, execution and measuring processes (Hartmann et al. 2012). Mobile Computing Apps appear to be part of the march toward better solutions for practitioners of all industries. Singularly focused individuals can author them and do not have to be integrated with other software modules (Weichbroth, P. 2020)

However, despite this literature, most software programs have been deemed insufficient to meet user requirements. Several comprehensive studies have been conducted to determine usability. The Software Usability Measurement, Inventory (SUMI) survey is specific to answering value-oriented questions. It uses 50-questions making use of five defined subscales for a) Efficiency, b) Affect, c) Helpfulness, d) Control and e) Learnability for querying users' attitudes toward the software. The work on SUMI began in 1986 by Kirakowski, who was entrusted with a project with two objectives: To examine the competence scale of the Computer User Satisfaction Inventory and to achieve an international standardisation database for a new questionnaire.

LEAN CONSTRUCTION SOFTWARE

Toyota's success was no accident. It has been cultivated through high-quality design, unyielding innovation, and bold moves. Their products have met their customer's needs and wants (Womack et al. 2007). Construction Software Developers should adhere to Lean Principles. Seeking perfection is understood as permanent incremental (kaizen) or radical (kaikaku) improvements, eliminating waste and improving value for the client. To achieve perfection, the product and its production process shall be highly specified as content, sequence, timing, and outcome (Spear and Bowen, 1999).

Lean Construction Management (LCM) targets value improvement by eliminating waste. This manifests in less wasted time, better cost performance, and more profit (Fernandez-Solis et al. 2012). Numerous ICT applications have been developed to achieve Lean Production goals in the Construction Industry. Sacks et al. (2010) proposed computer-enabled visualisation to support lean construction by making the whole construction process transparent ("exposing rocks in the lake") called VisiLean, which provides the construction team with a Lean production management system integrated with Building Information Modelling. Another application is KanBIM which supports Lean workflow control on construction sites facilitating short-cycle work planning and monitoring, visualising the age of tasks planned and the status of work in process. Additionally, SetPlan captures information from a BIM model and displays it in a dashboard that supports project participants in developing "one source of truth" for objects as the design unfolds. Ponz-Tienda and colleagues created in 2015, an integrated spreadsheet that computes and visually represents critical information from the Last Planner System for production control. Lastly, SimpLean facilitates the coordination of activities, staff and resources. The software operation mechanism enables the application of Lean Construction concepts, including the Last Planner® System (Dave et al. 2016). Notably, Lean researchers' software development is mostly project focused and does not assist organisational-wide processes such as work acquisition or project portfolio management (Lean Enterprise). A quick search on SCOPUS of the phrase "construction AND project AND software" querying titles, keywords, and abstracts produces 10,995 papers. Contrast that with the words "construction AND software AND organisation or firm or company" results in 5,001 articles. The selected practice featured in this article mainly serves the organisation in the acquisition, planning and execution of the multiple projects they construct each year.

LEAN CONSTRUCTION CONTRACTOR PRACTICES

Stevens and Smolders (2023) listed the following practices as efficacious for construction contracting operations. In this listing, the researcher has added the Lean effect each practice has on productivity.

1. *Dual Overhead Rate Application* – a methodology that precisely assigns overhead (Office G&A) cost to site labour, equipment, material, and subcontractors. This is used in both project estimating and job cost reporting. Accurate costing improves Tender success and flows through to job cost and project return on investment. This reduces wasted work acquisition efforts and gives a project's construction cost.

2. *Job Sizing Adjustment* – adjusting overhead due to the project size variation - the difference from the average job size of the company on average jobs - based on banking and industry data.

Accurate costing improves Tender success and flows through to job cost and project return on investment. This reduces wasted work acquisition efforts.

3. *Predictive Tender Modelling* – a competitive practice that determines a competitor's price from history. It utilises all the factors a constructor uses to adjust their price and systematises the process so the company does not grossly underbid. In other words, using it helps contractors leave less margin between their price and the competitors. Less time predicting and surmising where competitors will price a project and "leaving less money on the table" in a winning bid improves profitability. This reduces wasted work acquisition efforts.

4. *Forecasting Project Resource Demand* – limited and shared inputs such as cash, craftsperson, managers, and equipment must be placed where they produce the most benefit across the projects a constructor will build simultaneously. Forecasting from 6 weeks to 6 months ahead allows executives to ensure share resources are available when needed. In addition, contractors manage multiple projects at a time with limited resources. Therefore, getting more done with the same inputs positively impacts the company and its clients. This reduces wasted resources from quick decisions since planning starts six weeks in advance.

5. *Unit-Based Project Reporting* – utilises a count-based number for all products installed in a building. Units include each for doors or toilets, square meters of concrete forming, cubic meters of concrete or excavation, and linear meters of handrail or coping. This allows precise progress determinations and billing calculations while encouraging quality completion of each unit. A method to estimate, cost and administrate projects more precisely. Less conflict, especially in monthly pay requests. This reduces arguments (wasted time) about physical progress, thus, provides monthly payment justification.

6. *Task Completion Monitoring and Measuring* - all tasks to be completed are listed electronically and assigned to the responsible employee, such as planning or budgeting tasks. Construction firms may allocate many functions to the project manager for the job. Monitoring and measuring completion timeliness increases adherence. Teams build projects. Individual members complete critical tasks such as planning or procuring are best done in a pre-determined order. Accomplishing these tasks ultimately and timely increases multifactor productivity. This reduces wasted time and effort by keeping employees focused on critical tasks.

7. *Staff Load Balancing* – using a dozen or more factors, such as the number of duties, new clients, meetings, and project distance, to determine the relative utilisation of each staff member to ensure a relatively equal workload. People are the enabler of safety, quality, and productivity. Overloaded staff make mistakes; thus, rework negatively affects critical outputs. Employees feigning "overwhelm" is a character problem that should be addressed immediately. This keeps wasted time – underutilisation of some employees and overburdening of others – to a minimum.

8. *Project Site Material Laydown Planning and Logistics* – since approximately 70% of lost time is due to material logistics factors such as delivery timing, counts, product quality and handling, this is a critical practice to improve productivity. Since approximately 70% of lost time is due to material logistics, i.e., timely delivery, counts, quality, and handling, it is critical to pre-plan onsite material storage, handling, and flow. This reduces wasted worker time and effort handling material on the job site.

METHODOLOGY

The paper examines software information to understand the gap between the eight selected practices and the functionality of construction software modules. The user guides were reviewed for vocabulary and functions described in the chosen practices. In addition, the researcher selected a contemporary evaluation framework for software. The researcher decided not to list the specific brands of construction software (user guides) reviewed. This was done for fairness until a more complete and thorough review of the programs can be executed.

The selection of the leading software was executed using two factors: a) the popularity of construction software via an internet search (multiple rankings were considered) and b) industry communication with three experienced executives. This was not meant to be exhaustive or conclusive but a starting point for further research. This paper did not disclose the companies or products due to the nature of the methodology used and the limited data collected.

The selection of practices was determined by consultation with the same executives and the researcher's experience. These eight processes aligned with project operations as well as organisational throughput. More specifically, three were work acquisition, four were project portfolio management, one was project operation, and one was financial management. Generally, these could be considered practices that apply to all sizes and types of construction contractors. Importantly, each practice helps construction firms manage better and stay in business. Stated another way, these practices positively affect a company's risk/reward ratio.
The more mature software developer and contracting firms (existing for 20 years or more) appear to have developed the programming jointly for the flexibility needed. This supports a general perception of the construction executives interviewed and the researcher's experience.

In our research approach, we interview three people with executive-level experience.

- Executive 1 – Construction Contracting Firm Majority Shareholder and Managing Director. They have 20 years of experience in Main Building Work. Clients include national brands, universities and local entrepreneurs.
- Executive 2 – Retired Construction Contractor Firm Owner and Managing Director. Active in academia for an Australian Construction Management Program.
- Executive 3 – A person with over ten years of construction technology selection and implementation for construction contracting firms; still active in the industry but pursuing a PhD in BIM and related strategies.

We asked each executive the following:

- Six demographic questions, such as position and years of experience, and software use, such as weekly hours and discipline focus
- Presented the practice statements and queried for each item its strength - none, low, medium and high
  - The value of the practice
  - The performance of this practice by their firm
  - How strongly is it embedded in the firm's software

RESULTS OF USER GUIDE REVIEW AND EXECUTIVE INTERVIEWS

The results show that none of the eight practices was supported to a significant degree in the surveyed programming modules, as evidenced by the user guides and three knowledgeable industry professionals. However, we did not disclose the names of the software packages for confidentiality and legal considerations.

- Dual Overhead Rate Application - Three Leading Work Acquisition Packages - A supporting function was not found, nor were the executives aware of a software module(s) that offered this.
- Job Sizing Adjustment - Three Leading Work Acquisition Packages - A supporting function was not found, nor were the executives aware of a software module(s) that offered this.

- Predictive Tender Modelling - Three Leading Work Acquisition Packages - A supporting function was not found, nor were the executives aware of a software module(s) that offered this.
- Forecasting of Project Resource Demand - Three Leading Project Operations Management Packages - A supporting function was not found, nor were the executives aware of a software module(s) that offered this. Some packages can capture many variables, compute them and place them in a customer report.
- Unit-Based Progress Reporting - Three Leading Project Operations Management Package - A supporting function was not found, nor were the executives aware of a software module(s) that offered this. Some packages can capture many variables, compute them and place them in a customer report
- Task Completion Monitoring and Measuring - Three Leading Project Operations Management Packages - A supporting function was not found, nor were the executives aware of a software module(s) that offered this. One package can capture many variables, compute them and place them in a customer report.
- Staff Load Balancing - Three Leading Project Operations Management Packages - A supporting function was not found, nor were the executives aware of a software module(s) that offered this.
- Project Site Laydown Planning and Logistics for Material Installation -Three Leading BIM Packages - BIM software can represent this virtually or in print, depending on its the operator must capture the information and master the skills to produce it. However, there is no construction site-operations focus, i.e. 4D is scheduling, 5D is costing, 6D is sustainability, and 7D is facility management.

FUTURE INDUSTRY SURVEY

The researchers have created a survey and will recruit industry professionals. The researchers are applying to our university's Human Ethics committee for approval. The survey

- Asks nine demographic, such as position and years of experience, and software use, such as hours per week and discipline focus.
- Presents the practice statements and queries for each item below in none, low, medium and high
    - The value of the practice
    - The performance of this practice by their firm
    - How strongly is it embedded in the firm's software
- (Asks) What needed practices are not in the software you are familiar with? (text response)
- What mobile computing applications (Apps) are needed? (text response)
- Are any other thoughts you would like to share? (text response)

From this data, the researchers will have evidence of current construction contractor software's general value and utility in work acquisition, project operations, financial management, and building information modelling.

DISCUSSION

Lean Construction asserts that perfection serves the client's wants and needs. Toyota continues to delight its customers with vehicles (and houses) that provide "value for money". In economic recession or growth, the company is focused on perfection. Unfortunately, software developers appear not to have accomplished this goal for construction contractor users.

Software businesses, in general, are economically oriented, like most for-profit organisations. They appear to be falling short of providing high levels of usability and, thus, value. However, mature construction software developers have standardised many unique client requests. Their construction clients seem to have found "workarounds" to perceived gaps. Comments from executives suggested that developers may use construction software programming in other industries under different names. In the short term, this paper asserts that little reprogramming is needed for the construction industry's ICT to support proven practices. They appear to exist primarily in construction companies' authored Excel templates. Hartmann et al. noted (2012) that existing project management best practices guide understanding and supporting BIM implementations at the operational level of an organisation. Also, a group of researchers have advocated for tailoring software to support best practices for over a decade.

Focusing software programming on construction contracting firms' overall operational practices is a slight departure from the project orientation that has been a consistent trend in academia and ICT. This paper asserts that the construction organisation is an enabler of the project outcomes while building other projects simultaneously. Critically, the contracting firm supports the project team, i.e., with office personnel assistance, their experience, coordination of company assets, and enforcing contract terms and conditions. Project teams can be likened to residing on an island where the limits of resources are constrained to the area they occupy. Those in the corporation can connect the project team to capable resources facilitating task completion safer and faster with higher quality. So, systematising company-wide practices with the support of ICT can minimise or eliminate stubborn problems such as efficient resource allocation. Software developers should be incentivised to fill the hypothesised gaps with increased sales.

This paper's selection of effective practices represents critical contractor operational functions – Work Acquisition, Project Operations and Financial Management; not available in one package. Thus, software brands investigated were more than one type. Since the gaps appear consistent across developers and specialised software, there is credible evidence of the gap hypothesised. Importantly, these practices were selected because they generally satisfied the SUMI, SPI and Lean principles.

Some SME contractors rely on customising computer spreadsheets to calculate the supporting information needed to execute some practices. In contrast, others are unaware of the methods or have not taken this additional step. This apparent inconsistent application and execution can be improved by software developers creating interfaces that raise sufficient practice use levels.

Lastly, this previously documented gap in most software (all industries) raises the question, "What else has been overlooked in the programming of construction software now and in the future?" The researcher senses that there is a need for an association-sponsored panel for each construction segment. It might formally report on best practices to enlighten the industry and software developers.

SUMMARY AND CONCLUSIONS

Construction contracting software has the potential to solve the industry's stubborn problems, such as disproportionately high bankruptcy rates and stagnant multifactor productivity. The sources of these issues are many; however, this paper asserts that tailoring construction software to enable effective practices could lessen these problems. This paper documents a review of user guides and informal industry interviews to examine a significant blind spot in the construction industry. Developers have chaotic industry challenges regardless of industry.

The paper hypothesised that a significant gap exists between leading construction software modules and well-accepted practices. This assertion appears credible from interviews and a cursory examination of construction software information catalogues (however, we did not review the working software). Furthermore, the construction software industry seems chaotic and has commercial priorities, such as revenue generation and income diversity. Added to that, mobile computing applications are rapidly filling market voids. Finally, the beginning practices suggested have existed for decades and are considered valuable by many industry professionals showing a blind spot for programming.

ICT researchers have a substantial interest in future possibilities. However, some backfilling seems necessary to make the industry safer, more predictable, reduce costs and produce more value. Of course, realising software's full potential now helps many stakeholders, including workers and contractors, become safer and more efficient while delivering higher quality to society. Also, software firms grow their business. This paper attempts to point toward an alignment of software that can provide value to the industry.

The researcher's future investigation will include interviews and online surveys querying professionals' perceptions of the utility and value of their software and its functionality for supporting the eight selected practices. Specificity, the questionnaire will include brand names and articulated construction processes. A complete exam of product information, including user guides that demonstrate support for the chosen methods, and thus, a more substantial conclusion should be confidently made.

ACKNOWLEDGEMENTS

The researchers wish to acknowledge the assistance of the three experienced senior leaders. Also, we thank two construction software development managers who gave feedback about the general approach and assertions of this paper.

STRATEGIES FOR THE IMPLEMENTATION OF GREENBIM IN A DEVELOPING COUNTRY

Samuel A. Adekunle[1], Clinton Aigbavboa[2], Obuks Ejohwomu[3], Matthew Ikuabe[4], and Tunde Aregbesola[5]

ABSTRACT

Incorporating BIM and green buildings is a continuous task in the construction industry to achieve sustainable designs and achieve energy efficiency and performance. It entails integrating BIM, building energy performance assessment and sustainable design. Achieving GreenBIM in the construction industry has, however, struggled to achieve this successfully. This study identified the strategies for achieving the implementation of GreenBIM in a developing country context. Data was collected using a well-structured questionnaire from construction industry professionals in South Africa. The collected data were appropriately analysed. It was found that industry leadership, support assistance and promotion of BIM education programmes were the top three strategies for achieving GreenBIM. The study identified and ranked the strategies. This is important for industry stakeholders to achieve the implementation of GreenBIM.

KEYWORDS

BIM, Sustainability, South Africa, sustainable construction, SDG

INTRODUCTION

Most times, humans, through their various activities, ignore the environmental impact. The performance of different activities made by human beings, including a vast role played by the construction industry, has resulted in environmental imbalance. Ofori, (2007) observed that the construction industry impacts heavily on the environment. Construction activities cause excessive resource use, water scarcity, high demand for energy, and environmental pollution in different forms among others (Ametepey & Ansah, 2015; Wieser et al., 2021). For instance, during the lifecycle of a building, it is responsible for +/-37% of the global energy-related CO2 emissions directly and indirectly (Green Building Council South Africa (GBCSA, 2021)). Thus the construction industry products significantly impact the environment. However, the adoption of different measures, including materials, techniques and practices (Ofori, 2007), has been adopted to achieve a lower environmental impact and lately, the adoption of technologies in the construction industry to achieve this goal (Adekunle et al., 2021; Ejohwomu et al., 2021). One of the initiatives in terms of the use of materials to reduce environmental impacts is the

adoption of green buildings. The green building concept involves the use of different materials and processes throughout the building lifecycle aimed at reducing environmental impact and promote resource efficiency. It therefore contributes to keeping the environment in an environmentally balanced state.

Oguntona et al., (2019) opined that green buildings have outstanding benefits and notable structures compared to regular buildings. Some of the identified benefits of green building include better indoor air quality, protection of the ecosystem, improved energy efficiency, improved health and well-being of building occupants, less maintenance cost, increased marketability, and lower airborne disease transmission, among others(GBCSA, 2021; Oguntona et al., 2019). These benefits affect homeowners, end users, operators and other stakeholders in the construction industry. Parashar & Parashar, (2012) presented a green building as an implementation of constructing a building to be environmentally friendly and resource-efficient throughout the lifecycle of the building. A green building is a building that includes design, development, and operational practices and processes that fundamentally lower the negative effect on the environment. As mentioned earlier, combating the impacts of the environmental effects of the construction industry products and processes also involves the adoption of technology. Building information modelling (BIM) is critical and has a lot of identified benefits for the product, process, and people, among other aspects in the construction industry (Adekunle et al., 2022; Becerik-Gerber & Rice, 2010; Okereke et al., 2021). The combination of these two births the GreenBuilding information modelling (GreenBIM/GBIM) concept.

The implementation and benefits of green building and Building Information Modelling (GBIM) have significantly been recognised in the construction industry(Cassino et al., 2010). GreenBIM involves using BIM tools to achieve improved building performance goals and sustainability on a project throughout its lifecycle (Cassino et al., 2010). The adoption of BIM on green projects enhances the achievement of the project objectives throughout its lifecycle. The implementation of Green Building Information Modelling assists in improving and reducing the use of high energy, natural resources, and pollution and enhances end users' comfort and health. The interaction and integration of green building and Building Information Modelling improve and ensure the achievement of green objectives and sustainability outcomes throughout the building lifecycle. The implementation of Green Building Information Modelling is vital in analysing and understanding the sustainability of materials and other building performances during green building projects (Bonenberg & Wei, 2015). This study is aimed at identifying the critical strategies to achieve GreenBIM implementation in the South African construction industry.

The South African construction industry has been observed to be confronting some challenges impeding its efficiency. A critical one especially considering the target of achieving infrastructural development by 2030 (National Planning Commission, 2011) is the construction material challenge being experienced by the industry (Dithebe et al., 2018; Windapo & Cattell, 2013). Achieving the adoption of GreenBIM in the South African construction industry is important to achieve lower resource depletion and improves water efficiency. Furthermore, it contributes to the efforts of achieving sustainability and lean construction in the South African construction industry. One of the principles of lean construction is the reduction of waste (Sacks et al., 2010), which aligns with the benefits of GreenBIM. GreenBIM is a critical factor for achieving sustainability through environmentally sustainable design (Dall'O' et al., 2020). Also, the implementation encourages less waste production among others (GBCSA, 2021). It thus promotes material efficiency in the South African construction industry and sustainability right from the design stage.

STRATEGIES FOR THE IMPLEMENTATION OF GREENBIM

To achieve a reduction in the impact of construction activities and products on the environment, it is important that GreenBIM is implemented. GreenBIM promotes the achievement of the sustainability pillars of environment, economic and social, on both new building projects, refurbishment or major maintenance operations (Maltese et al., 2017). Various studies have identified some strategies for achieving GreenBIM implementation in the construction industry. A quick look into existing literature suggests that most studies have looked at the strategies to implement green building and BIM separately, but only a few have focused on GreenBIM. Hence most times, the strategies are derived from separate studies for achieving GreenBIM.

The McGraw-Hill report (Cassino et al., 2010) opined that to achieve GreenBIM implementation, there must be a seamless integration of software. According to the report, many software in use is not able to achieve this. Another factor identified by the study is the development of modelling standards towards achieving GreenBIM implementation. (Shukra & Zhou, 2021) opined that there must be an improved capacity in the functionality of BIM software for achieving the green building aspects.

The use of incentives as a strategy to achieve green building was critically examined by Olubunmi et al., (2016). Through a literature review, the study classified incentives into internal and external and examined them from the different stakeholders' perspectives. Similarly, Ebekozien et al., (2022), through a literature review, identified the development of policies as a strategy for achieving green building practices. These identified factors can also be applicable to the achievement of GreenBIM in the construction industry.

For construction industry professionals, there is a need to develop the required skills and expertise required to implement GreenBIM. Like other innovations adopted in the construction industry, there is a need to develop the required skills and competencies (Aliu, Aghimien, Aigbavboa, Ebekozien, et al., 2022). Required competencies for implementation are critical to the diffusion of new technologies and innovations in the construction industry. One critical aspect of the strategies for this study is that they are similar to those required for the implementation of Building information modelling.

RESEARCH METHODOLOGY

The study aims to identify the critical strategies required for implementing GreenBIM in the South African construction industry. A quantitative approach was adopted to achieve this, whereby a well-structured questionnaire was randomly administered to industry professionals online (background information on the professionals are provided under the findings). The research instrument was divided into two sections to collect data on the respondents' background (section A), and the other section (Section B) concentrated on the respondents perspective on the study focus. The section B of the research instrument was designed with the respondents showing their level of agreement from a five-point Likert scale for each of the presented ten strategies for GreenBIM implementation. The questionnaire presented respondents with ten strategies, and they were requested to rank the strategies on a five-point significance Likert scale. This approach has been shown to be effective in collecting data on different subjects in the construction industry and understanding professionals perspectives (Aliu, Aghimien, Aigbavboa, Oke, et al., 2022; Oladiran & Onatayo, 2019) and in studies involving emerging technological trends in the construction industry (Adekunle et al., 2022; Akinradewo et al., 2022; Ikuabe et al., 2022). A total of sixty-four responses were retriefved for the study.

To establish the reliability of the measurement instrument, a reliability test was conducted using the Cronbach’s Alpha. A value of 0.996 was achieved. This is considered a good value in light of the 0.7 minimum requirements for reliability (Kaiser, 1974; Pallant, 2010). Other tests conducted on the collected data include the mean, standard deviation and the Kruskal-Wallis test.

FINDINGS

BACKGROUND INFORMATION OF RESPONDENTS

The respondents for the study consist of sixty percent holders of a bachelor's degree, twenty percent of the respondents hold a diploma, 9.2% of the respondents have a Masters degree, this is followed by 7.7% possessing a Matric certificate, and 1.5% are PhD holders. The profession of the respondents comprises 33.8% Quantity surveyors, 21.5% construction managers, 16.9% electrical engineers, and 12.3% of the respondents are civil engineers. Other professions in the respondents are Architects (7.7%), Mechanical engineers (3.1%), safety managers and town planners (1.5% respectively). Respondents possess various degrees of industry experience; most of the respondents have between 0 – 5 years (67.7%). Other respondents possess 5-10 years of experience (26.2%), 15-20 years (3.1%) and 1.5% possess experience above 20 years in the construction industry. Furthermore, the respondents predominantly work with contracting organisations (32.3%), followed by those working with government parastatals (27.7%), 20% work with private organisations/clients, and 18.5% are consultants. The heterogeneity observed in the demography reveal the respondent are suitable for the survey.

STRATEGIES FOR IMPLEMENTING GREENBIM

Table 1 shows the respondents ranking of the strategies to implement green BIM in the South African construction industry. Based on the responses from the respondents, industry leadership was ranked first with (MIS=3.66; SD=1.250), support assistance from construction industry stakeholders was ranked second with (MIS=3.64; SD=1.252), quality of GreenBIM Model was ranked third with (MIS=3.63; SD=1.291), promote Green BIM educational programmes (MIS=3.63; SD=1.303) was ranked fourth, develop Green BIM training (MIS=3.63; SD=1.374) were ranked fifth, national standards was ranked sixth with (MIS=3.63; SD=1.202), business changes was ranked seventh with (MIS=3.58; SD=1.206), green BIM legal contracts was ranked eighth with (MIS=3.56; SD=1.296), government support was ranked ninth with (MIS=3.53; SD=1.272) and project procurement systems - integrated project delivery was ranked tenth with (MIS=3.52; SD=1.345).

Table 1: Strategies for GreenBIM implementation

Strategies	Mean	Std. Deviation	Ranking
Industry leadership	3.66	1.250	1
Support assistance from construction industry stakeholders	3.64	1.252	2
National standards	3.63	1.202	3
Quality of Building Information Modelling Model	3.63	1.291	4
Promote Building Information Modelling educational programmes	3.63	1.303	5
Develop Building Information Modelling training	3.63	1.374	6
Business Case	3.58	1.206	7
Building Information Modelling Legal contracts	3.56	1.296	8
Government support	3.53	1.272	9
Integrated project delivery	3.52	1.345	10

Table 2 presents the Kruskal-Wallis H statistics, where it was tested if there is a significant difference in the response based on the professional classification. It is observed that there is no significant difference in the responses except for "integrated project delivery" where the value achieved is 0.02. This is lower than the 0.05 established as the significant level (Pallant, 2010). Similarly, this was tested for the categories of respondents based on their familiarity with the GBIM concept, and it was revealed that there was no significant difference in the responses. It thus means respondents perceive the strategies similarly, irrespective of their familiarity with the GBIM concept.

Table 2: KW statistics of responses

	Professionals		**Familiarity with GBIM**	
	Kruskal-Wallis H	Asymp. Sig.	Kruskal-Wallis H	Asymp. Sig.
Government support	2.309	0.315	1.225	0.874
Industry leadership	0.277	0.871	2.717	0.606
Business Case	0.634	0.728	0.973	0.914
National standards	3.196	0.202	1.360	0.851
Develop Building Information Modelling training	1.829	0.401	3.070	0.546
Promote Building Information Modelling educational programmes	4.963	0.084	2.420	0.659
Integrated project delivery	7.800	0.020	3.242	0.518
Quality of Building Information Modelling Model	2.438	0.296	1.592	0.810
Building Information Modelling Legal contracts	2.613	0.271	1.994	0.737
Support assistance from construction industry stakeholders	1.814	0.404	2.368	0.668

DISCUSSION

The result suggests that there must be industry leadership to achieve GreenBIM implementation. This has been observed to be the case in most countries regarding BIM implementation (Edirisinghe & London, 2015; Smith, 2014). Although leadership can be provided by the government or other stakeholders, in some cases, a hybrid approach was adopted. It is, however, worth noting that the strategy adopted is often times tailored to the context and the prevailing factors (Adekunle et al., 2022).

Another result worthy of note is that respondents ranked integrated project delivery low. Cassino et al., (2010) identified integrated design and software integration as critical components for achieving GreenBIM. However, the promotion of BIM training for industry professionals and integrating BIM into educational curriculums are considered very critical to achieving GreenBIM implementation in the South African construction industry. There is a need to develop standards and frameworks to support the implementation of GreenBIM in the South African industry. Additionally, GreenBIM training frameworks to achieve the technical competencies required must also be developed. It thus implies that for GreenBIM to be adopted, all stakeholders must be actively involved and play significant roles.

The results also underscore the digital transformation of the construction industry specifically the adoption of BIM. The benefits, impacts and value of BIM implementation in the construction industry has been extensively researched (Adekunle et al., 2022; Akintola et al., 2016; Becerik-Gerber & Rice, 2010; Dakhil & Alshawi, 2014; Mostafa et al., 2018; Seyis, 2019). These studies has established the importance of BIM to the construction industry.

However, a critical aspect which has rather been given less attention but which is considered important to the implementation of GBIM is the quality of the BIM model. Considering the vital role of BIM in the impmentaion of GBIM, the quality of model geberated is considered critical in achieving GBIM. Thus there must be high level impelemtation of quality assurance process to ensure that BIM models produced are of meets the required industry standards.

CONCLUSION

This study identified the critical strategies for the implementation of GreenBIM in the construction industry. It revealed that to achieve GreenBIM implementation; there must be industry leadership; this might be undertaken and provided by the government. However, considering the respondents' response, there is a need to create awareness and practical benefits of GreenBIM for the South African construction industry to be done. Various professional bodies and private sustainability champion groups must embark upon this. However, there is a need for policy development to support the implementation and provide the legal framework. Therefore, GreenBIM leadership must be provided by a hybrid approach whereby the government and other stakeholders play different but intentional roles to achieve an industry-level GreenBIM adoption. This is imperative to achieve sustainability goals and promote lean principles of waste reduction, especially from an industry that contributes heavily to the environment. The strategies identified are important to achieving sustainability in the construction industry. It should be noted that this study was conducted in the South African construction industry context; however, the findings can be improved on by other researchers. Also, the findings can be adopted by other developing countries with similar contextual variables. In addition, the variables adopted in the study are majorly related to existing BIM studies as thereis a dearth on GBIM studies in the study area. Further research can be conducted on the assessment of the maturity of GreenBIM in developing countries and the framework for achieving industry-wide diffusion.

BUILDING INFORMATION MODELLING (BIM) FOR PROJECT PLANNING: MEASURES TO IMPROVE ITS ADOPTION

Opeoluwa Akinradewo[1], Olusegun Oguntona[2], Babatunde Ogunbayo[3], Clinton Aigbavboa[4], and Gilbert Chimbadzwa[5]

ABSTRACT

The Architecture Engineering and Construction Industry (AEC) uses Building Information Modelling (BIM) to simplify and enhance sustainability in construction projects. The industry experiences difficulties in achieving project success globally and nationally due to insufficient planning. Technology is required to address this issue by incorporating it into the project planning phase. Therefore, BIM is considered the necessary tool to bridge this gap. This research aims to examine the advantages of implementing BIM during the project planning stage of construction projects. To gather data, a quantitative research approach was employed, and professionals in the South African built environment were surveyed using a questionnaire. The data collected were analysed using descriptive and inferential analysis. Findings from the analysis discovered that the top three measures to improve BIM implementation for project planning in the construction industry are competitive advantage, cost and time savings, and collaboration among AEC professionals. The research concluded that these measures could encourage the adoption of BIM among construction professionals in South Africa.

KEYWORDS

BIM, built environment, collaboration, management, project planning.

INTRODUCTION

Various authors such as Adekunle et al. (2022a), Demirkesen & Ozorhon (2017) and Akinradewo et al., (2021), had submitted that professionals in the AEC community are not accustomed to collaboration. Sakikhales & Stravoravdis, (2017) noted that this is the case even in the early stages of a project. During the project planning stage, architects, engineers, and contractors work individually which eventually leads to double handling of some activities. Requests for Information (RFI), stagnation of work as drawings gets finalised, plant hired not being utilised all adds to the cost of a project (Azmy, 2012). Innovative technologies such as building information modelling (BIM) which has been adjudged to be effective in construction project management can be useful in this regard (Akinradewo et al., 2022). Although, Wang &

Chien (2014) discovered that BIM is widely used for visualisation and simulation of construction project. However, countries like the United Kingdom (Gledson, 2016) and United Arab Emirates (Mehran, 2016) are benefitting from BIM usage heavily due to its implementation in the early stages of the construction project. This saw BIM moving away from being a visualisation and simulation software to being used as a design and project planning tool.

Traditionally, each member in the construction industry looks out for their best interest (Hardin and McCool, 2015). The incentive for the assessment of BIM in project planning provides the building blocks which may provoke unification of AEC members. Technology is constantly evolving through updates and BIM is no different (Migilinskas, et al., 2013). Sakikhales & Stravoravdis (2017) stated that to effectively use BIM, it must be implemented in the early stages of the project life cycle. Project initiation and planning are regarded as the most crucial stages in a project life cycle by the authors, and they further explain the importance of integrating agile project management during these phases to realise profound results of ensuring quality is met during the planning phases. According to the Project Management Institution, a project life cycle has five stages (Akinradewo et al., 2022a). These five stages are project initiation, followed by project planning, followed by project execution, followed by project monitoring and control, and the last stage is project closure. Furthermore, Hardin and McCool (2015) agreed with this notion and suggest that to fully leverage BIM and its tools, the industry must adopt a modernised and collaborative project delivery method. While there are various studies carried out on BIM usage in the construction industry, majority of these studies focused on the adoption but not specifically on the applicable stages of its adoption. This research work presents a novel contribution to the field of construction by evaluating measures to improve the implementation of BIM in the project planning phase of construction projects. This research has not been carried out before in the research study area being a developing country with limited capacity to fully adopt BIM for construction projects. This is envisaged to help promote the awareness of BIM and how it is useful in achieving construction projects to time, cost, quality in an efficient manner.

BIM FOR CONSTRUCTION PROJECT PLANNING

The spread of an innovation, such as BIM, is dependent on methods to increase its growth after its initial acceptance. Implementing BIM necessitates a technical dramatic transformation in both developed and poor countries (Migilinskas, et al., 2013). Almost every step of the planning and design process can now be done digitally, with data being transferred and shared in a standardized digital format. Recent years have seen an increase in the proportion of data handled by BIM software. BIM is revolutionizing the AEC and the way buildings are built (Turka & Klincb, 2017). In a bid to promote the implementation of an innovation, Olarewaju & Ibrahim, (2020) outlined a requirement for positive and constructive policies as the driving force behind the construction industry due to the possibility for improved economic growth in their study. Adoption of BIM necessitates strategy, therefore, planning and coordination needs the use of these tactics. The challenges associated with design management and project delivery, as pointed out by Senthilkumar and Varghese (2013), have led to the adoption of BIM. BIM challenges existing methods like on-site modifications, project delivery approaches, and lack of standardization. BIM promotes the use of standardized “objects” and pre-fabrication, as noted by Davies et al. (2015). During the design stage, BIM transfers power upstream and reduces variation on the construction site, leading to a more uniform outcome. Altering the project managers traditional role in the process (Sakikhales & Stravoravdis, 2017).

According to Wibowo (2009) and supported by Adekunle et al. (2022b), the construction industry’s economic importance stems from the fact that it benefits multiple parties involved, resulting in a snowball effect that contributes to overall economic growth. Hence, Odubiyi et al. (2019) discovered that embracing BIM within the parties involved in the supply chain is key factor in stimulating the acceptance of BIM in the industry. Akinradewo et al. (2022b) highlighted that the public sector is the largest client for the construction industry in any given country. As Wong et al. (2010), Smith (2014), and Davies et al. (2015) noted, governments in countries such as the USA, UK, and Scandinavia can mandate the use of BIM to increase its adoption. Additionally, the private sector plays a vital role in creating new business techniques and opportunities (Akinradewo et al., 2021). Therefore, a collaborative effort between the public and private sectors, as proposed by Odubiyi et al. (2019), could promote greater adoption of BIM. Although Building Information Modeling (BIM) Level 2 has been widely adopted, there are still some indications that SMEs are slow to adopt the technology. Because of the delay in adoption, small and medium-sized enterprises (SMEs) in the public sector now face a competitive disadvantage (Awwad, et al., 2020).

Smith (2014) outlines that the possibility of BIM success is more likely when the client drives the implementation. NBS, (2020) reported a lack of customer demand being the most prevalent hurdle in the implementation of BIM. The report further stated that the client plays a substantial role in data management environment, associated with BIM. This prompts the need for more research since the available research does not focus on how to incentivise the client. According to Windapo and Cattell (2013), the construction sector contributes to economic growth, job creation, innovation, and business opportunities while enhancing the quality of life for its customers.

To operationalise the identified measures to the improve the implementation of BIM for Project Planning, Table 1 highlights the identified variables and their sources. These articles were extracted from SCOPUS database using the following keywords: "BIM" AND "Project Planning", "BIM" AND "Project Management", and "BIM" AND :Planning". This search yielded 47 documents but only 42 were accessible and therefore adopted for this study.

Table 1: Identified variables for measures to improve the implementation of BIM for Project Planning

S/N	Measures to Improve	Authors

RESEARCH METHODOLOGY

The objective of this study was to contribute to the existing knowledge on the effective implementation of BIM in the early planning stages of construction projects, using a quantitative research methodology. Quantitative research is useful for gathering data from a significant population and providing numerical measurements of specific aspects of phenomena. The study surveyed quantity surveyors, project managers, engineers, construction managers, and architects in the Gauteng province of South Africa using a pre-designed questionnaire with a 5-point Likert scale in two sections. The first section extracted information about the respondents' demographics in which three questions were asked. The second section focused on the identified latent variables to measure the benefits. In total, four questions were asked in the close-ended questionnaire. The choice of Gauteng province was because it houses the majority of the professionals within the country who are adopting modern technologies for construction activities. 189 questionnaires were randomly distributed to professionals within the study area between September and November 2022, and 167 questionnaires were recovered totalling 83% response rate. All the questionnaires recovered were deemed to be suitable after being reviewed for completion. The Mean Item Score (MIS), Standard Deviation (SD), and Exploratory Factor Analysis (EFA) were used to analyze the data obtained from the questionnaire. The reliability coefficient of the data collection instrument was determined using Cronbach's alpha, with a cutoff alpha of 0.70. The analysis revealed a coefficient of 0.91, indicating high reliability of the retrieved data.

FINDINGS AND DISCUSSION

According to the findings from the analysis conducted, majority of the respondents work at a consultancy firm with the data indicating a total of 48% while professionals working with contracting firm are 28% of the population sample. Also, tertiary students and government employees both make up 12% each. The most common qualification among respondents was the bachelor's degree (32%). In second place were Bachelor Honour's degree (28%) and Diploma (28%). Highest qualification possessed by the respondents was the master's degree (12%). An overwhelming majority of the respondents have worked for 0-3 years (60%), this indicates that the population sample is quite young in the industry, followed by 4-8years of experience (28%) while 8% of the sample has 9-15 years of experience. Only 4% of the respondents have worked for more than 15 years. This is an indication that the respondents possess above average knowledge to provide tangible answers to the research question.

Table 2 captures measures to improve the implementation of BIM for project planning in accordance with the opinion of the respondents. The highest ranked measure is Training workshops for BIM (MIS= 4.48, SD= 0.823), followed by Introduction of faster hardware and software (MIS= 4.32, SD= 0.802), in third there is tie between top management support (MIS= 4.28, SD= 1.208), and Increase BIM awareness (MIS= 4.28, SD= 1.137), in fifth the need to make BIM more user friendly (MIS= 4.20, SD= 0.913), was expressed by the respondents. The last five ranks are occupied by Shift to a collaborative project delivery method (MIS= 3.80, SD= 1.118), Adoption of BIM standards (MIS= 3.88, SD= 1.269), Client Incentivisation (MIS= 3.68, SD= 1.376), Subsidies for SME's (MIS= 3.60, SD= 1.323), and Altering project management role (MIS= 3.12, SD= 1.364) respectively.

Table 2: Ranking result of measures to improve the implementation of BIM for project planning

Measures	Mean Item Score	Std. Deviation	Rank
Training workshops for BIM	4.48	0.823	1
Introduction of faster hardware and software	4.32	.0802	2
Top management support	4.28	1.208	3
Increase BIM awareness	4.28	1.137	3

Make BIM more user friendly	4.20	0.913	5
Introducing Policy that encourage BIM usage	4.16	1.106	6
Raising BIM benefits awareness	4.08	1.038	7
Making BIM a mandatory requirement to construction supply chain	3.96	1.172	8
Government Intervention	3.88	1.269	9
Private Sector Intervention	3.88	1.301	10
Shift to a collaborative project delivery method	3.80	1.118	11
Adoption of BIM standards	3.76	1.332	12
Client Incentivization	3.68	1.376	13
Subsidies for SME's	3.60	1.323	14
Altering project management role	3.12	1.364	15

In addition, the collected information underwent exploratory factor analysis to identify how the variables were related based on the participants' opinions. The findings indicated that the KMO measure of sampling adequacy was 0.607, which is an acceptable value for conducting factor analysis since it is greater than 0.6. Bartlett's test of sphericity also produced 0.000 significant value, indicating the degree of multivariate normality of the distribution set. The total variance of the measures to improve the implementation of BIM for project planning revealed four components which had eigen value of above 1 namely (5.238, 2.429, 1.601, and 1.424). The components eigen value defined the 34.922%, 16.193%, 10.677%, and 9.496% respectively of the variance which indicates 71.288% of the total variance of the data set. The requirement that the combined proportion of variance in the extracted components should be 50% has been met, indicating that the four sets of factors can sufficiently represent the views of experts in South Africa. The research employed PCA-based factor grouping and direct oblimin rotation. Table 3 presents the pattern matrix which highlights how the factors have been clustered together.

Table 3: Exploratory factor analysis pattern matrix for measures to improve BIM implementation for project planning

	Component			
	1	**2**	**3**	**4**
Client Incentivization	0.859			
Subsidies for SME's	0.664			
Private Sector Intervention	0.557			
Government Intervention		0.867		
Top management support		0.805		
Making BIM a mandatory requirement to construction supply chain		0.776		
Training workshops for BIM		0.680		
Raising BIM benefits awareness		0.500		
The need for faster hardware and software			0.919	
Make BIM more user friendly			0.888	

Increase BIM awareness		0.539	
Introducing Policy that encourage BIM usage		0.491	
Altering project management role			0.821
Shift to a collaborative project delivery method			0.775
Adoption of BIM standards			0.617
KMO Value			0.607
Bartlett's TOS result	Chi-Square value		197.772
	Degree of freedom		105
	Sig.		0.000

Based on the opinion of the respondents, the clusters were named thus.

Component 1: Economic Stimulus Measures. BIM can help businesses and governments save money and be more productive by facilitating the timely completion of projects. As a result, the construction and technology industries stand to grow, and more people will find employment as a result.

Component 2: Implementation Initiatives. Efforts to implement BIM software in the building sector are becoming increasingly vital. Through the implementation of cutting-edge technological methods, these endeavours hope to boost teamwork, accelerate workflow, and finalize projects with better results. The construction industry is pushing for the widespread use of building information modelling (BIM) through a combination of government intervention, executive buy-in, mandated requirements, and educational events like workshops.

Component 3: Adoption and Promotion Efforts. The expansion and improvement of the building sector will be impossible without the widespread use of and enthusiasm for Building Information Modelling (BIM). Making BIM more accessible to the general public, spreading the word about its many advantages, and enacting policies that promote its use are all initiatives with the same goal in mind. BIM can significantly boost project outcomes and fuel economic growth by fostering better collaboration and cutting down on inefficiencies.

Component 4: Implementation in Project Delivery Processes. The use of Building Information Modelling (BIM) is critical to the success of today's project delivery methods. Project management is different now than it was before the widespread adoption of BIM standards and the move toward collaborative project delivery. By simulating and visualizing building projects in real time, BIM helps architects, engineers, and contractors head off major problems before they arise, saving valuable time and money.

Notably from the clusters is that some clusters like component 1 are well defined based on the variables that makes up the component, while the other clusters suggest that the needs are systemic and highly interrelated. This is allowed in EFA depending on the responses retrieved from respondents (Osborne & Costello, 2009). The findings of the measures to improve the implementation of BIM aligns with the opinion of authors in the body of knowledge. For instance, Davies et al. (2015) opined that it is widely regarded that government involvement is a key measure to improve the implementation of new technologies. Consequently, the findings of this study also ranked government intervention highly. Similarly, Odubiyi, et al., (2019) identified that making BIM a mandatory requirement to construction supply chain, will aid in the uptake of the software which also aligns with the findings of this study. Even though integrated project delivery method was identified as integral to the usage of BIM for project planning, respondents ranked it as the one least measure to increase BIM uptake for project planning. These findings are suggesting the need for education for BIM because most of the highly ranked measures are related to an investment into R&D. To increase awareness, people either have to see or hear about it. Respondents unequivocally agree that training workshops are an important measure to the implementation of BIM. Hence, education is key to ensure the longevity of BIM. Prominent companies, stand to gain the most from BIM for project planning as reported by Gledson, (2016) and Wang & Chien, (2014) who stated that BIM is more mature as a pre-construction design tool. However, as the biggest client, the government's involvement is required as well.

CONCLUSIONS

BIM is a technology that is getting much popularity among professionals in the construction industry. BIM enhances collaboration, planning, design, and project management. However, the widespread adoption of BIM is a challenging process, as it requires the industry to standardize its practices and information. Consequently, the support and involvement of both the public and private sectors are crucial to the success of BIM. The government, as the construction industry's biggest client, has a pivotal role in promoting the adoption of BIM, while the private sector drives its advancement by developing innovative business practices and opportunities. This study aims to evaluate measures to improve the implementation of BIM in the project planning phase of construction projects. The study used a quantitative research approach, employing a questionnaire survey to collect data. The data was analyzed using both descriptive and inferential analysis. The findings from the analysis revealed that training workshops, improved hardware and software, and top management support are the primary measures to enhance BIM's adoption for project planning. Based on the respondents' opinions, the study identified four main components of measures: Economic Stimulus Measures, Implementation Initiatives, Adoption and Promotion Efforts, and Implementation in Project Delivery Processes. The study concludes that there is a consensus on the importance of various measures to improve BIM's implementation in the construction industry. The findings align with previous studies emphasizing the importance of education and investment in research and development to promote BIM's usage. The study recommends that the government must be involved in promoting BIM's adoption, and professionals in the industry must be engaged in workshops and training. The study is limited to professionals in the Gauteng province of South Africa, and further research is required to get a more general opinion from professionals across South Africa.

ACKNOWLEDGMENTS

The authors wish to express gratitude for the financial assistance provided by the Global Excellence Stature 4.0 PhD Bursary from the University of Johannesburg's School of Postgraduate Studies, which funded this research.

BARRIERS TO THE ADOPTION OF BUILDING INFORMATION MODELING IN QUANTITY SURVEYING PRACTICE IN SOUTH AFRICA

Kenneth Otasowie[1], Clinton Aigbavboa[2], Matthew Ikuabe[3], Peter Adekunle[4], Ayodeji Oke[5], and Samuel Adekunle[6]

ABSTRACT

One of the occupations in the construction sector is quantity surveying (QS). This duty is essential to the accomplishment of a construction project since it decides whether it will be finished on schedule, on budget, and to the requisite standard. The practice has received several criticisms for failing to correctly carry out her duties. Adoption of contemporary technology like Building Information Modeling (BIM) in its practice has become necessary to eliminate mistakes, inaccuracies, and omissions. However, South African QS practitioners face challenges in implementing BIM. Hence, this study seeks to examine these challenges. A survey approach was utilised. Ninety (90) of the one hundred and fifteen (115) questionnaires that were distributed to quantity surveyors in Guateng Province, SA were returned and considered appropriate for analysis Kruskal-Wallis, percentage, mean item score, and standard deviation were used to analyse the collected data. The results indicate that the main obstacles to the adoption of BIM in QS practice are a lack of BIM competence, a lack of government enforcement, opposition to change, and a lack of client demand for BIM. This study therefore suggests that BIM trainings be given top priority and that the government take the initiative in promoting BIM adoption throughout the nation, especially for public projects.

KEYWORDS

BIM Adoption, Barriers, Profession, Quantity Surveying, South Africa.

INTRODUCTION

The quantity surveying profession is one the construction professions, who’s most common duties are to measure the quantity of materials as well as the workmanship required to get a construction work done (ASAQS, 2018). In order to establish an accurate estimate for construction work that would be utilised in the tendering processes that are necessary before any construction work can commence on a building site, the quantities of materials and labour needed to perform a task were measured. However, more responsibilities have been added to the roles of quantity surveyors as a result of the profession's evolution, including estimation for each of the six construction stages, advice and a plan for the client to ensure the best service and value of the product that the client is paying for, as well as recommendations on which

[6] University of Johannesburg, South Africa

contractor to choose, evaluation of the tender documents, Bill of Quantities pricing, valuations of the work completed and the work still in progress (Salleh et al.,2020). Despite these added responsibilities, quantity surveyors are still making use of the traditional procedures of quantifying and pricing even to this day, which are very time consuming and can give inaccurate figures most of the time (Olsen & Taylor, 2017). These have led to quantity surveyors failing to get the accurate figures when making a construction cost estimates due to the fact that they deal with a lot of unmanageable numbers being quantities as well as rates, while using the traditional method of quantifying and also preparing the bills of quantities. Hence, the profession has received a lot of criticisms due to inaccurate figures which at times leads to cost overrun of projects. As a result, the need for a technological tool capable of taking a lot of burden off the shoulders of quantity surveying professionals.

The Building Information Modelling (BIM) has been working its way into the construction industry. BIM is a novel technology that has been brought to the planning of building structures, their construction, and their digital administration (Raphael & Priyanka, 2014). BIM is a type of computer software that allows building structures to be digitally shown and all necessary digital activities to be taken before any physical construction work can begin. According to Boeykens (2018), the BIM is a tool or model that is used to share, collaborate, and coordinate the data of a specific building structure in terms of its design, construction, as well as its operation. This tool was created to aid in the transformation and advancement of the construction sector. BIM has advanced from 2D drawing to 5D presentation, object modeling, and analysis, making it easier for construction professionals, including quantity surveyors, to execute high-quality work (Boeykens, 2018). Hence, construction professionals are forced to evolve with this technological advancement or run the risk of being left behind. Considering the need to reduce errors, inaccuracies and omissions in the taking-off quantities and estimations of the building costs, and the need for improvement in the delivery of accuracy in quantifications and fast quantification and estimation processes in the South African construction sector, it is important the BIM tool is adopted by the quantity surveying professionals as it would lead to improvement in delivery of their services to the clients of the industry.

According to Odubuyi et al (2019), the total construction sector must develop in order to benefit the shareholders or investors in the sector, hence it is essential that quantity surveyors perform their tasks and responsibilities better. The use of BIM is one innovation that can revolutionise the construction industry and is the best strategy to advance the field (Odubuyi et al, 2019). The usage of BIM makes it possible for the quantity surveyors and the entire project team to have access to the data necessary for performing their tasks (Harrison & Thurnell, 2015), while also managing excellently the information that is included in it (Usman et al, 2015). Furthermore, Alhasan et al (2017) posited that every stakeholder or member of the project team wants to see an increase in project productivity. This can be achieved through efficient communication, automated data input, automatic taking-off of quantities, and improved cost estimates capability of BIM. There are several other benefits of BIM to quantity surveying practice that have been identified in existing literature. However, the move to adopt BIM in South Africa's private and public sector (client side) and amongst different building professionals (Quantity Surveyors, Architects, Civil Engineers, and Mechanical & Electrical Engineers etc.) has been very slow. The reason for this has been attributed to several factors. For example, Makenya & Ally (2018) opined that the slow uptake of BIM adoption might be due to lack of BIM expertise, while Criminale & Langar (2017) attributed it to resistance to change by the various professionals within the industry. Thus, the aim of this study is to examine the barriers to the adoption of BIM in quantity surveying practice in the South African construction industry. The conclusions will be useful in identifying the militating factors. An evaluation of the barriers as they were noted in the literature is presented in the following section. Following are the research techniques used and the findings of the study. The results are then discussed, and conclusions are then presented.

THE QUANTITY SURVEYING PRACTICES AND BIM

The primary responsibility of a quantity surveyor is to make sure that resources are used appropriately in the construction sector. They are also in charge of monitoring the project's finances and provide cost consulting services to the customer during the whole building process (Raphael & priyanka, 2014). A quantity surveyor's other crucial responsibilities include measuring construction projects and creating bills of quantities, or BOQs (Olatunji et al., 2010). A quantity surveyor's duties include providing advice on procurements, budgeting for construction costs, measuring on-site, organizing the schedule of work, preparing the final accounts, keeping track of expenses throughout the project, and negotiating tenders (Kottathara & Gunavel, 2017). Since quantity surveyors are the most crucial individuals in the construction sector, it is crucial that they carry out their responsibilities correctly and to the best of their abilities. However, when they carry out their duties, quantity surveyors frequently encounter difficulties that cause them to make mistakes in their job, such as errors in the movement or arrangement of data between their files, errors in numbers, duplications, and omissions of certain crucial data (Kottathara & Gunavel, 2017).

BIM makes it possible for those working in the architectural, engineering, and construction fields to plan, design, build, and manage building facilities in an efficient and effective manner (Rakib et al, 2019). Before the advent of BIM, building information was displayed using 2D drawings, making it challenging to understand the dimensions and specifications given. Later, Computer Aided Design (CAD) was introduced, allowing architects to view building plans digitally. This was followed by the development of 3Ds, which provided the realistic digital drawings of buildings (Lorek, 2018). The project's programming and scheduling of the data are integrated with the information from the 3D model in the 4D, which also monitors each action that is undertaken. The 5D then connects the previously mentioned information with the information cost, such as the quantities and prices or rates (Smith, 2007). Even if most quantity surveyors are unsure about it, the implementation of the BIM in a building project may help them increase the efficiency of the job they undertake (Fung et al., 2014). For instance, the usage of BIM can enhance and automate the present quantity surveying methods, such as taking off quantities from the construction drawings that have been created by the architects (Beukes, 2012). This reduces the amount of time required to quantify and estimate using the conventional approach, which South African quantity surveyors have always understood and continue to use. The ability of BIM to extract quantities from 3D designs and create bills of quantities simultaneously has helped reduce the amount of time spent on the building process, which is why BIM has been lauded as a huge technical advancement ever since it was first introduced (Olatunji et al., 2010).

BARRIERS TO THE ADOPTION OF BUILDING INFORMATION MODELING IN QUANTITY SURVEYING PRACTICE

LACK OF BIM EXPERTISE

The lack of competent individuals in building information modeling precludes most construction firms' quantity surveyors from implementing BIM in the majority of their procedures (Makenya & Ally, 2018). Chan et al. (2019) also highlighted that it is challenging for BIM to be incorporated in the quantity surveying operations due to the lack of available experienced and qualified professionals who have worked on BIM before.

LACK OF AWARENESS

According to Makenya & Ally (2018), there are low levels of knowledge about the implementation of BIM, which means that many individuals are unaware of how BIM may assist them in carrying out their jobs as quantity surveyors. In addition, the study by Criminale & Langar (2017) also mentions the fact that some individuals are not actually aware of BIM, despite the fact that there are not many of them, and on the other hand, others are aware of it but lack sufficient knowledge of it and how it functions.

RESISTANCE TO CHANGE

According to Harisson & Thurnel (2015) and Aibinu & Venkatesh (2015), quantity surveyors are so accustomed to carrying out the majority of their tasks in a conventional manner that they don't appear particularly eager to change their way of doing things. According to Criminale & Langar (2017), the interest in adopting BIM is hampered by the absence of corporate motivation to convert to building information modeling, which is often demonstrated by company leaders. This resistance to change behaviour is also brought on by the fact that the business is highly accustomed to carrying out tasks in a certain method, which makes them reluctant to adapt to the BIM procedures.

SCARCITY IN BIM TRAINING AND EDUCATION

According to Makenya & Ally's (2018) and Smith (2007), the majority of quantity surveyors do not utilize BIM mostly due to a lack of BIM training. The adoption and application of BIM by quantity surveyors are hampered by a lack of training programs that may facilitate the transfer of knowledge and skills (Chan et al, 2019). Another significant obstacle to the widespread usage of BIM technology is a lack of training for users on how to operate it. Organisations don't invest in staff training because they believe it to be time- and money-consuming (Criminale & Langar, 2017).

LACK OF KNOWLEDGE OF THE BUSINESS VALUE OF BIM

Makenya & Ally (2018) opined that one of the barriers to the adoption of BIM in quantity surveying operations was the lack of knowledge about the benefits that BIM may provide to these organisations. Another significant barrier to quantity surveyors adopting BIM is a lack of information or comprehension of the return on investments (ROI) brought on by its utilization (Haupt & Hefer, 2016). Another reason for BIM's delayed adoption and lack of acceptance is the challenges associated with monitoring or evaluating its effects on the project (Chan et al, 2019). The other businesses are prevented from adopting BIM technology and understanding the commercial value that BIM models convey because they are unaware of the financial benefits that are achieved by using BIM models (Criminale & Langar, 2017).

SOFTWARE COMPLEXITY

It is highly discouraging for quantity surveyors to accept the usage of BIM in the everyday services they give due to the complexity of the software (Haupt & Hefer, 2016). Criminale & Langar (2017) noted that the complexity of BIM, which prevents many professionals or construction teams from using it to execute their jobs, is one of the obstacles to its acceptance in quantity surveying techniques.

ADDITIONAL COSTS IN BIM TRAINING

Quantity surveyors in particular will need to receive BIM training, which will incur fees that most employers or business owners will be compelled to pay but most of them are unwilling to do so (Makenya & Ally, 2018). Because of this, most organisations' quantity surveyors are unaware of BIM and how it might help them with their everyday tasks (Horrison & Thurnell, 2015). Although it is also believed that the owners of the organizations investing in BIM may be a fantastic move owing to the advantages that are connected to the adoption and implementation of BIM.

Other barriers to the adoption of building information modeling in quantity surveying practice as obtained from review of existing literature can be found in Table 1 below.

RESEARCH METHODOLOGY

The study examined the barriers to the adoption of building information modeling in quantity surveying practice in South Africa. The study deployed a quantitative approach through questionnaires use as instrument for data collection. This approach was utilised due to the possibility of covering a large pool of respondents with the aid of research questionnaire (Tan, 2011). Gauteng Province of South Africa was the study area and the respondents targeted for the research were Quantity Surveyors. Relevant literature were reviewed for this study and information related to the objective of the study were obtained and used for the design of the research instrument, which is a structured questionnaire. The questionnaire had two sections, with the respondents' demographic information elicited in the first section. While the respondents' perspective on the barriers to the adoption of building information modeling in quantity surveying practice were elicited in the second section of the questionnaire. The libertarian scale of 1 (strongly disagree) to 5 (strongly agree) was used to rate the questions presented to the respondents. A total number of ninety (90) of the one hundred and fifteen (115) questionnaires that were distributed to quantity surveyors in Guateng Province, SA were returned and considered appropriate for analysis. Kruskal-Wallis as adopted by Otasowie & Oke (2022), percentage, mean item score, and standard deviation were used to analyse the collected data. In addition, the Cronbach's alpha reliability test was conducted for the purpose of determining the reliability of the data set and a value of 0.932, which represents a high consistency level.

FINDINGS AND DISCUSSION

The background information of the respondents revealed that 22% of the respondents has Diploma, 52% had a bachelor's degree, another 22% had an Honours degree, and 4% had a master's degree. Furthermore, 49% of the sample assessed was Contractor Quantity Surveyors, 14% were Professional Quantity Surveyors, 5% were Candidate Quantity Surveyors, and 32% were Junior Quantity surveyors. In addition, 36% of the respondents had ten (10) to fifteen (15) years of experience, 29% of the respondents had five (5) to ten (10) years of experience, and 35% had less than five years of experience as quantity surveyors in the construction industry. Finally, 58% of the respondents work for the contracting firms, 22% work for government, and 20% work for consulting firms. These findings suggest that the study's target respondents, who were quantity surveyors, were fairly represented and that they had a sufficient degree of education to comprehend the study's questions (Otasowie & Oke, 2022).

Table 1 below shows the barriers to the adoption of building information modeling in quantity surveying practice in South Africa in a ranked order from the highest mean to the lowest mean. It can be observed that barriers with the same mean were ranked based on their Standard Deviation (SD) from the mean. A scenario in which most data are close to the mean is represented by a small SD, while a large SD shows that the data point is widely apart from the mean (Field, 2005). Hence the barrier with the same mean were ranked based on this. The mean of each barrier is the average of the responses obtained from each respondent.

The results show lack of BIM expertise as the highest ranked barrier (MIS=4.22, SD = 0.86). This was closely followed by lack of government enforcement (MIS=4.20, SD = 0.88); Resistance to change (MIS=4.13, SD = 0.93); lack of knowledge of BIM value (MIS=4.02, SD = 1.09); no client demand for BIM (MIS=4.00, SD = 0.91); high initial cost of BIM (MIS=4.00, SD = 0.97); additional costs in BIM training (MIS=3.98, SD = 0.92); lack of support from company's executives (MIS=3.93, SD = 0.91); scarcity in BIM training (MIS=3.89, SD = 0.95).

Table 1: Barriers to the adoption of building information modeling in quantity surveying practice in South Africa

Barriers	Rank	MEAN	SD
Lack of BIM expertise	1	4.22	0.861
Lack of government enforcement	2	4.20	0.877
Resistance to change	3	4.13	0.933
Lack of knowledge of BIM value	4	4.02	1.090
No client demand for BIM	5	4,00	0.911
High initial cost of BIM	6	4.00	0.971
Additional costs in BIM training	7	3.98	0.921
Lack of support from company's executives	8	3.93	0.908
Scarcity in BIM training	9	3.89	0.945
Lack of BIM standards in construction	10	3.85	0.899
Lack of IT infrastructure	11	3.85	1.172
Scarcity in BIM education	12	3.83	0.986
Issues with skills transformation	13	3.72	1.089
Increased client cost	14	3.70	1.127
Lack of amendments in forms of contract	15	3.69	0.865
Lack of awareness	16	3.59	1.141
Software complexity	17	3.56	0.925
Changes in the duties of quantity surveyors	18	3.50	1.005
Difficulties using BIM	19	3.43	1.143
Threat to the QS	20	3.39	1.172
Technical risks	21	3.31	1.146

The research's findings corroborate a study by Makenya & Ally (2018) that found that most construction firms' quantity surveyors are not adopting the usage of BIM in their regular quantity surveying operations since there aren't enough competent individuals in building information modeling. The study concurs with a study by Chan et al. (2019) that found it challenging for quantity surveying practices to embrace BIM due to a lack of more seasoned and knowledgeable workers that have expertise with it. The study goes on to further concur with a study by Harrison & Thurnel (2015) that found there was insufficient government enforcement of policies that would have allowed the BIM to be included into the tasks performed by the design, construction, and engineering industries. It acknowledges that the absence of government initiative to adopt and use BIM is impeding and limiting its application in projects. Makenya & Ally (2018) agreed with this as well. Furthermore, according to Harrison & Thurnel (2015), whose study the present study confirms, opined that quantity surveyors are so accustomed to carrying out the majority of their tasks in the traditional manner that they don't even appear to be open to change in their working style. The findings of this study further corroborates that of Criminale & Langar's (2017), that the interest in adopting BIM is hampered by the lack of corporate willingness to convert to building information modeling.

In order to compare respondents' perspectives based on their years of experience, a Kruskal-Wallis test was conducted. It was shown that the mean values for the barriers to the adoption of building information modeling in quantity surveying practice in South Africa do not differ significantly. From the P-values in Table 2, it can be deduced that both entry level and experienced quantity surveyors that were the respondents for this study all responded and ranked the identified barriers similarly.

Table 2: Kruskal-Wallis Test Showing P-Values for Barriers to the adoption of building information modeling in quantity surveying practice in South Africa

Barriers	P-Values
Lack of BIM expertise	0.053
Lack of government enforcement	0.057
Resistance to change	0.053
Lack of knowledge of BIM value	0.090
No client demand for BIM	0.051
High initial cost of BIM	0.072
Additional costs in BIM training	0.081
Lack of support from company's executives	0.058
Scarcity in BIM training	0.054
Lack of BIM standards in construction	0.091
Lack of IT infrastructure	0.075
Scarcity in BIM education	0.086
Issues with skills transformation	0.079
Increased client cost	0.067
Lack of amendments in forms of contract	0.062
Lack of awareness	0.641
Software complexity	0.058
Changes in the duties of quantity surveyors	0.065
Difficulties using BIM	0.073
Threat to the QS	0.072
Technical risks	0.066

CONCLUSION

This study evaluated the barriers to the adoption of building information modeling in quantity surveying practice in South Africa. Relevant literature were reviewed for this study from which barriers to the adoption of building information modeling in quantity surveying practice were identified. The findings of the study show that lack of BIM expertise is the most significant barrier to the adoption of building information modeling in quantity surveying practice. Furthermore, the findings of the study revealed other barriers to include lack of awareness, lack of amendments in forms of contracts lack of BIM standards in construction, lack of government enforcements, lack of IT infrastructure, lack of support from the company's executives, lack of knowledge of BIM value, resistance to change, scarcity in BIM training, software complexity, additional costs in BIM training, high initial costs of BIM, changes in the duties of quantity surveyors, no client demand for BIM. These findings suggest the need for the government to make the use of BIM compulsory in construction projects in South Africa. This will in turn make quantity surveyors in the country to embark on BIM related trainings to improve their awareness and knowledge of the technology. Furthermore, there is the need to make provision for the training of quantity surveyors on BIM technology in the country to increase profitability, and improve the efficiency of quantity surveyors for greater cost certainty/ improve the cost estimation. In addition, by holding seminars, more quantity surveyors would be made aware of what BIM is all about. In order to consistently add value and improve their professional services, quantity surveyors must constantly reinvent themselves. Finally, although the current study provides insights into significant barrier to the adoption of building information modeling in quantity surveying practice, the study was conducted in the Gauteng Province of South Africa, which could be a limitation. Hence, similar studies should be conducted in other provinces within the country.

APPLICATION OF BIG DATA AND INTERNET OF THINGS IN THE BUILT ENVIRONMENT: A BIBLIOMETRIC REVIEW

Peter Adekunle[1], Cliton Aigbavboa[2], Ayodeji Oke[3], Opeoluwa Akinradewo[4], and Osamudiamen Otasowie[5]

ABSTRACT

Using big data and internet of things (IoT) technologies is without a doubt growing more and more important on a global basis. The two 4IR components stand out for their innovative methods that might aid organizations in developing high-performing teams and a culture that is performance-focused. Big data platforms offer methods for methodically eliminating data from data arrays that are too intricate to be used in standard data-processing applications. The Internet of Things and big data are used in every sector. The utilization of big data is significantly growing on a global scale. A staggering number of individuals, including architects, contractors, suppliers, and clients, are now involved in the building process. Large data warehouses are mined for information using big data analysis techniques, which then make the information available to all parties involved. With an overview of IoT and big data applications in the built environment, this research aims to tie current trends to them. In order to identify prior studies on IoT and big data in the construction industry, this study did a bibliometric evaluation and looked at the SCOPUS database. In addition, this probe only allowed recovery of documents from the previous 16 months. Papers based on quantitative, qualitative, and literary reviews made up the majority of the contents. The research also revealed that the bulk of articles were published in industrialized countries. Construction is under underway on phases that will largely focus on IoT research as well as an audit and assessment of the expansion of big data applications. The essay also evaluates and discusses recent advancements in the internet of things and big data industries. Data management, storage systems, automation, and retrofitting are the four main clusters of big data and IoT applications, according to the report. It has been shown that there are several potential when big data and IoT are combined. When properly implemented, such solutions provide professionals and other industry participants in the building sector an accuracy of over 90%.

KEYWORDS

Adoption, Industry 4.0, Big data, Internet of Things, Trend

INTRODUCTION

The desire to increase construction productivity is driven by the sector's well-known inefficiency in transforming raw resources into commodities and by the significance of

building or infrastructure development to economic growth (Hussain & Al-Turjman, 2021). Modern building techniques make use of cutting-edge digital technologies to improve building operations. Building project planning and execution are being revolutionized by the internet of things (IoT), big data, and cyber-physical systems (Bilal et al., 2016). Evidence suggests that the construction industry's transition to Industry 4.0 will require the integration of cutting-edge technologies like Big Data and the Internet of Things in order to automate value-added jobs and data-acquisition systems (IoT). IoT refers to a network of physical objects that are embedded with sensors, software, and other technologies for the purpose of connecting and exchanging data with other devices and systems over the internet and big data is data that contains more variety, arrives in greater volumes, and moves more quickly (Yin & Kaynak, 2015; Patel & Patel, 2016). The application of big data and IoT is then a thorough procedure that removes inaccurate information from construction operations, improving quality and efficiency, lowering costs, and increasing value for the client. Many Internet of Things (IoT) devices operate on remote servers that may be accessed via the cloud, however clients occasionally employ big data processing to speed up data transit (Hassanalieragh et al., 2015). This model enables more immediate outcomes for time-sensitive procedures by retaining power to analyze some data locally. The bulk of the Internet of Things (IoT) focuses on the instant analysis and utilization of incoming data, big data tools can help with some other crucial tasks including predictive analytics. Predictive analysis takes into account machine performance and service alerts over time, and then builds the library of data required to foresee impending issues (Sayad et al., 2019). Due to this, construction businesses can maintain their equipment proactively and prevent the potentially expensive downtime that comes with equipment breakdown.

Furthermore, users may monitor vital information about their cars through the Internet of Things, often known as telematics, such as idle speed, tire pressure, and GPS tracking (Gamil et al., 2020). Additionally, it increases productivity, helps employees visualize tasks and solve problems, and may be used to provide instructions for on-the-job responsibilities. Additionally, it promotes worker and workplace safety. Funding for the design and development of new technologies will increase as more people become aware of the potential and requirements of the Internet of Things (Gbadamosi et al., 2019). When it comes to what this kind of technology is capable of, the sky is the limit. Since they are designed to use automated systems to handle things like heating, cooling, and lighting, smart buildings are becoming more and more prevalent (Chen et al., 2022). Routine maintenance might be aided by smart buildings, which can also look for potential system issues. They are lauded for having little environmental effect and for assisting in lowering energy waste (Zhao et al., 2022). The building process could be hastened while preserving worker safety when new technologies are developed (Lawal & Rafsanjani, 2022). Big data and drones are two cutting-edge technologies that might be utilized to analyze and create a building design more quickly. Despite the Internet of Things' (IoT) sluggish adoption in the construction industry, many increasingly understand that adopting cutting-edge technology into operational strategies is essential for construction businesses to remain competitive.

As technology advances, the quantity of data in the world today only gets more and more overwhelming (Bilal et al., 2016). The construction sector now manages petabytes (1015 bytes) of data. The industry makes extensive use of data from several disciplines throughout the life cycle of a facility. Building Information Modelling (BIM) is a process for methodically collecting three-dimensional CAD data to promote multidisciplinary collaboration among stakeholders (Munawar et al., 2022). BIM data is frequently networked in a variety of distinct formats; it is typically geometrically stored in three dimensions, computationally expensive (using graphics and Boolean operations), and compressed. This scattered data is merged to produce federated BIM models, which are continuously produced and kept long after a facility has reached the end of its useful life (Teisserenc & Sepasgozar, 2021). The design data for a five-story building model may eventually be 80GB in size, demonstrating how rapidly BIM files may grow (Lin et al., 2016). No matter how they are presented, it is clear that the success of the industry is greatly influenced by these facts. The spectrum of Big BIM Data sources has expanded due to the introduction of embedded devices and sensors, which have caused facilities to start producing vast volumes of data both during and after construction. Due to the extensive collection of BIM data, the construction industry has entered the "Big Data age" (Su et al., 2021). Due to its enormous size (terabytes, petabytes, and beyond) and diversity (a wide range of heterogeneous formats, including text, sensors, audio, video, graphs, and more), big data stands out (rapid streams of the data). The generation of data serves as an example for all three aspects of big data. A huge, fascinating, and dynamic collection of construction data is usual. Due to the massive volumes of design data and timelines, construction data is vast (Moeini et al., 2017). The use of big data and the Internet of Things to improve building practices and lessen negative impacts has been covered thus far in this article. The connection between big data applications and IoT in the context of the built environment has not been extensively studied. The major goal of the study is to understand how big data and IoT applications connect to recent advancements in the built environment.

IOT AND BIG DATA APPLICATION

When construction companies effectively use technology to solve typical workplace difficulties and improve operations, they benefit from improved productivity and better response to the industry's growing requirements (Arai & Morimoto, 2021). Construction companies are exploring integrating IoT and big data for a number of reasons, including sluggish productivity, declining margins, increasing schedule overruns, and rising competition (D'Amico et al., 2020). The categories stated in Table 1 are what are driving the use of IoT and big data in the construction industry.

Table 1: Application of IoT and Big data

IoT and Big data application areas	Motivation	Reference
Productivity	The construction sector is governed by deadlines and goals. Because they force budget increases, backlogs must be prevented at all costs. IoT can increase readiness and efficiency, which will increase output.	(Opoku et al., 2021); (Aghimien et al., 2020); (Adekunle, Aigbavboa, Akinradewo, et al., 2022)
Maintenance	Real-time data is now available, making it feasible to arrange maintenance breaks or refueling as well as turn off idle equipment and determine the status of any asset.	(Zhang, 2020); (Dave et al., 2016)
Safety and Security	Any material or item theft may be easily prevented with IoT connected tags since these sensors will inform you of the whereabouts of the materials or item at all times. Sending a human worker to undertake a comprehensive check is no longer necessary.	(Awolusi et al., 2019); (Demirkesen & Tezel, 2022)
Unmanned aerial vehicles and Autonomous vehicles	Key construction equipment has to be manually tracked since it takes time and is prone to mistake. The installation and usage of unmanned aerial vehicles and autonomous vehicle on these significant assets has many advantages for the construction/project management. These vehicles can perform operation autonomously in areas where human interventions can be risky and dangerous.	(Gao et al., 2020); (Hacker, 2017)

BIM optimization and Digital twins	In addition to providing an ever-growing dataset that can be integrated with machine learning to perform predictive analytics, to monitor active job sites, a combination of historical data from prior jobs and the ongoing stream of real-time data from IoT sensors may be employed. This will make construction even smarter.	(Hmidah et al., 2022); (Jiang et al., 2021)
Data Mining	Waste management, BIM-based quality control in construction engineering, and other significant areas of the construction industry have all made use of data mining. For the purpose of making decisions on construction management projects, data mining finds relevant patterns and information. As it combines and analyzes various construction items into homogeneous groups, cluster analysis is a crucial data mining technique for the construction industry.	(Sacks et al., 2009); (Munawar et al., 2022)
Sensors	There are several types of sensors that may operate in a certain environment and be applied to improve management effectiveness by setting up and sending out alarms. They can be employed to find a number of alarming circumstances that demand rapid response. Humidity, temperature, and pressure calculations may be tracked by linked and monitored equipment utilizing IoT software and processes. This will notify management to any possible risk that needs rapid care.	(Heiskanen, 2017); (Andújar-Montoya et al., 2017)
Real-Time Site Map	Employers may use this technology to both identify workers on the job and prevent them from entering dangerous areas. Using this, a real-time map of the building site could be created so that everyone could see who is working where and when. If the situation is actually dire, some danger zones and managers' only zones can be highlighted on the map, and other individuals may be persuaded to stay away from such areas if they are not absolutely necessary. All of this data may be gathered by IoT devices on the internet and used for projects.	(Sharma et al., 2020); (Abu Ghazaleh & Zabadi, 2020)

RESEARCH METHODOLOGY

An exhaustive and thorough audit of big data and IoT in construction was achieved using a descriptive research method and bibliometric evaluation of the literature. According to Hallinger & Kovaevi (2019), a quantitative analysis of bibliographic data that categorizes research articles, authors, and themes provides a comprehensive view of a study field. The bibliometric review employs a variety of qualitative indicators to evaluate the current level of study on a certain subject utilizing a wealth of bibliographical data (Baas et al., 2020). Since content analysis enables one to generate logical conclusions from literature obtained from a database, the bibliometric evaluation was deemed appropriate for the study project that it was implemented into (Garrigos-Simon et al., 2019). The database to be utilized for the research study was chosen in the first phase to ensure that a sizable amount of literature could be acquired. Due of the popularity and effectiveness of Web of Science (WoS), ScienceDirect, and SCOPUS, we originally looked at these sources (Singh et al., 2021; Charoenthammachoke et al., 2020; Martn-Martn et al., 2018). The software utilized for this study can only examine data from one database at a time, even if it is possible that all three databases were used. SCOPUS was chosen following a preliminary search of all databases since it had a greater number of articles published and was found to have more comprehensive coverage, with the majority of publications on WoS and ScienceDirect also being indexed on SCOPUS. The search was limited to works published in 2019 and 2022 using words that includes “Big data”, “Applications”, “Internet of Things”, and “Building Sector” or “Construction sectors”. Table 1.0 contains papers from the top ten journals in order to achieve the study's objectives, the top 10 journals was derived based on the numbers of article published. Journal articles were preferred to book chapters and conference papers because the judgments and analyses that go into them are typically more thorough and in-depth. When these keywords were used to search through the title, abstract, and keywords of published articles, only 81 of the 104 items discovered were relevant to the study's objectives. Journal articles, conference papers, and book chapters make up the 145 items. The bibliometric network visualization tool VOSviewer was used to analyze these texts (Yu et al., 2020). Content analysis was utilized to describe the investigation's findings in order to achieve the study's objectives.

Table 2: Top ten journals explored

Journal	**Number of documents**

FINDINGS AND DISCUSSION

This study attempts to summarize the current research goals for internet of things and big data in the construction industry, as was already stated. A quantitative content analysis of the 145 recovered documents was used to achieve this. To do this, a co-occurrence network of terms was created using bibliographic data acquired from retrieved articles. The creator of VOSviewer claims that a minimum of three keywords should be used for keyword co-occurrence analysis (Anna & Mannan, 2020). Thus, among the indexed and author's keywords, our investigation used a minimum of three co-occurrences. Only 78 out of 960 keywords met the co-occurrence criterion; their frequency of recurrence and general strength were confirmed. The internet of things occurred the most in the documents that were retrieved, with a total link strength of 602, showing the magnitude of its involvement in the co-occurrence map (146 times). Given that this survey is focused on the construction sector, the building industry came in second (81 occurrences and 396 total link strength). Big data is the word for the many applications and components of the internet of things and big data, and it is placed seventh out of the remaining 76 terms used in the construction business. The network visualization map of the 78 co-occurring key phrases and their four different clusters is shown in Figure 1.

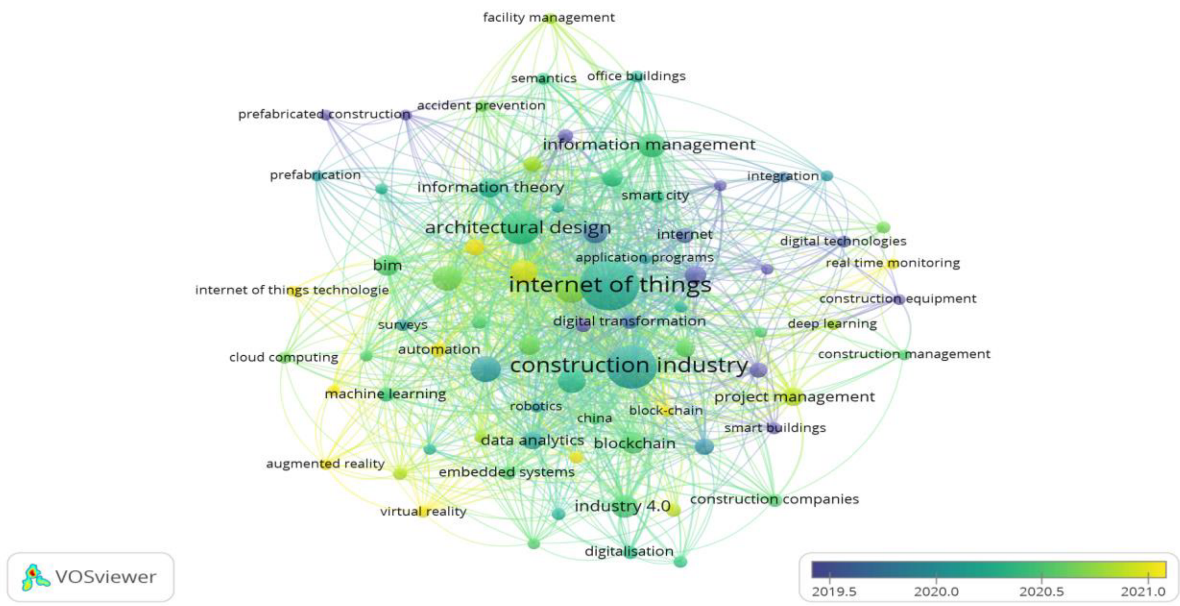

Figure 1: Publication keyword trend overlay visualization map.

Cluster 1 – Storage Systems: On the map, the deep green region with 25 co-occurring phrases represents the Internet of Things area. Construction projects, digital storage, industry 4.0, blockchain, artificial intelligence, embedded systems, and industry 4.0 are notable examples having connections to the core idea ("Internet of things and big data"). Because of this, this cluster may be thought of as a collection of key words for applications connected to the Internet of Things and big data storage. Opoku et al. (2021) claim that IoT technologies may be used to almost any device that can offer important data on its own operation, the success of an endeavor, or even the environmental conditions that we need to remotely monitor and regulate. As a result, they are said to have a wide range of applications.

Cluster 2 – Automating: is the area of light green on the map that has 20 related keywords. Important essential terms include "application programs," "automation," "sensor," "smart city," "digital twins," and others. The utilization of IoT and bid data for the automation of different activities inside the built environment is therefore thought to be the cluster's primary focus. It demonstrates that big data will be able to evaluate massive volumes of data at breakneck speeds, enabling construction companies to focus on the jobsite rather than IT problems (Dave et al., 2016).

Cluster 3 – The purple region on the map with 17 co-occurring terms is Retrofitting. Notable essential concepts include "construction equipment," "deep learning," "integration," "energy usage," "life cycle," and other connotations. Therefore, it is assumed that this cluster is interested in topics pertaining to retrofitting. According to a report by Demirkesen & Tezel (2022), IoT and big data technologies are more useful than ever for the construction industry because of their decreased prices and increased levels of reliability. The digital transition has enhanced productivity across many industries, but the construction industry has been slower to adapt. Building complexity makes things more challenging, but IoT and big data may be able to aid with many issues connected to energy consumption reduction. These strategies might provide businesses a competitive edge despite rising costs.

Cluster 4 – Data management: is the yellow region on the map which has 16 co-occurring keywords. Understanding the underlying concepts of augmented reality, data collection, cloud computing, machine learning, and other related topics is crucial. Therefore, it is expected that this cluster is working on data management issues. Data management's importance has been emphasized in earlier publications. The findings are in line with those of Jiang et al. (2021) and (Adekunle et al., 2022), who explain how the recent expansion of construction big data and the creation of computational tools in the area of information technology enable construction specialists and practitioners to extract and visualize big data for a variety of new applications.

CONCLUSION

Using bibliometric techniques, this study pinpoints areas of construction-related research that prioritize IoT and big data. The study was able to identify the major area of focus in research related to big data and IoT applications inside the built environment based on extracted articles published in the recent sixteen months and indexed in the Scopus database. The results show a rise in the amount of IoT and big data research papers published, with 2021 recording the most papers. This is useful because it highlights the need of having a solid understanding of big data and IoT applications in the built environment as well as the advantages of their adoption for the construction industry. When correctly considered, such technologies provide information to stakeholders and building industry experts that is up to 90% accurate. The paper examines current big data and IoT applications in the construction industry. Big data and IoT have a significant relationship that will only intensify as technology progresses. Construction firms that want to use data effectively should be very selective about the devices used and the data obtained. The process of analytics will be made considerably simpler by making an effort up front to collect only relevant, usable data and by creating internal systems to handle the data in industry-specific ways.

PROCESS ANALYSIS WITH AN AUTOMATIC MAPPING OF PERFORMANCE FACTORS USING NATURAL LANGUAGE PROCESSING

Svenja Lauble[1], Philipp Zielke[2], Hongrui Chen[3], and Shervin Haghsheno[4]

ABSTRACT

In lean construction projects, much information is collected during the process analysis with the trades. This data is increasingly documented as a reference for use in future construction projects. By doing this, efficient methods are required to use this data. Often, the unstructured naming of data is a challenge for a rule-based allocation of information, and manual work is required to identify the needed data. Therefore, the aim is to develop an automatic mapping of historical performance factors to the tender specifications of a new construction project. To support the process analysis with historical project data, a case study is executed using Natural Language Processing (NLP). With a NLP model, the process descriptions from the tender specifications of the new construction project can be compared with a master database, to filter the right performance factor and calculate the duration for a process. This procedure can be used to support the further process analysis together with the trades to generate a validated construction schedule. The case study shows promising results in the prediction results. First, the mapping quality and second, the prediction accuracy are evaluated. With the developed mapping concept, last planners can validate their estimations of durations in lean construction process planning with a target to support stability in a project. Still, a more detailed description of the processes could increase the prediction results.

KEYWORDS

Digitization, lookahead planning, work structuring, process, complexity.

INTRODUCTION

Regarding the continuous improvement process (CIP) and a well-founded knowledge management system in lean construction projects, companies tend to collect more and more data about their projects. According to a survey by Thomas and Bowman (2022) with 3.916 stakeholder in the construction industry, their data has doubled within three years (from 2019 to 2022). In lean construction projects, much information is documented about the processes. In the Last Planer System and in Takt planning (Haghsheno 2016) a process analysis is done together with the trades as knowledge carriers. A sequence of processes for each product type is compiled here, along with the time and resources required for each process step. This information is increasingly documented as a reference and updated with the real data during project execution. For example, Choo et al. (1998) collect weekly updated data of construction processes using a database called “WorkPlan”. This data is then used to update the weekly work

planning of the respective project. By documenting the duration of a work package and the manpower behind it, realistic performance factors can be documented (Haghsheno 2016). Figure 1 displays an exemplary database for lean construction projects. In this database, processes are described. With their durations and the manpower available, realistic performance factors can be calculated. A performance factor defines the required calculation time for one unit of a process task with one person. These performance factors, together with the process description, can serve as a master database for the process analysis of a new project (see Haghsheno et al. 2016).

For example, Frandson et al. (2013) define 'gathering information' about the process as the first phase of the Lean method's Takt planning. And, for the Last Planner System, the phase and lookahead planning with the trades can be supported by historical information. Here, the master database can serve as a starting point for planning and as basis for discussions with the construction trades.

Database for Lean Construction projects

Process name	**Duration (D)** (in hours)	**Manpower (M)**	**Units (U)**	**Performance factor (D/M/U)** (hours / unit)	**Comment (e.g. special conditions)**
XXX	8	4	10	0.2	Snow
XXX	6	2	40	0.075	-
…	…	…	…	…	…

Figure 1: Database example for Lean Construction projects.

As a result, unnecessary buffers and capital commitment costs for construction employees and their machines are reduced. Also, time pressure can be prevented by enhancing motivation, security, and quality (Rogel 2013).

With detailed work steps, covering different types of construction, and the existing product complexity in construction, databases can get very complex and large. This is also shown by publicly available databases. E.g., the Construction Cost Information Center for Architects in Germany, called 'BKI' (Baukosteninformationszentrum), is documenting several thousand possible work steps with their average performance factor and costs per process description. Besides complex databases, a mapping to process descriptions of new construction projects can get quickly complex, as often the naming is not standardized. Following a manual mapping of the correct performance factors causes high levels of manual work with the danger of a misallocation. With the prospect of manual effort, a detailed use of master databases in a process analysis can be prevented.

This paper therefore has the target of analyzing how an automatic mapping of performance factors from a master database to the process description of a new construction project can be designed. Figure 2 displays the concept of the automatic mapping with the master database (right) and the process descriptions of a new lean construction project (left). For example, the tender specifications can serve as the basis for the process descriptions. By mapping the processes of the new project with those of the database, a suitable performance factor is identified. Together with the units, a duration for each process can be calculated.

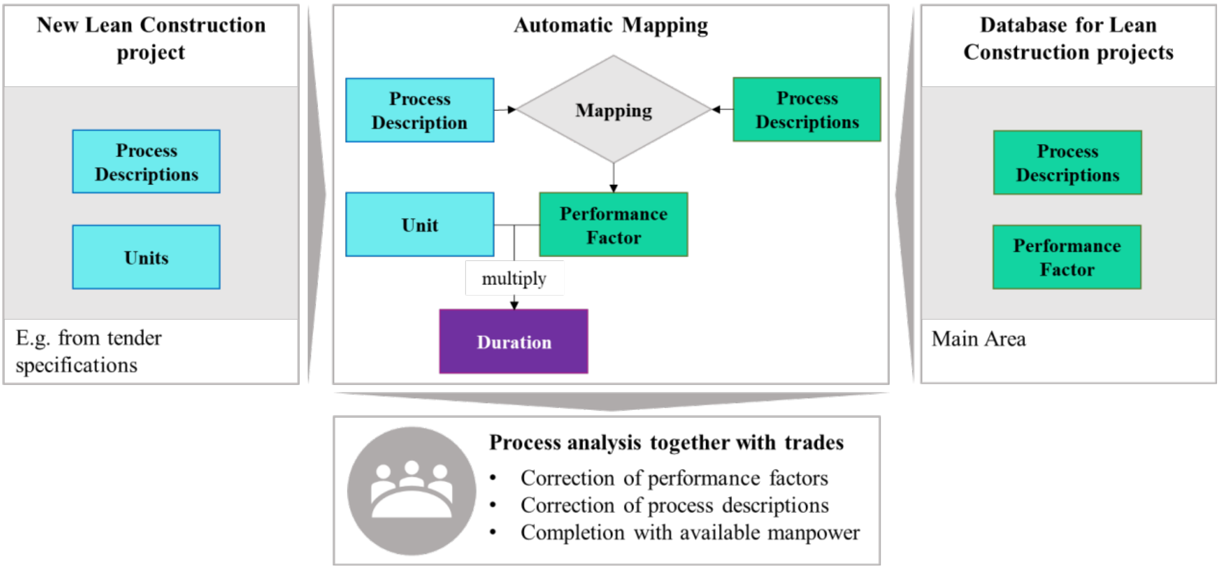

Figure 2: Concept of an automatic mapping of performance factors for a process analysis.

For the automatic mapping, the method of ‘Natural Language Processing’ (NLP) is first described and then evaluated in a case study.

THEORETICAL FOUNDATIONS OF NATURAL LANGUAGE PROCESSING

According to Cambria and White (2014), NLP is a theory-motivated range of computational techniques for the automatic analysis and representation of human language. IBM (Education, 2020) considers NLP to be a branch of Artificial Intelligence (AI). It is concerned with the ability to enable computers to understand text and spoken words in a way that is almost identical to that of humans. Liddy (2001) provided a detailed definition: “NLP is a theoretically motivated range of computational techniques for analyzing and representing naturally occurring texts at one or more levels of linguistic analysis for the purpose of achieving human-like language processing for a range of tasks or applications”. EasyAI (2019) explained NLP concisely and in an easy-to-understand way: “NLP is the bridge that communicates between machine language and human language.” Language is typically unstructured data. NLP is used to let the machine understand and use this information. A consensus can be seen: with the support of NLP, humans can be supported in the lean construction process planning.

So far, NLP has already been part of pilot studies in construction research. Jagannathan et al. (2022) apply NLP to analyze unstructured text data in annual reports of construction contracting companies. Li et al. (2020) use NLP to predict the probability of obtaining construction accident compensation through a practical example in Hong Kong. Wang et al. (2022) develop a virtual assistant with the use of NLP, with whom information retrieval for construction project team members is supported.

According to EasyAI, Deep Learning-based NLP can be divided into three steps: corpus pre-processing, design modeling, and model training. For the pre-processing, the following six tasks can be executed (EasyAI 2019, Bachani 2020):

Tokenization: Tokenization is the breakdown of long texts like sentences, paragraphs, and articles into word-based data structures for subsequent processing and analysis work.

Stemming: Stem extraction is the process of removing the prefixes and suffixes of words to get the root word. Common prefixes and suffixes are “plural of noun”, “progressive”, and “past participle”. For example, “playing” will be converted to “play”.

Lemmatization: Lexical reduction is based on the dictionary and transforms the complex form of a word into its most basic form. For example, “drove” will be converted to “drive”. Each language requires semantic analysis and parts of speech to establish a complete lexicon.

Parts of Speech: In traditional grammar, a part of speech is a category of words that have similar grammatical properties, such as “nouns”, “conjunctions”, and “verbs”.

Named Entity Recognition (NER): NER, also known as “proper name recognition”, refers to the recognition of entities with specific meanings in the text, mainly including names of people, places, institutions, proper names, etc.

Chunking: Chunking is the process of grouping the words in unstructured text and making up phrases.

Easily spoken to design the model, the pre-processed words are used in a **word embedding**. The purpose of word embedding is the vectorization of words. Each word or phrase is mapped to corresponding vectors of real numbers. With these dependencies, words can be allocated. Algorithms such as deep learning can ingest and process these vectors to formulate an understanding of natural language. (Collis, 2017)

Following, the process description of the master database as well as the process description of the new construction project, the data is pre-processed and afterwards vectorized. Hence, the tasks can be compared by their real numbers, and the effort value with the closest match is used as the planning basis for the process analysis. This procedure also serves as the foundation for the methodical approach.

CASE STUDY

METHODICAL APPROACH AND DATA

The methodical approach for the case study, is described in Figure 3. For the case study two datasets are used: the master database and the process description of tender documents from a real-world construction project. First, the mapping quality is evaluated with two indicators, and afterwards, the prediction accuracy for the duration is analyzed.

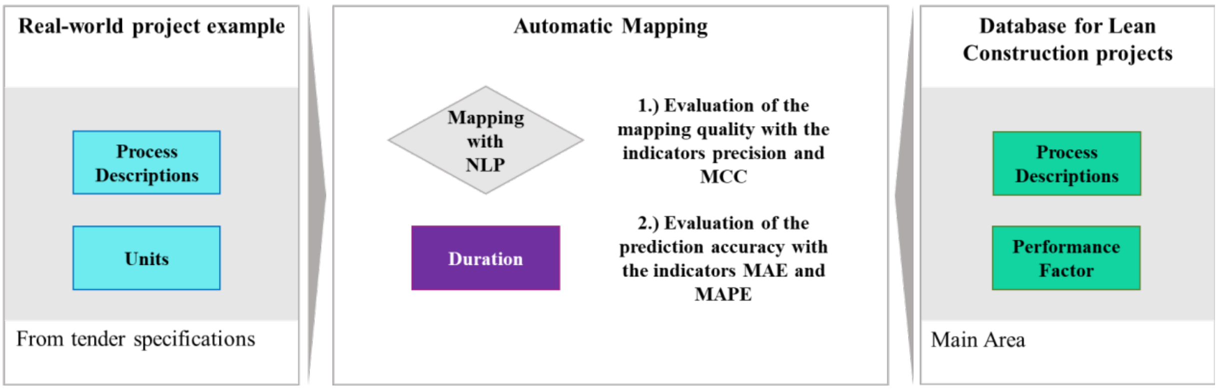

Figure 3: Methodical approach for the case study.

As a master database, the data from BKI is used for the research model. The available dataset contains 3.586 described process steps for new construction projects. The dataset is complete and free of missing data, and its reliability is high. The dataset is available in German and is annually updated. The dataset contains, after removing irrelevant features, six columns with: category type, short task description, long task description, unit, average cost per unit, and performance factor. The mean value of the short task description, text length are 34.29 digits, for the long task description it is 383.06 digits. The mean value is defined as the sum of all digits divided by the number of projects. The performance factor presents the working time in hours, based on one unit. The average performance factor is 1.23 hours with a standard deviation of 9.16 hours, a minimum of 0.01 hours, and a maximum of 260 hours per unit.

The real-world construction project data contains process steps for structural engineering work (earthwork, concrete, and masonry work) described in the tender specifications. In the real-world project data, there is no information about performance factors included. This information is needed to start a well-founded lean construction process plan. The dataset includes 194 entries with a short process description as well as the number of units. To these two columns, the corresponding process description and the performance factor of the master database are manually matched. Entries with no match and null values are deleted. The performance factor is then multiplied by the number of units to calculate the duration. This results in 93 data entries with an average duration of 0.52 hours per unit (performance factor) and 87.60 hours per process step (duration per unit multiplied by the respective unit). Table 1 summarizes the mean and standard deviation for the master database and the real-world project for the performance factors and duration. The performance factors of the real-world project are on average lower than those of the master database and show a lower standard deviation.

Table 1: Description of the data

	Master database	**Real-world project**	
	Performance Factor	**Performance Factor**	**Duration**
Mean	1.23 hours	0.52 hours	87.60 hours
Standard deviation	9.16 hours	0.57 hours	290.06 hours

In the first phase, the master database is prepared with data cleaning process, encoding, and splitting. The data cleaning contains data truncation, data enhancement, and selecting a classification objective:

Data Truncation: Nevertheless, the available dataset of real project consists only of structural engineering work. To control the required resources within the limits of Google Colab and maximize model performance with restricted resources, the master database is limited to the category of structural engineering. After restricting the range, the number of data sets dropped from 3.586 to 1.420.

Data Enhancement: Despite its high quality, the BKI dataset presents a problem for machine learning. In general, to train a classifier, each class always needs multiple data samples for algorithm learning. However, there is only one unique sample to be classified in each class in the current BKI dataset. Therefore, the expansion of the data cannot be avoided, and a replication is performed. In a study, IBM researchers explored different classifiers, and the performances of the classifiers with different numbers of training samples were compared. The results show that the model improves significantly with the inclusion of ten samples (Anaby-Tavor et al., 2019). Therefore, the number of replications of the master database is set to 10. After the data expansion procedure, the number of data points in the dataset increased from 1,420 to 14,200.

Selecting Classification Objective: After filtering the process steps with effort values, there are 14,030 data points left.

Afterwards, the data is encoded. After investigating the duplicate entries, label encoding is used for the short description. Label encoding assigns a number starting from zero to each possible category in the short description column (Yadav 2019). The new dataset includes 14.030 data points and 1.366 category encodings.

In the last step of data preparation, the master dataset will be divided into a training set, a validation set, and a test set. This procedure is known as data splitting. Brownlee (2020) defines data splitting as a technique that is used to evaluate the performance of machine learning algorithms and can be employed in any supervised learning algorithm. The training and test sets were split by 80% and 20%.

After data preparation, the model is developed and various publicly available libraries for Python are utilized: TensorFlow, Transformers, Tune and Scikit-learn. For the model, the framework GBERT is used, which Chan et al. (2020) state the best performing German framework for NLP. The model further on uses several pre-defined hyper-parameters, such as a dropout rate of 0.1, 10 epochs, a batch size of 16, and a learning rate of 2e-5. For the model, the short and the long process descriptions are combined by the separator token “[SEP]”.

After model training, the model will be evaluated by several metrics, such as:

Precision: Precision indicates the proportion of units that the model predicts to be positive and are in fact positive. The mathematical definition is the proportion of the true positives (TP, actual positive and labelled as positive) to the true and false positives (FP, actual negative and labelled as positive).

$$Precision = \frac{TP}{TP + FP}$$

MCC: Matthews Correlation Coefficient (MCC) represents the correlation between the true value and the predicted value. It ranges from -1 to 1. A score of 1 indicates a very good prediction, while a value close to 0 means that the model performs poorly and is like the random classification. The value -1 represents inverse prediction (Grandini et al., 2020). The metric focuses only on whether each class is well predicted, regardless of class imbalance (T, 2021). The formula of MCC with TP, FP, true negatives (TN, actual negative and labelled as negative) and false negatives (FN, actual positive, labelled as negative) is:

$$MCC = \frac{TP * TN - FP * FN}{\sqrt{(TP + FP) * (TP + FN) * (TN + FP) * (TN + FN)}}$$

MAE: To calculate the Mean Absolute Error (MAE) for each known output y and the associated predicted value ŷ, the loss is calculated from Loss (y, ŷ) = |y - ŷ | (Russell and Norvig 2012, Hyndman and Koehler 2006). This metric is characterized by a stronger robustness, and outliers do not affect the result as much. The MAE is calculated with (Sammut and Webb 2010):

$$\boldsymbol{MAE = \frac{\sum_{i=1}^{n} |y_i - \hat{y}_i|}{n}}$$

MAPE: The Mean Absolute Percentage Error (MAPE) serves as an indicator of how good the predicted duration is. The smaller the indicator, the higher the prediction accuracy. The MAPE is the ratio of the difference between the actual output value y and the predicted value ŷ to the actual output value y over all data points (Hyndmann and Koehler 2006).

$$\boldsymbol{MAPE = \frac{100\%}{n} \sum_{i=1}^{n} \left| \frac{y_i - \hat{y}_i}{y_i} \right|}$$

RESULTS OF THE CASE STUDY

To evaluate the performance of the mapping model, itis evaluated with the test dataset from the master database and the real-world dataset. The test dataset of the master database contains

2.806 data entries. The accuracy reaches 0.92. The MCC represents the correlation between the true value and the predicted value. With this metric, it is possible to observe whether each class is well predicted or not. Here, MCC is at 0.92. Overall, the performance of the model on the test set is reasonably positive.

For the real-world dataset, the accuracy reaches 0.65. The value of MCC is 0.64. It is possible to conclude that the model performs less well on the dataset of a real project than on the test set. For both, the metrics are summarized in Table 2.

Still, the matching effort values can be very close, as the assigned tasks can be similar and the matched performance factor is close to the correct one.

Table 2: Overview of the mapping quality

Indicator	**Value**	
	Master database	**Real-World dataset**
Accuracy	0.92	0.65
MCC	0.92	0.64

Therefor the manually mapped durations and the predicted ones are compared for the real-world dataset. As indicators the MAE and MAPE are used as metrics. The MAE is 48.75 hours and the MAPE is 17.63 % (see Table 3).

Table 3: Overview of the prediction results

Indicator	**Value**
MAE	48.75
MAPE	17.63 %

While further analysing these metrics with a histogram shown in Figure 4, there are five mismatches with a difference of more than 50 hours between the predicted and actual duration. The highest mismatch is 2.340 hours, a high outlier. The Q3-quantil shows that 75 % have a difference of 2.5 hours between the predicted and actual value. In 85 % of the mismatches the difference is less than 8 hours or a working day (with 8 hours). The distribution of the prediction errors is displayed in Figure 4.

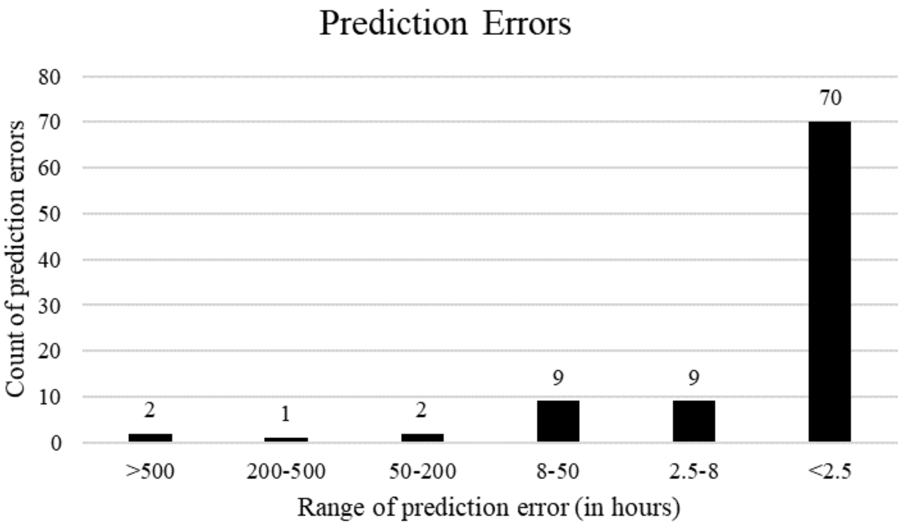

Figure 4: Distribution of Prediction Errors by hours.

Comparing the 2.5 hours in 75 percent of the cases to the 87.60 hours mean duration in the real-world dataset, the overall quality of the prediction is very good. Following, the predicted duration can serve as a basis for further planning. Due to the high deviations with high outliers, an expert must still be included in the scheduling with the target to reduce these outliers and correct the performance factors. These experts can be last planners, as they can validate the predicted durations best with their knowledge and, at the same time, challenge their own estimations.

CONCLUSIONS

In this paper, a concept was evaluated using a master database with historical project data to map the process descriptions to thoseof a new construction project. By doing this, the performance factor of the master database can be multiplied with the number of units of the construction project and a duration as the basis for planning is calculated. As the process description is often not standardized, the method of NLP is used. NLP serves as a bridge between machine language and unstructured human language.

For the concept evaluation, two databases were used. One master database with 3.586 entries describing new construction projects and the tender specifications of a real-world construction project with 194 entries. The mapping quality of the process descriptions between the master data base and the tender specification was 0.65 accuracy and 0.64 MCC. Both indicators show an average to good mapping quality. The higher mapping quality of the test dataset shows the need for a more detailed process description. When further comparing the prediction quality for the duration, the MAPE is 17.63 % and in 75 % of the mismatched cases, the prediction error is smaller than 2.5 hours. This deviation from the 87.60 hours of mean duration is very low, and the concept of mapping performance factors automatically shows its potential. With a first automatic mapping and prediction of the process durations, the time for scheduling can be accelerated and the quality of planning enhanced.

Figure 5 shows the full concept model with recommendations for the construction companies. The master database can be used to map with NLP models process description to the tender specifications of new construction projects. This information can serve as the basis for planning with the trades and their last planners. During the process analysis, performance factors and process descriptions are corrected, and the estimated durations are finalized with the available manpower. The result is a construction schedule that is validated by historical project data. When documenting the performance of the project during its realization, the performance factors can be updated and detailed, and the master database can be enriched by new entries.

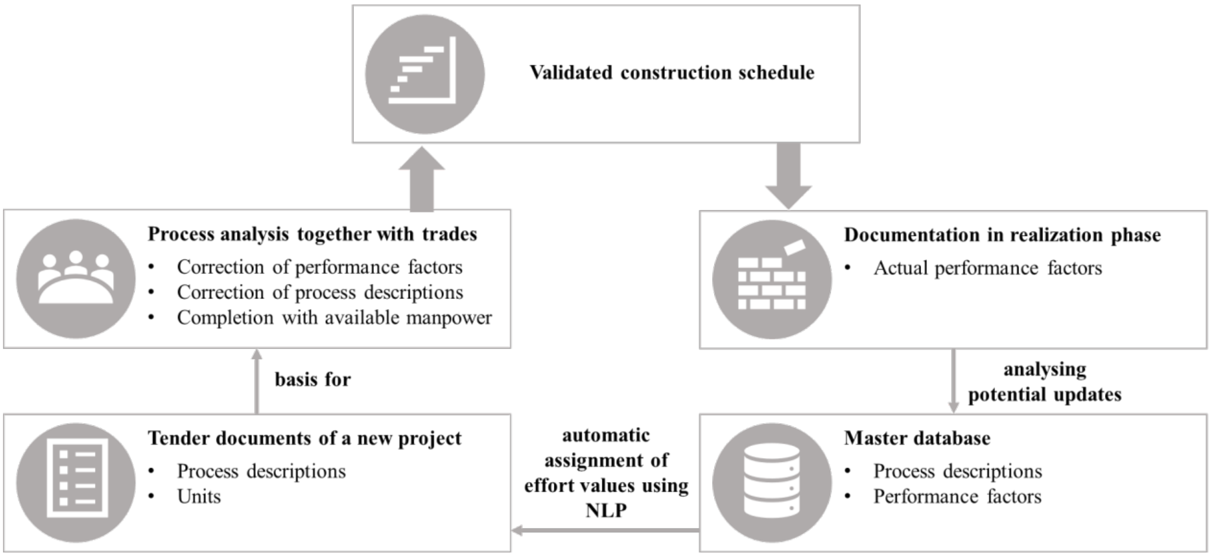

Figure 5: Concept model using NLP to automatically map performance factors to the tender specifications to support the process analysis.

As the case study is performed with one real-world dataset, there needs to be a broader field study using the tender documents of several construction projects. Also, the model acceptance of the schedulers and trades must be evaluated. Here, especially, the allocation of mismatches by the defined model should be analysed with the target of reducing the outliers and strengthening the collaboration between experts and machines.

PROMOTING THE IPD DELIVERY METHOD IN CONSTRUCTION PROJECTS: A BIM-BASED SMART CONTRACT APPROACH

Mohamed Assaf[1], Lena Salami[2], Diana Salhab[3], and Ahmed Hammad[4]

ABSTRACT

The adoption of integrated project delivery (IPD) provides several advantages over traditional delivery methods, such as shorter schedules, efficient communication, and higher performance quality. However, its implementation is constantly hindered by many barriers. Existing studies on IPD barriers are limited to quantifying and addressing such obstacles. Additionally, hardly any studies have addressed the potential of advanced technologies in exploiting the adoption of IPD projects. Thus, this study presents an automated system that integrates blockchain, smart contracts, and BIM technologies to facilitate the implementation of IPD projects. Hyperledger Fabric and chaincodes are used to develop the blockchain network in accordance with 4D and 5D BIM models. The developed system simplifies various financial transactions throughout different phases of the IPD project implementation. The system allows non-owner participants to submit requests and review transaction records with the aim of minimizing possible conflicts. The methodology is evaluated by testing it on a real-life case study. The case study is modeled using BIM tools, and the corresponding blockchain network and smart contracts are developed. The findings prove the capability of the developed system to provide a secure and trustworthy platform for managing IPD transactions without the need for third-party involvement.

KEYWORDS

Integrated project delivery (IPD), smart contracts, BIM, blockchain, construction projects.

INTRODUCTION

The integrated project delivery method (IPD) is an innovative delivery method that overcomes many of the limitations of conventional delivery (Ahmed et al., 2021). Conventional delivery methods are characterized by fragmentation (Teng et al., 2019), lengthy processes (Ghassemi & Becerik-Gerber, 2011), and poor information sharing (Rahman & Kumaraswamy, 2004). IPD was introduced to overcome these drawbacks. The IPD system is characterized by early involvement of participants and efficient risk-sharing and compensation systems (Faris Elghaish et al., 2020). Evidence in the literature has shown that IPD has the potential to enhance project performance. For instance, Ahmad et al. (2019) indicated that IPD improves 14 project

performance indicators, such as cost management, work quality, information sharing, and scheduling management.

However, the adoption of IPD projects always encounters many barriers. Rodrigues and Lindhard (2021) have discovered many barriers to IPD adoption using case-based studies. The found barriers can be summarized as follows: 1) difficulties in estimating the limbs values (components) in various project stages; 2) establishing the culture of having the same control over the project from all participants; 3) the dilemma of having transparency and trustworthiness through the entire project; 4) behavioral barriers as most participants can expect the higher profitability. Similarly, Yee et al. (2017) have categorized all of the barriers into four main categories: contractual barriers, behavioral barriers, structural barriers, and technological barriers. The study concluded that technological barriers are the most critical barriers that hinder the adoption of IPD. To be able to exploit the merits of the IPD system, advanced technology sharing and communication systems are required (Faris Elghaish et al., 2020). Building Information Modeling (BIM) is an example of technology adoption in IPD projects. As mentioned by Salman et al. (2012), BIM can enhance the delivery of projects by providing efficient collaboration between project participants. However, it is argued that integrating advanced technologies, such as blockchain, with BIM can further address many of the IPD barriers (Lamb, 2018).

The latest advances in blockchain technology have presented chaincodes (smart contracts) as an alternative solution that overcomes the downside of the fragmented nature of construction projects (Ahmadisheykhsarmast et al., 2020). Smart contracts are digitalized contractual agreements that provide solutions for the deficiencies in the payment systems of construction projects. Blockchain platforms act as a decentralized and secure system that provides an efficient implementation of smart contracts (Sigalov et al., 2021). It records any transactions or movements of the system on blocks that can be displayed on the ledgers. More on blockchain components will be discussed in the following sections.

To this end, many studies have addressed the potential of blockchain technologies in construction projects. However, the literature lacks the following aspects: 1) the majority of studies presented a conceptualization of the blockchain framework, with no actual implementation; 2) limited studies addressed the integration between IPD and blockchain in the construction industry; 3) potential claims on a construction project are yet to be addressed on the blockchain network. Considering these gaps, this paper presents an integrated system to overcome the obstacles of implementing the IPD method. The objectives can be summarized as follows: 1) identifying and (egorizing the barriers that hinder the adoption of the IPD method in construction projects; 2) studying the potential of advanced technologies (e.g., smart contract and BIM) to overcome some of the identified barriers; 3) developing an automated system that facilities the payment transitions and minimizes possible conflicts, hence promoting the IPD approach; 4) Validating the system by applying the proposed methodology on a real case study. The rest of the paper is structured as follows: the next section provides the literature, followed by the study methodology, which is then validated. Section 4 shows the validation and case study, and section 5 provides the conclusion and recommendations.

LITERATURE REVIEW

IPD is a highly collaborative approach to project management that involves the integration of all stakeholders engaged in a project, including the owner, architect, contractor, and other key team members, within an environment of trust. IPD aims to create a team environment where all parties work together towards a common goal, which is the successful completion of the project. The process begins with the development of a comprehensive project plan, which outlines the scope, schedule, and budget of the project. The project plan is then used to guide the team throughout the project, with recurring updates and revisions made as necessary. One of the key features of IPD is the use of BIM, which helps identify potential conflicts and design issues early in the project, preventing costly delays and rework (Ashcraft, 2011). This section provides a literature review on the barriers associated with IPD adoptions, the potential of BIM, blockchain, and smart contracts in construction projects, and a discussion on which blockchain platforms to be used in the current study.

BARRIERS TO IPD ADOPTION IN CONSTRUCTION

Many studies were carried out to identify and categorize IPD barriers. For instance, Sherif and Abotaleb (2023) classified the barriers of IPD adoption into five main categories. Their study indicated that the majority of construction projects in established and developing countries face technological challenges, such as integration issues between BIM and IPD and unreliable payment systems, which are well-known obstacles to IPD adoption (Durdyev et al., 2019). Further, the adoption of IPD projects requires a high level of information sharing, efficient communication technologies, and reliable payment mechanisms (F. Elghaish et al., 2020). IPD adoption in an emerging market is also hindered by ineffective profit distribution procedures, a low level of stakeholder trust, inadequate training, a lack of technological support, a lack of legal and contractual support, procurement problems, and a lack of a collaborative environment (Othman, 2020). An extensive literature review has revealed the following barriers categories: technological barriers (Durdyev et al., 2019), financial barriers (Georgiadou, 2019), lack of adequate research on IPD (Othman, 2020), cultural barriers (Sherif et al., 2022), and legal barriers (Rached et al., 2014). Despite the variety of barriers identified in the literature, this study focuses on the technological barriers and the potential of advanced technologies, i.e., blockchain and smart contracts, in addressing them.

POTENTIAL OF BLOCKCHAIN AND SMART CONTRACTS IN CONSTRUCTION

In recent times, blockchain technology has been introduced as a distributed ledger that can assist project teams with information decentralization and security (Assaf et al., 2022). Besides providing secure and reliable databases, it also promotes various payment transactions among project parties. Numerous benefits are perceived by the adoption of blockchain technology, such as trustworthiness, immutability, and traceability (Assaf & Zayed, 2022). Furthermore, blockchain technology has provided an efficient platform for the implementation of chaincodes (smart contracts) and automated transactions. Smart contracts can be defined as digital protocols that run on a selected blockchain network and enforce endorsement policies, as well as provide automated transactions (Ahmadisheykhsarmast & Sonmez, 2020). To this end, the association between blockchain technology and smart contracts has introduced a potential solution to address some of the IPD adoption barriers, such as the ineffective risk/savings distribution mechanisms (F. Elghaish et al., 2020).

Many studies have discussed the use of blockchain/smart contracts in the construction industry and, more particularly, in managing contracts and payments. Saygili et al. (2022) have discussed the application of blockchain in the reduction of construction disputes. Their study concluded that blockchain technology provides enforceable codes for transaction execution and efficient documentation of all of the transactions, minimizing the probability of disputes and claims. Moreover, Assaf and Zayed (2022) have studied the implementation of an integrated blockchain-based smart contracts system with BIM technology in automating the payment transaction in modular construction projects. Their study provided a claim resolution system to reduce the possible claims in modular projects. Elghaish et al. (2022) have developed a payment system to automate transactions in accordance with traditional and design-build delivery systems. Their study took into account the defects liability period (DLP) through the use of chaincodes to manage the remainder of the duties. Sonmez et al. (2022) have studied the integration between BIM models and decentralized blockchain networks to manage the project's progress payments. Furthermore, similar approaches of integrating BIM technology with supporting technologies were addressed to enhance construction procurement processes. For instance, Aguiar Costa and Grilo (2015) proposed an e-procurement system integrated with BIM technology to reduce the fragmentation in the procurement processes throughout the project life cycle. Different blockchain platforms were used in the mentioned studies, which raises the question of what indicators must be considered when selecting the blockchain platform. The following section will discuss the suitability of different blockchain platforms in the current study.

SELECTING THE SUITABLE BLOCKCHAIN PLATFORM

Several forms of blockchain platforms are available and vary in their functionality and level of privacy (Assaf & Zayed, 2022; Li et al., 2022). Some of the most used platforms are Ethereum, HyperLedger Fabric, Bitcoin Network, and R3 Corda (Perera et al., 2020). These platforms vary in many characteristics that specify their suitability to adopt for different purposes. Generally, blockchain platforms can be permissioned or permissionless. The permissioned blockchain platform allows certified participants only (with digital identity) to join the network. Conversely, the permissionless blockchain network, such as the bitcoin network, allows anonymous participants to join the network (Li et al., 2022). The characteristics that govern the selection of blockchain platforms include the following: permissioned or permissionless, support of smart contracts implementation, confidentiality, scalability, support of consensus mechanism, and batch size (Perera et al., 2020). Therefore, the developer of the network must consider all of these characteristics prior to the selection of the platform. In this study, the chosen blockchain platform is expected to satisfy the following criteria: 1) it should be permissioned to allow the creation of private channels; 2) it should support the creation of smart contracts; and 3) it should be able to handle a large number of transactions. Therefore, considering all of the mentioned selection indicators, the Hyperledger Fabric platform was selected in this study. More on the selection of the platform and architecture of the selected one will be discussed in the following section.

METHODOLOGY

In light of the previously mentioned aims and objectives, Design Science Research (DSR) is adopted as a methodology to achieve the purpose of the study. Generally, DSR is composed of three main parts, which are problem identification, solution design, and solution evaluation (Offermann et al., 2009). As already stated, there is a deficiency in the current payment system when implementing IPD. Therefore, the solution design consists of employing blockchain technology to overcome this issue, and the solution evaluation is done by validating the model by testing it on a real case study. As *Figure 1* illustrates, the model is divided into three main stages: the conceptualization stage, the implementation stage, and the validation stage. First, the conceptualization includes identifying the research's main objectives and the theoretical framework of the research methodology. Furthermore, the implementation stage includes the development of two interconnected systems: the BIM models and the smart contract-based blockchain system. The development of the BIM models includes 3D, 4D, and 5D BIM models. These models were used to feed data to the smart contract-based blockchain system. The development of the smart contract system includes many steps: assigning certificate authority for each participant, identifying the public and private channels, identifying the endorsement policy for the transactions, developing the smart contract (chaincode) in accordance with the endorsement policy and the contract requirement, and building an end-user application to ease the interaction with the blockchain network.

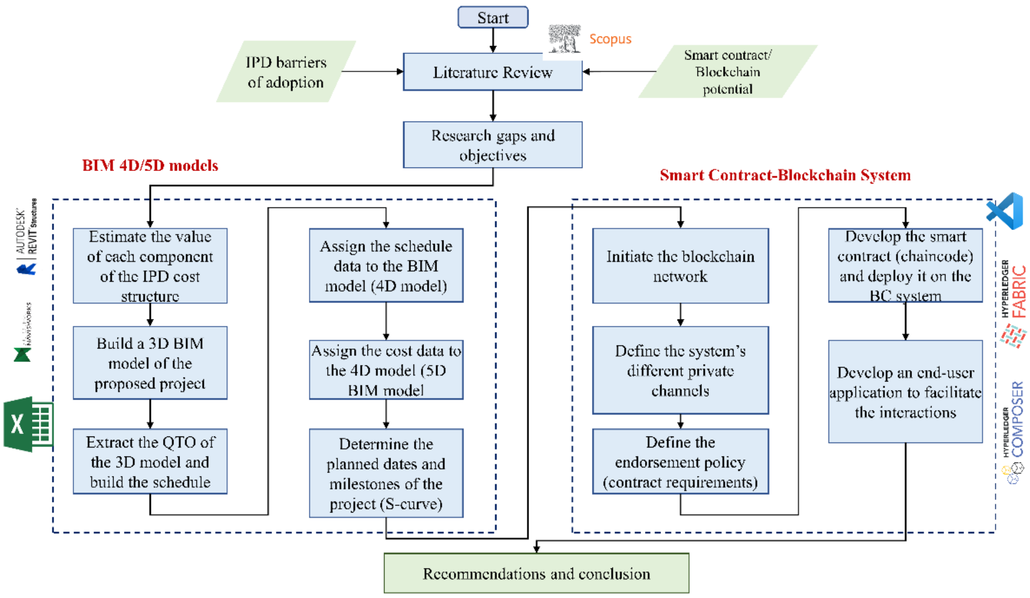

Figure 1: An overall framework of the solution design

One critical part of the developed systems is data flow. The data is considered interchangeable among the developed systems. Figure *2* shows the flow of data among different systems. The development of the 3D BIM model requires 2D drawing (if BIM was not adopted since the project's start). The quantity take-off (QTO) for all elements is exported to Excel sheets to perform the needed calculations. The 3D BIM model is then exported to Navisworks. The estimated durations and costs by Excel are also imported to Navisworks to build the 4D/5D BIM models. Milestone data and planned values are then deployed on the smart contract, as well as the endorsement policy. The endorsement policy can be defined as a protocol to check the validity of the submitted payment requests. Finally, the developed overall system is deployed on the Hyperledger Composer tool to provide an end-user application.

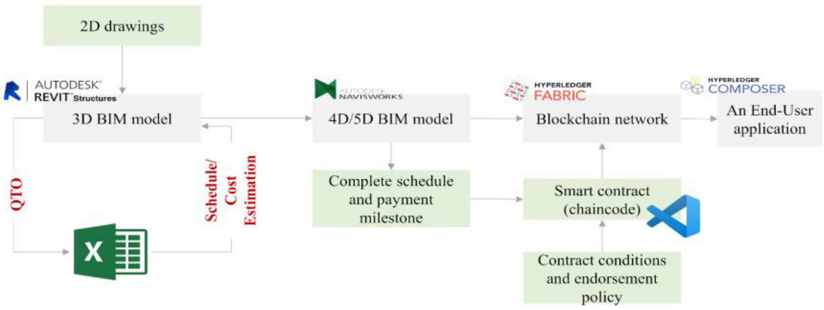

Figure 2: the flow of the data through different systems

4D/ 5D BIM Models

BIM models developed in this step contain geometric and parametric information, which is expected to assist owner and non-owner participants in estimating accurate costs and schedules (Amin Ranjbar et al., 2021). The accuracy of the estimation of the cost and schedule significantly depends on the level of model details. After the 3D BIM model development, the objects (elements), the quantity take-off (QTO) is exported to Excel sheets so that it can be processed by the project management team (PMT) office without the need for a high level of BIM experience by the employees (Amin Ranjbar et al., 2021). Needed materials, unit costs, labor resources, and equipment resources are retrieved by the participant procurement team. Navisworks tool is used to build the 4D BIM model by integrating the schedule data into the 3D BIM model developed by the Revit Structure tool. Moreover, the 5D BIM model is generated by integrating the cost data into the developed 4D BIM model on the Navisworks tool. The developed BIM model is considered to have a level of detail (LOD) of 300, as it covers the following criteria: precise information on quantities and cost and schedule data (Latiffi et al., 2015). It is worth mentioning that the payment figures for the IPD project follow the LIMBS cost structure that will be discussed in the below section.

IPD COST STRUCTURE

This section illustrates the IPD cost arrangements and characteristics. As mentioned before, the compensation (sharing) system forms a critical part of IPD projects (Elghaish et al., 2019). IPD participants usually go through multiple validation phases prior to the start of the project to agree on the sharing ratio (Thomsen & Faia, 2009). This sharing system must specify the distribution of the risk/profits when cost overrun or underrun occurs. As addressed by Elghaish et al. (2019), integrating BIM with the IPD system can facilitate the compensation system through the early involvement of participants. This can be done by developing 4D and 5D BIM models to have a reliable budget and cash flow for all participants before deciding profit/risk ratios. Ross (2003) states that the compensation system of IPD projects generally follows the '3-LIMB' (components) method. Figure 3 illustrates the characteristics of the 3-LIMB method.

Ross (2003) explained LIMB 1 as the direct costs paid by the contractor plus the overheads of this particular project. The reimbursement of LIMB 1 is guaranteed for the contractor and is not subject to the value of LIMB 3. LIMB 2 represents the agreed profits and general office overheads. Unlike LIMB 1, LIMB 2 is subject to the condition of the submitted payment request by the contractor. In other words, if the submitted value exceeds the target value, the reimbursed cost will be subtracted by the risk share ratio stated in the contract. The final reimbursed cost should not be less than LIMB 1. Each of the mentioned LIMBs is calculated based on a set of equations. The following sections will illustrate the equations included in calculating each LIMB.

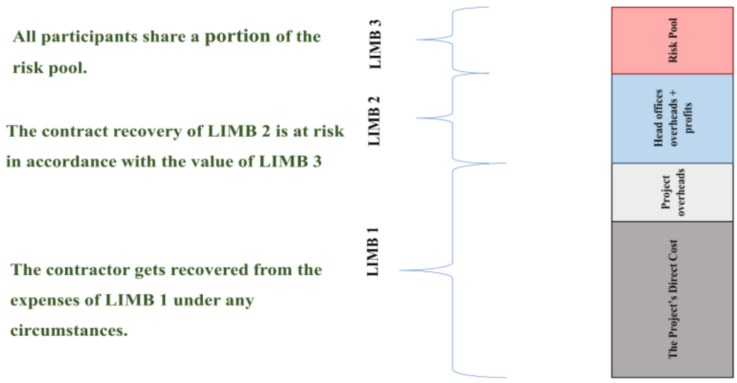

Figure 3: the cost structure of IPD projects

IPD COST ESTIMATION

This section demonstrates the formulation of each LIMB in the IPD system. The presented equations are retrieved from (Elghaish et al., 2019), (Faris Elghaish et al., 2020), and (Ross, 2003). Equation 1 shows the estimation of the LIMB 1 value. It is worth mentioning that the quantity of work used to estimate the direct cost is extracted from the 3D BIM model.

$$LIMB1_{ij} = \sum_{j=1}^{n} (CoDA_{Kj} + CoIA_{Kj})$$ Equation 1

Where $CoDA_{Kj}$ is the direct cost for contractor i to perform activity k in work package j. On the other hand, $CoIA_{Kj}$ is the indirect cost incurred by contractor i to perform activity k.

Furthermore, the estimation of value for $CoDA_{Kj}$ can be calculated using Equation 2, as mentioned by (Assaf & Zayed, 2022).

$$CoDA_{Kj} = \sum_{k=1}^{n} (MC_{kt} + LC_{kt} + EqC_{kt}) \quad \text{Equation 2}$$

Where MC_{kt} is the material cost for activity k at a particular time t, LC_{kt} is the labor cost for activity k in a particular time t, EqC_{kt} is the material cost for activity k at a particular time t. On the other hand, $CoIA_{Kj}$ is generally calculated as a ratio of $CoDA_{Kj}$, considering the fixed and variable indirect costs.

As mentioned above, LIMB2 accounts for the pre-defined profits and general office overheads. The office overheads can be calculated in accordance with the approach followed by Elghaish et al. (2019). The profit ratio is applied to the total cost calculated in LIMB1 and was added to the equation following the illustration of the IPD cost structure by Ross (2003). Equation 3 shows the method followed to calculate LIMB2.

$$LIMB2_{ij} = \sum_{k=1}^{n} (NOA_{OK} \times MVOCD_{k}) + \%PR \times LIMB1_{ij} \quad \text{Equation 3}$$

Where $LIMB2_{ij}$ represents the profits and office overhead cost for contractor i to perform work package j. NOA_{OK} is the number of operations O needed to perform activity k's overheads. Further, $MVOCD_{k}$ represents the cost of one operation needed to perform activity k. $\%PR$ represents the pre-agreed profit ratio in the contract.

LIMB 3 value represents the amount of money saved (or additionally incurred) compared to the target value specified in the contract. The value of LIMB 3 is added to the risk pool of the project and shared with all of the nonowner participants in accordance with the adopted compensation system. The value of LIMB 3 can be calculated as in Equation 4.

$$LIMB3_{ij} = MVP_{ij} - (LIMB1_{ij} + LIMB2_{ij}) \quad \text{Equation 4}$$

Where $LIMB3_{ij}$ is the monetary value added to the risk pool and incurred by contractor i to perform work package j. MVP_{ij} is the monetary value planned in the contract to perform work package j.

THE BLOCKCHAIN NETWORK

As mentioned above, many blockchain platforms are available and can be adopted across various industries (Perera et al., 2020). To achieve the study objectives, three main indicators were used to select the appropriate blockchain platform. These indicators can be summarized as follows: First, the chosen platform should support the involvement of smart contracts (chaincodes). The smart contract feature is an essential component of this study as it defines how the automated transactions are executed. Second, the chosen platform should be permissioned and allow the creation of private channels. Channels provide privacy between two participants when needed, such as sharing information between the owner and contractor. Third, each platform has a block size that determines the maximum number of transactions that can be included in one block. The Hyperledger Fabric platform was selected for the study to build the blockchain network. Many components are included in the Hyperledger Fabric platform, among which, seven main components are considered to reach the research objectives. These components are the peers, ledgers, smart contract(s), orderer(s), channels, end-user applications, and certificate authorities (CAs).

SMART CONTRACT AND PERMISSIONS

This subsection illustrates the formation of the smart contract. The smart contract specifies the endorsement policy by which the submitted transactions are evaluated. The transactions included in this study reflect the payments in the context of IPD projects and cost plus with target value contracts. However, the developed smart contract can be reconfigured to suit any delivery method and contract type. Many functions are included in the created smart contract and can be summarized as follows: 1) to validate the submitted transactions against the identified endorsement policy; 2) submit payment by the contractors to the owner; 3) pay the valid payment request by the owner to the contractor; 4) calculate the limbs and allocate the right transactions to all participants. Furthermore, the developed network is permissioned, meaning that not all participants have the ability to view each component of the network. These permissions are used to enforce access control for participants. For instance, contractor *i* does not have access to submit transactions to other contractors in the network. Figure 6 shows a sample of the permissions given to participants in the Hyperledger Fabric network.

IMPLEMENTATION AND RESULTS

This section presents a case study of a residential building constructed in Cairo, Egypt. The building has ten floors and a floor area of 600 m2. The presented case study is used to validate the proposed methodology. The project was done using cost-plus (with target value). Autodesk Revit was used to develop the 3D BIM model. Figure *4* shows the developed BIM model. The QTO of the project is exported to Excel Sheets, and the total cost and duration were calculated.

Figure 4: the 3D BIM model

4D/5D BIM MODELS

The developed schedule was added to the 3D BIM model to develop the 4D BIM model. Autodesk Navisworks tool was used to develop the 4D BIM model. Figure 8 shows the developed 4D model. Bar charts are presented for each activity to demonstrate the calculated durations. Furthermore, the cost data was integrated with the 3D BIM model to develop the 5D BIM model. Figure *5* shows the 5D BIM model. The 4D and 5D BIM models are used to estimate the target values for the project (schedule and cost).

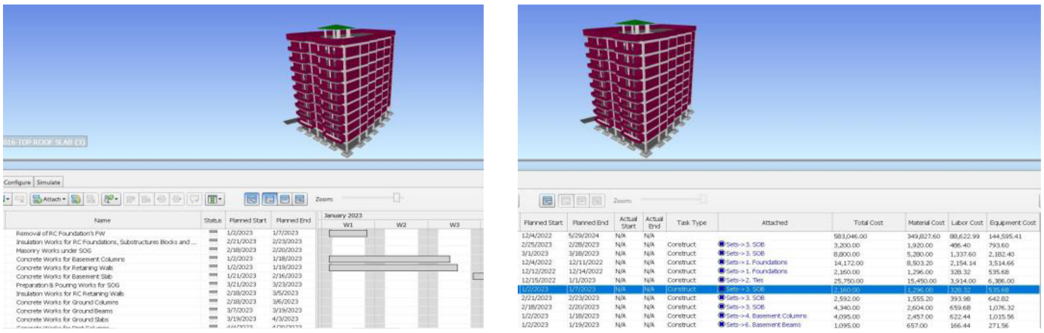

Figure 5: the developed 4D/5D BIM models by Navisworks tool

DEVELOPING THE SMART CONTRACT

In the proposed system, the contractor submits a payment request following the agreed milestones of the project. Therefore, the project PMT develops an S-curve specifying the planned dates and costs (targets). The contractor is expected to submit this payment request on the blockchain system, and the submitted request will be evaluated based on the endorsement policy. The contractor's reimbursement of the incurred cost depends on the target cost for the corresponding milestone. The cost overrun will be shared with each participant in accordance with the agreed sharing ratio. Similarly, the savings will be shared with all participants according to the sharing ratio. The developed smart contract has many functions. Figure 6 shows the transaction part of the smart contract. The smart contract code was written using two main languages: JavaScript and Hyperledger Composer. The code automatically calculates the three values of limbs. It also uncovers whether there are cost savings or cost overruns in accordance with the target values. Moreover, the code acts when the target cost is exceeded and modifies the reimbursable cost according to the cost structure of the IPD approach. Other functions of the code are claims submissions and extending the completion date by the owner. The following section will illustrate the outputs of the developed system.

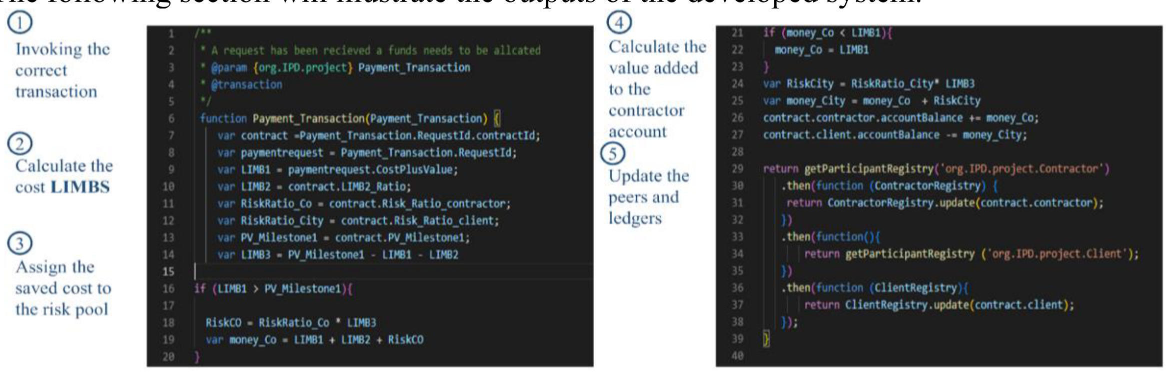

Figure 6: the transaction code on the smart contract

END-USER DEVELOPED APPLICATION

All of the code is integrated into the Hyperledger Composer tool to facilitate interactions among all participants. Figure *8* shows the interface of the end-user application. The system allows only specific participants to add private channels, which must be verified by the network orderer. The accessing participant is only eligible to read, create, update, and delete assets that are within their scope. This access control is implemented using the ACL feature of Hyperledger Composer. Transactions are governed by hash values, meaning that any amendment of a previously invoked transaction can be easily located on the network, enhancing the trustworthiness among participants.

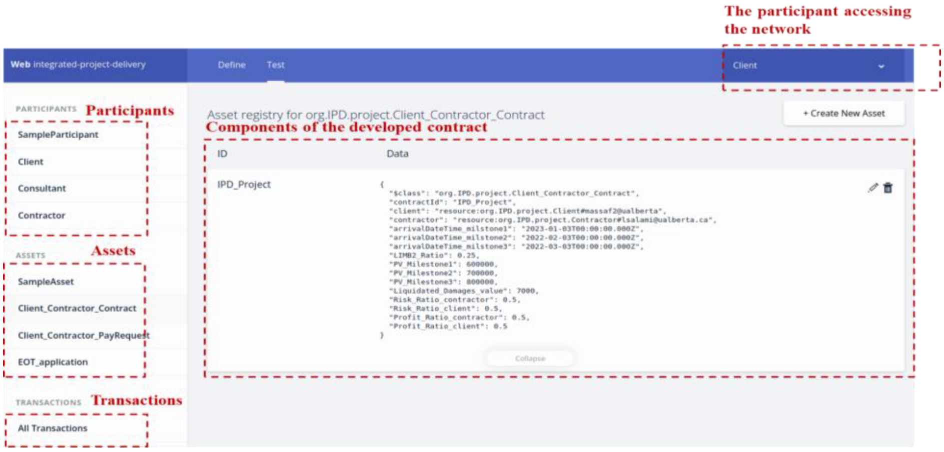

Figure 7: the interface of the developed end-user application

Figure 8 shows a closer look at the formed contract on the network. The contract specifies all the attributes of the IPD projects and is accessible to all the individuals that are part of it. It specifies the included participants, target values, target costs, and sharing ratios. Furthermore, this efficient documentation of the transactions and movements can help minimize possible conflicts and disputes. Despite the contribution of IPD in minimizing possible conflicts, claims still exist according to the clauses mentioned by CCDC-30 (2018) that need to be minimized.

Figure 8: the developed smart contract presented on the blockchain network

CONCLUSIONS

This study is motivated by the lack of research on practical solutions to the technological barriers of IPD adoption in construction projects. It presents an integration of the IPD delivery system with innovative technologies to overcome deficiencies in payment systems, which forms a barrier to IPD adoption. The proposed approach develops 5D BIM models that feed various data, such as milestone dates, into the developed blockchain network that uses the Hyperledger Fabric platform. A smart contract representing the cost structure of the IPD project is developed and employed on the developed blockchain network. The developed smart contract enforces an endorsement policy that verifies the validity of the submitted transactions by the project parties. Additionally, the developed blockchain network provides access control, allowing the corresponding participants only to submit (or issue) transactions. The model provides fair profit and risk-sharing among project participants.

This study contributes to the body of knowledge by: 1) providing a secure automated system that can promote the IPD adoption in construction projects; 2) providing efficient documentation that can help minimize possible claims; 3) developing a system that can be reconfigured to suit other contract types and delivery methods; 4) providing an automated sharing of risks and gains through smart contracts, without the need to involve third parties. Despite the contributions provided by the presented study, it still includes some limitations. The development of the smart contract is considered complex and could include human errors. Furthermore, the developed system supports only extension of time claims. Future research may also consider more types of claims submission, such as loss of productivity claims. Future studies can also focus on integrating financing strategies, such as joint ventures, in the developed system.

LEAN SUPPORTING A FRAMEWORK FOR THE CONSTRUCTION INNOVATION PROCESS

Bernardo Martim Beck da Silva Etges[1] and Carla Schwengber tem Caten[2]

ABSTRACT

The construction sector has gradually been restructuring to advance the use of digitalization and taking advantage of Industry 4.0. Recent studies in the IGLC Community have emphasized the need to connect Lean Construction with the innovative movement by promoting and advancing the use of Industry 4.0 technologies. However, it is well known that innovation approaches are successful when they achieve the goal of problem solving. Considering this context two questions are set: (a) Does the innovation process in construction sector understand how to capture pain-points of the industry and in how it organizes itself? (b) Does Lean Construction contribute by offering a conceptual basis for reaching a better understanding of innovation? This paper aims to develop a framework for analyzing and catching the pain-points as the starting point for the innovation process. As a result, a Problem-space-framework (PSF) was proposed and validated in a empirical study. The first question was tackled by conducting a qualitative analysis and holding a workshop, the outcome of which was that eight out of 98 pain-points identified were prioritized towards the solution design. The second question was also fully answered identifying that 89% of the participants understood that Lean Construction contributed to the PSF and most of Lean tools proposed were regarded as having high usability during the implementation phases.

Lean construction, innovation, pain-points, problem-space-framework

INTRODUCTION

Throughout history, humans have managed to innovate and evolve different industrial solutions, to improve their labor processes but also, and, to a greater extent, their wellbeing (Noueihed, K., Hamzeh, F., 2022). Considering that innovation is needed in industry to enable a better quality of life, we may also say that innovation in a business environment defines the organization's ability to create and achieve competitive advantages that can generate a range of sustainable opportunities (Aranha, 2016). According to Audy and Piqué (2016), society now has a strong base that is founded on the knowledge of highly qualified professionals and teams, in addition to which this is reinforced by new technologies having been developed and mastered. These factors give society a new characteristic which focuses on knowledge and innovation.

An analysis of the construction industry shows that it configures an important pillar of the economy in many countries since it contributes greatly to GDP and is a major employer. However, construction is perceived as a sector that lags behind other industries with regard to innovation (Wang et al., 2021). A plethora of studies regarding many countries acknowledges

that construction falls behind other industrial sectors in relation to improving productivity (Vrijhoef and Koskela, 2000, Kapelko et al., 2015, Zhan et al., 2018). Productivity in the construction industry is still described as having scarcely evolved, being nearly stagnant in the last 20 years and there having been a low rate of investments in digitalization and innovation (Mckinsey, 2017). However, the characteristics of the ecosystem of construction can pose several obstacles to innovation. These include the temporary nature of the relationships in construction projects, which hampers the exchange of knowledge and building trust between different parties (Greco et al. 2021) or due to construction having special operational characteristics, namely it is project-based, resource-intense and risk-related (Wang et al. 2021).

Given the above context, the next section of the article will undertake a panoramic review of the literature, considering the characteristics and main positions of the innovation process in the construction industry and its interfaces with Lean Construction. A gap in the literature and in knowledge is identified with regard to there not having been, hitherto, a structured process for identifying pain-points in the construction sector for innovation processes integrated with Lean Construction concepts and tools.

Therefore, this paper identifies an opportunity for developing practical proposals for guiding and implementing the innovation process in the civil construction value chain. The general objective of this paper is to develop a framework to analyze and capture pain-points as the starting point for initiating an innovation process in construction companies. To do so, two questions are set: (a) Does the innovation process in the construction sector understand how to capture pain-points of the industry in principle, and also, in practice, within a given company? (b) Does Lean Construction contribute by offering a conceptual basis for understanding innovation?

LITERATURE REVIEW

Lindgren and Emmitt (2017) state that technological innovation in construction depends on and involves a broad and complex network of stakeholders, from customers to product manufacturers and designers, contractors and end users. In addition, there is the relationship with governments and direct action with society to be considered. Seeking to identify these multiple relationships between stakeholders, Xue et al. (2017) and Larsen (2015) view the relationships of the innovation process as collaborative relationship networks and highlight the key roles that some parties play in the innovation process. The decomposition of collaborative relationships together with network analysis allowed a better understanding of the innovation process in construction. In particular, this enabled the so-called “real problems” that support the definitions of greatest impact regarding innovation to be identified (Xue et al., 2017). Taylor et al. (2006) had already concluded that, only by having organized and interdependent processes would significant performance improvements in innovation be achieved in the construction industry.

On the other hand, the focus of innovation research has tended to concentrate largely on traditional and hierarchical industries. When project-based industries are included in innovation studies, analyses rarely explore the implications for the organizational structure nor the specific characteristics of these industries with regard to the spread of innovation. Hopkins et al. (2011) suggested that project-based organizations are inherently more open than other organizations, and their efficiency comes from economies of the system, rather than from economies of scale. Hence, the paucity of studies on project-based industries and the Innovation Process is surprising.

Multiple authors have studied innovation in construction in terms of the product, new materials, building systems and design tools (Azhar, 2011). Their studies show that most companies generate innovative products and processes; however, they have difficulty in carrying out continuous and structured innovations (Pellicer et al., 2017). Viewing innovation as an organizational process, some studies in recent years have focused on the interrelationship between the various players and stakeholders. Network-based, inter-organizational arrangements emerged as new means to facilitate the development and spread of innovation within the construction industry (Keast; Hampson, 2007). According to Pellicer et al. (2017), innovation in companies in the construction sector needs to stop being a spontaneous act that only arises when the solution of a specific problem is found, and to become a systematized management process integrated with the development of knowledge. Larsen (2015) indicates the importance of building an integrated and flexible innovation network into a continuous process of developing solutions and knowledge where good practices can be used collaboratively (Pellicer et al., 2017, Larsen, 2015).

Recently, Hamzeh, et al. (2021) suggested an important topic considering innovation and technology. Even with the arrival of the "fourth industrial revolution" or Industry 4.0, the attempts of research to acknowledge the influence of Industry 4.0 on the architecture-engineering-construction (AEC) industry, have been primarily on technology. Some studies point out that Lean Construction has become a major tool for learning, collaboration and for sparking an environment of innovation. A survey developed by Trentim and Etges (2021) identified that 92.6% of their respondents understood that implementing Lean Construction supported the development of knowledge and critical analysis of problems and solutions. Christensen and Christensen (2010) Zhang and Chen (2016), Tyagi et al. (2015) and Skinnarland and Yndesdal (2012) have similarly demonstrated that projects that implement Lean Construction (LC) have huge potential for generating knowledge and are fertile areas for collaborating due to LC's characteristic of creating interdisciplinary and collaborative innovation. Taggart et al. (2014) argued that, when a collaborative and proactive environment is provided to supply chain partners, the root causes of defects are more likely to be identified leading to cost-effective solutions being proposed (Greco et al. 2021). Hamzeh et al. (2021) highlighted the need to connect LC with this new innovative movement by introducing Lean Construction 4.0 principles into established practices so as to keep pace with the advancing technologies of Industry 4.0.

In the current paper, we will seek to understand how "real problems" can connect with innovation in different construction phases, given a LC background, collaboration and technology (Hamzeh et al., 2021, Xue et al, 2017, Azhar, 2011, Taggart et al., 2014).

RESEARCH METHOD

The current paper is part of a broader research activity for a doctoral thesis by the first author. The stage described in this article covers the validation of the first construct within a broader methodological approach of Design Science Research (DSR). This paper was undertaken in 3 stages divided into two phases, as illustrated in Figure 1. The first phase took a broad view of the construction market in relation to innovation on the way to support the questions set. The second phase (which includes stages A and B) is a an empirical study developed in a construction company within the Brazilian real estate market.

The first phase consisted of determining how specialists in the sector understand the innovation process in the Brazilian construction sector. Hence, a qualitative study was engaged on which drew on the experiences and opinions of a group of professionals. The technique adopted was an open individual interview, using a semi-structured script. As to the method used, it took a qualitative approach. A group of professionals was invited to take part, in order to have additional opinions and content about the object of study. The distribution of interviews was planned in order to obtain a balance between the number of respondents in each segment of innovation, thereby seeking to ensure a diversity of responses, which is desirable in qualitative studies (VOSS et al., 2002).

Since this paper focuses on validating the first construct of a DSR, it is important to note that one limitation of the second phase is that it was conducted with a company that already has experience with Lean Construction methodologies. Based on the results obtained in Phase 1, Phase 2 aims to develop a model for implementing the innovation process in a civil construction company. Stage A of phase 2 seeks to develop a model for structuring the performance of the innovation process in order to allow for greater efficiency and to capture value due innovation. This step was based on the conceptual model of the Double Diamond (Design Council, 2016). The case study company has a corporate innovation strategy and has already been involved in a broad Lean Construction implementation project. Last year, it defined its objective as being to centralize its investments in improvements by strengthening the innovation process.

The Double Diamond model was proposed by the British Design Organization in 2005. The model emphasizes the analysis of a problem as the basis for building 4-phase solutions using two adjacent diamonds. The two diamonds are (i) the problem and (ii) solution spaces. In each space, a diverging phase that expands the space is followed by a converging phase that narrows the space (Zhang et al. 2019)

Finally, Stage B of Phase 2 seeks to understand if Lean Construction favors innovation. Thus, the third stage of the research aims to answer the second question by applying a questionnaire to those involved in Stage A, in order to capture perceptions and map possible benefits of or weaknesses in integrating Lean Construction into the innovation process.

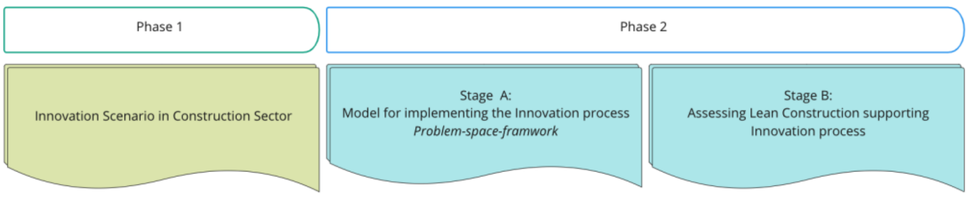

Figure 1: Structure of the Paper

RESULTS

Identification of the Scenario of Innovation in Civil Construction

The group of professionals chosen by the researcher was formed in order to elicit and add opinions and content about the object of study. Numerical representativeness is not the main focus, but it was considered important to have a diversity of respondents. By consisting of accelerator managers, innovation specialists and startup directors, the sample population is more likely to succeed in identifying gaps, generating insights and forming hypotheses. Thus, by adopting a qualitative approach, it is possible to explore the object of research in depth, because one can understand the cause-and-effect relationships and can seek ideas and new hypotheses (RIBEIRO and MILAN, 2004).

The interviewees were selected by the researcher who sought companies and professionals involved in the civil construction and engineering sectors, in innovation processes and who had taken part in founding startups in the sector. Eight interviewees were selected: (i) Two specialists in implementing innovation projects in engineering-based industries; (ii) Two managers of acceleration and open innovation programs, focused on the civil construction sector - the programs were selected considering that both had already concluded at least one complete cycle of acceleration; and (iii) Four Chief Executive Officers and founders of startups which have undergone at least one acceleration cycle and are already in the market operation phase. Choosing a startup was based on three criteria (a) it must be from the civil construction sector, (b) it already has a product, a Minimum Viable Product that has been validated, tested and is in the market phase, (c) it has undergone at least one full acceleration cycle.

The interviews were conducted, resulting in 6 hours of recordings. These recordings were transcribed into a text editor and compared to the notes of main topic notes made by the researcher during the interviews. After being transcribed, the interviews were prepared for analysis. Each of them was grouped according to the sequence of questions asked by the researcher using content analysis using the NVivo sotware

When questioning the interviewees about the perception of the innovation movement in Brazil, they all answered that it is a growing movement, but only one of the interviewees was openly optimistic: “I perceive that the movement has been gaining a lot of strength, but it seems to me that the people inserted (in startups, in companies and investors) are lost and so are the needs of the sector”. Five of the interviewees stated that it is up to companies and startups to better understand the pain-points of the sector to bring solutions that can add greater value to organizations: “The launch of a company as a result of a problem experienced, in my experience, is 50% of the success. Finding the problem is key to thinking about a solution.”

At the same time, six of the eight interviewees expressed apprehension regarding a certain trivialization of innovation and the loss of credibility of the proposed initiatives and solutions: “We are at a time when everyone has access to low-quality information, and therefore, there is much focus on "we need to innovate", "we need technology" without thinking about the real problem [...] There are solutions that generate zero value for the market. Not generating value compromises the fundamental objective of innovation processes. I fear the topic will become another "buzz-word" in the market. We must protect the innovation topic!”. Figure 2 shows the result collected from the content analysis of the interviews. All interviewees identify investments in innovation and the structuring of innovation processes in the construction sector are a growing movement, but they also associate the current situation with a certain pessimism. A large part of this sensation is due to the perception of the sector's difficulty in directing innovation actions and investments at the real problems and pain-points (six out of eight interviewees), which for also leads to the loss of credibility of innovation in the sector.

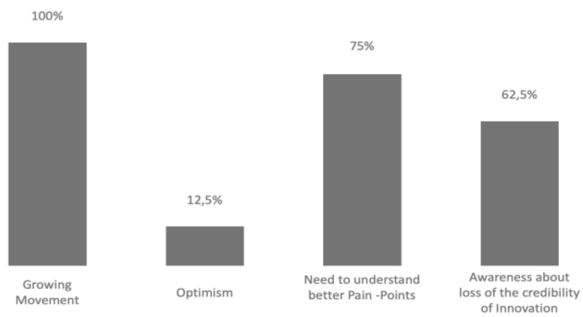

Figure 2: Perception of innovation in Brazil

Content analysis identified three main directions: (i) the movement towards innovation and access to new technologies is growing in the construction sector. However, (ii) there is a divergence between the interviewees about their perception of the value delivered by innovation initiatives and (iii) there is difficulty in measuring the results and impacts provided by implementing innovation in the construction sector.

Considering the above, two aspects can be raised that have an impact on the credibility and results of the solutions implemented in the proposed innovation processes analyzed. First, the gap in identifying the real pain-points or problems of the sector can make it difficult to understand what the innovation is (XUE et al., 2017, TAYLOR et al., 2006); second, the lack of definition of follow-up metrics and of a clear zero line distort, or make it impossible to understand, the result obtained.

MODEL TO IMPLEMENT THE INNOVATION PROCESS IN CONSTRUCTION SECTOR

The conceptual reference for the structure of the Workshop was that of the Double Diamond Framework. In the stage covered by this study, we are working on the first cycle of the diagram named Problem Space, seeking to Discover the problems and Define the actions. Figure 3 shows the association of the steps described with the Double Diamond Model.

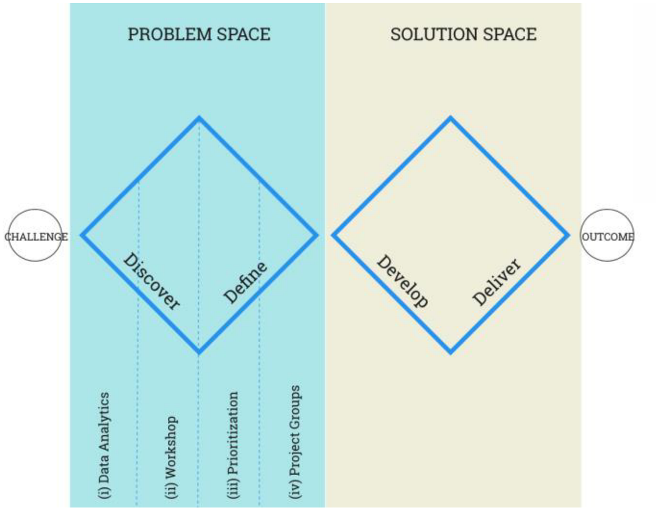

Figure 3: Double Diamond Framework adapted to the current research - Problem-space-framework (PSF)

Having obtained results from qualitative research conducted with specialists in the sector's innovation process, and having added these to the perception of a large-scale developer company in the Brazilian housing market, phase 2 of this study then set out to develop a model for guiding the innovation process of the company. To define this model, the current stage was divided into 4 sub-stages: (i) Preparation, carried out by collecting data and interviewing company representatives; (ii) Development and implementation of a model of a workshop on validating Pain-points; (iii) Prioritization of classification; and (iv) structuring of project teams to direct solutions to the Pain-points identified. For the first sub-stage, we made a comprehensive analysis of the company's budget, costs, and the performance of its supply chain. This involved a thorough examination of factors such as costs, savings, and construction terms. We also conducted open interviews with a group of site engineers and managers to gain a better understanding of the company’s current situation.”.

It should be noted that the company in the empirical study, which in this article is called Company A, has been investing for two years in a wide-ranging Lean Construction implementation project, a project that has already reached more than 150 construction sites. This consideration is important, as most of the leaders involved in this stage already participate in the Lean Construction project and are familiar with process design tools, how to identify causes and problem solving.

Company A has always held a prominent place in terms of innovation in the Brazilian Civil Construction market, featuring in important national awards (those given by the Brazilian sectorial journals); however, the team from the Innovation in Production sector has become aware of the difficulty of understanding, mapping and consolidating results of the multiple initiatives that were conducted. In addition, planning for the year 2023 required assertive investment planning in initiatives that addressed the company's real problems and pain-points. In numbers, the present situation covers 89 projects at some stage of implementation and with different levels of expected result and necessary investment, but without a clear governance to accompany them. Of this total of projects, 49 started from initiatives promoted by the Lean Construction project in the construction works. Nevertheless, their results have not been managed nor have the results and lessons learned from acting on these initiatives been disseminated throughout the company.

Considering the context described, we first sought to understand the main problems of Company A based on data analysis (Data Analytics) and interactions with the company's Production team. It is important to mention that the company has a large source of consolidated information in Data Analytics and Business Intelligence in Microsoft Power BI and a specific sector that guides the business strategy and compiles and publishes indicators of the productive processes. At the same time, a questionnaire was sent via Google Forms to those involved in the production process. 42 responses were obtained, 6 from directors, 11 from managers, 5 from engineers, 3 from Backoffice consultants and 17 from Lean Construction project consultants. As a way to ensure more managers listen to what kinds of problem occur during production, two online workshops were held attended by 15 engineers from the company. They listened to and discussed openly the main problems that impact their production activities. As output from these three sources of evidence, five pain-points were addressed: i) Quality of budgeting; (ii) Site productivity; (iii) Management of metal forms; (iv) Excessive bureaucracy for services and materials supply chain; (v) Terms in design and construction phases. Regarding the strategic position of the data for Company A, the pain-points could not be detailed in the current paper for reasons of confidentiality

This base of pain-points identified was presented and made available as a reference for the leaders group that was elected to participate in the 1st Workshop on Innovation in Production. 30 leaders (directors, managers and engineers) and 6 moderators participated in an immersive and face-to-face workshop held to reach a more detailed understanding of the production Pain-points of Company A in order to structure innovation project plans for 2023. The one-day Workshop was structured as per the sequence below. The outputs are shown in Table 1:

- (i) Pain-points brainstorming: based on the previous analysis of the data, the participants were divided into 5 working groups and by using mind maps or brainstorming dynamics they discovered the pain-points that they identified that impact production. In this stage, the groups mapped 98 pain-points;
- (ii) Prioritization of pain-points: in the second stage, the groups were asked to prioritize pain-points using an effort versus impact matrix. 26 pain-points were listed;
- (iii) Design-sprint for prioritizing pain-points: Each group took the pain-points prioritized in a table that was divided into 10 themes corresponding to Company A's enterprise cycle. which for them were the ones that had the most impact on production. 8 pain-points were prioritized;
- (iv) Linking projects in progress to the pain-points mapped: In the end, the 89 projects at some level of development and already distributed in the 10 themes of the company were made available to the groups The working groups then linked these projects to prioritized pain-points. Of the 89 initial solutions, it was found that 35 would address prioritized pain-points.

The third phase of structuring the innovation process consisted of analyzing prioritized outputs and understanding whether the projects really address the pain-points and which projects will be selected for the 2023 strategy. To do so, a senior management group was formed consisting of the Vice-President of the company, 5 directors and the Innovation team. The post-workshop stages first of all positioned the pain-points and solutions in the progress of the development project, from business planning and real estate development, through the pre-work stages and execution of the construction work, to the delivery and post-delivery technical assistance. A critical analysis of the 35 listed solutions was made to determine the degree to which they actually solve pain-points. Of these, 28 solutions can address 7 listed pain-points satisfactorily.

Table 1: PSF Workshop outputs

Phase	Mapped Pain-points	Linked Solutions
Pre-Workshop	5 Main Pain-points discovered	89 Projects
Brainstorming to identify Pain-points	98 Mapped Pain-points	
Matrix Prioritization	26 Prioritized Pain-points	
Design Sprint	8 Selected Pain-points	35 Potential Projects
Senior management group Analysis	7 Prioritized Pain-points	28 Potential Projects 4 working groups

Finally, senior managers deliberated on the progress of the undertaking, the pain-points identified and the related solutions. Of the eight pain-points identified in the Workshop, seven were prioritized by the senior managers. (1) and (2) are related with commercial strategy, (3) and (4) are related with budget information and accuracy; (5) is related with labor turnover; (6) concerns the planning and construction terms and (7) the effort and bureaucracy needed to control costs and monitor productivity. These seven pain-points were classified into 4 categories and addressed to 4 specific working groups.

It is important to note that there is a convergence of seven prioritized pain-points with those identified in the first stage of Discovery by consulting the analysis and data collection from Company A. Three of the five pain-points identified during the Pre-Workshop phase were maintained and attested to during the Problem Space (Data Analytics, Workshop, Prioritizing and Project Groups): Quality of budgeting, Site productivity and Terms in design and construction phases are still in the final seven main pain-points. The second stage of the Diamond, the Solution Space, is the subject of the next steps of this research.

INTERFACE OF THE INNOVATION STRATEGY WITH LEAN CONSTRUCTION

To meet the second specific objective, this section summarizes the analysis of a survey regarding the perception of possible contributions of Lean Construction in the innovation process. As a first output, 49 of 89 projects were identified with Lean Construction and possible solutions in progress came from approaches of operational improvements catalyzed by the Lean Construction Project, which shows the relevance of the philosophy applied. In the second moment, the participants were invited to fill out an online survey form in order to evaluate in the first stage the level of involvement in the Lean Construction project and then to evaluate to what extent Lean contributes to the participation, knowledge of tools and approaches proposed in the Innovation Workshops

The Form was sent to all participants of the Innovation in Production Workshop or any of its working groups. We had received 26 responses and among the respondents, 18 (69%) had also taken part in the Lean Construction implementation project. For these 18, the Form led them to a specific section with the aim of evaluating the Lean Construction project and its relationship with the Innovation Workshop. In the first question, 14 participants said that they had a high (44%) or very high (33%) level of involvement in the Lean Construction implementation project and assessed their knowledge of Lean as high (39%) or very high (33%).

In the question "In your opinion, how much did Lean Construction contribute to the development of Innovation in Production projects?" 16 participants (89%) answered that Lean's contribution to the Innovation Workshops was high (39%) or very high (50%).

In the third section of the Form, where all the participants responded, the aim was to evaluate their perceptions regarding the format, model, and methodology used in the Innovation in Workshop. The first question was to evaluate the Workshop. The answers were categorized as:

- Methodology, where 69% responded "Very Good" and 31% "Good";
- Tools presented, where 81% responded "Very Good" and 19% "Good";
- Moderation, where 69% responded "Very Good" and 31% "Good";
- None of the dimensions were evaluated by the participants as "Bad" nor did any participant respond that he/she was "Indifferent" towards a dimension.

The answers to the question "How do you evaluate your ability to use the tools proposed in the Innovation in Production Workshop?" are presented in Figure 4. Note that the 5 Whys and Problem-Solution Fit Canvas tools are the ones that were best evaluated i.e., the participant stated that his/her skill in using these tools was high. And the Cause and Effect Diagram and the 5 Whys are the ones which 95% of the participants demonstrated that their skill in using them was average or high. It can be seen that these are tools that interact very well with Lean and indirectly this may have influenced participants to consider they had mastered using them.

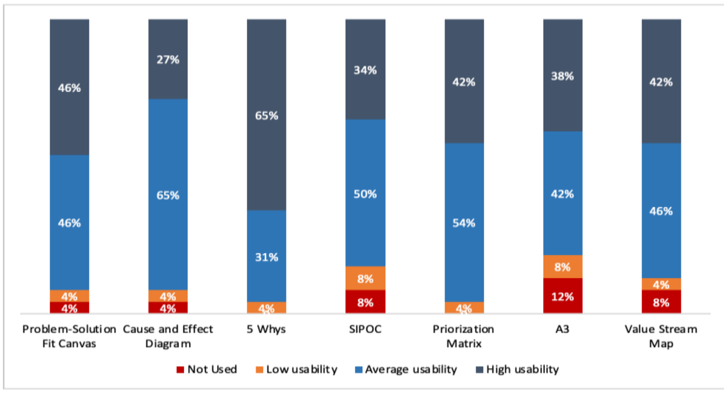

Figure 4: Usage of tools proposed in the Innovation Workshop

DISCUSSION AND CONCLUSIONS

Considering the main objective of this paper is to develop a framework to analyze and identify the pain-points as the starting point for the innovation process in construction companies, this objective was met. This was achieved by developing a model based on the Double Diamond that allowed Company A, in the case study, to direct its approach to a solution by basing it on a deeper understanding of the problem and of the pain-points of its processes and of the market in which it operates. The PSF presented seeks to deepen the understanding of pains by undertaking the steps of (i) conducting data analytics and promoting a collaborative understanding of identifying and mapping pains and by (ii) mounting a collaborative workshop. In the second dimension of the first diamond, we sought to define the focus problem through approaches of (iii) prioritization and (iv) definition of project groups and a work Roadmap. As already mentioned in the literature review, it is only by conducting organized and interdependent processes that significant improvements in performance due to innovation can be achieved in the construction industry and thereby enable the so-called "real problems" to be identified that support the definitions of greatest impact regarding innovation (Taylor et al.,2006; Xue et al., 2017). By providing a comprehensive understanding of pain-points and aligning them with a series of multi-collaborative workshop phases, the Framework focused on the Problem-space offers an innovative approach to the innovation process in the construction industry. This approach not only allows teams to address the real cause of problems more effectively, but also fosters a culture of collaboration and innovation that can drive long-term success. Figure 3 illustrates the PSF developed and validated in the case study. As results of applying the PSF, we have prioritized 98 pain-points and thereby reduced the number of main pain-points to 8 which will be directed as leverage for designing a solution.

The first research question was validated using qualitative analysis with interviews of experts, which showed that the construction industry is at risk of losing the benefits of its innovation processes and investments due to a lack of directing itself towards the pain points and problems of the sector. A lack of understanding of these pain points makes it difficult to measure and perceive the value of improvements made due to innovative initiatives. The use of discourse analysis revealed that this observation was the view of six out of the eight experts consulted.

Regarding the second research question, it was validated by the participants' perceptions during the Workshops and the proposed PSF that Lean Construction plays a significant role as a conceptual foundation and collaboration environment for fostering innovation. The results showed that 89% of the participants understood acknowledged that the Lean Construction project contributed to the Innovation Workshop, and 46% of them recognized that participating in Lean Construction routines was an effective way to prepare their teams for the Innovation Workshop. Furthermore, the participants evaluated all the tools used in Lean Construction routines as having a high or medium level of usability, with the 5 Whys and the Problem-Solution Fit Canvas standing out with 65% and 46% respectively of participants regarding them as having high usability.

It is worth emphasizing that the themes prioritized during the workshop phases are interconnected and cover the entire life cycle of construction projects, from commercial strategy to construction control. This holistic approach considers key aspects such as project design, budgeting, planning, and productivity in the field, and it recognizes the cause-and-effect relationship between decisions made in the early stages and their impact on construction sites. By taking this comprehensive view, teams are able to identify pain-points and develop effective solutions that drive long-term success.

Finally, while this study is part of a broader research effort and represents the initial exploration of a DSR approach, we can affirm the effectiveness of the proposed PSF framework. Although there may be improvement opportunities, such as to improve aspects regarding the prioritization tools and methods used, or the timing and duration of workshops, the results validate the model's efficiency both in prioritizing pain-points and in the perception of benefits by the teams involved. In line with our research plan and with the goal of continuously improving the model, we will conduct a further round of review and application of the PSF at Company A, to further validate the framework and explore its potential for implementation in other construction companies.

It is important to note the limitations of this paper, which is based on a single implementation cycle in one specific real estate company, that had undergone a Lean Construction project. This limitation is an improvement opportunity for future research as to implementing the PSF in different companies and also in those that are not working with Lean. Another important limitation is that, given the phase of the ongoing projects in the 4 working groups, it has not yet been possible to measure the effective results of the project. It is estimated that the first results will be measured at the end of the first 12 months after the workshop. Therefore, it is estimated they will become available in October 2024.

The use of PSF for defining the strategy for the Innovation process emphasized the significance of an unencumbered approach to innovation. The outcomes of the PSF emphasized that limiting the development of improvements can hinder progress in the innovation process. The 4 stages of the PSF strengthened the link between continuous improvement methods, such as those practiced in Lean Construction, and their relevance in the wider context of innovation.

ZOOMING INTO WORKERS’ PSYCHOLOGY AND PHYSIOLOGY THROUGH A LEAN CONSTRUCTION LENS

Lynn Shehab[1] and Farook Hamzeh [2]

ABSTRACT

Lean construction has long been a constant advocate for perceiving humans as the driving force for most ventures and projects. Among the enablers of investigating the potentials and capabilities of humans are wearable sensors for collecting physiological measurements. Current research on wearable sensors in construction has not yet touched on its applicability or integration with Lean construction. Therefore, this conceptual paper “zooms into the workers’ psychology and physiology through a Lean construction lens” by exploring the potentials of employing wearable sensors in Lean construction. It aims to revamp current applications of wearable sensors by providing a comprehensive overview of the current state of wearable sensor technology and its applications in the construction industry. It also discusses how current studies on wearable sensors may be linked to Lean construction principles and how Lean concepts can further enhance and foster their potentials. The paper concludes by presenting the future possibilities and directions of wearable sensors in Lean construction and the impacts they can have on the industry.

KEYWORDS

Wearable sensors, physiology, psychology, measurements, Lean construction.

INTRODUCTION

The seemingly inexorable march of new technologies has rendered some industries negligent of not only the wellbeing of humans, but also their unexploited potentials that got concealed under the new technologies’ alluring capabilities. Industry 5.0, a successor to Industry 4.0, has emerged as a supporter for human-centricity, sustainability, and resiliency, which have somehow been overlooked in Industry 4.0 (Leng et al. 2022). A long-standing advocate for human-centricity is Lean management generally, and Lean construction specifically, which bears “people” as a main pillar to its core people-processes-technology triad (Hamzeh et al. 2021). In fact, Lean construction explicitly considers “people” as a main element for the transformation culture that it promotes (Hamzeh et al. 2021). Several studies in the domain of Lean construction have integrated the human touch into their objectives, means, or concepts. However, this touch could pertain to interrelationships, partnerships, physical abilities, cognitive abilities, or more. One approach to this concept is the investigation and analysis of construction workers’ physical and cognitive abilities through digital technologies. Barbosa and Costa (2021) identified and analyzed the commonly used methods for measuring, analyzing, and improving construction productivity using digital technologies. Such technologies were

[1] PhD Student, Civil and Environmental Engineering Dept., Hole School of Construction Engineering, University of Alberta, Edmonton, Canada, lshehab@ualberta.ca, https://orcid.org/0000-0002-2708-3550

[2] Associate Professor, Civil and Environmental Engineering Dept., Hole School of Construction Engineering, University of Alberta, Edmonton, Canada, hamzeh@ualberta.ca, https://orcid.org/0000-0002-3986-9534

classified into several categories, including vision-based technologies, sensor-based technologies, and audio-based technologies. Perhaps sensor-based technologies allow for the most intricate exploration of the “people”, while still maintaining a non-invasive approach and healthy boundaries. A search for the term “sensor” on IGLC.net only results in seven studies; three of which refer to location sensors such as GPS and RFID technologies, two refer to visual management sensory aids, and one refers to the sensors that a human uses to capture stimuli in an environment as part of a biological mechanism. Only one study by Barbosa and Costa (2021) is related to wearable sensors for physiological measurements. While we might not be there yet in terms of exploiting the potentials of wearable sensors for physiological measurements in Lean construction research, the potentials of revolutionizing this field by intertwining Lean construction and wearable sensors – two independently powerful fields - is promising.

Therefore, this paper conceptualizes on sensor-based technologies in construction by conducting a conceptual walkthrough among extant studies utilizing wearable sensors for physiological measurements in construction and exploring potentials for exploiting Lean principles in this domain. Its objective is to provide research on wearable sensors in construction with a new insight through bridging extant research attempts in this domain to Lean concepts. In addition to embedding Lean concepts into previous studies, Lean theories and the perks that they provide are suggested to further refine future attempts. In this regard, several research questions are put forward and answered: (RQ1) What are wearable sensors and their usages? (RQ2) What studies employed wearable sensors in construction and what were their objectives? (RQ3) Which of the identified studies fall directly under the umbrella of Lean construction? and (RQ4) Which of the identified studies have objectives that fall under Lean construction goals?

This approach is established based on a distinction between two theories: Lean construction and the use of wearable sensors in construction. According to Lukka and Vinnari (2014), there are two types of theories: a domain theory and a method theory. A domain theory is a set of knowledge in an area of study with particular theories and constructs, while a method theory provides new insights into the domain theory to expand or offer an alternative explanation of its concepts. They also note that this distinction between the two theories is rather relative than absolute, and a theory may either be a domain or method theory depending on its role in the paper (Lukka and Vinnari 2014). As the scope of this study is to introduce Lean construction principles and tools as a novel perspective to the research on wearable sensors in construction, wearable sensors in construction are the domain theory that will be analyzed and have its concepts and applications re-evaluated through the method theory, Lean construction.

In the absence of studies utilizing wearable sensors in the context of Lean construction, this study contributes to the body of knowledge by proposing a new perspective to wearable sensor applications and possibly inspiring future research that bridges the two concepts. The paper starts off with a review on Lean construction principles, followed by a definition and classification of wearable sensors for physiological measurements, and a review on studies utilizing wearable sensors in construction. Finally, a bridging attempt between wearable sensors and Lean concepts is carried out. Final conclusions and future research recommendations are eventually proposed.

METHODOLOGY

As this conceptual paper aims to bridge existing theories in two separate contexts, the research methodology followed is theory adaptation. Theory adaptation papers “introduce alternative frames of reference to propose a novel perspective on an extant conceptualization” (Jaakkola 2020). The first step in theory adaptation papers is problematizing a particular concept (domain theory), followed by suggesting some perspective shifts to align the concept to its purpose by drawing from another theory (method theory) that is befitting to guide this shift (Jaakkola 2020).

Having already defined wearable sensors as the domain theory and Lean construction as the method theory of this study, wearable sensors in construction are investigated, and Lean concepts, principles, and tools are suggested to provide a perspective shift to wearable sensor applications. For this purpose, Lean construction principles and tools are discussed to establish a clear basis for the method theory. However, since the objective of this study is to correlate wearable sensors applications in construction to Lean construction, a thorough discussion of Lean construction principles will not be carried out. Instead, a cross-sectional approach will be adopted in an effort to provide a bird's-eye view of Lean construction. Afterwards, wearable sensors in general are introduced by defining and categorizing them. Research on wearable sensors in construction is then reviewed to provide better understanding of this domain theory in the context of construction. To conduct this review, keywords such as "sensor", "physiological measurement", "wearable", "EEG", "heart rate", "EDA", "eye movement", and "breathing rate" were searched for in databases from Google scholar and IGLC.net. Finally, Lean construction principles are used to propose a novel perspective on wearable sensors and their applications, in hopes of stimulating innovative future research for bridging the two theories.

LEAN CONSTRUCTION PRINCIPLES AND TOOLS

A study by Mossman (2018) aimed at answering the question "what is Lean construction?" and compiled results from previous presentations, research papers, and survey responses. One of the definitions described Lean construction as "an application to construction of a management ***philosophy*** defined by the ***ideal*** it pursues, the ***principles*** followed in pursuit of the ideal, and the ***methods*** used to implement the principles." Therefore, perhaps a good start for describing Lean construction without diving into trying to philosophize the ***ideal*** is through the 14 ***principles*** of the Toyota Production System elucidated by Liker (2004). Liker developed the "4P" model that divides the 14 principles into four categories: Philosophy, Process, People and Partners, and Problem Solving as shown in Figure 1. It is worth noting that the 4P model takes the shape of a pyramid, which implies that the foundation of the 14 principles is understanding and embracing the "Philosophy" and that the journey of adopting the principles is rounded off by a successful and perpetual approach of "Problem Solving".

Another famous concept in Lean is its approach towards eliminating three types of waste: Muri (overburden), Mura (unevenness or inconsistency), and Muda (waste) (Hamzeh 2009). Muri entails driving humans (or equipment) beyond their natural thresholds and can lead to safety issues and quality problems. It may be mitigated by ensuring proper process and resource planning (Hamzeh 2009). Mura in workforce (or materials) occurs in response to fluctuations in the process resulting from various factors such as unbalanced loads and highly variable demand (Hamzeh 2009). Muda may be identified as any element that increases cost in the absence of value creation, including workers waiting, unnecessary movement, unused employee talent, "making-do" or starting an activity before it is ready, and so on (Hamzeh 2009).

Moving forward with the elucidated principles, some of the Lean ***methods*** that offer process improvement and waste elimination include Bottleneck Identification and Analysis (BIA), Value Stream Mapping (VSM), Error Proofing (Poka-yoke), and Root Cause Analysis (RCA). In any system, the bottleneck is the subsystem that forms a point of congestion and limits the capacity of any system because of having lower efficiency than other subsystems. This renders the bottleneck the main determinant of the capacity of the system. Bottleneck identification provides the prospect of improving the process after pinpointing its source of impediment, and bottleneck analysis allows improving the system by analyzing the reasons behind the identified low throughput and drawing recommendations for improving its efficiency. An enabler for bottleneck identification and analysis is VSM, where all process steps necessary to transform raw materials into a completed product are visualized as a collection of value adding and non-value adding activities linked together (Liker 2004). VSM provides leeway to eliminate bottlenecks and wastes and to increase process flow and value. One way to minimize human errors in any process is "Poka-yoke" or error proofing, which refers to creative measures adopted to prevent errors committed by workers (Liker 2004). Liker (2004) also suggested that the 6th principle of the Toyota Way (standardized work) is a poka-yoke measure as it pertains to tailoring and continuously updating the "standard work chart" to incorporate error-proofing measures. Another view could be the learning curve associated with standardized work, which in turn could minimize errors among workers through unconscious execution of repetitive and previously verified procedures. Finally, RCA fosters searching for the root cause of problems rather than the source, as the root cause often lies beyond the source (Liker 2004). Toyota's problem solving process includes perceiving the initial problem, clarifying it, locating the point of cause, performing root cause analysis, implementing countermeasures, evaluating them, and finally standardizing the process (Liker 2004). Root causes for inefficiencies in a process could go beyond equipment or materials, as human factors could play significant roles in this aspect.

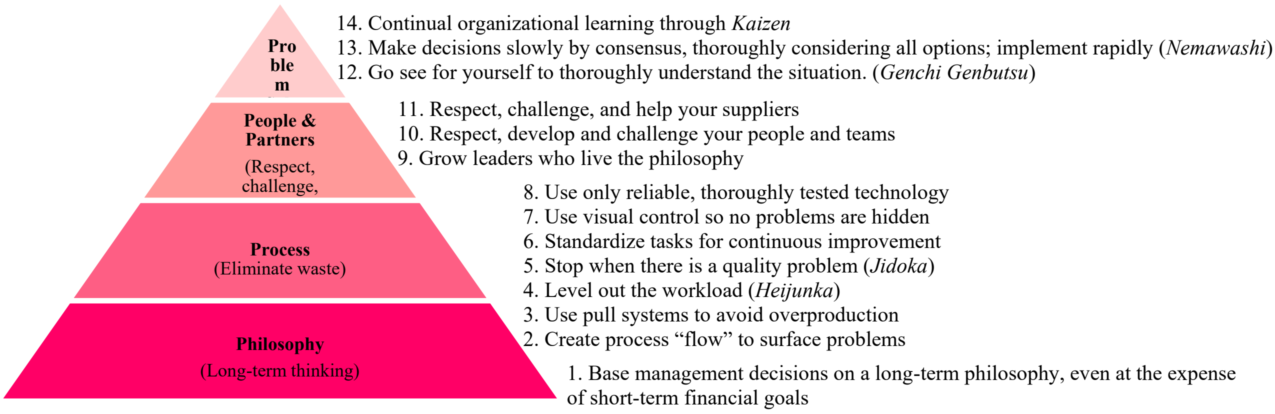

Figure 1: The "4P" Model of the Toyota Way (Liker 2004)

WEARABLE SENSORS FOR PHYSIOLOGICAL MEASUREMENTS

The advancements in wearable technologies have enabled the introduction of real-time wireless sensors for physical and physiological measurements into various industries including healthcare, sports, manufacturing, and construction. Wearable sensors for physiological measurements vary in terms device size, point of application, subject body part, and target measurement. A discussion of the available wearable sensors is carried out to classify the different sensors into categories pertaining to target body parts and target measurements.

Starting with the brain of the human body, electroencephalogram (EEG) devices are used to collect electrical signals created by the activity of neurons near the surface of the brain (Giannakakis et al. 2019). They measure the electrical current fluctuations between the EEG sensor electrode and the skin and amplify these fluctuations before performing any necessary filtering. EEG headsets are available in wired and wireless options and require a consistent electrical connection between the scalp of the subject and the electrodes (Giannakakis et al. 2019). Research has shown that EEG measurements are considered a reliable indicator of mental stress, fatigue, arousal, or psycho-emotional states. Moving to the eyes, eye-tracking sensors are typically used to measure blink counts, eye fixation times and counts, and pupil diameter. Eye blink rate has been analyzed and used by researchers as an indicator of stress in humans, while fixations are the time periods between eye movements when the eye stops at a specific position, and they reflect gazing on an object of interest and can be used to indicate situational awareness or stress. Pupil diameter was proven to indicate processing load and mental effort being exerted by the subject. Eye-tracking has generally been used by researchers in various domains such as risk perception (Hasanzadeh et al. 2017a) and human-computer interaction (HCI).

Heart measurements are arguably some of the most commonly collected measurements, and they include measuring the heart rate, the electrical activity of the heart through electrocardiogram (ECG) devices, and the volumetric change of the blood in the heart through photoplethysmogram (PPG) devices. Heart rate is the number of heart beats per minute, and it is used as an estimate of levels of stress (Giannakakis et al. 2019). Heart rate variability is another measure that is the distribution of the RR interval (interval between consecutive heart beats), and it is considered a valid indicator for stress. ECG, on the other hand, is the signal of the electrical activity manifesting in the heart's contractile activity (Giannakakis et al. 2019) and has been linked to stress in various studies. Finally, PPG is a non-invasive technique used to monitor changes in the blood flow in the cardiovascular system. It is based on illuminating tissues with a specific wavelength and measuring the reflected light (Banerjee et al. 2017). It has also been used to evaluate stress among subjects (Giannakakis et al. 2019).

Another vital component of the human body is the lungs, from which respiration or breathing rate may be measured. Respiration is the rate or volume at which humans exchange air through the lungs. Changes of respiration are observed with changes in the subject's emotional states, where respiration increases with emotional arousal, decreases with relaxation, and undergoes momentary interruption with tense situations (Giannakakis et al. 2019).

When it comes to limbs, movements and muscle electrical activity have been perceived as two significant measures that can help indicate psychological states among subjects. Limb movements are classified into upper and lower body movements, with upper body movements being positively linked to stress levels (Giannakakis et al. 2019), while lower body movements being linked to subjects' safety behavior due to their cyclic nature (Sun et al. 2020). Inertial Measurement Unit (IMU) sensors or motion suits track body motion by being attached to the subject's body. They have been used for various purposes including workers' safety and level of exertion (Ryu et al. 2020). Muscle electrical activity, on the other hand, is measure using electromyogram (EMG) devices. EMG devices measure a muscle's myoelectric activity to assess physical loads acting on a muscle. They are commonly used to evaluate the causes and potential interventions for work-related musculoskeletal disorders (Al-Qaisi et al. 2021).

Finally, the human body's largest organ, i.e., the skin, has also been a target for researchers attempting to identify stress among subjects by measuring the skin temperature and the electrodermal activity (EDA). Generally, variations in the temperature of the skin have been associated with anxiety and stress conditions and are measured at different body parts, such as the finger, face, or arms. EDA is the measurement of the electrical flow through the skin surface and has been extensively linked to stress measurement (Giannakakis et al. 2019).

WEARABLE SENSORS IN CONSTRUCTION RESEARCH

Construction research has been successful in adopting real-time measurement of physiological factors among construction workers using wearable sensors. Such adoptions vary in terms of target measurement, used sensor, human factor, and study objective. Table 1 represents a summary of a review of studies that have adopted this approach in the construction industry. For each study shown in Table 1, the target measurement and the sensor used to measure it are shown, in addition to the human factor that was investigated in the study in terms of measurement, prediction, or detection. Table 2 shows the objectives of the identified studies.

Table 1: Summary of Select Studies Employing Physiological Sensors in Construction

Study	Target Measurement	Sensor	Human Factor

Table 2: Objectives of Select Studies Using Physiological Sensors in Construction

Study	Objective
(Al Jassmi et al. 2019)	To assess the ability of capturing the effect of construction workers' happiness on their productivity using physiological signals.
(Anwer et al. 2021)	To establish absolute and relative reliability of textile-based wearable sensors to monitor physical fatigue during bar bending and fixing construction tasks.
(Aryal et al. 2017)	To show that physical fatigue in construction workers can be monitored in real time using wearable sensors.
(Chen et al. 2017)	To measure task mental load using EEG and explore the possibility of assessing the cognitive/mental workload of construction tasks through EEG
(Choi et al. 2019)	To show the feasibility of using wearable sensors to understand workers' perceived risk in construction sites continuously.
(Dzeng et al. 2016)	To compare the search patterns of the experienced and novice workers using an eye-tracker by creating a digital building construction site and designing a hazard-identification experiment involving four workplaces featuring obvious and unobvious hazards (e.g., falls, collapses, and electric shocks
(Hasanzadeh et al. 2016)	(1) To identify workers with lower situational awareness (SA) and pinpoint opportunities to provide proactive training and develop guidelines for workers that will reduce human error and accidents; (2) To measure the same workers' SA level after training to determine if their SA improved
(Hasanzadeh et al. 2017a)	To provide a proof of concept that certain eye movement metrics are predictive indicators of human error due to attentional failure and use these findings to identify at-risk construction workers, pinpoint required safety training, measure training effectiveness, and improve future personal protective equipment.
(Hasanzadeh et al. 2017b)	To demonstrate the potential application of eye-tracking technology in studying the attentional allocation of construction workers and to show that eye tracking can be used to improve worker training and preparedness.
(Hwang et al. 2018)	To investigate the feasibility of measuring workers' emotions in the field using a wearable EEG sensor.
(Jebelli et al. 2018)	To improve workers' safety, health, wellbeing, and productivity through the early detection of workers' stress
(Jebelli et al. 2019)	To enhance workers' health, safety, and productivity through early detection of occupational stressors on actual sites.
(Lee et al. 2021)	To provide a new means of automatic, continuous, objective, and non-invasive method for monitoring construction workers' perceived levels of risk
(Lee et al. 2017)	To examine the reliability and usability of wearable sensors for monitoring roofing workers' on-duty and off-duty physiological status and activities.
(Plarre et al. 2011)	To propose, train, and test two models for continuous prediction of stress from physiological measurements captured by unobtrusive, wearable sensors and provide the first classifier of stress that can be readily used in natural environments without pre-calibration
(Ryu et al. 2020)	To provide an in-depth understanding of the linkage between body loads, work experience, techniques, and productivity.
(Sun et al. 2020)	To demonstrate the potential of using wearable sensors to identify workers with personality traits associated with unsafe behavior.
(Umer et al. 2020)	To highlight the advantages of using combined cardiorespiratory and thermoregulatory measures to enhance modelling physical exertion using machine learning algorithms.
(Wang et al. 2019)	To propose a new hybrid kinematic-EEG data type and adopt wavelet packet decomposition to compute the vigilance (risk perception) measurement indices with the

	redefined EEG sub-bands.
(Wijsman et al. 2011)	To detect mental stress by measuring physiological signals using a wearable sensor system

WEARABLE SENSORS FROM A LEAN CONSTRUCTION PERSPECTIVE

It is rather evident that all of the mentioned studies do not bear on Lean construction in terms of directly stated objectives or methods. A search for the terms “Lean”, “Kaizen”, “Toyota”. “Value Stream”, “Root Cause”, “Bottleneck”, or “Proofing” gives back zero results. An inspection of the stated objectives and methods also verifies the lack of link between the studies and Lean.

Liker (2004) referred to “Lean Company X” that claimed to be Lean but ended up being in need for radical improvements to attain the “Lean” attribute. On the other hand, a company can foster the same principles that Lean promotes and employ the same methods and techniques for improvement and control as those adopted by Lean but not identify as a “Lean” company. An analogy between the given example and the current situation of research on wearable sensors in construction and their remoteness from Lean may be drawn. Despite not being referred to as studies in the field of Lean construction, all of the mentioned studies hold Lean principles and goals, such as enhancing safety and the wellbeing of workers, improving productivity, and matching the load to the capacity of the workforce. To further reinforce this view, a bridging attempt between the studies and Lean principles and methods is carried out. In this attempt, every Toyota Principle addressed in each of the identified studies is listed. Additionally, each type of waste among the three wastes identified in Lean (Muda-Mura-Muri) that the studies attempt to eliminate is also listed. Finally, for each study, the Lean tool or technique that may complement the study’s objectives is identified.

All of the identified studies mentioned in Table 1 were found to address Toyota’s principles 1, 5, 8, 12, and 14. Principle 1 calls for basing decisions on long-term philosophies, even at the expense of short-term financial goals. As all studies utilize wearable physiological sensors, it is no secret that some financial compromise is expected from organizations that are willing to invest in some wearable sensors or collaborations with other organizations offering services in this area. However, such investments guarantee financial gain from productivity improvements among construction workers, as all studies have successfully proven a direct negative relationship between physical fatigue and productivity. Principle 5 promotes building a culture of stopping to fix problems. By analyzing physiological measurements and deducing productivity and safety performance, organizations are enforcing a culture of direct intervention when workers’ physiological statuses indicate unsatisfactory conditions. This would not only enhance the workers’ safety and wellbeing, but also improve their productivity and the overall project performance. As for principle 8 calling for using reliable technologies that serve the people, all studies employ verified sensors whose primary goal is to serve the mental and physical wellbeing of the workers. Regarding principle 12, it encourages organizations to monitor the process closely and personally, and what better way could this concept be implemented other than by collecting and analyzing the workers’ physiological and psychological statuses to ensure their mental wellbeing and physical safety are maintained? Finally, principle 14 entails maintaining a culture of continuous learning and improvement or “Kaizen”. By “zooming into the minds and bodies of construction workers” which are in daily variation, we would be instilling the belief that continuous monitoring and learning about the workers’ physiological and psychological statuses are essential for improving the performance of the project, leading to a notion of continuous improvement among all organization members.

Studies addressing risk perception based on eye movements touch on principle 7, which promotes using visual controls to unhide all problems in the process. This link is established through the studies' aim to track eye movements to monitor if and how safety hazards are detected by the subjects. By doing so, they are fostering the importance of visual control in detecting and unhiding risks that may face workers while performing their work.

When it comes to how the selected studies attempt to eliminate any of the three wastes through their objectives, Muda, which is any kind of waste in the process including inefficiency in the workers' efforts, may be considered a prevalent target among all studies. Fundamentally, all of the included studies have one common vision: enhancing construction workers' productivity; some achieve this goal by focusing on stress, mental load, or emotional state, while others achieve it by focusing on physical fatigue or risk perception. When it comes to Muri, or overburden, if perceived from a human-oriented lens, it directly signifies physical or mental overload. For example, studies addressing physical exertion or fatigue may be linked to Muri in terms of their approach to matching task physical loads to the workers' physical capacities, from which their study objectives originated. This also applies to studies addressing mental stress, which arise from tasks' mental loads overpowering workers' mental capacities. Finally, Mura, or unevenness, is mainly manifested in studies that also exhibit Muri-elimination approaches. In fact, Muri is often described as overburden resulting from Mura, which further reinforces this concept. Table 3 summarizes the human factors and the sensors that can be used to identify them and maps them with the discussed Lean concepts in order to visualize the embedded links between the two topics.

Table 3: Mapping of Human Factors, Sensors, and Lean Concepts

Human Factor	Sensor	P1	P5	P7	P8	P12	P14	Muda	Muri	Mura
Stress & Mental Workload	PPG – EDA – EEG – ECG – EMG - skin temperature - ambient temperature – accelerometer - respiration sensor	X	X		X	X	X	X	X	X
Safety & Risk perception	EEG - EDA – PPG - accelerometer - thermopile - eye tracking sensor	X	X	X	X	X	X	X		
Fatigue	EEG - ECG – PPG – thermopile - breathing rate monitor -heart rate monitor	X	X		X	X	X	X	X	X
Happiness	PPG – EDA – thermopile - heartrate monitor - breathing rate monitor	X	X		X	X	X	X		

INSIGHTS AND GAPS

So far, means of utilizing wearable sensors for physiological measurements have been analyzed from the perspective of their potential to revolutionize the area of Lean construction by providing valuable insights into workers' physiological and psychological statuses on the jobsite. However, by switching the lens to analyzing how Lean construction can complement research advancements employing wearable sensors, some key areas where more research is needed to optimize wearable sensor applications in construction are identified. For example, the **standardization of physiological measurements** is vital for ensuring the viability of this approach. Currently, there is no standardization of the type of physiological measurements that should be collected or the method of data collection, which can complicate the comparison of the results between studies and drawing meaningful conclusions. As a major promoter for standardization, Lean construction can help address this limitation by providing guidelines for the measurement and collection processes. In fact, in the discussion of the 6th Toyota principle, Liker (2004) states that "today's standardization is the foundation on which tomorrow's improvement will be built". By standardizing (1) the set of sensors to be used collectively and (2) the method of data collection based on verified studies and analyses, a reliable standard for similar studies adopting this approach can be developed. Another concern is the **integration of wearable sensors into construction workflows**, such as how to minimize disruption to work processes, how to manage the data collected, and how to ensure that the sensors are used consistently and effectively. Many studies in Lean construction have addressed measuring and optimizing workflow in terms of value, labor movement, and design. Such approaches may be adopted to tackle this limitation in the integration process of wearable sensors with Lean construction. Above all, **ethical and humane considerations** such as sustaining the human touch, privacy, and the use of the data for performance management represent additional concerns. With Lean construction's notion towards a human-centric approach in construction 4.0 technologies, unconscious consumption of technological advancements that may backfire and corrupt the construction industry is resisted (Noueihed and Hamzeh 2022). Attempts to demarcate the expansion of technology and its uses in construction are constantly being evoked within the Lean construction community, which can address the concerns around disregarding the ethical aspect of employing wearable sensors in the industry.

CONCLUSION

Most studies using wearable sensors in construction identified their objectives and means from a general productivity or safety standpoint. However, further meta-analysis brings uncovered relationships between these studies and Lean construction to light. This study relates wearable sensors in construction to Lean principles as an initiative to bring about innovative research approaches in this domain. Upon exploring some Lean concepts such as Toyota's 14 principles and the three types of waste, evident links between them and the objectives of existing studies on wearable sensors can be drawn. Results showed that all of the identified studies specified objectives that directly pertain to five of Toyota's principles, while some studies specified objectives that pertain to one additional Toyota principle. Additionally, Muda was a common target among all identified studies to be eliminated, while Muri and Mura were a common target among those pertaining to mental and physical workloads. This conclusion addresses this study's fourth research question as to which of the identified studies have objectives that fall under Lean construction goals. From a different standpoint, a brief analysis on how Lean construction can help foster the utilization of wearable sensors in construction is presented.

This study sets a cornerstone for future research that could use the advancements provided by wearable sensors and put them into use from a Lean construction perspective. Future research could develop conceptual models or frameworks for the use of wearable sensors in a Lean context by systematically specifying steps and measures to be applied for successful implementations. Future studies could also highlight the challenges and opportunities that come with the implementation of wearable sensors in Lean construction, including issues of data privacy, accuracy, and compatibility. Furthermore, from an opposite perspective, wearable sensors can help enhance Lean construction research approach by providing real-time data, improving worker safety and productivity, and reducing waste and errors. Further analysis on this subject may be conducted to reinforce the built connection between the two topics.

A CONSTRUCTION INFORMATION SYSTEM AS A LEAN INFORMATION MANAGEMENT ENABLER – CASE STUDY

Yanh Ribeiro[1], Jorge Teixeira[2], Pedro Mêda[3], Joaquim Moreira[4], Rui Sousa[5], and Hipólito Sousa[6]

ABSTRACT

Information Management Systems, or just Information Systems (IS), are important platforms to manage processes with a large volume of information exchange, guaranteeing the appropriate flow of accurate information. In the Architecture, Engineering and Construction (AEC) industry, the use of information systems is still modest in contrast with the volume of data produced in the industry. However, with the advance of the digital transformation of Construction 4.0, this information gains even greater prominence and can be considered the most valuable asset during construction phases such as Pre-design, Design, and Procurement. Lean Information management is the application of lean thinking to information management, where the information can be considered a value and able to flow, removing waste, pull, and being in the process of continuous improvement. This paper presents an analysis of an Information Management System, ProNIC, intensively used and endorsed in Portuguese public construction contracts. Originally conceived to add value to the end-user (customer), the Portuguese Government, ProNIC is now being assessed as an enabler of lean processes in the management of construction information.

KEYWORDS

Information systems, lean construction, digitization, process, enabling lean

INTRODUCTION

Information is a critical resource for the efficiency of today's businesses, and their management systems are essential for the performance of organizations that depend on knowledge. Information management can be defined as the activities that involve the creation, presentation, organization, maintenance, visualization, reuse, sharing, communication, and disposal of

information. Information can be considered as value, due to the way it is processed and flows to the end user through the exchange, sharing and collaboration procedures. (Hicks, 2007).

Lean information management (LIM) is a concept that links two well-established fields in the literature: Lean thinking and information management. The objective is to improve the flow of information by eliminating or reducing waste and non-value-added activities (Teixeira et al., 2019). Therefore, Information Management Systems, or just Information Systems (IS), are the key to treating information with proper value, managing it, and getting it flowing, with due relevance and at due time.

In AEC industry, data waste or inefficient flow can potentially causes loss of important information, rework due to missing or outdated information, delays due to waiting for information, and unnecessary processing of information, among other wastes (Ré & Teixeira, 2018; Tribelsky & Sacks, 2011). There are a large number of different IS that process business information, such as financial, payroll, customer relationship management (CRM), product data management (PDM), and inventory management systems (Hicks, 2007), However, a range of technical information is neglected by the more spread systems, such as design information, which requires specific treatment (Ahankoob et al., 2020).

ProNIC (Portuguese acronym for Construction Information Standardization Protocol) is a construction information system that manages specific information from the construction process (Sousa et al., 2012). The origin of ProNIC comes from the Portuguese Government awareness that there was a lack of standardization on construction projects at the bill of quantities level, as well as flaws at the specifications level supporting the design stage documents (Mêda, Calvetti, Ribeiro, et al., 2021) . Therefore, ProNIC was conceived from the perspective of client improvement, specifically the Portuguese Government. From this evaluation, it is possible to envision that ProNIC can act as a Lean Information Management enabler, even though it was not originally designed in this context.

The analysis of construction information from a lean perspective is necessary to recognize the function fulfilled by the IS themselves under managed information. Analyzing the performance of these systems under a lean vision will enable continuous improvement of the processes involved.

BACKGROUND INFORMATION

LEAN INFORMATION MANAGEMENT

Lean Manufacturing was developed from Toyota Production System (TPS) to increase the competitiveness of the automotive company (Womack & Jones, 1997).

Taiichi Ohno, a Toyota engineer and executive, started the TPS application, by identifying seven types of waste found in any process, and Womack & Jones (1997) added the eighth waste: **Transportation**; **Inventory**; **Motion**; **Waiting**; **Overprocessing**; **Overproduction**; **Defects**; **Underutilization of people**. To prevent, reduce, or eliminate the above-mentioned waste, five Lean principles have been defined, which are (Hicks, 2007; Womack & Jones, 1997): **Specify Value**; **Identify the Value Stream**; **Flow**; **Pull;** and **Pursue Perfection**.

These principles can also be applied to information flows. Ensuring that useful information is produced promptly and made available only to the right people at the right time is the goal of information management. However, waste in the context of information management is less clear and is generally not as visible (Hicks, 2007).

The waste in the context of information management is related to the downtime or additional activities that are a consequence of not providing the stakeholder with the necessary information with immediate access, in a simple, accurate and updated way. Like lean thinking in the manufacturing context, lean in information management is about identifying and enabling improvements in the flow of information, eliminating, or reducing waste in the various aspects of information management. The objective, as in manufacturing industries, is that these improvements are reflected in efficiency, productivity, overall process and product quality, also by allocating specialized human effort where value is added to the final product (Hicks, 2007). The waste associated with the information flow may include the effort necessary to overcome difficulties in retrieving or accessing information, or in activities that require the confirmation and the correction of inaccurate information. The principles that LIM considers are:

- the information should only be created if it is useful to decision-makers (add value).
- the information should only be sent to those who need them.
- the information should be quickly processed, preferably in real-time, avoiding waiting on the part of the users; and
- the information should be provided by sources without duplication of data.

So even though the concepts have originated in the field of production processes, it is possible to apply Lean principles to information flow processes. The following are examples of how Lean waste can be understood for information flow (Ré & Teixeira, 2018):

1. **Transportation**: consists of the unnecessary movement of information between various sources, manifesting itself, for example, in the re-insertion of information, due to incompatibility of systems or resistance in the use of IS.
2. **Inventory**: supplying more information than is necessary for decision-making at a given moment. In practice, it may also refer, for example, to information that although it exists, is not in the right place, conditioning the execution of certain activities due to lack of information.
3. **Motion**: consists of unnecessary steps to collect information that is not easily accessible.
4. **Waiting**: refers to the time it takes to obtain information, reflected in the time that a task or process cannot be carried out due to lack of information.
5. **Overprocessing**: related to the lack of information and the activities required to fill that lack, which may include the creation of new information or the identification of additional information.
6. **Overproduction**: all the effort devoted to identifying valuable information due to the high volume of existing information, much of it worthless.
7. **Defects**: consists of inaccurate, wrong, outdated, or incomplete information.
8. **Underutilization of people**: consists of the incorrect use of an organization's human resources, due to inadequacies in the processes or in the information itself.

PRONIC

ProNIC – Protocolo para a Normalização da Informação Técnica na Construção (Portuguese Construction Information Standardization Protocol) – is a computer platform initially developed in 2005 – 2008 to promote the standardization of technical contents for the construction of buildings and road works, supported by the Portuguese Government. It quickly grew in scope and functionality, allowing collaborative work, delivering high-quality Bill of Quantities (BoQ) from standardized, comprehensive work break-down structures (WBS), and possessing an organized document repository that could aggregate information throughout the construction process, including managing the monthly measurement reports of the construction phase, as well as producing a variety of indicators and metrics (Mêda, et al., 2021). It was also compliant with the newly launched CCP – Código dos Contratos Públicos (Public Procurement Code), and has been heavily used by Parque Escolar, EPE – a public company overseeing a very large, ongoing, high-school renovation campaign in Portugal (Mêda & Sousa, 2016).

ProNIC perform document collection, storage, management, and sharing functionalities that work exactly like a **Common Data Environment (CDE)**, even before this concept became widespread due to its use for BIM projects (Mêda, et al., 2021). A CDE is a central space for collecting, managing, evaluating, and sharing information. All stakeholders can obtain information and store their data concerning the project in a single environment. The CDE also allows the creation of models for coordination, partial models, databases, and documents for specific phases of the construction process. In addition, the CDE leads to a higher rate of information reuse, simplifies the aggregation of information models, and simultaneously serves as a central archive for documentation (Preidel et al., 2016).

Figure 1 summarizes the processes supported by ProNIC. For the project phases indicated, the listed stakeholders undertake the corresponding activities in the system, promoting the standardization of information throughout the process.

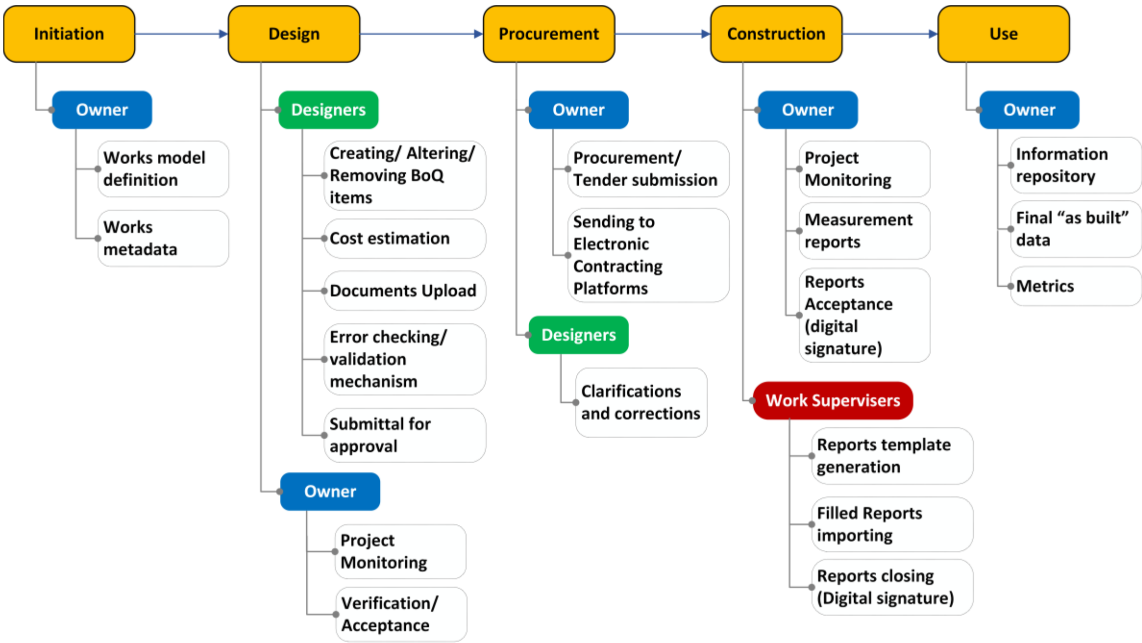

Figure 1: ProNIC Process Overview

Within the scope of the REV@CONSTRUCTION Mobilizer Program (https://revconstruction.pt/), aiming at accelerating the adoption of Construction 4.0 in Portugal, ProNIC is currently being updated: its IT platform is being redesigned and its technical contents are being revised, in order to prepare ProNIC for a new phase within Construction 4.0. New functionalities, such as integration and interoperability with BIM models, a cost database, new classifications tables related to the construction process, and BIM object libraries are being planned for future implementation (Mêda et al., 2016). This evolution is also being designed under a lean perspective to deliver continuous improvement not only in the System itself but also in the processes related to it.

METHODOLOGY AND RESEARCH QUESTIONS

This study grounds a critical analysis of construction project processes performed by different agents considering the support or not of information management platforms. The findings and intuitions are evaluated by facing the basic principles of lean and Lean Information Management. ProNIC is used as the case study to observe improvements in the processes, as shown in Figure 1: ProNIC Process Overviewin terms of information flow, work overload reduction, and suppression of activities not adding value.

The research is motivated to provide answers to the following questions: Can a construction Information System be a tool promoting Lean Information Management? What Lean thinking improvements has ProNIC implemented? How can the processes performed by ProNIC be further improved based on Lean Information Management?

FINDINGS

COMMON DATA ENVIRONMENT

The Common Data Environment feature plays a central role in the operation of ProNIC as an information manager. The research conducted found that, as a CDE, ProNIC follows Lean thinking in the aspects shown in Table 1.

Table 1: Lean Wastes and Benefits of ProNIC as a CDE

Lean Wastes	ProNIC Benefits
Transportation	A single "information container" where all files must be, eliminates the need for the same information to be addressed to all stakeholders.
Inventory	Organizing the files in a predefined directory structure makes it possible for a file to be available only in the right place, in the right version, avoiding being available in multiple versions and multiple locations.
Motion	According to the information above, simply organizing the files eliminates steps such as contacting the responsible parties to request information or confirming that the available version is the current one, for example.
Waiting	All current information is available to all necessary stakeholders at the time it is loaded into the system.
Overprocessing	Using the directory structure you can check the currently available version, and if in doubt you can avoid the trouble of checking and evaluating what is available, for example.
Overproduction	No effort is devoted to searching for valuable information among the vast amount of existing information, much of which is not important.
Defects	Only the current information is available. This is sufficient to ensure that no outdated versions can be used, preventing defects in subsequent processes.
Underutilization of people	The efforts expended for all information organization are usually skilled professionals' time spent on activities with low or no added value.

Therefore, the CDE provides gains in the entire ProNIC process under the Lean perspective. Schimanski et al., (2021) conclude that there was greater confidence in the reliability of the information used in a project when using a CDE workflow, including regarding the conjunction of Lean Construction techniques.

OWNER

The Portuguese government was the one that initially demanded to use ProNIC. Therefore, its functionalities were designed to improve the flow of information related to this specific client. However, only with the in-depth use of Parque Escolar, EPE, the Owner's current scope was defined, with all the phases and activities performed shown in Figure 2.

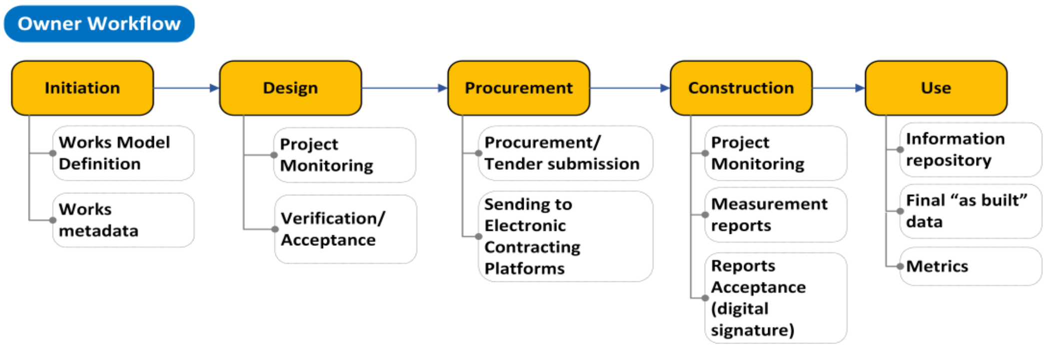

Figure 2: ProNIC Owner´s Workflow

The most relevant flows benefited were:

Works Model Definition/ Works metadata: The Owner defines the Work Model, with information such as Construction Type, Intervention Type, Construction Units, etc. This information is available to the project team at any time from the beginning of the process, avoiding delays in defining information, overproduction of elements with wrong data, and especially minimizing defects in the compatibility of disciplines.

Project Monitoring: In agreement with the CDE definitions, the necessary information for monitoring is always available in its current version, avoiding waiting, searching for information, confirmation of versions, and updates.

Verification/ Acceptance: The confirmation of the reception of the projects, properly formatted to meet the legal requirements, guarantees that the process will only move forward with all the necessary information, avoiding the production of elements not needed at the moment, eliminating the need to search for these projects, move them, store them in intermediate directories, reducing the work of the specialized team with non-technical functions.

Procurement/Tender submission/ Sending to Electronic Contracting Platforms: Like the reception and fulfillment of legal requirements, the tender submission and sending to the contracting platforms benefits from the organization of pre-determined files facilitating the management of the information needed for submission.

Construction Management: The automatic emission of the measurement reports for those involved in the process (Contractor, Supervision, and Owner) avoids divergence in the information, simultaneous verification, and promotes compliance with legal limits regarding modifications of the contract and other legal requirements.

In terms of Lean Wastes, Table 2 shows a summary of the benefits of ProNIC to the Owner.

Table 2: Lean Wastes and Benefits of ProNIC to the Owner

Lean Wastes	ProNIC Benefits
Transportation	Taking advantage of ProNIC's CDE role, the information needed for legal purposes is organized in its respective directories as soon as the appropriate versions for these uses are available, with no need for movement between directories.
Inventory	Once again, the CDE role allows the elimination of intermediate directories to organize files for submission to platforms, provisioning, validation, and other legal provisions.
Motion	The ease of access to information by the owner, with directories organized for the proper uses, avoids unnecessary steps for collecting the correct information.
Waiting	The request for information is one of the primary causes of waiting. Immediate access to all current information by the owner eliminates this wait.
Overprocessing	The predefined structure of the documentation directs the need to create files

	with only the information needed for the procedure at hand.
Overproduction	There is no need to search for information needed for procedures.
Defects	The owner can monitor the entire process, have access to intermediate versions, control demands, and pull production enabling a correct flow of information, without defects, outdatedness, or incompleteness.
Underutilization of people	The team allocated by the owner for process monitoring oversees technical and management checks, releasing them from the role of mere file organization.

In conclusion, the owner mainly benefits from ProNIC's CDE functionality to achieve a better flow of information. It is worth noting also that the workload at the end of the processes for preparing files and information for tender no longer exists with the automation provided by ProNIC.

WORK SUPERVISORS

The role of the work supervisors in the execution of Portuguese public contracts is linked to the owner, and consequently, the activities performed regarding measurement reports are related to the owner's project monitoring activities. Therefore, the analysis made above for the owner, concerning construction management, can be equally replicated for the supervisors.

DESIGN TEAM

Since a traditional AEC design project contains two major groups of documents, Drawings, which provide a complete visual representation of the final product, and Specifications which are essential for the proper understanding and execution of the Drawings by providing technical specifications, Bill of Quantities (BoQ), material and equipment lists, detailed measurements, and construction/functional descriptions, ProNIC assists in the management of both (Ribeiro et al., 2022).

For the drawings, ProNIC's CDE feature promotes the benefits previously discussed in the specific section of this paper. For specifications, ProNIC stands out in its role with the design team for the creation of the Standardized Bill of Quantities. Although these two facets of the same design project are interdependent by nature, they tend to have incompatibilities due to the segmentation into numerous design disciplines involved, the types of documents created, and the separate production of these documents (Ribeiro et al., 2022). Digitization, on its own, can facilitate how the different elements of design information are related, however, for it to be effective it requires standardized and interoperable information structures (Mêda et al., 2022).

Therefore, ProNIC's role in producing the design specifications begins by providing a Work Breakdown Structure - Construction Works (WBS-CW) with the appropriate parameters that differentiate the items and that influence the activities' price. This serves as the basis for the creation of the Standardized BoQ. At the end of the process, the validation work has partially been done during the process by performing error checking, and the consolidation between all project disciplines, which tends to be time-consuming and error-prone, is automatically performed by ProNIC.

It is for this reason that ProNIC came to have immense importance in the designers' work, even though it is summarized in the overview presented in Figure 3.

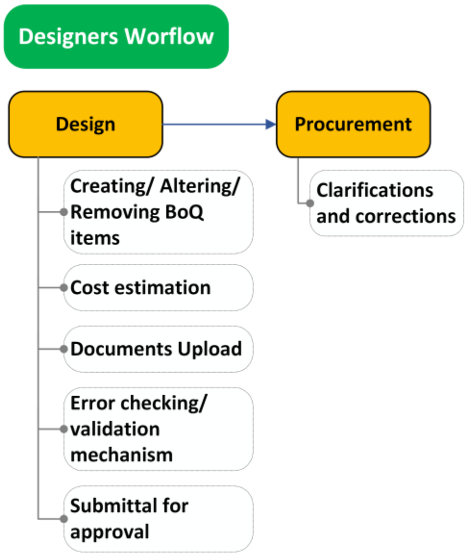

Figure 3: ProNIC Designers overview

However, despite the summary presented, the interaction between ProNIC and the design teams is more intense and can be best represented by the flowchart in Figure 4.

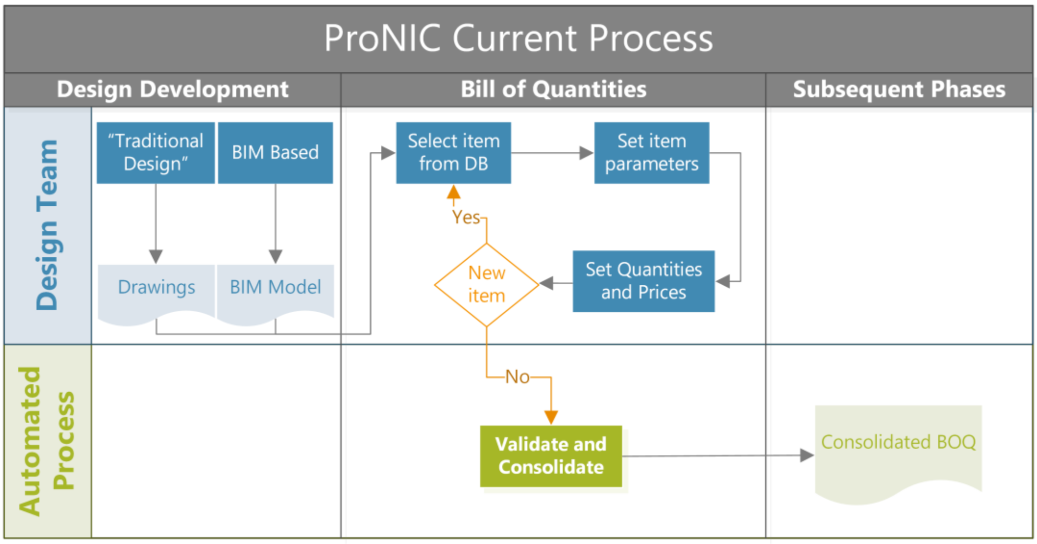

Figure 4: ProNIC designer changes process

Thus, standard BoQ creation in the current ProNIC process is independent of the chosen design method, whether "traditional" or BIM. The design team does most of the work, while ProNIC combines the BoQs from each design discipline to create the consolidated BoQ. The flow of creating a BoQ item is therefore repeated for the totality of items. The predefined WBS-CW items and parameters assist the design team in using complete, correct, and up-to-date design information, and error checking, in addition to the digital signatures and document uploads present at the end of the process. Cost estimating and quantification are also inputs to be filled by the design team.

Therefore, the flow between the design team and ProNIC proves to be one of the most intense, frequent, and repetitive in this process. It is in this perspective that it is possible to verify the advantages achieved in this flow from a lean information management approach:

Creating/ Altering/ Removing BoQ items: This is the main interaction flow between ProNIC and the design team. Therefore, the action takes place from obtaining the Works definition, set by the owner, to the validation and consolidation of the BoQ from all project disciplines, to allow the creation of the Standardized BoQ.

However, the largest share in the significance of information exchanged between ProNIC and the design team is due to the use of WBS-CW, which directs designers to standard information, with items, parameters, options for filling in the parameters, measurement units, all standardized and technically aligned, avoiding erroneous, incomplete, duplicated, or missing information.

Cost estimation: With BoQ standardization, ProNIC allows the project team to have a cost database for comparison at the item level. This comparison is not direct and demands coordination by the team, however, the information is available for use.

Documents Upload: The CDE function along with automatic validation, and error checking, allows the design team to be aware of which documents should be uploaded at the appropriate stages of the process, enables validation by the owner and other stakeholders involved in this process, and that the available versions are always the current ones.

Error checking/ validation mechanism: Occurs simultaneously with the creation of the BoQ, indicating existing items, and creating the consolidated Bill of Quantities.

Submittal for approval: Design team document's final validation. Only from this submission, the information can be considered able to be used in the following process.

The benefits of ProNIC to the Designers regarding Lean Wastes are shown in Table 3.

Table 3: Lean Wastes and Benefits of ProNIC to the Design Team

Lean Wastes	ProNIC Benefits
Transportation	A major gain in face of the number of people involved in this phase of the process inputting information in a unique document. Avoids constant requests and exchange of different versions of the information.
Inventory	Uses the CDE function to organize data to avoid multiple directories and files with the same information.
Motion	Again, due to the CDE function, it eliminates all the need to search for information in different places and with different actors in the process.
Waiting	Automatic error checking at the moment the item is created in the BoQ, without the need to request information. It allows the creation of immediate partial versions of the BoQ, allowing the checking of the process' progress. Submission and immediate availability at the end of the work.
Overprocessing	The creation of intermediate BoQs is a necessity for the proper monitoring of the process, but it demands almost an identical amount of work as the definitive one. This process automation is already an immense gain of information overprocessing for the design team.
Overproduction	CDE allows avoiding the production of unnecessary information at the moment and the immediate identification of current information.
Defects	The biggest gain and the goal of using the system. The standardized information, from previous phases prescribed by the owner to the consolidation with error checking at various moments, allows the creation of construction documentation to be a process with a much-reduced error occurrence.
Underutilization of people	The design team stays fully focused on value-adding activities, especially in the consolidation phase, which tends to be a high-volume phase.

In conclusion, once again the CDE feature plays an important role in this interaction. But this time the emphasis is entirely on the creation of the design specification documents, specifically, the Standardized BoQ.

The creation of a single, standardized document, under intense activity at various times by several distinct participants, and the need for monitoring, required special attention and led to the development of a very robust module allowing only a single flow of information, avoiding overproduction in the consolidation phase, allowing automatic and immediate error checking, directing to assertive information in the WBS-CW items, and minimizing intermediate files.

PROPOSED UPDATES FOR PRONIC

ProNIC is undergoing an update of its technical contents and IT platform, including integration and interoperability improvements – key concepts of Construction 4.0.

The implementation of new interoperability mechanisms should foresee that BoQ information is available throughout the life cycle of the project, so that existing data structures in a 3D model should be interpretable by ProNIC and associated with WBS-CW items/parameters, and a BoQ created in ProNIC can be a structured data source, usable to support, for example, a Digital Building Logbook (DBL) (Mêda, Calvetti, Hjelseth, et al., 2021; Ribeiro et al., 2022).

In future ProNIC, when the design is BIM-based, the intent is to reduce the design team's work within ProNIC to validations and reviews of the information interpreted by the system. As presented in Figure 5, the system will obtain information directly from the model, filling out some of the parameters and item quantities, and suggesting narrowed down lists of other items and parameters for review by the designers. Remaining and additional items or parameters, which may not exist in the modeled elements, need to be defined by the designers as well.

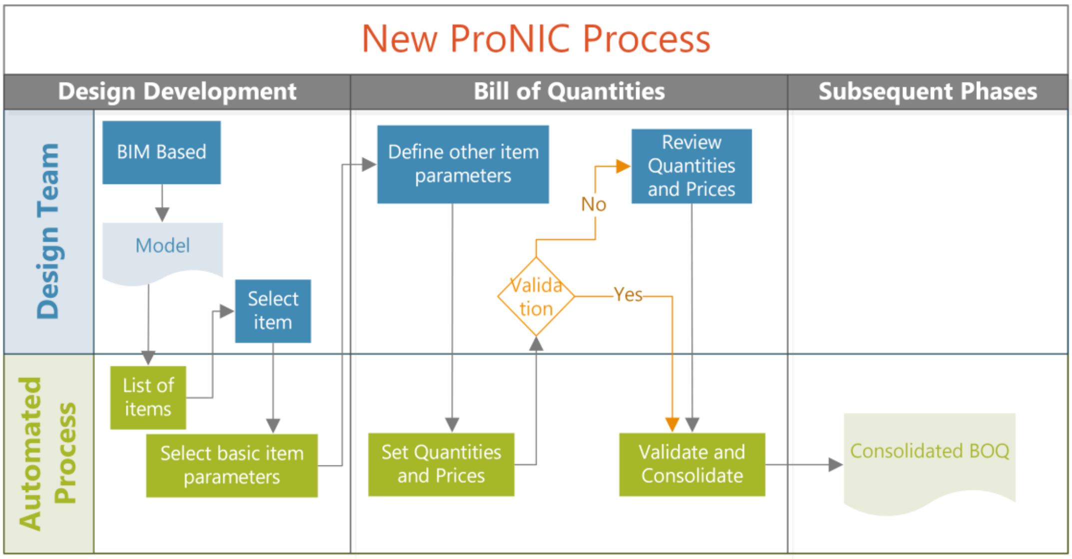

Figure 5: New ProNIC process

Another ProNIC process that can be improved by adopting Lean is the usage of its technical content management module, where the WBS-CW items and technical specifications of construction works are created and maintained by specialist content administrators, for later use by designers. This module allows recent changes in construction technologies and standards to be reflected throughout ProNIC.

To prevent the Underutilization of people, ProNIC should add new mechanisms to simplify repetitive operational tasks such as the updating of references to standards: when standards are replaced with newer versions, the specialist should focus on whether ProNIC's content is still conformant, and not on manually editing potentially hundreds of text fragments. The automated replacement of references to standards also embodies the Lean principle of continuous improvement/pursue perfection and minimizes defects by preventing outdated references.

Lastly, a suggested system-wide improvement is the adoption of a Kanban-like (Arbulu et al., 2007) interface for management of tasks by each ProNIC user, according to their role, and an associated push notification messaging system. In combination with the CDE, this ought to minimize the Wait, Inventory and Motion wastes, by providing streamlined workflows with just the right amount of information at just the right time, ready to be actioned upon.

CONCLUSIONS

The analysis performed in this paper showed that a Construction Information System can ensure a better flow of information, approaching Lean Information Management, by balancing information production, reducing the workload in the construction document production phase, minimizing defects, and eliminating information waste in the design phase. ProNIC brought tangible improvements to traditional workflows by implementing these Lean concepts, despite not being originally conceived under a Lean perspective. ProNIC's key LIM features are:

- Increased reliability throughout the construction process due to standardization of information, error checking, process monitoring, and information available always in its latest version in the CDE.
- Reduction of work overloads due to process automation.
- Each specialized team can focus on activities that add value.

Processes in ProNIC can be further improved by communicating directly with BIM models, reducing complex, error prone activities to mostly verifications and validations. Leveraging Lean principles, proposals for updates related to other operational tasks were also made.

LEVERAGING BIM AND MIXED REALITY TO ACTUALIZE LEAN CONSTRUCTION

Alessandro Carbonari[1], Massimiliano Pirani[2], and Alberto Giretti[3]

ABSTRACT

Lean construction is made of principles, measures and methods that aim at maximizing process efficiency. Several tools have been developed to minimize waste, maximize customer value, improve the conduction of processes, and pursue other sub-objectives in construction. This effort is becoming more and more important due to the rising construction project size and variety, displacement of resources in diverse geographic locations, high-performance pressure.

This paper reports the development and on-site tests in a real-life demonstrator of two management tools, which apply some principles of lean construction management at the design and delivery phases. The first one takes advantage of the integration between BIM and mixed reality, having the final aim of improving collaboration and communication among the actors involved. The second one exploits BIM modelling and search algorithms within a process-based management platform, in order to facilitate short-cycle planning and distributed decision-making in the production process.

Both tools have been tested in the case of a building renovation project. The results show that they can improve communication efficiency, reduce rework, speed up work monitoring, control and supervising in construction management, and that they can address several of Liker's lean principles, as classified by the 4P model.

Lean construction, collaboration, BIM, mixed reality, process.

INTRODUCTION

Many actors participate in the administrative and operational levels of the building business, which makes it a complex business area. The construction supply chain often involves a number of participants even in small construction projects. As a consequence, complexity mainly arises at the interfaces between sub-processes (Dirnberger, 2008; Kolberg et al., 2017) and it has become a critical topic in the field of construction project management (He et al., 2015; Brady et al., 2018). Although there is no consensus on the exact definition of complexity (Ma et al., 2020; Gu et al., 2022), construction processes can be considered to be some of the most complex ventures across all industries, even because the construction industry has experienced speedy progress in projects of rising size and variety. Large scales, sophisticated technical processes, long lead times, huge numbers of people involved, diverse geographic locations, and high-performance pressures make these projects even more complex (Mirza et al., 2017; Zegarra et al., 2019). The developers of the Management 3.0 approach provided several basic

recommendations (Appelo, 2011): to address complexity with complexity; to use a diversity of models; to assume dependence on context; to anticipate, adapt and explore; to develop models in collaboration; to manage changes. Nowadays, dealing with complexity has never been more important and it requires that an organization is connected with its environment and can adequately react to its changes (Frahm & Roll, 2022).

In such a scenario, most of the principles, measures and methods of planning, designing and controlling applied by lean construction thinking can help the construction industry to deal with external factors that characterize the economic framework, such as high demand (and increasingly scarce resources), low price levels, an increasing competition and constraints determined by political and normative factors. Furthermore, the demand for renewable energies, resource conservation, and rising qualitative standards asks for the adoption of new methods that are able to improve the overall process efficiency, which is one of the main objectives of lean construction (Fiedler, 2018; Neve et al., 2021). Lean construction pursues important goals such as maximizing customer value, continuous improvement of processes, elimination of waste, application of flow and pull principles (Seed, 2015). Waste can be found in many interfaces between processes, due to insufficient communication and collaborative work between teams (e.g. lack of operational management, deployed international teams), but waste can also be generated by low price levels in budgeting and legal proceedings against projects. During on-site activities and in case of a tight work schedule (e.g. parallelization of activities), issues can arise because of mutual obstructions of trades, high costs of rectifying defects, increased need for control by site managers. As a result, projects often are not able to adhere to deadlines (Frahm & Roll, 2022).

In this paper, lessons learned from a three-year EU-funded project entitled “ENCORE – ENergy aware BIM Cloud Platform in a COst-effective Building REnovation Context” will be presented. More specifically, a couple of web services that can help achieve a possible implementation of lean construction methods will be showcased. The first one integrates Mixed Reality (MR) tools to show how they can be used within construction projects to enable collaboration between the design team and on-site users to identify errors/omissions quickly and correctly (Surendhra Babu & Nayath Babu, 2018). This approach makes the decision-making process at the design phase reliable and efficient, because it avoids time delays due to re-works, thanks to an on-site acquisition of information about the designed model and the opportunity to do adjustments in an immersive hybrid environment (Orihuela et al., 2019). The second one is a process-oriented planning and control platform, which exploits BIM, advanced computation and visualization to enhance decision-making in work planning, workspace management, coordination and collaboration during work execution, in order to eliminate wastes due to delayed response to the unexpected, blocked space and passages (Singh & Delhi, 2018). Both tools have been enabled by the development of the design model within a Building Information Modelling (BIM) environment. Experimental tests were performed in the specific case of energy renovation of residential buildings.

The technical details of the platforms will be described in the next chapter. Findings from these experimental tests and lessons learned will be reported and discussed right after that. A conclusions section will end the paper.

TECHNICAL DEVELOPMENT

The architecture of the ENCORE platform (CORDIS, 2023) is structured into four layers: (i) data sources; (ii) data capture; (iii) engines; (iv) applications. It is based on micro-services. The “Applications” layer contains that set of services visible to the main end-users. Among them, the MR web service supports the architect in the creation of renovation options for building efficiency improvement, until one of them is selected as the preferred one. The other web service performs process-oriented management of construction works: it accepts the IFC model of the selected renovation option as input and produces the first work plan and a list of spatial clashes between trades as output. Indeed, site managers and planners can use this platform to check whether the site layout has been arranged accurately, to control the actual work progress, and to update the work plan.

COLLABORATION PLATFORM AT THE DESIGN PHASE

The final purpose of the MR web service was to facilitate the assessment of alternative options for the energy renovation of buildings. In this phase, quite close cooperation between the architect and a few technical experts may be required. Indeed, the feasibility and constructability of renovation options must be checked by means of on-site surveys, due to the limitations and technical constraints caused by the layout and components of the existing building. Thanks to the integration between MR and BIM modelling, the on-site verification can be performed more efficiently, mainly because of the immersive visualization of renovation option models and because of the enhanced collaboration and communication between the architect and involved experts.

The workflow enabled by this platform is sketched in Figure 1. First, the architect is supposed to develop alternative renovation options in the form of BIM models. Every option must be assessed in terms of energy performance. Then, the architect is expected to single out that subset of studies that must be verified by means of an on-site survey, due to constructability issues. Once an expert gets on-site to perform such an assessment, they will enrich every candidate option with information regarding their expert opinion. Eventually, the architect is able to combine all the available information (e.g. feedback received from experts, information embedded in the IFC model) until they can make a decision and select the preferred solution that will be built.

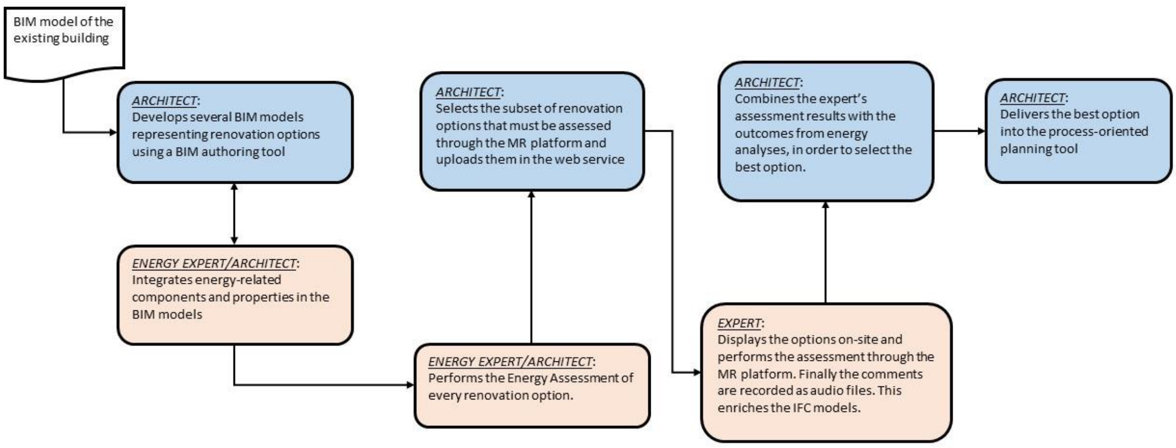

Figure 1: Workflow enabled by the collaboration platform

The platform enables seamless communication and coordination according to the cognitive interpretation of holonic management systems (HMS), which is depicted in Figure 2, and which provides greater agility and increased robustness against disturbances as compared to centralized systems (Mella, 2009). In this view, holons are defined as cognitive units of holarchies that are made of one or more agents and can dynamically reconfigure themselves into new holarchies. As long as this approach is transferred to the case at hand, the holon representing the on-site expert can either make individual decisions or can participate in the collective decision. In the latter case, they give birth to the multi-agent system in a distributed collaborative framework, made up of the on-site expert and members of the design team, thanks to the MR interface and the web service (Figure 2). This avoids requiring centralized decisions only (Valckenaers and Van Brussel, 2016; Derigent et al., 2020).

To this purpose, renovation options are stored in the Encore platform by designers as IFC files and by means of a dedicated Graphical User Interface or GUI (Carbonari et al., 2022). They can be received by the platform through a Restful API. Then, they are passed through an IFC2GLTF translator that converts them into the GLTF 2.0 specification. In this step, a JSON file that contains data and relationships other than geometrical and metadata is created, too. This set of information will be used to produce the game scene by the expert's MR App. In fact, as soon as an expert gets on-site, they will execute the MR app that was developed in Unity 3D 2019 environment with Mixed Reality Toolkit, compiled and deployed in the Hololens by Visual Studio 2019. Once the App has been started and authentication accomplished, the MR App invokes an URL of the App Restful API returning the list of projects to be assessed. Once one of the projects has been selected, this triggers a GET request to fetch the GLTF file ready to be rendered in the game scene of the MR App, together with complementary information included in the JSON file. The model is ready to be aligned by means of visual tags. First, the expert gazes at a tag placed on-site. Then, the MR app sends the serial number to the web server, which localizes the same element in the IFC model. As soon as at least two tags have been scanned, an internal routine aligns the model around the expert. Here is when the immersive experience starts. The user can navigate the model on-site and upload their remarks and suggestions onto the web service, recording voice comments as audio files linked to relevant components of the IFC model. The architect can access the service and go through annotations produced in the assessment until they reach the final decision.

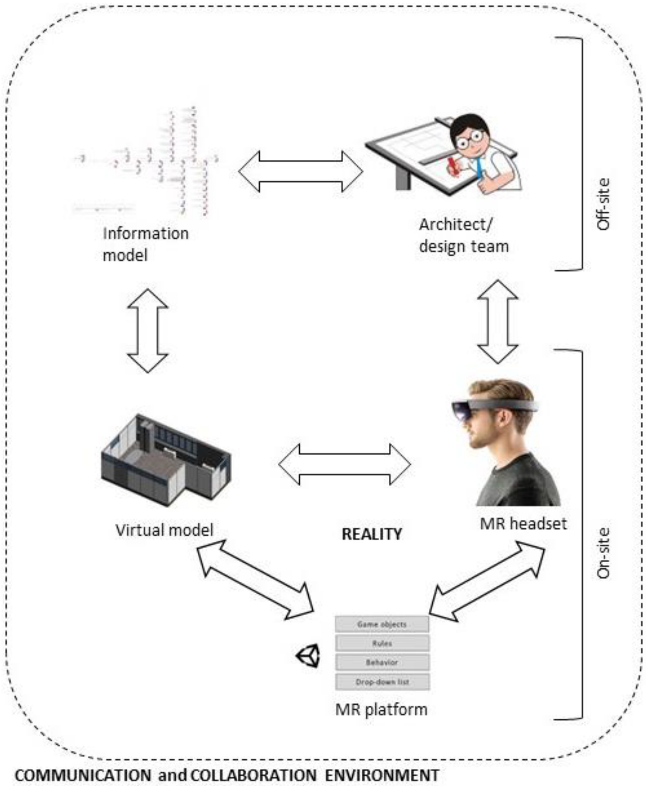

Figure 2: Conceptual diagram of the collaboration platform

PROCESS-ORIENTED PLATFORM TO MANAGE THE EXECUTION OF WORKS

The second web service consists in a proactive, partially automated, human-machine cooperation platform, that was based on the operative interpretation of the Holonic Management System (HMS) architecture, which is made of self-organizing modules (Mella, 2009). Its implementation followed the PROSA (Product-Resource-Order-Staff Architecture) reference architecture (Valckenaers & Van Brussel, 2016), because of its capabilities of mediating between low-level and high-level decisions while sticking to a shared objective.

Basically, this process-oriented platform adopts a process-based representation and an ontology that facilitates the creation of the initial work plan and its regular update during the execution of renovation works (Figure 3). It requires that the renovation project input is provided as a BIM model, including the current state, the demolish phase and the renovation phase. Then, the planner can cluster the components into construction deliverables and can define any applicable milestones (Messi et al., 2021). This web service helps the planner to retrieve information about the BIM product and the applicable price analysis and to bind this information with the construction processes represented in Business Process Modelling Notation (BPMN). As a result, every construction deliverable will be associated with the corresponding process and required resource skills (embedded in the resource/cost analysis source repository valid for the selected price list). Then, a stigmergic planning algorithm works out a plausible work plan labelled as the baseline. This approach facilitates even re-planning during the control phase, once data about work progress are collected from the job site. Finally, an external visualization and spatial simulation tool to check spatial conflicts were developed, in order to warn whether two trades would work in overlapping workspaces.

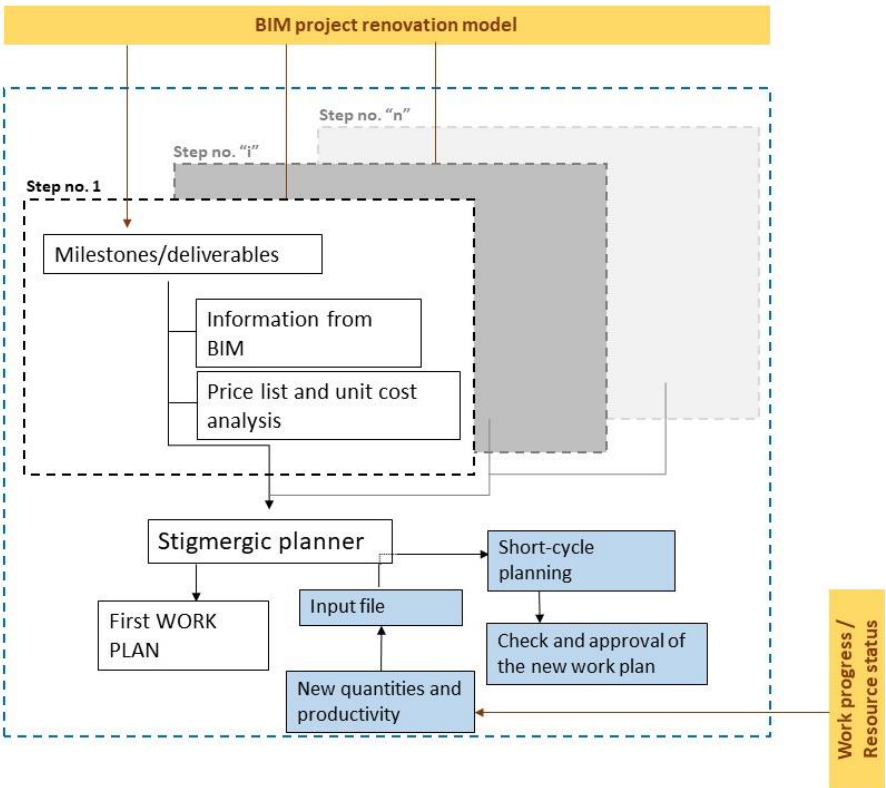

Figure 3: Conceptual diagram of the process-oriented platform

The interaction with the platform is managed through a Web GUI that integrates the sub-services (Figure 4). Once the login is successful, a member of the design team can import two IFC2x3 Coordination View files, which is one of the MVD types provided by BuildingSmart and available as a function in all certified BIM platforms. They are the existing and the to-be-renovated design models of the building, respectively. They can be compared using an in-built function that recalls one of the "IFC Web server" functions to compute differences and work out the list of components to be demolished and the list of components to be built, eventually stored as an editable CSV file.

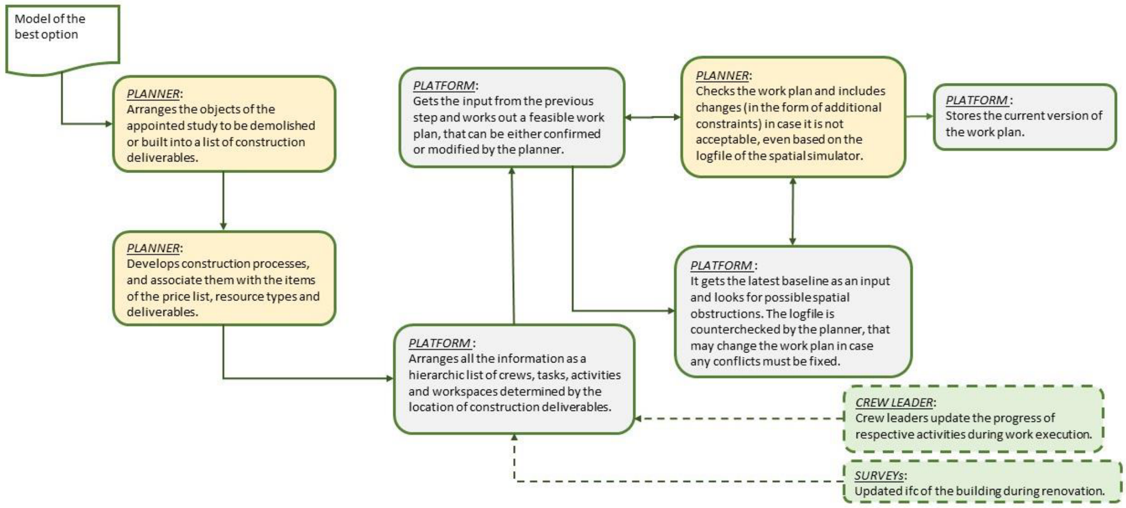

Figure 4: Workflow enabled by the process-oriented platform

The GUI allows the user to edit such a CSV file and generate the list of deliverables. It consists of the rearrangement of those components in order to put together sets of components that will be executed in the same workspace and by the same crew, hence it can be described by one process. A built-in BPMN editor facilitates the creation of BPMN models, either generated from scratch or imported from previous sessions. Thanks to its formal specification in XML, every activity in these processes is linked with the deliverables and the corresponding item of the applicable price list, called by invoking a Python web service. It interacts with the main web service by means of an API REST. Crews are automatically imported from the price list and the analyses of unit costs. Bills of quantities and efforts of crews are generated automatically using the size and other attributes included in the MVDs and deliverable list. They can be counter-checked by the user. All this information is accommodated in a JSON file that is the input of the stigmergic search algorithm, which is started by invoking a Matlab™ simulation environment (Naticchia et al., 2019) and produces work plans. These processes are supported by a multi-model DB developed in ArangoDB (ArangoDB, 2020). The resulting work plan can be imported into an external service developed within Unity3D™, along with the IFC model of the building. Its engine displays workplaces and, then, it checks for spatial conflicts, that is workspaces that may be occupied by different trades at the same time. The list of conflicts can be checked and fixed by the site manager. Finally, a web interface was set up to type in percentage values of work progress. These figures are transferred to the web server by means of a REST API. They overwrite the quantities included in the JSON input file to the stigmergic planner and trigger the algorithm again, until a new workplan is provided as output. As a result, the on-site cooperation among crews providing progress data, the search algorithm for planning, the construction manager, and the information included in the BIM environment realize a collaboration environment, partially automated, that can be regularly and often implemented during work execution.

LESSONS LEARNED

RESULTS OF EXPERIMENTAL TESTS

The tests carried out in the demonstrator building in Caceres showcased the functionalities of the MR service and the main advantages derived from its adoption. The collaboration environment is hosted by a web service in which designers and experts can upload and share design options. As shown in Figure 5-a, several studies or solutions can be associated with a project. They are uploaded by the architect. Once the experts have downloaded those files in their headset on-site, and have accomplished the on-site survey, they are expected to enrich the model with remarks, that are linked with the relevant components of the building and can be retrieved and listened to by the architect at any time. The web page in Figure 5-b shows that as soon as a comment is played, the web service highlights in colour the component to which the comment is attached, thus facilitating the exchange of relevant information.

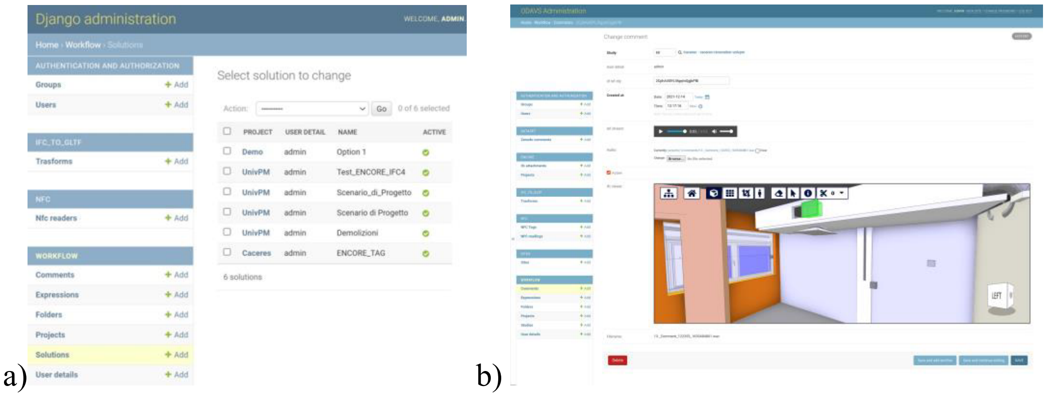

Figure 5: Collaboration environment supporting the evaluation of renovation options

The enrichment deriving from the generation of comments and remarks was made possible by the combined visualization of the physical environment and the virtual model (Figure 6-a). In this Figure the pointer of the user that queries the properties of a vertical pipe is well visible. Figure 6-b depicts an on-site user in the process of interacting with the mixed environment and reaching out a physical component. They can measure the size of a component, can touch and sense the surface of a component to infer the material that it is made of. While interacting with the physical part and wearing the MR headset, the latter does not interfere with these actions. Rather, the MR headset facilitates such navigation and the gathering of additional information. The first-person view of a recording session is shown in Figure 6-c, where the virtual menu handled by the expert is located at the forefront. The recorded remark will be saved in the web service and can be retrieved as shown in Figure 5-b. Additional pictures and videos of these tests are available in a repository authored by Carbonari and Vaccarini (2022).

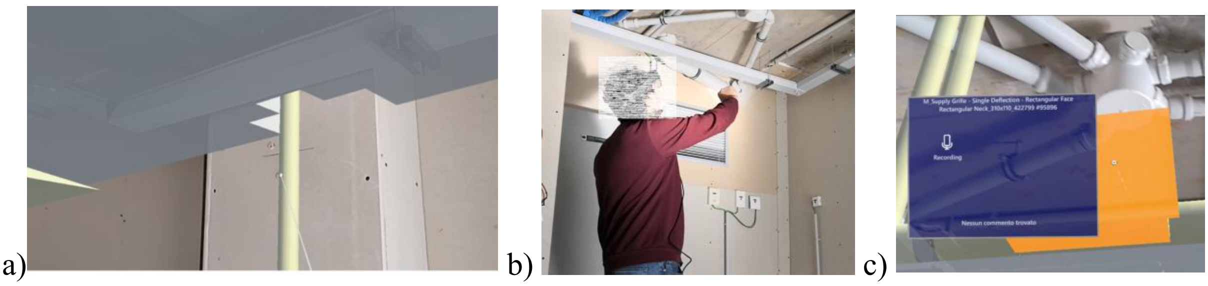

Figure 6: First-person view of an operator mixing information of the current and renovated building (a); use of the platform during the tests (b) and virtual menu to record a comment (c)

Also, the web page of the process-oriented platform that enabled the development of the BPMN processes to manage the renovation works to be executed in the demonstration building located in Caceres is shown in Figure 7-a. According to what reported in the previous section, every node of the process represents a type of activity, which is later instantiated by the system in order to generate the input for the planning algorithm. In other words and as an example, the node “remove plaster” generalizes the two tasks “removal of plaster on the north facade” and “removal of plaster on the south facade”. These instances will be created by the system thanks to the relationships among these nodes, the items of the price list and the deliverables edited and approved by the planner in the previous step. The last step of the planning process that generates the schedule of renovation works is shown in Figure 7-b, along with the baseline worked out by the system. To sum up, the baseline includes five groups of activities: removal of some components and of the plaster; application of insulation layers and of the new plaster on the facades; installation of temporary structures (e.g. scaffolding); installation of sun shading systems and robotic arms to control window opening; replacement of windows. The same data structure and the stigmergic algorithm applied to work out the baseline will be executed during work progress management, in order to perform a short-cycle replanning. The overall duration of this plan spans from March 12th until April 25th, 2022.

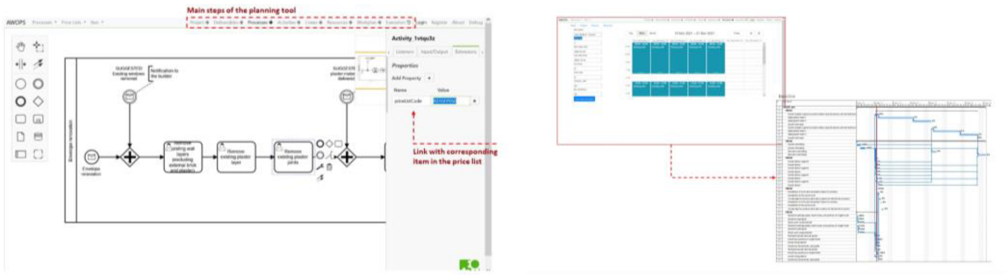

Figure 7: Notation used to model processes (left) and schedule generated by the platform about the renovation works performed in the pilot building (right)

Then, work progress was controlled and plan updates were worked out quite often, as listed in Table 1. At every replanning step listed in this table, work progress was updated and a new work plan was generated by the platform.

Table 1: Re-planning dates during project control

Date	Work progress	Estimate completion date
2022/03/12	Temporary structures are done.	2022/04/25
2022/03/14	Demolitions; envelope insulation (partial).	2022/04/04
2022/03/17	Envelope plaster and insulation; shutters (partial).	2022/03/31
2022/03/21	Shutters; replacement with new windows (partial).	2022/04/04
2022/03/24	Sealing around windows (partial); finish layer (partial).	2022/04/25
2022/03/28	Sealing around windows (partial); finish layer (partial).	2022/03/31
2022/03/31	Renovation works on hold.	2022/04/06
2022/04/07	Installation of shutters (partial).	2022/04/11
2022/04/11	End of renovation works. Construction site dismantled.	-

Work progress was monitored thanks to a web service which could receive percentage values of completion of every single task. The site manager and supervisor may be in charge of gathering such data. The same people can be in charge of changing any relationships among activities and including new constraints whenever applicable, e.g. a supply of windows was late; a precedence between tasks was created due to operational issues. Basically, this is how the platform helps managers to react against disturbances generated by unexpected events occurring during the execution of works. Late deliveries of materials and breaks due to bad weather were the main reasons why the estimated completion date of the project varied so much during the process (see the rightmost column of Table 1). Every time these data had been updated, the planning tool was executed and a new work plan was generated. Then, every work plan was checked using the spatial simulator shown in Figure 8-b. Such a tool displays a coloured box around every workspace; the association between trades and workspaces is listed in the leftmost column in the graphic environment. In case any obstructions were noticed, crew leaders would be asked either to adjust the size of or to move their workspace. In case this action was not determinant, the supervisor or site manager was required to adjust the work plan and fix the issue. In this way, the supervisor was involved in the decision if and only if strictly required.

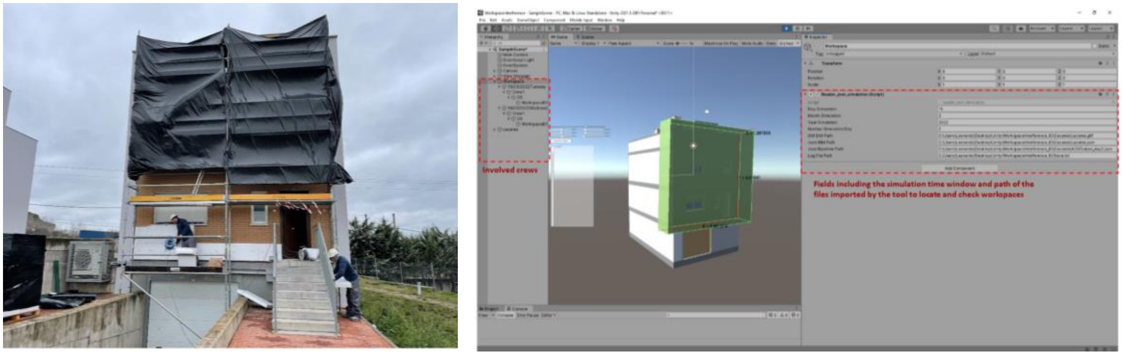

Figure 8: The crews carrying out the execution works on the facades (left) and check of obstructions between trades (right)

DISCUSSION ON LESSONS LEARNED

The volunteers who tested the MR-based platform managed to enrich the BIM model with their opinions, and most of those remarks were available on the platform at the architect's disposal. In particular, 85% of the audio files recorded in the first experimental session and 77% of the audio files recorded in the second experimental session were saved accurately. This is a high percentage if we keep in mind that the volunteers had had no previous experience with the technology. Also, the process-oriented platform supported the creation of the baseline and worked out a new plan on the occasion of each of the eight control milestones of the work progress (Table 1).

Besides these successful quantitative figures, the results of the tests showed that they can address some of the principles underpinning Liker's 4P model (Puram et al., 2021). They are classified into four categories, i.e. philosophy, people and partnership, process, and problem-solving.

The collaboration platform addresses both "process" and "problem-solving" principles. Indeed, it was able to generate a shared environment to be consumed by two types of users in different locations. The first type is the architect and the rest of the design team, which could upload and share information created by experts at any time. The other one is the pool of on-site experts, who could work in an immersive environment and retrieve, edit, or create information enriching the model. These capabilities facilitate the generation of consensus among decision-makers prior to moving forward into the next step and implementing the project. What is more, the information embedded in the virtual model could be combined with the information related to the actual building. The platform allows all of them to organize asynchronously their job. This eliminates waste due to scarce collaboration or difficult communication. In addition, the concurrent assessment of the to-be-renovated design inside the existing building, increased the quality of the assessment and reduced defects in the project. As a result of interviews carried out among the volunteers performing the tests (Carbonari et al., 2022), it came out that the customer/owner could benefit from this platform, because they could have a better understanding of the design and would improve their communication with the design team. Other suggestions concern the extension of the capabilities of the virtual menu in order to increase the possibilities of handling the virtual model, and a more refined selection of the components, so that experts could assess even smaller parts of the project.

The process-oriented platform facilitated the rapid implementation of the execution phase, which is a principle belonging to the "problem-solving category"; it was able to standardize tasks and avoid overproduction, which are classified under the "process" category. In fact, the data model underlying the renovation design models in the IFC files facilitated connection with external sources, such as the price list, and the rearrangement of those data into a format that could be managed by the stigmergic planning tool. Thanks to this approach, the burden of work in charge of the planner got limited and the work plan worked out through computations always minimized the cost function regarding resource usage over time. The second feature is the stigmergic algorithm itself that is able to work out a new plan within a time span in the order of a few seconds. In this case, the combination of BIM and BPMN dramatically speeds up the planning and re-planning process. This figure depends on the number of iterations performed by the search algorithm and by the number of activities. In the case of the demonstrator, which has a limited number of activities, increasing the number of iterations from 10 to 100, would increase simulation times from 3 s up to 29 s. Finally, the integration of the spatial interaction environment as an external tool helped avoid obstructions among trades and helped involve crew leaders at the right time and only when needed, in order to agree on the site layout and the organization required to carry on renovation works.

CONCLUSIONS

Two web services were showcased and evaluated through on-site testing, in order to show how the adoption of a BIM-based work environment coupled with state-of-the-art technologies could realize a lean management approach.

In the first case, mixed reality and BIM models of building renovation projects were combined to create a shared environment inside which many actors could enrich those models with additional information; they could interact with both the physical and the virtual domains; they could cooperate until the selection of the best renovation option was made. The most important benefits brought to the surface by this demonstrator are that communication among the involved actors has been made easier and the quality of the assessment has been enhanced. As a result, the expected collaboration and rework burden will be reduced.

In the case of the process-oriented platform, the combination of modelling techniques to develop process models and the development of BIM project models for the renovation of buildings, allowed the adoption of a planner to speed up the processes for the creation of the baseline. In addition, this technology supported a short-cycle replanning, which realizes a prompt reaction against disturbances generated by external factors and the environment. The BIM and the work plan were imported into a spatial simulator to compute any obstructions between trades that could generate hazards. Several actions in the process were made automatic and did not require manual processing by the planner. Also, decisions could be made at different levels. The adjustment of workplaces to avoid obstructions usually were to be made by crew leaders; however, sometimes a change of relationships between tasks and their start and end dates required a briefing between the supervisor and suppliers. In other words, this approach required the involvement of only the necessary people at every step, with no waste of resource effort. Finally, enhanced visualization of information and models and the continuous availability of data increased operational efficiency.

BARRIERS TO BIM IMPLEMENTATION IN BRIDGE CONSTRUCTION: A CASE STUDY

Eric Forcael[1], Alonso Castro[2], Francisco Bedwell[3], Euro Casanova[4], Francisco Orozco[5], and Francisco Moreno[6]

ABSTRACT

The purpose of this research was to find the barriers that hinder the implementation of BIM in bridge projects (BrIM). This was done by a bibliographic analysis and the application of an evaluation tool to a case study, corresponding to a Chilean road project with an important number of bridges. Based on the literature, twenty-three barriers were found, which were then validated through the application of the survey to the case study, resulting the main barriers: "Interoperability problems between different BIM software", and "Differences between BIM for buildings and BIM for bridges". Then, a risk analysis was run, concluding that the barriers in bridge projects cause high levels of impact when implementing BIM. Thus, this research may help project and engineering managers to have a first approximation to the most recurring barriers in BrIM and how to rank them according to their impact. Finally, for future research, the findings of this study can be extended to other complex projects —such as bridges— but with different levels of uncertainty, that allow finding new barriers or confirm those found here.

KEYWORDS

BIM, management, bridges, barriers, Chile.

INTRODUCTION

CONTEXT

Since the first industrial revolution, the impact of new technologies has been of utmost importance to obtain better results in the highly competitive areas that have characterized the construction industry. In this way, factors such as resistance to change, and lack of training, financing or knowledge have jeopardized the advancement of new technologies. Building Information Modeling (BIM) has been part of this reality, facing barriers in its implementation. Thus, this methodology has caused a great impact on construction projects, bringing a new way to develop them in each stage (pre-design, operation, maintenance, among others).

This has led to an increase in the number of BIM users, along with government programs for its progressive implementation in different institutions. In this scenario, countries such as

Chile, through its Ministry of Public Works, have promoted initiatives to increase the use of BIM methodologies in all their infrastructure projects, where the case study considered in this research (a major road project located in southern Chile), is a good example to show this effort.

THE PROBLEM, SCOPE, AND OBJECTIVES OF THE INVESTIGATION

This research consisted of an exhaustive literature search to determine the main barriers to BIM implementation, which were then ratified through the application of an evaluation instrument to various stakeholders belonging to the Ruta Nahuelbuta project, a major road project located in southern Chile. This allowed answering the following questions: what are the most relevant barriers to the implementation of BIM in bridges, what is the probability of these barriers occurring, and what level of severity will these events have in the development of the project?

The general objective of this research was to determine the barriers that limit the implementation of BIM methodology in bridge construction projects, from which the following specific objectives are derived: to determine the barriers to be studied based on an exhaustive literature review; to validate the barriers previously found in the literature, through an evaluative tool; to analyze quantitatively and qualitatively the results obtained.

ACADEMIC BACKGROUND

The necessary information for this research was gathered through a literature review on the fundamentals, vocabulary, and key concepts related to Bridge Information Modeling (BrIM).

BRIDGE INFORMATION MODELING (BRIM)

First, bridge information modeling (BrIM) is essentially BIM applied to bridge projects (Maire & Brinckerhoff, 2012). On the other hand, Cho *et al.* (2009), establish that BrIM corresponds to a 3D concept for design, construction, maintenance, and operation, where the system displays data that allows its use in real-time as conditions change throughout the life cycle of a bridge.

Additionally, Gaitá & Gómez (2014) defined this concept as a set of systems, methods, and digital storage media used to generate the information model of a bridge, which allows combining the information associated with the design and construction from several disciplines.

There are some differences between BIM and BrIM, which according to Bartholomew *et al.* (2015) correspond mainly to a geometric difference since buildings are developed on a rectangular grid system, while bridges are defined with curved or straight horizontal alignments, vertical slopes, elevations, and superelevations. Another difference is the number of specialties since the number of disciplines and trades in buildings is significantly higher than in bridges.

SOME OTHER ASPECTS OF BRIM

Chronologically speaking, Heikkilä (2001) started by determining the content of bridge information models, their technical guidelines and promoting the use of 3D models in Finland. Later, Shirole *et al.* (2009) summarized the main problems and challenges when implementing BrIM in the construction industry. Subsequently, Shim *et al.* (2011) worked on an informative scheme to avoid possible interoperability problems between bridge design and construction processes. Then, Marzouk & Hisham (2012) present a methodology to use BrIM as a tool to estimate costs, who later in 2014 present another cost estimation methodology but adding the estimation of a work schedule for the construction phase (Marzouk & Hisham, 2014). Bartholomew *et al.* (2015) studied alternative BrIM standards and a method for exchanging information modeling data. Meanwhile, Kasireddy & Akinci (2015) analyzed a case study to demonstrate the benefits and challenges of implementing BrIM for bridge life cycle inspection. Other authors, such as Markiz & Jrade (2019) conducted research to demonstrate the feasibility of integrating a support system with the use of BrIM, and overcome subjectivity in decision-making. Finally, Zheng & Xu (2020) conducted risk analyses on the implementation of BrIM.

CASE STUDY

PROJECT DESCRIPTION

The interurban road infrastructure project considered as a case study is called "Improvement of the Nahuelbuta Route", which search for improving connectivity and maximize economic and social benefits of people by reducing transport costs and accidents. This project entailed the improvement and widening of an existing dual carriageway running between two important cities located in southern Chile. It is a public-private partnership (PPP) project, under a modality of Build-Operate-Transfer (BOT), reaching a budget of US$254 million and a road concession period of 35 years (2 years for administrative and project procedures, 3 years for construction and 30 years for operation under a toll mechanism). The project includes an extension of 55 km of dual carriageway, with 17 low-grade intersections, 30 at-grade intersections, 3 toll plazas, 78 bus stops, 2 viewpoints, 2 railroad crossings, 23 pedestrian walkways, 32 km of service roads, 21 km of bicycle lanes, 1 control area, and 15 bridges of different characteristics.

SOFTWARE AND WORKFLOW USED

As for the software used in the project, the architecture and engineering specialties used *Revit* as an information modeling tool for obtaining plans, modeling structures, and calculating the amount of work. *Tekla structures* was used for the modeling of steel reinforcement of bridges.

For the geometric design of road works, *Istram* was used, which is an application specialized in the design of civil engineering projects. On the other hand, it was necessary to use *Autodesk BIM 360* as a cloud platform, to upload, visualize and manage the project models of different specialties and subspecialties. Also, *Naviswork* was used for the compilation and simultaneous review of models, which was able to identify and resolve discrepancies in project coordination.

Finally, *BIMcollab* is a virtual platform for communication and control of the project, through functions such as reporting discrepancies in 3D modeling to the responsible user, sending images of modeling problems, generating reports with the dates on which errors were detected and solved, and thus facilitating review by the client and external users.

METHODOLOGY

BIBLIOGRAPHIC RESEARCH TO DEFINE BARRIERS TO BRIM IMPLEMENTATION

To define the main barriers encountered in the literature when implementing BIM in bridges, an extensive literature review was carried out using the Systematic Literature Review (SLR) method, which is a way of evaluating and interpreting all available research so that it is relevant to a particular research question in a thematic area or phenomenon of interest (Kitchenham, 2004). On this basis, an analysis of the selected documents was then carried out to identify the most frequent barriers and, therefore, the most important according to several authors.

BIBLIOGRAPHIC COMPILATION

At this stage, it was necessary to develop a search protocol, compile a database and make the bibliographic selection, as follows:

Search protocol development

First, the methods proposed by Kitchenham (2004) and Borrego *et al.* (2014) were implemented. In particular, the main filters used were keywords and research questions, among other criteria established in the development of this stage, such as: reading the abstract, title, and internal references of the documents. *Google Scholar* was used as a search engine to retrieve academic content (papers, books, theses, etc.). The keywords used were *barrier*, *building information modeling*, *challenged*, BIM, *bridge information modeling*, BrIM, *construction,* and *risk*.

Database

The search yielded more than 500 bibliographic items, where the vast majority of them came from journals such as *Automation in construction*, *Building and Environment,* and *Journal of Construction Engineering and Management*.

Bibliographic selection

Here, the aforementioned filters were used to select the material, reducing the information to be analyzed to less than 20%. Then, we proceeded to read the content and determine which texts contributed information to the study, obtaining about one hundred documents. Finally, the references of each research were reviewed in search of the most relevant material.

DESIGN AND APPLICATION OF AN EVALUATIVE TOOL

As evaluation tool, a survey was chosen (through the *SurveyMonkey*™) since it is a widely used method and easy to distribute. The survey was applied to stakeholders belonging to the Nahuelbuta Society (owner of the project used here as a case study), and divided into 3 sections:

- Basic information on the respondents (years of experience and specialty).
- Assignment of the probability, between 0 and 100%, of an event, occurring and the level of severity, also between 0 and 100%, it would have on the project. It should be noted that the probability of occurrence was quantified according to the following ranges: very unlikely = 0-20%; unlikely = 21-40%; expected = 41-60%; likely = 61-80%, and very likely = 81-100%. In the case of severity, the ranges were: insignificant = 0-20%; minor = 21-40%; moderate = 41-60%; significant = 61-80%, and disaster = 81-100%.
- Application of a survey to case study stakeholders on the main barriers to the application of BIM in bridge projects.

RESULT ANALYSIS

Based on the results obtained from the surveys, we then proceeded to analyze these results, to construct a ranking of the barriers that impact the most on the implementation of BIM in bridges and a probability-severity matrix associated with this categorization of barriers**.**

BIBLIOMETRIC ANALYSIS

After applying the respective filters, 64 documents were obtained from the literature selection. The purpose of this stage was to distinguish the material according to its origin, year of publication, and the number of cited times. Then, a content analysis was carried out to match the documents that mentioned the same barrier when implementing BIM in a bridge project.

Main sources of information and countries

Out of the 64 documents selected, 46 were journal articles (71.8%); 16 came from conferences (25%) and 2 were theses and 1 survey (3.2%). Most of the research cited comes from five countries. In first place is the United Kingdom with 16%, followed by the United States with 13%; in third place is Hong Kong with 9%, and finally China and Spain, both with 6%.

BARRIERS TO BIM IN BRIDGE PROJECTS

Twenty-three barriers were established, which are listed below and then corroborated through an exhaustive literature review, which results are shown in Table 1. Although the number of barriers to be analyzed may seem to be high, other similar studies have been effective in drawing conclusions from large number of variables (Forcael et al., 2018; Sun et al., 2017):

1) **Need to train a greater number of BIM users:** The number of users trained to work with BIM is limited, and the consequence of this is the difficulty of its implementation.

2) **Ambiguity about the intellectual property of modeling:** Due to the collaborative nature of the BIM methodology, issues related to the intellectual property of the modeling emerge.
3) **Cost associated with the implementation of the software:** BIM works with multiple software, along with the purchase of equipment (hardware) and training courses.
4) **Ambiguity regarding the chain of legal liability:** New obligations for BIM professionals related to work scopes, roles, and responsibilities in case of errors or miscoordinations.
5) **Resistance to change the way a project is built:** Resistance to change due to work culture, lack of commitment and innovation, or the idea that the current way of working is sufficient.
6) **Low use of standards for the description of BIM objects and coding systems:** A BIM standard grants information regarding possible uses, benefits, technical glossary, etc., where the idealistic holy grail of BIM has been to create a common language for builders.
7) **Low demand for the use of BIM by the client/manager:** The lack of demand is due to the lack of knowledge of the program or the client's perception (since his/her requirements are met with conventional tools, he/she considers the implementation of BIM unnecessary).
8) **Interoperability problems between different BIM software:** Fragmentation between participants in each project phase can be caused by the diversity of software and can contribute to the interoperability problems, because of the diversity of software formats.
9) **Lack of knowledge of the benefits of implementing BIM:** The low number of studies of the BIM impact on the projects has caused uncertainty among senior executives and clients.
10) **Time and/or cost for training personnel in the software:** The difficulty of handling the software results in a slow learning pace, bringing a high investment of time and cost.
11) **BIM is still little known and/or complex to use:** BIM is described by users as "rigid" due to the specific order of actions to coordinate the diverse software, along with an "unfriendly" interface, which makes self-learning difficult, made worse due to constant software updates.
12) **Low collaboration among Project participants using BIM:** The "fragmented nature" of the construction field causes the main obstacles of peer-to-peer input.
13) **Lack of government intervention in massive BIM use:** Low participation of the government as a change agent. For BIM to become widespread, the role of the State is essential, through subsidies, courses, or promotion of public projects that require its use.
14) **Low support from managers and decision-makers in the implementation of BIM:** The support offered by top management is a relevant element to implementing BIM in the construction industry, through the necessary investments for training in this methodology.
15) **Lack of experience or expertise in BIM use:** Due to the low number of regulated BIM users, there is a lack of experience, causing difficulties in the implementation.
16) **Limited existence of BIM protocols:** The launch of protocols in the scheduling phase is crucial to ensure consistency in the information and formatting styles for BIM implementation, if not, it increases the occurrence of mishaps.
17) **Changes in workflows within and between projects:** Because of the collaborative nature of BIM, it is important to give way to radical changes in the workflow. These changes are not entirely linear but produce feedback loops between BIM specialties.
18) **Limited access to a stable connection to servers for storing and coordinating information:** There was no stable internet service or hardware (*IT infrastructure*) with the necessary capabilities to be efficiently connected to external or internal servers.
19) **Cybersecurity risk:** Cybersecurity becomes a major threat when an unauthorized user or hacker get access to a BIM project. In addition, confidential information, such as electronic signatures on documents, can be easily forged or replicated, creating authenticity doubts.
20) **Need for a BIM manager in projects:** Because information models are shared among users, it is crucial to hire an employee who updates the BIM data with accuracy.

21) **Low availability of specialized BIM software for bridges:** It is caused due to the low availability of specialized software that has specific "families" for the modeling of bridges.
22) **Difficulty in making updates to bridge models on-site:** When wanting to perform on-site inspections of a bridge to update the information of its real conditions, a lack of flexibility to represent and exchange information parametrically has been found.
23) **Differences between BIM for buildings and BIM for bridges:** The differences that contrast BIM and BrIM lie in the procedure for modeling the parts of each project, since, in general, roadway elements must be adapted to the geometry of the terrain.

Table 1: Barriers found in the literature

CASE STUDY EVALUATION OF THE BARRIERS FOUND IN THE LITERATURE

To evaluate the impact of the barriers found in the literature, an evaluation instrument (survey) was applied to a group of 17 professionals belonging to the case study described above. This survey consisted of two parts: questions associated with the probability of occurrence of an event (in this case a barrier), and questions related to the severity that could cause the occurrence of such an event. Based on the results of both indicators (probability and severity), the impact caused by the existence of barriers in the implementation of BIM in bridges was calculated.

For the validation of the evaluation instrument applied, it is necessary to ensure its understanding and whether its design is self-explanatory (Forcael et al., 2022). For the present study, eminent practitioners and researchers reviewed the survey and made relevant comments to improve its comprehensibility, repeating the process until the survey was fully refined.

Once the data was processed, Cronbach's alpha coefficient (α) was calculated to evaluate the reliability of the survey, ensuring the survey's objectivity. This value was calculated with equation 1, where K is the number of questions, V_i is the sum of the variances of each question and V_t is the variance of the total results of the respondents.

$$\alpha = \frac{K}{K-1}\left(\frac{\sum_{i=1}^{K} V_i}{V_T}\right) \quad (1)$$

Along with the validation of the interview described above, according to Oppenheim (2000), a pilot interview was also applied to measure and calibrate the interviewee's response time and ensure that the questions were explicit and did not confuse the interviewee. Thus, for the survey applied, Cronbach's alpha values obtained were 0.869 for questions related to probability and 0.909 for questions associated with severity, values with a more than acceptable reliability according to Doloi (2008). The response rate of the applied instrument reached 47%, which is considered satisfactory as it exceeds the minimum value suggested by Fellows & Liu (2015). The survey is available on request from the authors. The sample consisted of architects, builders, civil engineers, BIM managers, and BIM coordinators, whose profiles are shown in Table 2.

Table 2: Respondent profile.

Labor sector	Private	50%

IMPACT ANALYSIS OF THE BARRIERS PRESENT IN BIM FOR BRIDGE PROJECTS

Calculation of indexes

The methodology proposed by Akogbe *et al.* (2013) was used to calculate the indexes, which allows the factors to be classified in terms of impact, using probability and severity responses:

- Probability index (P.I.): represents the probability of occurrence of an event, with values between 0% and 100%, and calculated with equation 2.

$$I.P = \frac{\sum_{0}^{100} a_i * n_i}{N} \quad (2)$$

Where a_i represents the value assigned to each answer (0%, the impossibility; and 100%, the certainty); n_i represents the frequency of each answer, and N is the total number of answers.

- Severity index (S.I.): represents the severity of an event on the project if it were to occur, ranging from 0% (no severity) to 100% (total severity), calculated with equation 3.

$$I.S = \frac{\sum_{0}^{100} b_i * n_i}{N} \quad (3)$$

Where b_i represents the value assigned to each response (where 0% is no impact and 100% is high impact); n_i represents the frequency of each response and N is the total number of responses.

- Impact Index (I.I.): impact of an event based on the probability of occurrence and its severity, classifying the barriers according to their risk for the project and calculated with equation 4.

$$I.P \; x \; I.S = I.I \tag{4}$$

Impact Index Ranking

Table 3 shows the results from the evaluation tool, which are broken down into the probability index (P.I.), the severity index (S.I.), and based on these two indicators, the impact index (I.I.).

Table 3: Impact factors ranking.

Barrier	P.I.	P.I. Ranking	S.I.	S.I. Ranking	I.I.	I.I. Ranking
8. Interoperability issues between different BIM software.	85%	3	87%	4	74%	1
23. Differences between BIM for buildings and BIM for bridges.	86%	2	80%	6	69%	2
16. Limited existence of BIM protocols.	72%	10	82%	5	59%	3
15. Lack of experience or expertise in BIM use.	76%	7	76%	7	58%	4
17. Changes in workflows within and between projects.	81%	4	64%	13	52%	5
21. Availability of specialized BIM software for bridges.	56%	16	92%	1	52%	6
6. Low use of standards for BIM object description and coding systems.	78%	6	64%	12	50%	7
12. Low collaboration between project participants using BIM.	74%	9	66%	11	49%	8
5. Resistance to change the way a project is built.	78%	5	61%	14	48%	9
19. Cybersecurity risks.	52%	19	90%	2	46%	10
3. Cost associated with software implementation.	76%	8	59%	17	45%	11
22. Difficulty in making updates to bridge models on-site.	46%	21	88%	3	41%	12
1. Need to train a greater number of BIM users.	61%	15	67%	10	41%	13
9. Lack of knowledge of the benefits of implementing BIM.	70%	11	58%	20	41%	14
2. Ambiguity about the intellectual property of modeling.	66%	13	58%	19	38%	15
4. Ambiguity regarding the chain of legal liability.	69%	12	53%	22	37%	16
7. Low demand for the use of BIM by the client/manager.	64%	14	54%	21	35%	17
11. BIM is still little known and/or complex to use.	48%	20	70%	9	33%	18
14. Low support from managers and decision-makers in the implementation of BIM.	55%	17	60%	16	33%	19
10. Time and/or cost for staff training on the software.	52%	18	61%	15	32%	20
18. Limited access to a stable connection to servers for storing and coordinating information.	40%	23	76%	8	30%	21
13. Lack of government intervention in massive BIM use.	41%	22	59%	18	24%	22
20. Need for a BIM manager on projects.	90%	1	25%	23	22%	23

It can be seen that the “Need for a BIM manager on projects” is the barrier with the highest probability of occurrence according to the respondents (90%), followed by “Differences between BIM for buildings and BIM for bridges” (86%), and in third place “Interoperability problems between different BIM software” (85%). In terms of severity, the factor with the highest index was “Availability of specialized BIM software for bridges” (92%), followed by “Cybersecurity risks” (90%) and “Difficulty in making updates to bridge models on-site” (88%).

The impact index (I.I.), as previously explained, is related to the two previous indexes, and provides an overview of the impact of the barriers on the project. The first is "Interoperability problems between different BIM software" (74%), which is not surprising, since it is in the top five of the previously ranked indexes. Next are "Differences between BIM for buildings and BIM for bridges" (69%), "Limited existence of BIM protocols" (59%), "Lack of experience or expertise in the use of BIM" (58%), and "Changes in workflows within and between projects" (52%). In this research, any barrier that exceeded the median I.I. was classified as relevant. Thus, the P.I. and S.I. of the barriers mentioned in the classification by I.I. have values that meet this criterion, except for "Changes in workflows within and between projects".

Probability-severity matrix

Figure 1 shows a probability-severity matrix, which was used to determine the impact zone in which each barrier is located. The impact categories range from very low (lower left zone), to very high (upper right zone). The matrix design is based on the research of Dumbravă & Vladut-Severian (2013). It is seen that most of the factors are in the very high and high impact zone.

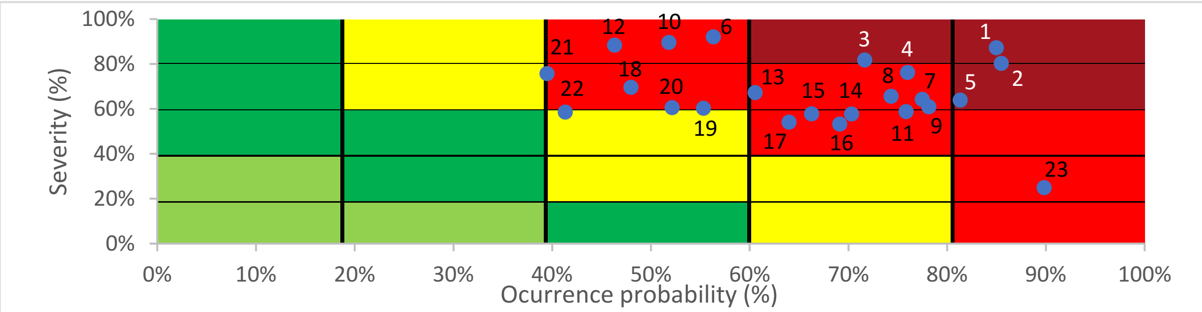

Figure 1: Probability v/s severity matrix

CONCLUSIONS

In terms of contributions for practice, this research may help project and engineering managers to have a first approximation to the most recurring barriers in BrIM and how to rank them according to their impact. Despite the findings of this study are based on survey responses from BrIM projects, they can be extended to complex projects with different levels of uncertainty. As found, this research shows that "Interoperability issues between different BIM software", "Differences between BIM for buildings and BIM for bridges", "Limited existence of BIM protocols", "Lack of experience or expertise in the use of BIM", and "Changes in workflows within and between projects" are the main barriers to implement BIM in bridges. Therefore, a project manager should pay attention to the existence of BIM protocols for bridges and to count on professionals with proved BIM experience. From a technical point of view, it is relevant to focus on interoperability between BIM software packages and the main differences found when using BIM for bridges instead of BIM for buildings. Finally, the last barrier found —related to changes in workflows within and between projects—, accounts for the importance of having competent managers to coordinate the whole project properly.

The only factor unique to bridge projects was the "Differences between BIM for buildings and BIM for bridges". It is also important to mention the close relationship between the barriers "Interoperability problems between different BIM software" and "Limited existence of BIM protocols", as they may allow writing a guide for interoperability between software to be used. Finally, in terms of risk, as most of the barriers were grouped in the upper right corner of the probability-severity graph, i.e., high probability of occurrence and high severity levels, it was possible to confirm that the barriers present in bridge projects generate high levels of impact when implementing BIM. Because of the exploratory nature of this study, for future research it is recommended to consider a larger number of interviewed professionals belonging to multiple bridge projects, which could provide other barriers or confirm those found in this study.

THE ROLE OF LEAN IN DIGITAL PROJECT DELIVERY

Kevin McHugh[1], Bhargav Dave[2] and Marzia Bolpagni[3]

ABSTRACT

The role of digitalization in delivering construction projects is ever increasing as digital tools and processes are pervading the entire construction lifecycle. Lean processes have a proven track record in improving construction project delivery while playing a positive and important role in the deployment of digital processes.

This paper discusses the key lean drivers for introducing digital production management systems to support efficient production planning, monitoring and controls. The paper also highlights the role of Last Planner System® (LPS) in the development of centralized digital command rooms to integrate disperse project teams. The research methodology was action research using a case study of a data centre.

The use of digital tools to support the last planner system can affect the behaviours of the participants. Improved transparency with an increased understanding from using digital platforms can improve the understanding between project stakeholders. It was found that the lean collaborative processes based on the LPS, especially the lookahead and commitment planning processes contributed significantly to the successful deployment of the digital platform and improvement of the control cycle.

To manage global networks and integrate fragmented project teams, Lean construction methodology supported using digital tools can enhance the collaborative environment. Digital construction can enhance the knowledge sharing that in turn improves social networks that can increase innovation.

KEYWORDS

Lean Construction, Digitization, Project Management, Last Planner System®

INTRODUCTION

Lean thinking and lean processes have proven to be successful and to positively influence major operations and improve productivity. Using digital tools to support lean concepts by providing near real time information that can be formatted and displayed can support multi stakeholder engagement and increase the effectiveness of collaborations (Sepasgozar et al. 2021). This information should underpin lean social collaborative production planning, where information is used to understand productivity rather than direct operational decisions using data alone (McHugh, et al., 2021). The correct management of digital platforms can support and increase the effectiveness of lean construction methods for project teams. The use of cloud based platforms and organized data, project teams can share a single source of truth that can improve communication to avoid delays and minimize reworks (Quiso et al. 2020).

LITERATURE REVIEW

The international construction industry is vast, according to the Confederation of International Contractors' Association (2022), global construction industry represents a global turnover of US$14 trillion and employs around 120m people. The industry relies on specialized contractors and designers who work with international clients. Standardized delivery methods for projects are desired to manage productivity. Productivity loss is experienced when a contractor has not accomplished anticipated achievable or planned rate of production (Gibson and Edwards 2015). Lean Construction (LC) methods have been identified as a possible improvement to construction project management. Technology has been identified as key element to support LC, however barriers to implementation include technical barriers, organizational fragmentation, and organizations unwilling or prepared to make the necessary changes to adopt LC (Hamzeh et al., 2021).

The availability of skilled workers is an issue for the industry with the current global growth (Ceric & Ivic, 2020). This deficit of skilled operatives effects the quality and overall project performance resulting in higher costs (Karimi et al., 2018). Utilizing key staff and bringing the required expertise is a challenge to the construction industry. The availability of skilled staff and underutilization of staff hinders construction productivity.

There is an increased focus on the adaption of construction 4.0 technologies and methodologies (Bolpagni et al., 2022). The digitalization of the construction industry and the advancement of Building Information Modelling (BIM) have highlighted opportunities for projects to harness construction 4.0 technologies (Kunz & Fischer, 2020; Sacks et al., 2010). The Internet of Things (IoT) can seamlessly interconnect components and improve the quality of performance and output of information systems. While Industry 4.0 is the bedrock of technological change through an adaptable tool to ensure desirable change and automation occur in the process of adopting IoT and Lean concepts, which was supported in (Ballard & Howell, 2003; Dave et al., 2013, Dave et al., 2016). Digitalization can potentially prove beneficial for large scale projects where project teams are fragmented and where project scope is vast. Effective and immediate access to information minimizes the time and labour needed for retrieving information and reduces the occurrence of ineffective decisions that are made in the absence of information (Ergen et al. 2007).

The adaption of digital technology and platforms can assist lean construction where production networks can be deployed for all stakeholders that can improve productivity both on and off site. This can improve efficiency, accountability, sustainability and scalability where dispersed project teams can collaborate (Frazzon et al. 2013). These processes can further be supported by providing digital collaboration spaces where teams can join collaborative meetings in digital operation rooms. This improves the effectiveness of collaborations as the correct stakeholders and decision makers are available to participate in the sessions. With live digital information at hand stakeholders are prepared for collaborative meetings where the project information available on the cloud for interrogation which increases the value of the meeting (McHugh, 2021).

LEAN BASED MANAGEMENT

Lean thinking, tools and methodology can influence major operations and improve productivity. Continuous innovation and supporting a learning environment are core elements of lean construction (Zhang and Chen 2016). As construction projects become more complex, specialization of specific functions has introduced complex project organizational structures and interfaces that require integration to complete the project. How a project performs is linked to how efficient the bounded activities are planned, managed, and how permeable the boundaries are to support information flow, share knowledge and learnings (Hobday, 1998).

The use of digital tools supporting lean concepts of management can provide innovative solutions to maximize the availability of near real time information. This information should underpin lean social collaborative production planning, where information is used to understand productivity rather than direct operational decisions using data alone (McHugh, et al., 2021). Construction research theories provide insights, but it is the nature of the markets—notably, the diverse objectives of stakeholders and the procedures and their practices in pursuit of self-oriented benefits—which are the main impediments to achieving greater coordination and collaboration (Fellows & Liu, 2012).

Digital platforms can support the generation and sharing of knowledge and will need to be adapted and improved as construction management progresses. Hamzeh et al., 2021 introduced the concept of Lean Construction 4.0 which recognizes the advancement of digitization in the industry with the need for a human centric rather than a technologically centric philosophy to advance the industry. Using cloud platforms and organized data, project teams can develop an information system where all stakeholders can commit and also be held accountable (Hicks 2007). This also provides a collective collaborative platform where the project interests are highlighted rather than interest of just individual stakeholders. This reinforces positive behaviors where project constraints can be identified and shared clearly, and project commits can be shared and validated using acquired data.

RESEARCH METHOD

Action Research (AR) has expanded over the years across varied disciplines as a means for improving the quality of interactions and understanding among people in social situations (Burns, 2005). In this study some of the authors were participant in the study. The results and actions outlined were created collaboratively with the project participants. The study focuses on generation of public sphere where participants can engage. This participation is relevant in critical participatory action research. However, authors have emphasized that the key form of participation in this kind of research is participation in a public sphere and participation with others in communicative action. This approach is analogous to a conversation in which people strive for intersubjective agreement about the ideas and the language they use, mutual understanding of one an - other's perspectives, and unforced consensus about what to do (Kemmis et al., 2013).

A case study was developed to represent the research where a "case study" can be defined an intensive study about a person, a group of people or a unit, which is aimed to generalize over several units (Heale & Twycross, 2018). Case studies by their nature, are more concerned with depth of analysis than with generalization (Borgman, 2015). This study follows on from previous research developing digital social environments (McHugh et al., 2019; McHugh, et al., 2021). Case studies provide a deeper understanding, for example, causal relationships than controlled experiments do (Host et al., 2012).

The research will be led by one of the authors who is an industry practitioner of lean construction. Action research is participant research that comprises of taking actions while studying a problem whilst also producing knowledge accumulating experience and contributing to the discussion of problems (Collatto et al. 2018). This research will support the development of an information system to support the efficient phased handover process that is essential for commissioning stage of the project.

CASE STUDY

The case study is on a €1.2bn data centre project where lean project management systems have been used during the construction phase. The project was based in Ireland and had initially started in 2016. This facility is an 86,000 m² structure consisting of 8 single storey data halls with associated electrical rooms and external backup generator systems. The facility also consisted of an administration block and external security centre. This study was carried out on the third phase of construction on the campus. For this phase there was a fundamental change of the design where a First of a Kind (FoK) cooling system was designed for the client. This required significant equipment changes along with layout and build sequence alterations.

This study will focus on the final phase of construction the Commissioning (Cx) phase. The (Cx) phase of data centre projects have traditionally proven to be more difficult to execute as there are more stakeholders involved. Since they are highly dependent on each other, developing schedules in parallel without adequate coordination can lead to misconceptions and, therefore, a great deal of rework (Garcia et al., 2004). It has been identified that the Cx phase requires a greater level of collaboration with an increased integration of project stakeholders. The problem posed was how to gather, share and use information acquired to integrate construction, commissioning, and quality functions for all stakeholders.

Digitized LPS was use on previous project phases on the site where they were completed and handed over to the client defect free. The resultant predictable and reliable phase handovers enabled the client to challenge the team to construct and commission a FoK construction project. This case study documents how digitization supported the process and assisted the integration of teams and it supported the execution of complex tasks.

PREPARATION FOR DIGITAL COLLABORATION

The Production manager, Cx manager and programme manager developed a high-level work breakdown structure. Early engagement from the project vendors and design team highlighted project constraints. The Cx phase of the project started with a pull planning session where all stakeholders developed a commissioning plan. There were approximately 20 different organizations ranging from designers, specialist vendors, quality assurance and trade contractor teams. This exercise identified and exposed issues with the construction and Cx sequencing and provided the team with a greater understanding to complete the Cx programme. Figure 1 illustrates the progression from reviewing the proposed master schedule to development of an actionable commissioning programme,

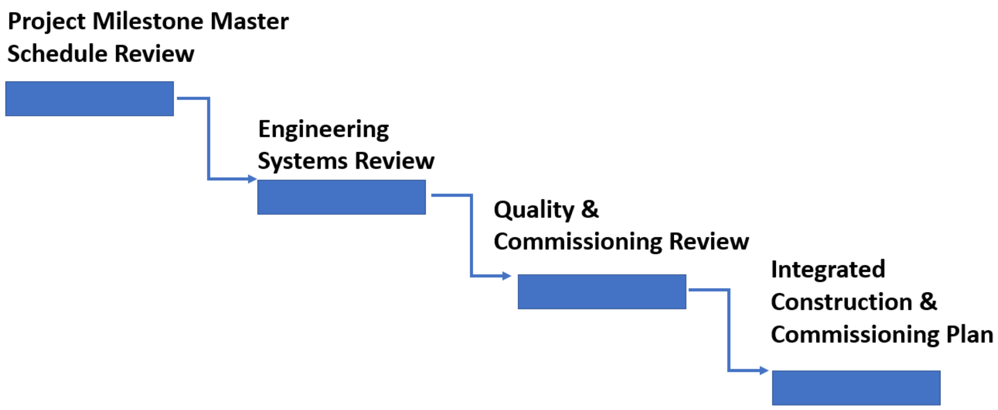

Figure 1: Cx Framework development phase

This was then cascaded to the trade contractors to review and resource in advance of a pull planning digital mapping day. A digital hybrid method of mapping was used for the first time instead of using ‘post-it’ notes in the room. Project resequencing and constraints were highlighted in the collaborative session. A dedicated digital hub (Figure 2) was used with technology to virtually interact using web cameras, mist microphone room pick up and high-definition touch screens and sound bars. This room was designed to improve interactions between site-based teams and virtual remote teams. The use of touch screens and smart microphone functions improved collaboration between team members.

The use of this technology allowed interaction between professionals connected remotely and the ones in presence. The command room has been present on the project since the first phase. The digitization of the room began early in the project and has evolved and improved on each phase where new available and affordable technology has been introduced. The room was designed with collaboration in mind where interaction is key to good communication and collaboration.

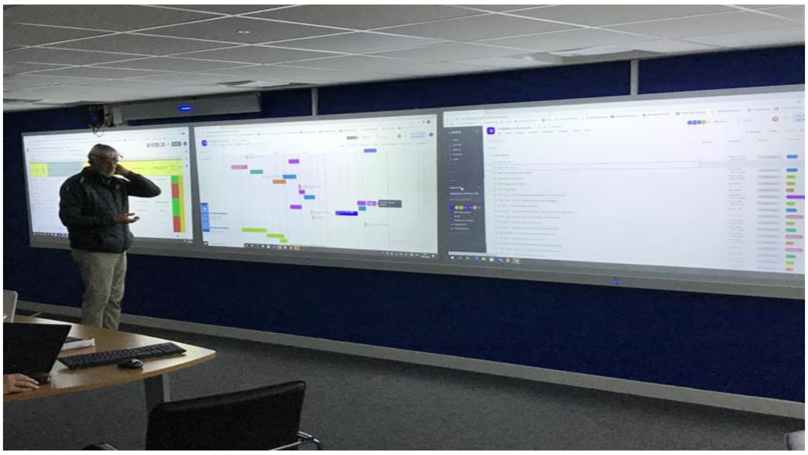

Figure 2: Digital hub with Digital Pull Planning sequence

DAILY OPERATIONS PREPARATION

The quality of collaborative meetings observed relied on participants being informed and prepared. Information quality is key to the success, shared information platforms aided the acquisition and validation of key project information. The identification and tracking of key activities were important to successfully achieving defined targets. Therefore, the more extensive and balanced the inputs of information (i.e., options, alternatives, predictions, and criteria, which we call collectively decision contents), the more informed the decision basis becomes (Kam and Fischer 2004). Following the initial mapping day there was a series of targeted workshops to map the critical air, water & electrical systems. Visilean (Dave, B., 2013) was used to prepare these plans and it was used to highlight and manage constraints raised.

Figure 3: Weekly Work Plan PPC live dashboard

This plan was then further broken down to develop look ahead planning and weekly work plans using the Last planner System ® (LPS). Digital platforms were identified to gather information and share the status of the project as shown in (Figure 3). BIM 360 Field was used to prepare and manage the quality check sheets which are necessary for the Cx stage. There are limited mitigation measures at Cx phase for not completing the preceding Cx activities, therefore it is necessary to have an accurate picture of the current activity status. This allowed project teams to develop and manage the required check sheets collaboratively. This provides the Conditions of Satisfaction (CoS) necessary for seamless staged handovers. Daily morning huddles previously held on site were relocated to the digital command room. Digital white- boards were prepared by each trade contractor and vender. This board was designed to include client issues, design issues, quality issues and commissioning status of activities.

A Cx dashboard was developed to capture the project status and improve communication between project stakeholders. Constraints were raised and incorporated into daily meetings where the team removed constraints and improved the delivery process. The status of each piece of equipment was managed for installation. The status of each piece of equipment tracking was essential to map the critical Integrated system test (IST). IST can begin when all equipment has passed the required testing and initial commissioning.

Daily huddle meetings are an important meeting in the production control system cycle. This is where daily commitments are reinforced and where the team members collaborate to execute defined assignments, this is where the quality of the planning and preparation is validated. It is important that commitments can be communicated effectively and trade to trade handovers are delivered efficiently. These meetings are the foundation for all future planning and ensure that the quality of the installations is validated and ready for the next stage of commissioning. Dashboards were an effective way of managing commitments as shown in figure 4.

Figure 4: Cx Dashboard

Reporting & Communication

Project data was collected using multiple digital platforms. This information was integrated by developing Business Intelligence (BI) dashboards. Dashboards played an important role for communication between project stakeholders. PowerBi® platforms were used to gather information from different sources to integrate into a single visualisation platform. Data was collected from multiple platforms that were used for daily works planning, material delivery, safety documents, quality documents, design, with laser and scanning/reality capture sources. This data was formatted and sorted by area and by utility and then by trade contractor.

It was important to code and identify all assets and functional areas correctly to allow data from different formats to be integrated correctly. There were over twenty different organizations imputing information daily into the system from daily activity reporting to quality check status and BIM coordination and scanning. This form of bottom-up communication really meant that there were over one hundred individuals managing the Cx programme between site teams and planning teams. It was important that all teams could work effectively and the ability to report accurately on daily Cx activities was important. This allowed teams to work effectively together with a shared understanding of the project.

The purpose of developing of digital dashboards was that they could be used in a digital control room to support allowed project teams' ability to communicate effectively. The dashboards were configured to be used at the different stages of the LPS. Short term forecasting and PPC dashboards were primarily used for site supervision collaborative meetings. Weekly work plan dashboards were used at daily huddle meetings. The information collected from the field fed directly into operational and planning dashboards.

Figure 5: Quality Dashboard

The project team focused on improving the sequencing and trade to trade handovers of this FoK project. Quality trade to trade handovers are an important gateway for the Cx stage of the project. The status of equipment was visually displayed on the quality dashboard (Figure 5). There are multiple stakeholders involved in this quality function. Defining what the correct parameters and requirements for each stage is important. Communicating this and measuring adherence to the defined parameters is also required. Firstly, in design the quality of the documentation and design modelling is a make ready need for construction. Procurement of materials and the validation of installation by construction teams is then required. The demonstration of how to present the soundness of installations to the project quality teams is required. The development of a detailed quality plan ensured that all stakeholders understood the steps to handover installed works. The sign off for the equipment and associated services before the Integrated Service Test (IST) is the focus of the Cx phase of the programme. In terms of planning, each sequence of work is directly linked to the next.

Forecasting and ensuring quality inspections passed first time was a key focus for delivery. Scheduling quality walks and confirming commitments were ready is an important process for accurate look ahead planning. This ensured that all project stakeholders could schedule and utilize their resources effectively (Figure 6). The raising of issues was promoted to provide learnings and to support developing a plan to execute the works to complete each phase of the project. The importance of the quality dashboard ensured that when handover of a section of works was panned, it was possible to demonstrate in advance that the works were completed to the correct standard.

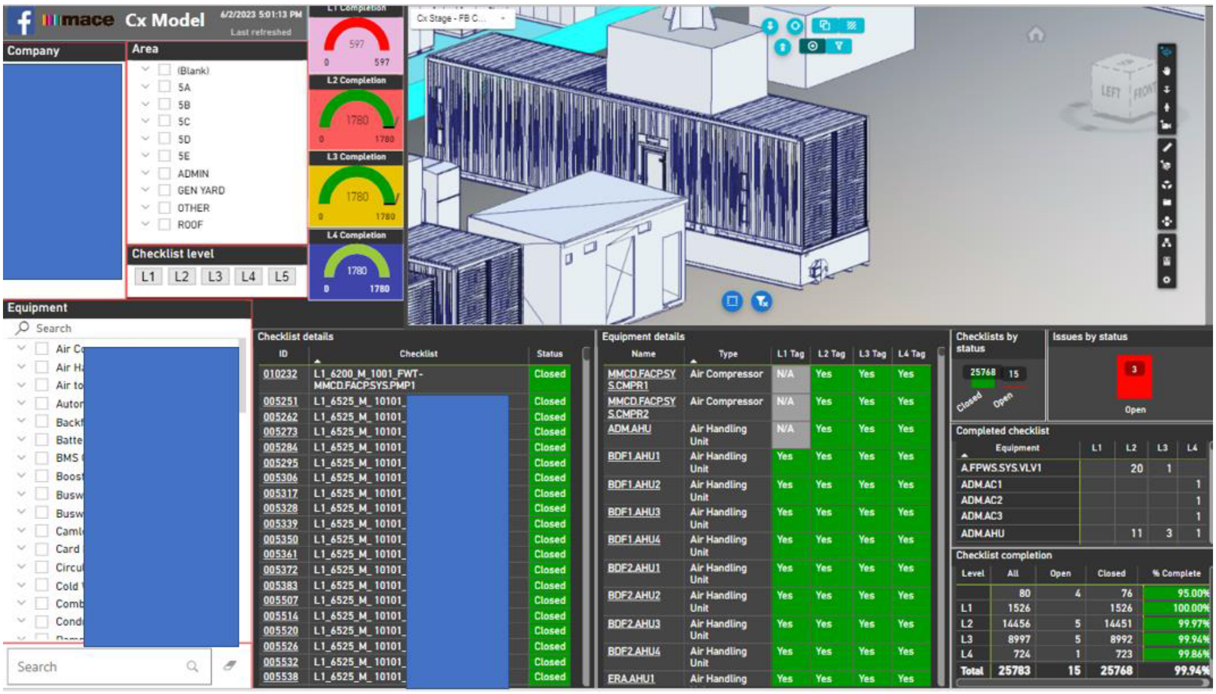

Figure 6: Progress Dashboard

FINDINGS

The use of digital tools was integral to the success of developing the Cx phase plan for a first of a kind mechanical cooling process. The construction and commissioning processes were integrated to achieve a successful project delivery. The ability to collaborate and generate near live data to track the elements of the project efficiently provided project teams the resource to make informed decisions.

Presenting complex project data in a form that allowed all stakeholders to engage effectively improved communication between project stakeholders. Near real time information increased the accountability of all stakeholders and increased the quality of commitments.

The use of collected field information provides certainty of the quality of the works. At each stage of the process the conditions of satisfaction were communicated, and the overall project performance was measured and displayed digitally. This provided the correct environment where transparency created trust and the digital information provided accountability against commitments. It was clear as the project developed that the complex nature of the Cx phase required greater co-ordination and involved multiple stakeholders to collaborate to complete.

This was particularly important in this phase as often specialist personnel would be required to be scheduled to be available weeks in advance of attending the project. This also gave assurances to all parties that the works were available and could be coordinated effectively. This was crucial to the success of this phase of the project. Specialist commissioning teams could be booked in to attend the project well in advance. The visibility and execution of make ready tasks increased the certainty of work being available for these teams when they arrived on site. This increase of resource utilization increased the productivity of the Cx phase of the project as commissioning could only continue when the preceding phase was completed. The use of near-live information and production dashboards allowed remote teams to collaborate effectively.

DISCUSSION

The forming of temporary alliances is typical in construction and the parties to these alliances change from the various stages from design to handover of construction projects. The social technical element provided by lean construction can develop the capabilities of the project by the process of continuous improvement.

New roles and responsibilities have been identified to support lean construction. Process facilitators assist collaborative meetings and now with increased digitization data management roles are important to manage the acquired data. Digital dashboarding were manged daily using technology syncing of acquired information for the digital control room and collaboration rooms. This support structure maintained the quality of the information that was increasingly relied upon for project status reporting and planning. It was important to the success of the project that all project teams could report information and communicate effectively.

The importance of using a single source of production and planning data positively influenced behaviours on the project. The quality of information collected from the field was high because it was used daily to inform operational meetings. The bottom-up communication stream integrated site teams and office teams which increased trust. The transparency of using shared dashboards improved accountability and allowed the teams to communicate effectively. The design and development of digital platforms and digital collaboration areas need to be considered to allow innovation and adaption of digital technology to support project production.

CONCLUSION

It is recognized that the adaption of Lean Construction 4.0 is driving innovation in the construction industry. This paper shows that building a digital environment to work effectively and interact with digital media virtually and in person promotes the adoption of digital tools. This in turn stimulates innovation and increases the use of digital tools to support construction management activities. The recognition of the role of digital in lean construction is important to note when identifying digital hardware and software to support construction management. Digital tools however cannot take the place of skilled workers and managers.

The creation of a lean production management system where tools and practices are supported by digital tools improves LC. The digital platforms were transparent, and the project status is visible to all stakeholders which in turn increases the collaboration and focus the deliver the project holistically.

There is an importance to ensure the quality of the data is correct. This requires multiple tools and constant maintenance of data. The coordination and collection of data to support managers is vital to the success of clarity of collaborative sessions both virtually and in person. The amount of information that can be collected is enormous. It is important to understand where the value is in the information and avoid overproduction of information that can over complicate and undermine the production control system.

The use of digital tools and platforms to effectively communicate and to demonstrate honoured commitments positively influences behaviours on the project. The flexibility provided by using digital tools, allows all stakeholders to engage and influence the workflow on the project. This improves the quality of engagement between project stakeholders where the acquired data forms the basis of the argument rather than a perception of how the project is progressing. This also encourages a holistic project continuous improvement process where stakeholders can continuously improve delivery and increases predictability of the project schedule.

DEVELOPMENT OF AN IMMERSIVE VIRTUAL REALITY PROTOTYPE TO EXPLORE THE SOCIAL MECHANISMS OF THE LAST PLANNER® SYSTEM

Canlong Liu[1], Vicente A. González[2], Gaang Lee[3], and Roy Davies[4]

ABSTRACT

A successful implementation of the Last Planner® System (LPS) requires not only education on its principles, but also managing social mechanisms it brings up to reach outstanding outcomes. Simulation games have been widely applied to teach LPS principles, but they do not seem to appropriately capture the social mechanisms due to lack of socio-technical realism and inadequate gaming controls (i.e., control external factors other than one of interest). Immersive Virtual Reality (IVR) technology has the potential to reveal the LPS's social mechanisms by providing a highly-controlled and realistic simulation environment. However, how to effectively leverage IVR for LPS simulation is not well understood. In order to bridge this gap, we identified the essential elements that an IVR simulation should have to study the LPS social mechanisms. We then developed and tested a multi-user IVR prototype with the identified elements to simulate the LPS use in a "hypothetical" construction scenario. The results show that the prototype is feasible for studying LPS's social mechanisms. This study lays a foundation for future research in using IVR simulation games to study LPS social mechanisms.

Simulations, immersive virtual reality, Last Planner® System, social mechanism, collaboration

INTRODUCTION

Managing traditional construction projects is perceived as challenging due to the complexity of the construction environment, the interdependency of production processes, unreliable production pace, communication and coordination problems, antagonist organizational environments in projects, among others, resulting in uncertainty that negatively affects workflow reliability and project performance. Ballard (2000) pointed out that these problems in construction projects are exacerbated due to the traditional approach of viewing their production nature as a process of converting inputs into outputs, neglecting value generation and flow management. To address these issues, the Last Planner® System (LPS) has been introduced as a Lean based production planning and control tool. It intrinsically deals with the dual and symbiotic socio-technical nature of construction projects (Liu et al., 2020, 2022; Priven

& Sacks, 2015). Technically speaking, the LPS deploys a robust methodological framework for production planning and control, which reduces workflow variability and uncertainty (Ballard, 2000). From another perspective, LPS can be seen as a social system comprised of project participants who work together to make plans and control project production (Ghosh et al., 2019). Therefore, social interactions among the project participants play a critical role in LPS implementation, improving project coordination and, thus, workflow (Ghosh et al., 2019; Priven & Sacks, 2015).

In spite of the increasing efforts to implement the LPS in the construction industry over the last 30 years, the comprehensive application of LPS principles on projects is still fragmented, and lagging behind (Ebbs et al., 2017; Priven & Sacks, 2015). Some studies have realized that this problem originates from the social-driven barriers: (1) Resistance to change; (2) Lack of cooperation, and technical-driven barriers: (3) Lack of understanding of LPS principles (Liu et al., 2020; Perez & Ghosh, 2018). Some researchers argue that the social and technical aspects associated with these barriers were not managed adequately in the past decades, impeding more effective dissemination and implementation of the team dynamics, LPS practices, knowledge in the construction industry (Gonzalez et al, 2015; Hamzeh 2011; Liu et al., 2020).

To achieve excellent implementation results, LPS requires not only effective implementation of tools and processes (Ballard, 2000; Ebbs et al., 2017) but also individuals to be motivated and empowered to complete teamwork in a highly collaborative environment (Kim & Rhee, 2020). Thus, studying and analyzing the project participant's social interactions, emergent psychological states, and their influence on enhancing positive teamwork, as well as how those behaviors seamlessly match the technical components of LPS, can bring valuable insight into realizing the full potential of LPS (Asadian & Leicht, 2022; Liu et al., 2022).

LPS SIMULATION GAMES

Simulation games are a hybrid of games and simulations that aim to train, educate, and entertain players while simulating the context of social system (Klabbers, 2009). Simulation games are often regarded as valuable in the Lean Construction industry because they offer a clear, realistic, and straightforward way of imparting knowledge about various Lean concepts. (Bhatnagar et al., 2022).

On the other hand, simulation games can be used to explore the social psychological phenomenon (McFarlane, 1971; Yiannakoulias, 2022). For instance, some simulation games are designed as digitalized environments, making data collection easier and allowing researchers to manipulate and control the experimental environment where hypotheses can be validated by manipulating specific variables (Lukosch et al., 2018). Simulation games can also create a situation or context through their sequence-specific rules or game controls, making it easy to elicit the participant's response to that situation (e.g., project teams may need to decide on adjusting plans when facing construction constraints). Also, it allows researchers to easily develop a coding or measuring approach based on these sequential rules that determine the specific behavior of game users (Lukosch et al., 2018; McFarlane, 1971). In addition, they allow researchers to replicate the same experiment multiple times without having to change the experimental design or set-ups (Lukosch et al., 2018). Therefore, simulation games have the potential to analyze the social mechanisms of LPS by evaluating individuals' behavior and psychological responses to controllable stimuli or scenarios.

There has been a growing interest in adopting Lean simulations and games in Lean academia and community (Bhatnagar et al., 2022). Several Lean simulation games teach different LPS principles through hands-on activities, such as building a schematic house with Lego™ bricks, to show the benefits of LPS compared to traditional management. The most popular training method is the commercial product LPS-based Villego game, which teaches LPS through two round games in a day (Warcup & Reeve, 2014). Another example is LEBSCO (González et al., 2015), which provides quick LPS training in a classroom setting, and COLLAPSE, a digital simulation game that requires users to complete LPS-related activities on spreadsheets (Raghavan et al., 2018). These engaging games, particularly Villego, make LPS knowledge more accessible to participants.

However, these games are not suitable for uncovering social mechanisms and generalizing findings to real-world settings, which is essential to devise practical intervention strategies for changing their social cooperation accordingly. There are four reasons. Firstly, the sense of presence in the tasks and contexts is too weak for users to perceive and act as a social self (for instance, COLPLASSE uses spreadsheet templates to simulate the operation of the project with an abstract environment) or over-complicated to play (for instance, Villego, which is a highly intricate simulation game requiring an in-depth understanding of LPS concepts and following rules, leading some people to lose their interest in participation). Secondly, they have inadequate gaming controls associated with the LPS principles and procedures. The successful running of the existing simulation games relies on the facilitator's intervention and the participants' accurate understanding of the rules. For instance, analyzing behavior responses from inconsistent experimental controls among groups is difficult when players break the rules and deviate from the LPS workflow. In other words, researchers are less likely to isolate extraneous effects that are irrelevant to social mechanisms, hindering the reproducibility and validity of results. Thirdly, they normally need physical models and additional set-up times, which hinders large-scale experiments. Fourthly, these games are designed for collecting the technical indicators of LPS implementation, such as PPC, time, cost, and knowledge uptake, but not for social indicators emergent during LPS-based teamwork.

IMMERSIVE VIRTUAL REALITY

Immersive Virtual Reality (IVR) involves computer-generated virtual environments with high visual impact and immersion levels, leading to increased engagement and perception (Feng et al., 2018). Thus, IVR can elicit targeted behavior using artificial sensory stimulation, even when the user is unaware (Lavalle, 2017). This virtual environment allows participants to feel as if they were physically present, and the high level of realism can make it difficult to distinguish between the virtual and real worlds. Thus, users' behaviors and responses in IVR are likely to match their real work context (Lavalle, 2017). The ability to conduct behavioral research using IVR offers numerous opportunities (Feng et al., 2018). In particular, a multi-user IVR has gained attention among researchers due to its capability to simulate social interactions in a realistic manner, for instance, where individuals can engage with either a virtual agent or another real person. Therefore, multi-user IVR environments are rapidly becoming popular in the fields of social behavioral and psychology studies. This is due to the flexibility of these environments in investigating and analyzing social cognition and social stress in psychological experiments (Bernard et al., 2018).

In this regard, we argue that there are several reasons supporting the use of IVR to address the limitations of existing LPS simulation games in conducting social experiments. First, its ability to edit the storyline (a collection of scenarios or events in which individuals can make decisions and act to advance the story's progression) and gaming controls have the potential to create the situation that researchers desire, which means the people are more likely to follow the game rules and procedure, making researchers obtain reliable results. Second, with the advent of cost-effective, portable, and networked-supported IVR head-mounted displays such as the Meta Quest 2, researchers can conduct large-scale experiments online to study the social mechanism of LPS.

On the other hand, by using IVR, researchers can obtain additional benefits for studying LPS social mechanisms that cannot be obtained from non-IVR simulation games. First, IVR enables individuals to behave as close to reality as possible (Feng et al., 2018), which has the potential to make the transferal of the simulation results to the real world more feasible. Second, with its high compatibility with biometric sensors and wearable instruments that participants can use during experiments, it has become easier to observe social behaviors and collect physiological data, such as galvanic skin response (GSR) and Heart Rate Variability (HRV). These features can provide a more robust result and help the researcher to gain a deeper understanding of social mechanisms of LPS.

Despite the potential of IVR technology to study the social mechanisms of LPS, there are still limitations to effectively integrating IVR functionalities and LPS principles into a simulation game to deepen the understanding of LPS. Specifically, at the preliminary stage, we do not know how to enable users to follow the LPS workflow using IVR-powered gaming controls. Additionally, we do not know how to design tasks and rules to create scenarios where social mechanisms can be captured. We also do not know what suitable technical solutions enable users to conduct teamwork, communicate, and finish tasks in the IVR environment. More importantly, we do not know how to enable researchers to collect behavior and physiological data in such an environment.

RESEARCH OBJECTIVES AND METHOD

As a preliminary step in filling the aforementioned knowledge gaps, this study aims to explore the viability of using IVR to create LPS simulation games, focusing on technical development. The purpose of developing the IVR simulation game is not for training but for experimentation, which opens doors to the broader use of IVR technology to conduct "controlled" Lean-driven social experiments. Specifically, the study aims (1) to explore the simplified LPS simulation workflow and rules, as well as related IVR prototype designs, and (2) to demonstrate the effectiveness of using IVR technology for LPS simulation games to explore the social mechanisms of LPS.

To achieve the objectives, bearing in mind the nature of the intended simulation game aimed to develop in this research, we first identify and determine the essential elements and rules that the VR-based LPS simulation should have. Then we developed the IVR prototype based on these findings. To test whether the developed IVR simulation game is feasible to study LPS's social mechanisms, we did "actually what" with a typical pavement task scenario. Specifically, it contains two testing rounds of the simulation case: traditional and LPS. We checked: (1) whether every user can complete their task and follow the procedure and rules using the proposed gaming controls; (2) whether our design in task dependencies and variations trigger social interaction among users; (3) whether the researcher can use this IVR prototype to conduct large-scale experiments and collect behavior and physiological data.

DEVELOPMENT OF THE IVR PROTOTYPE

CONCEPTUAL DESIGN AND GAMING CONTROLS OF THE IVR SIMULATION GAMES

The simulation games should have the ability to create a realistic and engaging setting allowing users to feel things like "it was a very meaningful experience" and respond to what they perceive as a realistic situation (Bhatnagar et al., 2022; Lukosch et al., 2018; McFarlane, 1971). We argue that IVR simulation games should offer users realistic construction scenarios and scenes to complete construction tasks. In this regard, the IVR environment should mimic real construction scenarios with 3D models, meeting areas, and construction sites. Second, The simulation game should find suitable navigation (moving around and exploring the virtual environment) solutions and interaction (communicating with people and interacting with virtual surroundings) solutions, allowing users to complete the tasks intuitively and realistically, as inappropriate navigation solutions may cause the motion sickness (Lackner, 2014). Third, cooperation and goal are important motivations that drive the users to complete tasks in the simulation games (Koivisto et al., 2018), so the IVR simulation games should allow users to make plans and complete construction tasks collaboratively, but limit their completion time. Fourth, the IVR prototype should simulate real-world construction and production systems. This requires users to perform key last planners, order materials in meetings and carry out tasks. In turn, the systems should respond to users' behavior like the real world (Lukosch et al., 2018). Sixth, the IVR simulation should have simplified rules and procedures, given that long duration and complex simulation rules are the major reasons for users' reluctance to participate in LPS simulation games (González et al., 2015). Lastly, to obtain better user experience and engagement, the IVR system should have a tutorial session to ensure every user can understand the game mechanism and goals.

On the other hand, simulation games should allow researchers to study social mechanisms by observing behavior and measuring psychological states. However, some social mechanisms are not easily found if users deviate from the rules. This requires the IVR system not only to allow the researcher to capture the social mechanisms but also to have gaming controls to create situations that induce these social nuances. Communication and decision-making are induced by dealing with uncertainty and task dependencies in construction management activities (Priven & Sacks, 2015). Thus, If a simulation game creates such a situation, the researcher can easily identify the emergent social mechanism. In order to identify these mechanisms, the IVR system must have a robust method to collect and analyze behaviors and psychological responses during the simulation. Therefore, the IVR simulation game should give users a level of freedom to finish tasks while also imposing dependency restrictions and uncertainty.

In order to study the social mechanism behind LPS, the prototype should provide two rounds of experiences (i.e., traditional and LPS) so that researchers can clearly see the social nuance when comparing the result of these two rounds. In that respect, it is necessary to determine the key principles and tools among traditional and LPS-based project teams, and design corresponding simulation rules and principles. Table 2 presents the LPS elements and devised rules in IVR simulation. It selected eight elements of the LPS based on Ballard's research (Ballard, 2000). The framework links the LPS elements and rules of simulation games to articulate the IVR design environment. In the traditional round, the LPS elements consider master scheduling, push planning, centralized decision-making, as well as the Planned Percent Complete (PPC) measure. In turn, the LPS-based round considers master scheduling, pull planning, constraint management, lookahead planning, commitment planning, distributed decision-making, continuous flow, and continuous improvement (discuss and analyze PPC). The implementation of these rules will be described in the next section.

Table 1: The LPS elements and devised rules in IVR simulation

LPS elements	**IVR simulation rules**	
	Traditional round rules	**LPS-based round rules**
Master scheduling	The manager released the plan	All users discuss the plan
Decision-making authority	Only manger	The manager along the other users develop the plan
Constraint management	Not applied	Users should discuss the constraints and remove them
Pull planning	The manager pushes the plan on others	The last planner can request resources when needed verbally and directly to the supplier
Lookahead planning	Not applied	Applied
Commitment planning	Tasks released by manager's requests	Tasks released by users' commitments
Continues improvement	Only PPC measure	Users should review and analyze the PPC.
Continuous Flow	Batch size is limited	The batch size can change if needed

SYSTEM ARCHITECTURE

Figure 1 depicts the architecture for a multiplayer IVR prototype designed to run both traditional and LPS-based rounds. It consists of a host acting as the researcher and clients. The prototype utilizes cutting-edge standalone wireless IVR headsets, Meta Quest 2, which offers a high level of mobility and a seamless match between users' movements and gestures in the virtual and real worlds (Meta, 2023). The controllers utilized in the prototype are wireless and do not require any additional tracking devices (the headset has integrated tracking sensors), providing users with the freedom to use them in any location. Also, the headset provides a casting function allowing users to share their IVR screen to a computer or smartphone. Wearable biometrical sensor sets: Shimmer3 GSR+ were attached to users' palms and ear to capture physiological data such as GSR, and HRV. The IVR prototype was created using C# programming language and the Unity game engine. Unity, a commonly used platform for creating desktop and VR video games and applications (www.unity.com), is compatible with the Meta Quest 2. Unity program provides basic modules to support the execution of the game. The login module defines the user identity by configuring the user roles and names; the production module provides the basic game mechanism that simulates the project lifecycle. The navigation and interaction model gives users a great degree of freedom to move, turn, and interact with the environment. The event module use a timer to measures and records the amount of time taken in a game. The timer has several timestamps or milestones associated with the pre-defined events waiting to be triggered. If a timestamp is reached, specific users will be notified and the environment will be influenced by the corresponding event. For example, suppliers will receive the notification of increasing delivery time, while global environment variables (e.g., delivery time) will be modified for all users. The network module provides an interface that synchronizes the local datasets to the cloud. All headsets are connected to a cloud server with Wi-Fi. Pun 2 and Photon voice (Photon, www.photonengine.com) are chosen as online hosting platforms, providing multiplayer supports. In addition, a researcher will join the network as a host by using a laptop with an Intel Core i9-10980HK processor, NVIDIA GeForce RTX 3080 graphic card, 32 GB of RAM, and a Windows 10 operating system. The host uses the Unity desktop editor to control the game, including starting and stopping the game, observing behavior, and accessing data from iMotions. The iMotion platform (iMotions, www.imotions.com) also operates on the laptop along with the game. It can read data generated by biometrical sensors wirelessly and capture headsets' screen.

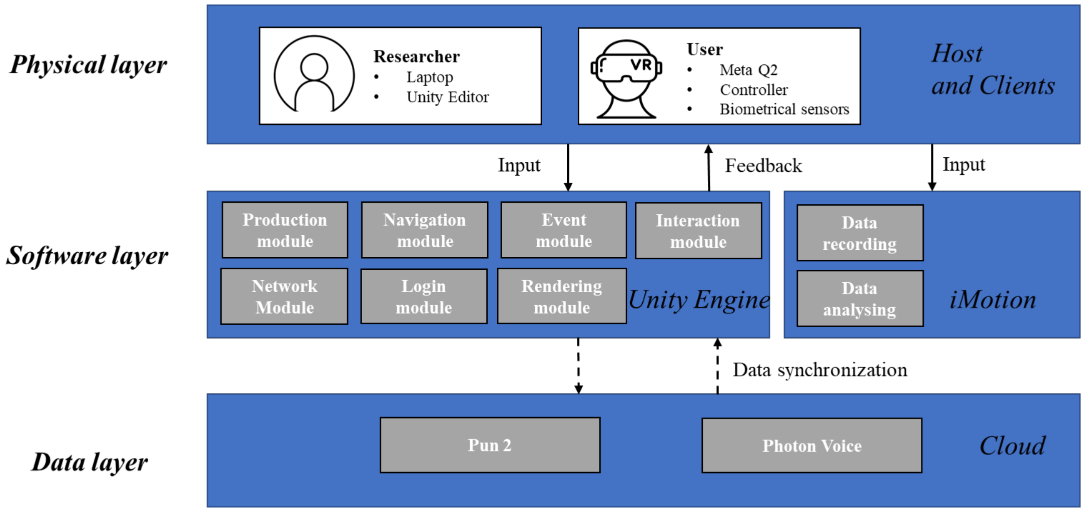

Figure 1: System architecture

IVR ENVIRONMENT

Four scenes and associated user interfaces have been devised in the IVR environment: (1) A Login scene enables users to use a virtual keyboard to enter a username, use a ray to select a role and different simulation scenes (see Figure 2a); (2) A Tutorial scene features an instruction board to provide game rules and guidance (see Figure 2b); (3) A Traditional Construction scene includes multiple sub-scenes: Construction, Production & Shipping, and Meeting & Planning sub-scenes (see Figure h). Figure (2c) shows that the users can control an embodied avatar. Figure (2d) shows that if the user presses the button, a ray will be cast from their hand to indicate the destination. Their embodied avatar will move the destination instantly after the user release the button. Figure (2e) shows the Meeting & Planning sub-scene is equipped with whiteboards, and users can use a virtual keyboard to make plans. The Production & Shipping sub-scene has a workstation for producing bricks and shipping them, allowing users to select the number of materials to be produced (see Figure 2f), while the Construction Site sub-scene has roadbeds where user can realistically use their hand to lay bricks and retrieve shipped bricks from pallets (see Figure 2g). (4) A LPS Construction scene is another scene that incorporates LPS procedures and tools into the production planning and control process of the project. It features similar sub-scenes and layout as the Traditional Construction scene, but with different rules and processes (e.g., the traditional Meeting & Planning sub-scene is replaced by a Lean-based Meeting sub-scene).

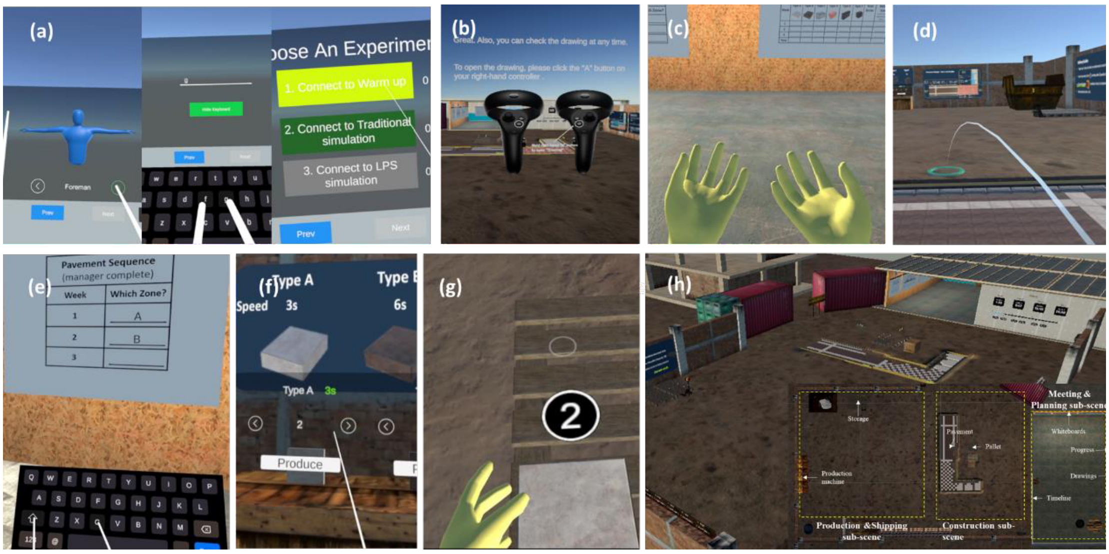

Figure 2: The user interfaces and scenes of the IVR environment: (a) A user selects roles, inserts usernames, and chooses simulation round; (b) A user read the tutorial boards; (c) A user has an embodied avatar; (d) A user moves to a position; (e) A user uses a virtual keyboard to make the plan (f) A user produce materials (g) a user grab materials (h) a construction simulation scene and a map.

PROTOTYPE TEST

TEST SCENARIOS AND STORYLINES

Hypothetical cases were created to test whether the architecture prototype presented in the "Development of the immersive virtual reality prototype for LPS simulation" section works as designed. In this hypothetical case, users must complete a pavement project (containing three different zones) within three weeks (simulated as 5 minutes per week in the IVR environment). This prototype should be played by three users maximum, including a manager, subcontractor, and supplier, which enables the exploration of the social interaction among key Last planners. Generally, the subcontractor is accountable for performing paving tasks at the construction site. The supplier is responsible for producing and delivering specific bricks to the subcontractors. The manager makes a plan and monitors the workflow. To achieve reliable gaming control, we use programming to restrict each role to only access its role-specific functions when performing tasks. Other than measuring and instruction before the game, the researcher does not provide cues or feedback to the users on the optimal way to complete the tasks. Before the game starts, all users will have a tutorial to learn how to interact with the VR environment and controls, as well as basic LPS procedures. Users must follow traditional (non-Lean) and LPS-based production planning and control approaches to complete the same tasks.

A simplified storyline was devised in this section, which presents a typical one-week simulation for all users. The IVR simulation has both the Traditional-based and the LPS-based construction rounds, which contain four main scenarios: Tutorial, Meeting & Planning, Construction, and Recap.

It is assumed that, in the beginning, users go through the Traditional round (see white blocks). Three users and a researcher meet for briefing goals and rules. In the Meeting & Planning scenario, the manager is responsible for compiling the plan (deciding on paving sequences, bricks production schedule, brick delivery schedule, and batch size). This simulates the Master scheduling and Weekly Work Plan (WWP) meetings. Once the meeting ends, the supplier and subcontractor are automatically taken to the production and delivery area and the construction area respectively to carry out the paving tasks. The supplier produces different types of bricks and delivers them in fixed batches, while the subcontractor executes the paving tasks. The manager is able to roam in all areas to monitor the project's progress and guide them to perform tasks. After the week ends, all players are immediately brought to the meeting area for a recap, where they discuss the previous week's outcomes, such as PPC, time, and quality. During this time, the supplier has notified the bad weather condition, and the supplier may report this issue to the manager. These processes will repeat three times (three weeks) to finish the project using the Traditional approach. After that, users will go through the LPS round. The workflow is similar to the Traditional round but has different planning and control rules and tasks (see the difference in Table 1). We envisaged that the researcher designates the traditional group as the control group and the LPS-based group as the experimental group, where the behavior and physiological data are to be collected.

TEST RESULTS

We illustrate the example screenshots of the demonstration case scenarios (see Figure 3a-e). Figure 3a shows that two users are controlling their embodied avatar and discussing the plan in the third user's view at the Meeting & Planning scenario. Users' positions and gestures have been synchronized with other users across the network. These features simulate a realistic social interaction environment, which could improve users' sense of presence during communication. Figure 3b shows the users' inputs on the commitment log, and the PPC register with automatically updated figures according to the planning status and the project progress. This information reveals the constraints among tasks, creating a situation where researchers can analyze social mechanisms by observing how users make decisions. In addition, their attendance in commitment analysis shows that users are able to complete the tasks following the procedure and rules (both traditional-based and LPS-based). Figure 3c shows an uncertain event is triggered and information (delivery time increase) pop-up on the supplier's screen, which provides a realistic situation in which the project team must address constraints. It also allows the researcher to compare the user's psychological responses to such situations in different experimental groups (e.g., compare each user's stress level between LPS and the traditional round in dealing with uncertainties). Figure 3d shows that the subcontractor has grabbed a brick and is placing it on the roadbed, while the manager is checking the time lapse on the timeline. The timeline shows that the second week is about to end, and all players will be brought to the meeting room to make a plan. The evidence suggests that the IVR system not only allows users to act on their own, but also has programmed gaming controls to ensure the simulation operates under the rules and procedures. Figure 3e shows that the researcher successfully uses the IVR system to observe behavior and collect GSR and HRV data during these situations. Notably, the behavioral and biometrical data can be aligned and streamed, which provides robust data collection methods for unpacking the social mechanisms.

Overall, the gaming control of the IVR prototype has the potential to enable robust experiment controls, thus ensuring the experiment's reproducibility, while time restrictions and few user requirements indicate its feasibility for conducting a large-scale experiment.

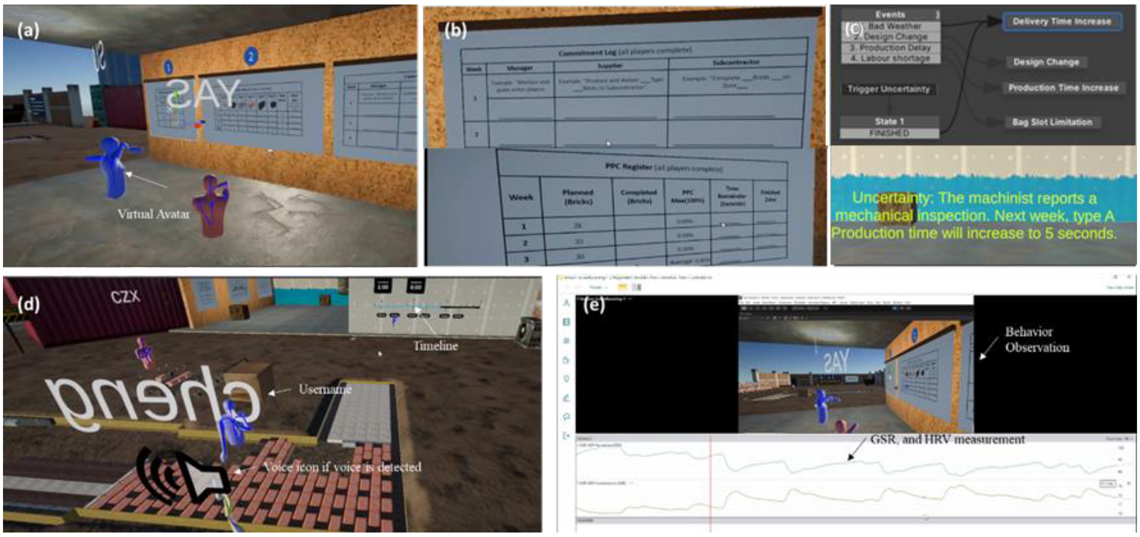

Figure 3: Screenshots of the demonstrative case and data collection platform: (a) During the Meeting & Planning scenario, a user interact with another user; (b) During Meeting & planning scenario, in the Meeting & planning sub-scene, users make the commitment plan, and analysis the PPC; (c) During Construction scenario, the system triggers uncertainties and impose the effect; (d) During Working scenario, in the Construction Site sub-scene, a user provide suggestions; (e) After the game, researcher code behaviors and analyses biometrical data.

DISCUSSION AND CONCLUSION

The purpose of this paper was to explore the viability and feasibility of using IVR to create LPS simulation games, with the goal of being able to develop methodologies to use these to better understand the social mechanisms of LPS. To do so, this paper determined the rules and essential elements of the IVR-based LPS simulation games. In this regard, this paper developed the IVR prototype, and illustrates a hypothetical case to demonstrate the realizations of these purposes.

The results show that the proposed IVR system is feasible for simulating the LPS and can improve our understanding of it by supporting the implementation of social experiments. This is due to its advantages in experimental control and support for large-scale experiments that involve the collection of behavioral or physiological data. The theoretical contribution lies in advancing Lean project management by providing a prototype design and data collection approach (containing technical requirements and design principles) that steps a stone for a new experimental avenue to study the social mechanisms of LPS. From a practical standpoint, using this IVR platform combined with gamification principles for purpose-training could improve the implementation of LPS in the construction industry. The use of IVR technology is not without limitations. (1) The IVR environment is a simplified representation of the LPS, only simulating a few technical and social dimensions of the LPS in real life. (2) ecological validity test of this prototype is needed before using it to conduct social experiments.

LEAN CONSTRUCTION WASTE REDUCTION THROUGH THE AUTONOMOUS VEHICLE TECHNOLOGY

Omar A. Owais[1], Mani Poshdar[2], Ali GhaffarianHoseini[3], and Amirhosein Ghaffarianhoseini[4]

ABSTRACT

In the automotive industry, autonomous vehicles (AVs) are an advanced innovation that has the potential to revolutionise the existing transportation system significantly. In addition, AVs provide benefits for society, the economy, and the environment. As far as Lean Construction (LC) is concerned, these features appear promising. LC's primary objective is to minimise the waste of resources, time, and effort. This study examines the potential contribution of AVs to LC through two exhaustive rounds of literature review. The research aims to establish the links between AVs and the overarching LC philosophy and principles. The first round of the literature review identified that AVs could reduce waste in three areas: inventory, transportation, and waiting time. Moreover, they can support solutions to environmental concerns. Additional literature reviews have identified five potential approaches for a new technology that can be applied to the construction industry to enhance the implementation of AVs. As well as the anticipated developments in each case are discussed accordingly. The practical implications of the findings are that AVs can reduce waste and cost, increase efficiency and productivity, and help create a more sustainable construction industry. According to the study, the construction industry should take a proactive approach to implementing AVs.

KEYWORDS

Lean construction, AVs, transportation, waste

INTRODUCTION

The fully advanced autonomous vehicles, known as driverless cars, are capable of identifying their surroundings by increasingly dependent on sophisticated technology to replace the actual human driving tasks, decisions, and behaviors (Ma et al., 2020). It is able to travel independently to various locations while excluding any human driving assistance (Litman, 2017). In fact, the Society of Automotive Engineers (SAE) has developed the SAE international standards J3016, which illustrates the AV's six categories, starting from the most basic (nonautonomous) to the most advanced vehicle (fully autonomous) (SAE International from SAE J3016™, 2021). This

innovation offers a major breakthrough in the existing transportation system to benefit society, the economy, and the environment. It also offers improvements in automated driving-assist characteristics and capabilities with enormous advantages for the AV lower levels (Katrakazas et al., 2015; Le Vine et al., 2015).

It is anticipated as a realistic solution for future transportation that will increase traffic efficiency, decrease fuel consumption, and importantly reduce carbon dioxide emissions, to name a few. It is, also largely relies on a computerised system equipped with advanced technologies that have been built inside the vehicle (Parkin et al., 2018). Furthermore, it may communicate traffic information among cars through advanced communication equipment utilising advanced Internet Technologies (IT) via a cloud service. Additionally, super-fast communication technology between cars that are based upon the Fifth Generation (5G) network to improve its vision in a fully secured manner (Storck & Duarte-Figueiredo, 2020). Vehicles are considered the heart of land transportation, as well as play a vital role in the construction industry. However, transportation has been identified as one of the leading waste types in the LC. It, therefore, requires more collaborative efforts to minimise its impact on society, the economy, and the environment. Also, to achieve the fundamental philosophy and principles of lean construction.

Lean construction (LC) presents "a way to design production systems to minimize waste of materials, time, and effort in order to generate the maximum possible amount of value" (Koskela et al., 2002). Lean construction recognises eight types of waste in the construction sector (Aziz & Hafez, 2013; Koskela, 2004; Sarhan et al., 2017) as follows:

1- Overproduction: Linked to the creation of a larger volume than requested or earlier than desired, which results in a waste of work efforts and materials.

2- Substitution: Financial waste produced by the replacement of a less-priced product with a more costly one, easy duty performed by an over-skilled individual, or the use of extremely advanced technology for simpler jobs.

3- Waiting time: Related to idle time resulting from a shortage of material supply chain coordination and levelling, as well as the speed of activity by subgroups or equipment.

4- Transportation: The internal materials flow in construction sites could result from improper handling, the application of insufficient machinery, or poor passage conditions. It has the following significant consequences as loss of manpower, energy, storage area, and potential material loss while transfer.

5- Processing: Associated with the processor (conversion) operation, which can possibly be prevented by adjusting building technology.

6- Inventories: Relating to overstocks or unused stockpiles that cause waste of materials.

7- Movement: Deals with activities performed by employees that are needles in the workplace.

8- Production of defective products: It occurs when the final result fails to fulfil the quality standards.

As indicated earlier, the AVs provide enormous features that could boost the entire land transportation sector. However, transportation has been identified as one of the main waste types in the LC. Therefore, the research aims to explore the links between the use of AVs and LC fundamental philosophy and principles, which might offer a significant waste reduction in some of the earlier identified and widely agreed areas. This could consolidate the LC philosophy and support its concepts overall. Nevertheless, AV technology is still in its infancy stages of development, and studies that provide information on this matter are lacking. By examining the potential contributions of AVs in the LC industry, this study seeks to identify any further potential reduction in the LC waste types through the deployment of AV innovation. It also provides five different approaches to assist the decision-makers in deploying the AVs based on their risk assessments (on a governmental scale) in order to maximise their value in lean construction.

METHODOLOGY

Using a two-stage research design, this study investigates how AVs can contribute to lean construction, as shown in Figure 1.

In the *first phase*, a comprehensive literature review was conducted to identify the current state of the art in autonomous vehicle features, as the research parameter has been selected to search the “autonomous vehicles" AND "technology features" terms in google scholar to end up with 337 articles ranging from 2015 to present. Furthermore, the research team has analysed the identified articles based on AV aspects that could contribute to the reduction of waste recognised by lean construction to end up with 23 related articles. By utilising this information, the team developed comprehensive analogies linking the prominent features of AVs with the purpose of lean construction in order to reduce waste.

In the *second phase*, a literature review was conducted to identify existing strategies that could be used to support the application and utilisation of AVs in construction supply chain management. A set of keywords of "Autonomous vehicle" AND "deployment strategies" has been searched on google scholar from 2015 to date to end up with 260 related articles. It led us to identify common strategies for the application of AVs. Based on the results of the second literature review round and the best practices reported, we have identified a comprehensive set of guidelines that can be applied to the construction industry to assist in the implementation of AVs. These guidelines provide an outline of the necessary steps to be taken in order to successfully incorporate AVs into construction supply chain management based on the situation and risk acceptance level by the industry. They should be used to ensure the successful adoption of these vehicles and ensure that the full potential of their use is realised.

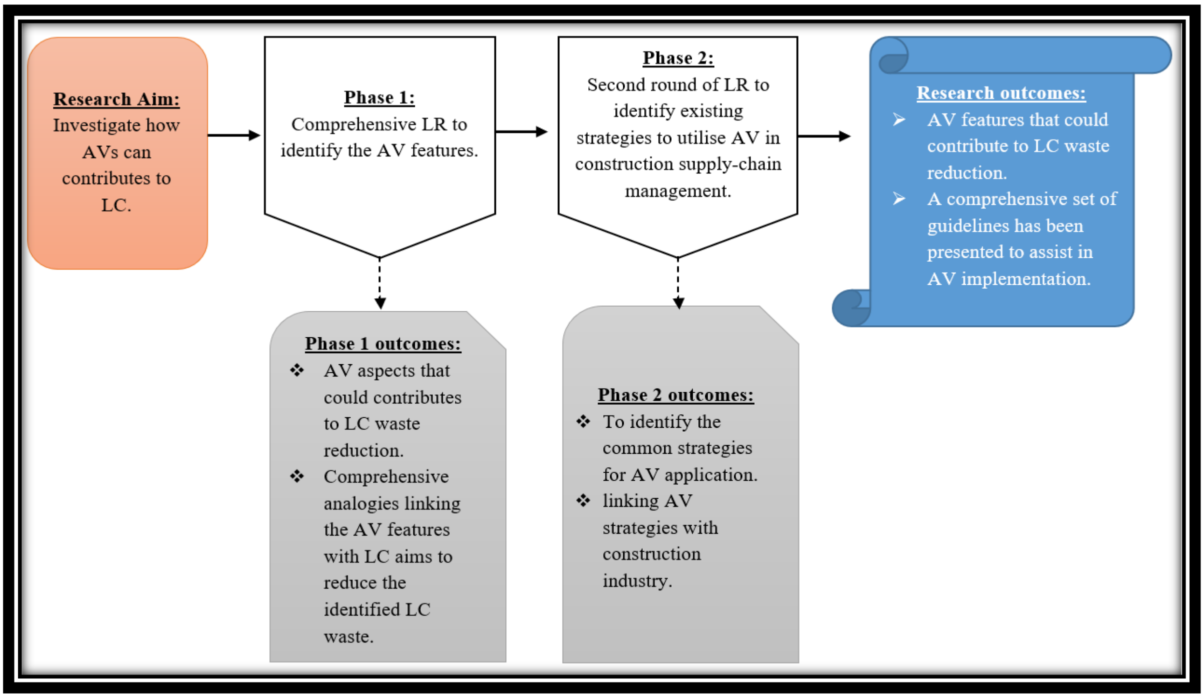

Figure 1: Research Outcomes

AVS AND THEIR STANDARDS

AVs or driverless vehicles are laying the foundation for future sustainable transportation (Chehri & Mouftah, 2019; Owais et al., 2022; Zou et al., 2021). It has the ability to navigate to numerous locations while responding quickly to signs, humans, and animals. It is also capable of overcoming unexpected obstacles independently (Greenblatt, 2016; Xing et al., 2021). The AV is anticipated to reduce transport emissions, vehicle journeys, and occupied road vehicles by 66, 30, and 28 per cent, respectively (Namboodiri, 2018). It could, also, reduce parking spots by 44 per cent and up to 87 per cent of road accidents. Therefore, the emergence of AVs could offer several benefits for society, the economy, and the environment.

It is predicted, for instance, to boost road capabilities by up to 100 per cent to accommodate more vehicles on the roads and smooth traffic patterns by up to 20 per cent, reducing unnecessary expenditure, fuel consumption, and time waste on the roads (Sundquist, 2016). Besides, it is expected that up to 75 per cent of fully driven AVs will occupy the roads by 2040 (Luttrell et al., 2015). Moreover, AVs are predicted to have around 70 per cent impact on large transportation vocations in the US and Europe by 2030 (Baratta, 2021). Researchers estimate that five per cent of this innovation would be expected to improve road congestion associated with stop-and-go behaviour, which would result in a 60 per cent reduction in transport emissions (Stern et al., 2018). Resulting in timesaving for people, and a decrease in the vehicle journey period on the roads, which will greatly reflect on transportation emissions.

As humans constantly depend on advanced technologies to replace traditional driving techniques and unexplained human driving behaviours, AV innovation could be a novel solution since they are able to assess their environment and proceed accordingly (Ma et al., 2020). Furthermore, despite the necessity of human participation in traditional driving tasks, AV could fully replace traditional driving to increase human efficiency in other activities (Litman, 2017). Therefore, the Society of Automotive Engineers (SAE) global standardisation J3016 has been issued aiming to define the six AV layers (SAE International from SAE J3016™, 2021-04-30). Starting with the least sophisticated layer, which requires the full involvement of the driver (nonautonomous), and proceeding up to the most sophisticated layer, which excuses the driver from duty (fully autonomous). These global standardisation levels had "become a de facto global standard adopted by stakeholders in the automated vehicle technology", in 2018 (Hopkins & Schwanen, 2021). Therefore, the SAE international standards aimed to illustrate the AV levels to aid in embracing the technological revolution and assist the deployment of AV locally.

WASTE REDUCTION THROUGH THE USE OF AVS

The adoption of AVs allows lean construction to further enhance one of its main objectives associated with waste reduction/elimination. It can lead to increased efficiency and productivity in the construction industry, as well as an environmental impact reduction. According to our analogical analysis, three primary waste categories could significantly benefit from automated vehicles:

1- **Inventory waste:** It presents a common waste in the construction industry and a challenge for lean construction practices (Ansah et al., 2016). It is the goal of LC to reduce waste by keeping inventory levels low, and ordering only what is required when the need arises. This goal is challenged by the risk of inadequate supply on-site, burglary, degradation, and material damage (Aziz & Hafez, 2013). To prevent these challenges, in the construction industry, it is often necessary to order materials in advance and in excess to ensure that they are available when needed. This excess inventory takes up valuable space, ties up capital, and increases the risk of obsolescence (Lim YenWui et al., 2009). Therefore, the collaboration between advanced automotive technology and lean construction could help reduce excessive inventory problems as a type of construction waste by facilitating inventory management and reducing uncertainty around resource availability. Also enables the accurate tracking of resources in real-time and improves delivery times.

Improved delivery: The use of AVs, such as advanced driverless trucks, can improve the speed and accuracy of delivery and reduce the uncertainty surrounding the delivery of materials and equipment (Teoman, 2020). With autonomous vehicle delivery, there will be no need to keep excessive inventory in storage, which can be costly and inefficient as identified as one of the waste types in LC. This ultimately leads to significant cost savings and operational efficiency, as well as improved customer satisfaction with faster and more reliable deliveries.

Better tracking: By utilising autonomous technology, materials, and equipment can be tracked from the supplier to the construction site, providing a more accurate picture of what materials are available and where they are located through the Internet of Things (Liu et al., 2019). As a result of collaboration with AVs, losses, damages, and materials are minimised, and unnecessary lead times are avoided, which results in improved project outcomes and enhanced cost efficiency.

2- **Transportation waste:** AVs can play an instrumental role in reducing transportation waste by providing more efficient, safe, and sustainable solutions. In addition to the improved delivery schedules discussed in the previous item, AVs may also contribute to further reduction of transportation waste in several ways, including:

Increased capacity: AVs have the ability to operate 24/7 without the need for rest breaks, allowing more materials to be transported in a shorter amount of time. Additionally, they can be used in hazardous conditions where manual drivers cannot operate (Teoman, 2020). They can also be used to transport large amounts of materials in one trip. Furthermore, they can be operated more efficiently than manual drivers, resulting in fewer trips and better materials delivery (Heutger & Kueckelhaus, 2020).

Enhanced safety: AVs can reduce the number of accidents on the job site, minimising the risk of injury to workers and reducing the potential for delays (Fagnant & Kockelman, 2015). AVs use sensors and cameras to detect their environment and navigate around obstacles (Parkin et al., 2018). This eliminates human error and increases safety by ensuring that the vehicles are operating in compliance with safety regulations independently.

Lower emissions: AVs can be designed to be more energy efficient than conventional vehicles, thereby reducing their carbon footprint and the overall impact of transportation on the environment (Massar et al., 2021). AVs use advanced navigation and control systems that allow them to optimise their routes autonomously, resulting in less wasted energy and fewer emissions (Weimerskirch & Dominic, 2018). At any point in time, the AVs engine must use an efficient design because their need for efficiency in the engine is driven by timeless concerns such as environmental sustainability, resource scarcity, economic benefits, and technological innovation. As autonomous vehicles remain a relatively younger technology, they keep offering significant opportunities for innovation and advancement. By improving the efficiency of engines and powertrains, manufacturers can develop new and innovative technologies that can further improve the performance and efficiency of AVs, which further contributes to emission waste reduction.

Better coordination: AVs can be integrated with other management systems, such as construction supply chain management, allowing for real-time monitoring of delivery schedules and reducing the potential for bottlenecks or other delays (Sharm, 2022).

3- **Waiting time:** This is another challenge in the construction industry and presents a major waste source as discussed under LC (Lim YenWui et al., 2009). It can result in higher costs, reduced efficiency, and decreased overall project productivity (McBride, 2003). Implementing AVs can contribute to the reduction of waiting time in several ways, including the following:

Reduce delivery waiting times: AVs can deliver materials to the job site more frequently and more accurately, decreasing the wait time for materials to arrive, and cutting logistic costs (Xiaosheng & Hamzeh, 2020). AVs are able to calculate the most efficient route to the job site independently and can travel non-stop, which reduces travel time. Also, as time passes and technology becomes more accessible, the cost is expected to reduce. In addition, AVs do not require a human driver to operate the delivery vehicle. Therefore, the driver could be relocated to another construction site activities to increase construction performance and reduce unnecessary expenditure. For instance, driver expenditures account for a significant portion of total freight journey expenses, accounting for approximately 40 per cent of truck operational expenses in a high-wage nation (Engholm et al., 2020). The logistic cost might be significantly decreased through autonomous vehicles.

Improve equipment utilisation: AVs can be used to transport equipment between job sites, reducing the wait time for equipment to be available on a specific job site (Gružauskas et al., 2018). AVs can provide a continuous flow of equipment to job sites, allowing for faster completion of projects. Furthermore, AVs can reduce the amount of manual handling of equipment which can lead to fewer accidents and improved safety.

Streamline transportation: AVs can be programmed to follow the most efficient route so that less time is lost in traffic or on non-optimised delivery routes (Namboodiri, 2018). Autonomous vehicles have access to more advanced mapping and navigation techniques. Companies like TomTom are making automated driving more comfortable, efficient, and safer by offering technology that aids AV planning in advance and acts as a security net for sensors whenever vision and situation are unacceptable (Strijbosch, 2018). TomTom’s technology is scalable and cost-effective, seamlessly integrating with internal systems, and currently powers autonomous driving for leading car manufacturers. Besides, Nvidia has also introduced its latest mapping platform, providing the AV sector with accurate mapping that covers more than 300 thousand miles of highway in Asia, Europe, and North America (Bellan, 2022). Moreover, they are equipped with a range of sensors, cameras, and other technologies that enable them to detect and avoid obstacles in real-time (Parkin et al., 2018). This means that they can make on-the-fly route adjustments to avoid traffic congestion or road closures, without requiring any input from the driver.

Enhance coordination: Through the use of IoT, AVs can be integrated with other construction management systems, enhancing coordination and reducing the risk of bottlenecks (Sharm, 2022). With the use of IoT technology in AVs, it is possible to keep track of a number of different aspects of the delivery process. These aspects range from loading and unloading to the route taken and the arrival schedule of the delivery without the requirements of manual updates. This data can be used to reduce the risk of delays or bottlenecks.

Besides increasing productivity and efficiency, automated vehicles can also be environmentally friendly. Despite the LC philosophies of "respect for people", "maximizing value while minimizing waste", and "continuous improvement" (Do, 2022), sustainability and lean methodologies tend to clash whenever the supply chain is geographically expanded and participates in carbon dioxide emissions (Sertyesilisik, 2016). As the research aims to assist lean construction in achieving one of its primary objectives, namely reducing and eliminating waste, AVs can also help LC to address environmental concerns as well. After illustrating the AV benefits and how collaboration with LC could aid to support its core philosophy, it is crystal clear that waste reduction could be achieved through AVs. This can provide tremendous value to the environment, the economy, and society as a whole.

STRATEGY TO IMPLEMENT AVS IN THE CONSTRUCTION INDUSTRY

Previously, it has been discussed how AVs can assist the construction industry in achieving LC objectives if they are adopted by this sector. For AV to be successfully adopted at the industrial level, it must be accepted at a higher governmental level. Nevertheless, many developed countries have not fully implemented AV due to unforeseen long-term risks such as safety, liability, and cyber security (Milakis, 2019; Taeihagh & Lim, 2019). Essentially, autonomous technologies are widely acknowledged for their benefits, but questions are raised about their deployment, hazards, and unanticipated outcomes (Taeihagh & Lim, 2019). In fact, several scholars have admitted that the adoption of new technology would surely result in some unexpected risks (Taleb, 2007; Clarke, 1999). These risks frequently result in major expenditures for the interested parties (Perrow, 1999). Therefore, safety, liability, and cybersecurity as risk factors remain significant challenges for the industry to adopt such innovation.

To overcome these challenges, five AV-related governing approaches are presented by Li et al. (2021), and Li et al. (2018), which define the potential scenarios when deploying new technology. The governance measures that decision-makers may use to manage risks associated with the deployment are intended to achieve optimal user advantages while reducing technology-associated risks. For this scenario, the proposed approaches for deploying AV innovation in the construction industry are presented as follows:

- **Adaptation-oriented:** The industry can be more flexible if it accepts uncertainty and enhances its ability to handle disturbances. This approach integrates the factors of collaborative responsibility, long-term strategy, and co-decision (Li et al., 2018). This technique aims to develop strategies to cope with uncertain events. It is similar to resilience and adaptive resilience developed by Nair and Howlett (2016) and Walker et al. (2012). The construction industry can use this approach to create plans that are flexible and can be adjusted to changing conditions arising from the adoption of AVs. This allows the industry to stay ahead of potential risks and remain competitive. Construction organisations can also make better decisions and improve service quality by collaborating among stakeholders with this approach. However, some may argue that this approach is not fool proof. What if the conditions change too rapidly for the organisation to keep up? What if stakeholders do not agree on a course of action? These are valid concerns that should be considered before adopting this approach.
- **Toleration-Oriented:** The approach’s main objective is tolerating risks. Operational decision-makers are in charge of inspiring the industry to perform efficiently in a constantly changing environment in light of the adoption of AVs (Nair & Howlett, 2016). On the other hand, this approach may not be the most effective. Tolerating risks can lead to more accidents and injuries, which is not ideal for either the industry or the public.
- **Controlled-Oriented:** This strategy is focused on the prevention of future accidents by providing employees with training and knowledge that will empower them to make

better decisions. It also emphasises compliance with laws and regulations, as this will help ensure that risks are managed appropriately. Furthermore, by using realistic risk estimations, the organisation can ensure that its risk assessments accurately reflect the current risk level. (Krieger, 2013). A focus on compliance, however, has been argued by some experts to cause more accidents. Organisations often create rules and regulations that are too restrictive when they focus on compliance. Thus, compliance-focused strategies may actually result in more accidents than those that would otherwise occur. Consequently, employees may take shortcuts or take risks that they would not otherwise take.

- **Prevention-oriented:** Decision-makers implementing AVs use this defensive strategy to reduce their associated hazards (Li et al., 2018). Nevertheless, its slow response time makes policy meaningless. As a result, it is important to invest in more rigorous safety measures and driver education to ensure that AVs are used safely and responsibly.
- **No-Response:** The hazards are not addressed by decision-makers due to the low level of knowledge about AVs and their abilities (Walker et al., 2010). Consequently, decision-makers often overlook the potential threats of autonomous vehicles, resulting in inadequate safety policies.

A variety of these five governing approaches can aid decision-makers in selecting the appropriate approach during the implementation phase. Depending on the environment, one approach may be more cost-effective, while another may be more expedient. One approach may also be more sustainable, while another may be more appropriate for a particular environment. Each of the five AV-related governing approaches must be carefully analysed before implementation to maximise AV benefits while minimising risks in the construction sector.

CONCLUSION

It has been shown that AVs offer a wide variety of benefits, including improved safety due to the absence of human error, improved fuel economy, and reduced congestion. Furthermore, it provides a convenient alternative to traditional transportation modes, in addition to providing new employment opportunities in the development and maintenance of automated vehicles and other activities. The purpose of this study was to examine the potential contribution of AVs to the waste reduction goal of lean construction. The contributions were categorised into three groups: Inventory waste, which can benefit from the ability of AVs to offer improved delivery and better tracking; Transportation waste, which can benefit from the increased capacity, enhanced safety, lower emissions, and enhanced coordination offered by AVs; and Waiting time, which can be reduced by improving equipment utilisation, streamline transportation, and improving coordination among activities.

Also, AVs can help LC address environmental concerns. Furthermore, the paper discussed potential strategies for implementing AV technology within the industry. A discussion of five possible scenarios was provided, including adaptation-oriented, tolerance-oriented, control-oriented, prevention-oriented, and no-response scenarios. This study contributes to the knowledge base by providing an analysis of the potential contributions of AVs to LC waste reduction. Additionally, the examined scenarios in this document aimed to enhance the implementation of AVs in the construction industry to support the decision-makers in selecting the most suitable approach during the implementation phase. The practical implications of the study suggest that the construction industry should take a proactive approach to the implementation of AVs. This is especially true in light of the anticipated environmental benefits and cost savings. These conclusions are made based on an exhaustive round of literature review however future research may involve different chains of keywords and different databases.

EFFICIENT PAVEMENT DISTRESS DETECTION AND VISUAL MANAGEMENT IN LEAN CONSTRUCTION BASED ON BIM AND DEEP LEARNING

Ting Deng[1] and Yi Tan[2]

ABSTRACT

With a wide range of road construction worldwide, the focus of road engineering has shifted to road maintenance and management. This paper presents a research aimed at developing a lean management framework that integrates BIM and deep learning technology to guide lean production applications in road maintenance management. Firstly, the pavement distress dataset is established based on the obtained road point cloud data. Secondly, a deep learning-based 3D object detection network is applied for automatically detect the pavement distress and improve the accuracy and reliability of the detection. After obtaining the detection information of the distress, Dynamo is utilized to realize the efficient visualization management of pavement distresses. Finally, an untrained road section is applied for the experiment. The predicted information of distress is integrated and visualized in BIM model can provide a better maintenance guidance and well promote the transformation of pavement intelligent maintenance management.

INTRODUCTION

Infrastructure maintenance is crucial for ensuring the safe and efficient functioning of roads, bridges, and other structures. For example, as large-scale roads are built and operated over time, there will be exhibited a range of distresses, including cracks, potholes, and so on. These distresses may directly reduce the driving comfort and safety (Zhong et al, 2022), affect the performance and normal service life of the road, and even lead to serious traffic accidents. Therefore, it is significant to detect the pavement distress efficiently and accurately for the pavement maintenance.

Traditional pavement distress detection methods include manual inspections, visual assessments. However, these methods are often time-consuming, labor-intensive, and may be not able to provide the detailed information for making accurate evaluation. To improve the efficiency and reliability of pavement distress detection, the concept of lean construction is introduced. Lean construction is an approach that focuses on reducing waste, streamlining processes, and improving efficiency. This concept is particularly important in the pavement

distress detection and management process for more efficient analysis of road pavement conditions. In fact, with the development of computer vision technology, there has been a significant amount of research on image-based pavement distress detection over the past few decades. This automated pavement distress detection technology can greatly improve the efficiency and accuracy of distress detection. However, image-based road data lacks depth information and cannot clearly express the spatial relationship of pavement distress.

With the cost reduction of 3D data acquisition devices, 3D laser scanning technology has gradually become an important ways of road data acquisition. The 3D point cloud data collected by this technology can obtain the depth information of pavement, and is not easily affected by the environment, making it an effective data source for improving the accuracy and reliability of pavement distress detection. Although some 3D data-based pavement distress detection algorithms (Guan et al, 2021; Huang et al, 2014; Jiang & Tsai, 2016; Li et al, 2017; Ouyang & Xu, 2013; Zhang, Wang, et al, 2017a, 2017b) have achieved certain success in recent years, most of these methods convert point cloud data into other forms and do not fully leverage the advantages of point cloud data. On the other hand, point cloud-based object detection algorithms have been widely used in fields such as autonomous driving and have achieved good results. However, at present, point cloud-based object detection is mainly tested on some public large-scale datasets [30], and has not yet been implemented in pavement distress detection task. In addition, there is limited research on effectively managing distress information by further connecting detected road distresses to the real world.

Therefore, in order to directly apply 3D point cloud data to automate pavement distress detection and improve the lean effectiveness in road maintenance, this paper proposes a framework that integrates lean management into pavement distress detection and visualization management based on 3D laser point cloud data, deep learning methods, and BIM. The proposed method aims to automatically detect pavement distress through deep learning methods to improve accuracy and reliability, and then visualize the detected results in BIM environment to improve management efficiency.

This paper is organized as follows. Section 2 reviews the literature of lean concepts, pavement distress detection, and BIM-based pavement maintenance management. Section 3 introduces the detailed information of the proposed method. Section 4 used an experiment to demonstrate the applicability of the proposed method, and finally, Section 5 has the conclusions and future work.

RELATED WORKS

LEAN CONCEPT IN THE CONSTRUCTION INDUSTRY

The principles of lean thinking are based on the lean production philosophy originated by the manufacturer Toyota and developed under the guidance of engineer Taichi Ohno(Howell, 1999). The underlying philosophy of lean production theory is to minimize costs, materials and time(Anandh et al, 2021), and evaluate working practice to eliminate unnecessary activities while preserving or increasing value(Chen et al, 2012). The idea of Lean concepts originated in the manufacturing industry, but have since spread to the construction industry. At first, the goal of lean construction was to apply manufacturing principles by standardizing processes. However, practitioners and researchers soon discovered the dynamic nature of construction project management and adapted their approach to fit the unique requirements of each stage of the project(Hamdar et al, 2015). Shou et al (2021) develop a lean management framework for guiding lean production applications in the oil and gas industry. Forbes et al. explored the management of roadway safety from a Lean perspective and put forward methods to prevent accidents and eliminate related wastes(Forbes & Ahmed, 2010).

The purpose of Lean Construction (LC) is to eliminate non-value adding activities, also known as waste, in construction projects and increase the value for relevant parties. The implementation of LC principles can result in substantial improvements in road maintenance projects where the impact of delays can be severe and affect all parties involved. Despite this, traditional approaches in infrastructure asset management have yet to fully embrace lean thinking in their planning for road maintenance (Mohammadi et al, 2022). Therefore, this paper combined lean principle to improve the pavement maintenance in distress detection and visualization management.

PAVEMENT DISTRESS DETECTION USING INNOVATION TECHNOLOGY

Traditional method of manually detecting pavement distress is time-consuming, inefficiency, and low accuracy. With the amount of pavement maintenance continues to increase, there is a significant need for automatic distress detection technologies which can improve the detection efficiency and accuracy. (Zhong et al, 2022). Over the past decades, there have been various researches focused on image-based pavement distress detection. Traditional approaches for pavement distress detection using image algorithms include edge detection-based methods (Zou et al, 2012), threshold-based segmentation methods (Wang & Tang, 2011),et al. However, these methods are Those methods are greatly impacted by the presence of shadows and varying lighting conditions in images, leading to negative detection results.

In the past few years, deep learning-based methods have been extensively researched in pavement distress detection, particularly the deep convolutional neural networks (CNNs) (Zhang, Wang, Li, et al, 2017). These methods have proven that the CNNs to be more efficient and stable than other traditional machine learning detection methods. For instance, Li et al (2020) used a CNN-based method on 3D pavement images to detect pavement distress and demonstrated the suitability of CNNs in classifying defects on pavement images. However, the focus of these methods aimed at classifying of the pavement distress without location information. Therefore, object detection methods have been introduced to enable the precise estimation of distress features. Du et al (2021) used the YOLO network to predict both pavement distress category and location using the information from road images in complex environment. Ibragimov et al (2022) proposed a pavement distress detection method based on Faster R-CNN and applied it to a full-size pavement image framework which allows to reduce the sliding window size and enable to detect cracks in larger images. Despite the high accuracy achieved by existing image-based pavement distress detection methods, there are still some limitations. The detection effect is inevitably limited under complex road conditions such as varying light and shadows. Furthermore, pavement images lack depth information and unable to express the spatial relationship of distress clearly.

With the development of 3D laser scanning technology, it is easier to obtain road point cloud data. This kind of data is not affected by shadow and light, and also contains the depth information and can express the spatial positions and geometric dimensions (Medina et al, 2014). Several researches have explored the application of point cloud data for pavement distress detection. Zhang, Wang, et al (2017a) proposed a 3D shadow modelling method to transform the original point cloud data into binary images which combined with noise suppressing algorithms to attain the target descended patterns. Tan and Li (2019) have utilized road images from UAV oblique photogrammetry to reconstruct road 3D point cloud models. However, there methods either manually extract features or process 3D pavement data from a 2D perspective before applying 2D-based deep learning methods for distress detection. Therefore, this research attempts to directly utilize the 3D point cloud data for automatic pavement distress detection by using the deep learning method which can improve the detection accuracy and generalization capability.

BIM-BASED PAVEMENT MAINTENANCE MANAGEMENT

In recent years, the advancement of pavement inspection techniques has brought attention to the optimal solutions for data management. The traditional approaches of Pavement Management Systems are inadequate to exploit the potential of this information, particularly for visualization and infrastructure modelling (Bosurgi et al, 2021), which can be addressed by using BIM. In practice, BIM is widely used in the processes and activities of construction projects to improve the outcome of lean production, but its application during the operation and maintenance stages remains limited. D'Amico et al (2022) demonstrated the possibility of creating a digital twin model by combining geometric and design information with monitoring results obtained from road infrastructure. Bosurgi et al (2020) attempted to apply BIM in road maintenance management by incorporating survey data related to road conditions into the I-BIM model, resulting in a more efficient and simpler management system. However, it was a preliminary experimental approach, and the detected distresses were not visually presented to provide maintenance guidance. Therefore, this paper aims to enhance the efficiency of pavement maintenance management by visualizing pavement distress using BIM.

METHODOLOGY

The proposed framework integrates the concept of Lean to increase the efficiency and accuracy of pavement distress detection and management. The process consists of three parts and the framework is shown in Figure 1. The first step involves collecting point cloud data and preprocessing it to create a labeled dataset for network training. Second, a 3D object detection method-PointPillar(Lang et al, 2019) is applied to detect pavement distress. Finally, the results are integrated into a pavement BIM model by using Dynamo to establish families of pavement distresses and visually manage the detected distresses. By continuously improving the accuracy of distress detection and efficient visualization management, this method will drive the transformation towards a more intelligent and effective pavement maintenance system.

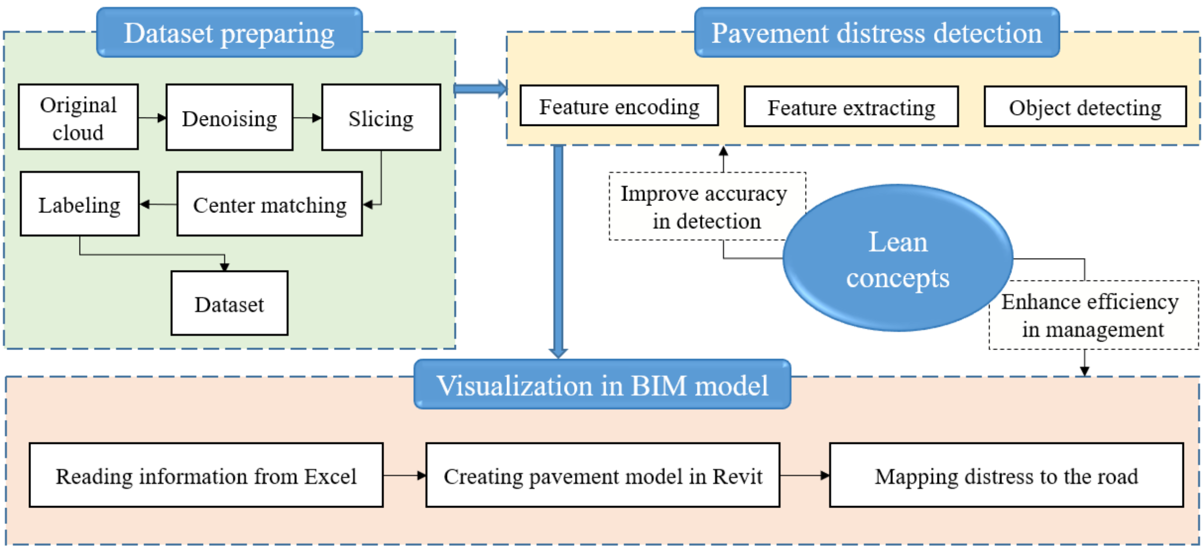

Figure 1: Workflow of pavement distress detection and visualization

ESTABLISHMENT OF PAVEMENT DISTRESS DATASET

This paper applies the vehicle-mounted LiDAR system to acquire pavement point cloud data and the types of pavement distress include transverse crack, longitudinal crack, alligator crack and pothole. Before sending point cloud data into neural network for training, the data needs to be preprocessed and annotated to create the dataset. The process of point cloud data processing is shown in Figure 2.

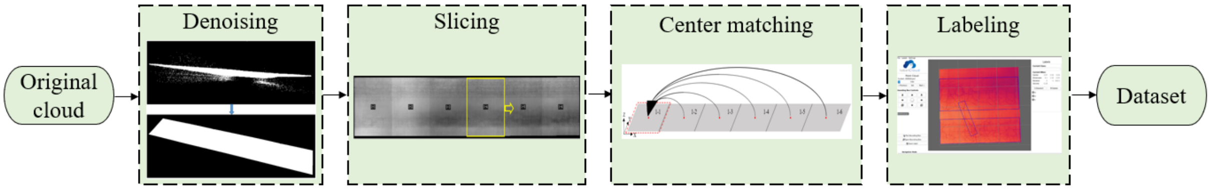

Figure 2: Data processing flow

The original point cloud data contains a large amount of noise and other less useful points, which can negatively affect the accuracy of detection results. To address this problem, this study combined two different methods to filter out the noise. The first method used is passthrough filtering, which is applied to eliminate the noise present in a wide range above the road surface. This method works by removing points that have values outside the given range in the specified dimension. After rough denoising, the statistical outlier removal (SOR) filter is used to remove noise more finely. The SOR filter calculates the average distance of each point to its K nearest neighbors. Assuming that the distance of all points in the point cloud data conforms to a Gaussian distribution, with its shape determined by the mean μ and standard deviation σ, the distance d from the nth point P_n (X_n, Y_n, Z_n) to any other point P_m (X_m, Y_m, Z_m) is calculated as follows:

$$d=\sqrt{(X_n - X_m)^2 + (Y_n - Y_m)^2 + (Z_n - Z_m)^2} \tag{1}$$

$$\mu=\frac{1}{n}\sum_{i=1}^{n} Si \tag{2}$$

$$\sigma=\sqrt{\frac{1}{n}\sum_{i=1}^{n}(Si - \mu)^2} \tag{3}$$

After denoising, the collected pavement point cloud data need to be divided into smaller one to adapt the training requirement of network model due to the limited computing resources. In this paper, in order to reduce the computational cost during model training, the full-scale point cloud is divided into many smaller size blocks by using a sliding window with size of 4×4 m^2. These smaller blocks are indexed to represent different sections of the road, and rough registration is necessary to ensure that the coordinate values of the point cloud blocks fall within the same range, which can provide more standardized data for neural network model training. Finally, the point cloud labelling tool is used to label the category and position of distresses with 3D bounding boxes and created the pavement distress dataset.

DEEP LEARNING-BASED PAVEMENT DISTRESS DETECTION

The aim of pavement distress detection is to classify and localize pavement distress automatically based on collected point cloud data, and provide specific information for pavement maintenance and management. The network architecture used in this study is called PointPillar(Lang et al, 2019) which offers a balance between speed and accuracy in 3D object detection algorithms. The implementation of PointPillar involves three main steps and the framework is shown in Figure 3.

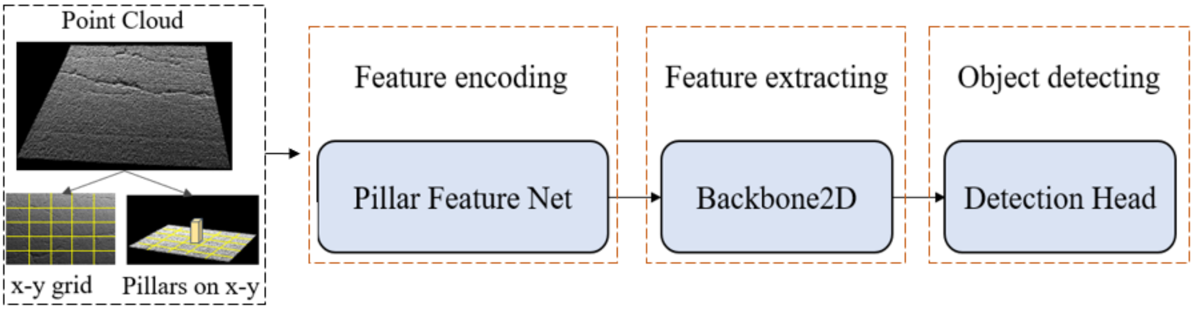

Figure 3: The detection framework of PointPillar

The first step is feature encoding. The point cloud is divided into a grid in the x-y plane and pillars are created with unlimited z extent. The points in each pillar are then represented as a 9D tensor. The input data is then sent through a linear convolution, transforming the 9D feature to 64D. Max-pooling is performed to create an output tensor of size (C, P). Finally, the encoded features are transformed into a pseudo-image by scattering them back to the original locations.

The second step is feature extracting. The backbone of PointPillar has two subnetworks: one is a top-down network that produced features with sufficiently small spatial resolution and this process can be represented by a series of blocks with Conv2D (C_{in}, C_{out}, k, s, p), where C_{in} and C_{out} are represented the input and output channels, k, s , and p are represented the kernel size ($k \times k$), stride size, and padding size respectively. The other one is a upsampled network with $Deconv2D$ (C_{in}, C_{out}, k, s, p), and each 2D convolutional layer followed by BatchNorm and ReLU sequentially. Finally, the upsampled features are concatenated to constitute high resolution feature map.

The third step is object detecting. After the feature map is extracted by the backbone network, the detection head is used to predict 3D bounding boxes of distress. The approach involves setting default boxes for each category, and each default box with two rotations and one scale which can roughly represent the dimension characteristics of different distresses. The default boxes are then matched with ground truth using 2D IoU and the shape offsets and confidence for all object categories are predicted. The height of the bounding box is not used for matching, but rather as an additional regression target.

BIM-based Pavement Distress Visualization and Management

After the distresses are detected by PointPillar, Dynamo is utilized to visualize the pavement and distress in BIM environment. This process simplifies the representation of the pavement in the realistic 3D environment, and specific routines have been coded for distress mapping to the pavement model, which can provide more intuitive information for road maintenance. To visually manage the detected distress in BIM environment, the pavement BIM model is created according to the collected point cloud data in this study. Then, the projected images of various distresses from point cloud are converted into maps by the method of generating ground, and their morphology and related parameter information can be shown in BIM environment. The procedure is shown as Figure 4.

This section mainly includes creating a node program by using Dynamo which is capable of reading data from Excel spreadsheet that contains the detected pavement distress information. Then according to the geometry and coordinate information of different distresses, the distribution scope of length and width on the pavement is calculated, and a number of points with corresponding X and Y coordinates can be generated based on the scope matrix. Finally, the pavement distresses were created in the BIM model for visual management.

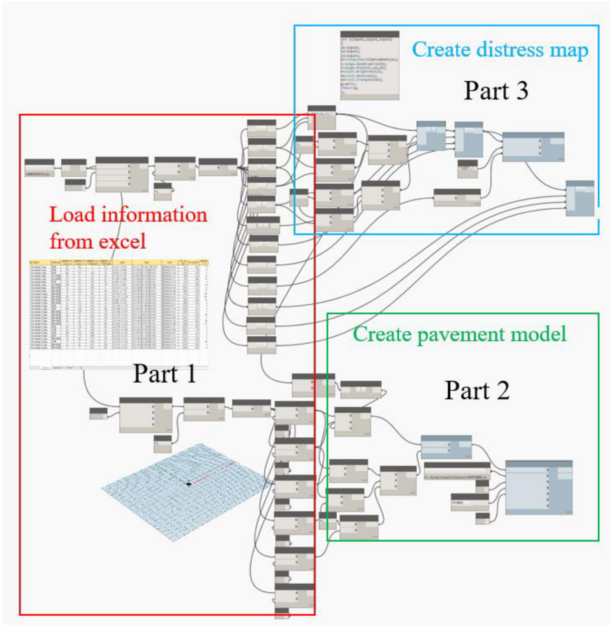

Figure 4: Visual programming to generate model in Dynamo

THE APPLICATION OF THE LEAN CONCEPT

The implementation of lean principles in the proposed method is based on the idea of continuous improvement. The solution uses a combination of advanced technologies, including deep learning and BIM, to streamline the pavement distress detection and visualization management process. By using the 3D object detection network PointPillar to automatically detect pavement distress, the solution reduces the time and effort required for manual inspections. Additionally, the use of BIM for visualization of the pavement and distress allows for a more efficient and effective management of the pavement, as the information is presented in a clear and intuitive manner.

The method also incorporates a proactive approach to maintenance, which is an important aspect of lean principles. By detecting pavement distress early and visualizing it in BIM, maintenance can be planned and executed more efficiently, reducing downtime and the potential for safety hazards. In addition, this study provides specific information about the pavement distress such as dimension and location, which can be used to inform maintenance and management decisions and continuously improve the process.

EXPERIMENTS AND RESULTS

To demonstrate the practicality of the proposed method, the prepared dataset is used for the model training, and then the trained model is used to detect the distress on a new complete road section. After obtaining the detected information of the distress, Dynamo is successfully applied to map the distress to the road model in BIM. And the detailed information of the distress can be viewed in the attribute column, which provide efficient and effective guidance for pavement maintenance.

THE EXPERIMENT SETTING

To carry out the experiment, high performance workstations are utilized with the following specifications: 4 NVIDIA GeForce RTX 3090 GPUs, 1 Intel Xeon Sliver 4210R CPU, and a Linux system to set up the training environment. The detected network PointPillar is initially designed mainly for use in the field of autonomous driving, and all experiments are based on the KITTI object detection benchmark dataset (Geiger et al, 2012) which consists of both lidar point clouds and images. Therefore, before model training, some details need to be adjusted to adapt the detection task of pavement distress. Firstly, the custom $Dataset$ need to be developed, and the most important step is to load prepared training data, then the annotated point cloud coordinate system must be adjusted to the Lidar coordinate system through a simple transformation, with X, Y, and Z being the inputs for the network and x, y, and z being the label coordinates and d being the height of the Lidar sensor.

THE RESULT OF PAVEMENT DISTRESS DETECTION

The trained model is utilized to detect the pavement distress and predict 3D bounding boxes for each object with a confidence score. Figure 5 shows the detection results and different colored 3D bounding boxes represent different distresses. Compared with the ground truth, the predicted result of the trained model has a good performance.

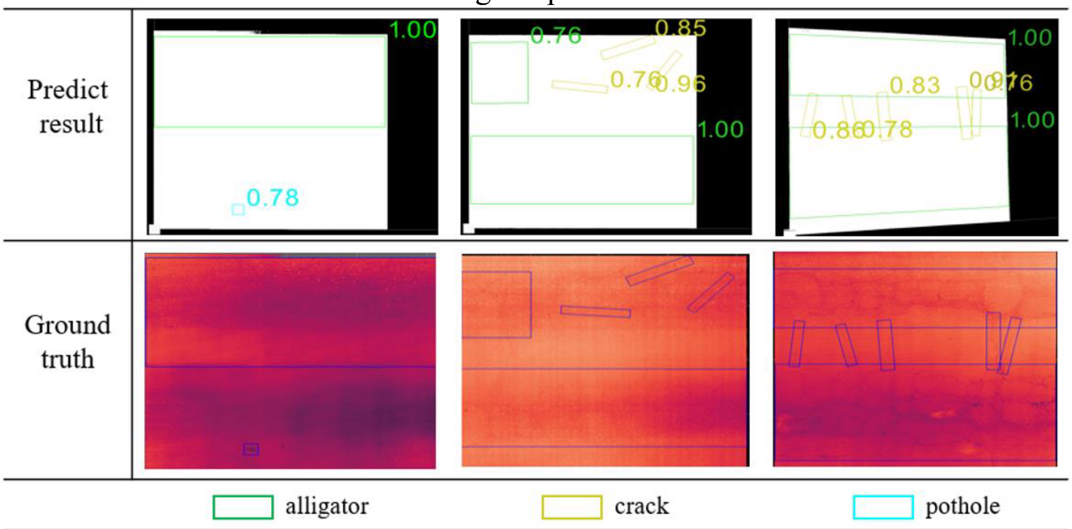

Figure 5: The comparison between predict result and ground truth

Then, the features of the distress including dimension and location information of the predicted 3D bounding boxes are extracted and stored in the spreadsheet. A portion of the collected information is shown in the following Table 1. The experimental results demonstrate that the 3D object detection algorithm based on point cloud data applied in the field of autonomous driving, as presented in this paper, has been successfully applied to automatic pavement distress detection, exhibiting both logical and functional correctness, and possessing certain practical value.

Table 1: Pavement Distress Information

Point cloud index	Class	Center coordinate X(mm)	Center coordinate Y(mm)	Rotation（rad)	…
1	Alligator crack	207	307	3.1408	…
2	Alligator crack	204	89	3.1323	…
. . .	. . .	. . .	. . .	. . .	…
26	Pothole	2191	139	4.1863	…
27	Transverse crack	2324	226	3.1565	…
28	Transverse crack	2449	204	3.1356	…

The Result of Pavement Distress Visualization

After preparing the information of pavement distress, Dynamo is used to read and import those data into Revit for modelling. As described in Section 3.3.3, the pavement model is established first and the detail information of the pavement is shown in the Table 2.

Table 2: Pavement parameters

Length(mm)	Width(mm)	Material	Original point
2480	392	asphalt	(0,0)

Finally, based on the coordinate and dimension information, all the distresses are created and mapped on the pavement with different colours representing different types. The parameters of each distress will be displayed in the attribute column and the visualization results are shown in Figure 6. After the successful modelling of pavement distresses, road managers can use the information query function of Revit to view the coordinates and dimensions quickly and analyze the distribution of the defects efficiently, and provide intuitive and reliable information for road maintenance.

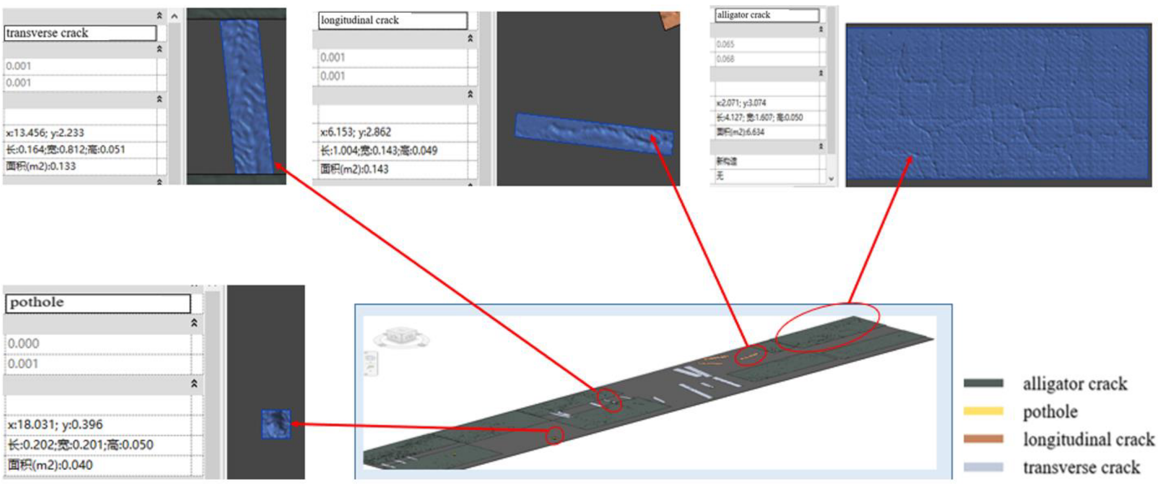

Figure 6: The visualization result of pavement distress

CONCLUSIONS AND FUTURE WORK

With the increasing total mileage of road maintenance management worldwide, traditional manual methods and two-dimensional inspection processes are no longer able to meet practical needs, and more efficient and reliable new technologies must be introduced. The advantage of 3D point cloud data makes it a potential method to improve the accuracy and reliability of road maintenance for detecting and quantifying the pavement distress. Therefore, a framework for automatic pavement distress detection and visualization management by using point cloud data, a deep learning-based 3D object detection algorithm, and BIM technology is proposed to improve the efficiency and effectiveness of pavement distress detection and visualization management.

Firstly, the collected point cloud data are pre-processed and a dataset of pavement distress is established. Then, the deep learning-based 3D object detection model PointPillar is applied to detect the distress automatically. After obtaining the detection information of the distress, Dynamo is utilized to realize the visualization of pavement distresses. In conclusion, the method utilizes advanced technologies to automate and streamline the process, while also incorporating a proactive approach to maintenance and a focus on continuous improvement.

However, in this study, the point cloud labelling process is manual and time-consuming which lead to a heavy workload. Therefore, a semi-automatic point cloud annotation method will be explored to reduce the burden of labelling. In addition, while the current 3D object detection method can achieve distress classification and localization, the extracted geometric features for severity assessment are region-level. To improve accuracy, point-level segmentation will be considered for more accurate distress quantification in the future.

CONSTRUCTION PRODUCTIVITY GRAPH: A STRUCTURED FRAMEWORK TO ENHANCE PRODUCTIVITY AND SAFETY ON CONSTRUCTION SITES

Francesco Livio Rossini[1] and Gabriele Novembri[2]

ABSTRACT

The construction industry is characterised by the constant production of unique products in dynamic contexts where, moreover, the workplace coincides with the product itself. This limits the adoption of standardization and process automation methodologies. Furthermore, the average size of professional firms and companies often does not allow for investments in process innovation or skills development. Then, we need to consider that construction is a highly risky activity, also to the lack of standardization as aforementioned.

The paper aims to present the framework of a methodology based on linking the information managed by a BIM model with Agent-based simulation techniques - ABS. The scope is to simulate the duration of the work under efficient conditions, understood as the best occupation of the available areas by a suitable number of workers. The result is the Construction Productivity Graph - CPG, a graph that indicates the optimization level of the construction process.

INTRODUCTION

Nowadays, the situation of the construction industry sees an important recovery in demand against a significant increase in the cost of raw materials. This, combined with the difficulty in finding skilled labor, has led to a significant increase in costs, after decades of stagnation and recession in the construction sector.

This situation leads to a renewed interest in reducing the resources to be used in building processes, above all by aiming to reduce waste in terms of materials and time spent.

This research has the objective of saving resources by optimizing construction times, intervening through more efficient management of the work areas. At the same time, it is important to reduce interference, an important cause of injuries during construction works. So, the optimized management of the areas also brings a higher level of safety, given by the lack of overlapping of activities with different risks which, if overlapped, can cause accidents. Finally, especially in the early experimental stages, it was possible to verify how this type of approach also leads to an optimization of the supply chain, due to the possibility of managing the material

storage areas in a better way and reducing wasted time due to inefficient material handling. (Amiri et al., 2017) and the reworking activities due to variations, which can also result from design errors (Scherer & Schapke, 2011). This issue is known in the building industry for decades, finding a whole series of answers in the application of lean methodologies. However, their diffusion is affected by the traditionally low interest of the construction industry towards technological innovation. Furthermore, it should be considered that these approaches still require investments which, in an economic context that sees companies fragmented in size that limit the possibility of investments, ends up always believing in consolidated procedures or, in the worst-case scenario, evaluating the inefficiency more cost-effective. Finally, it should be noted that a process supplied with optimization methodologies has a lower accident rate, due to the organizational level that lie beneath optimization techniques in general (Elghaish et al., 2019).

An important contribution to process optimization has been given by the growing diffusion of the BIM methodology. This allows the exchange of information through a single and shared model, on which a whole series of verification and analysis activities capable of increasing productivity and the reliability of results can be activated.

In the proposed framework, the BIM model is connected to an agent-based simulation model via API. Each component of the model is connected to an agent equipped with rules, objectives, and behaviors to achieve them. These aspects, typical of agents, allow the model to adapt to any changes in objective (design intent) and context (BIM environment). Furthermore, the agent can carry out self-test activities, and therefore dynamically verify the maintenance of any parameters set by the designer.

Once the characteristics of the project have been defined, the agent model activates a 'Master Actor' who, being hierarchically above the others, has the role of activating the agents who represent the working groups. These are related to the work to be carried out in the assigned work area (location) therefore the agent system defines the duration and the number of resources foreseen. The result is the representation of the Construction Productivity Graph - CPG, a synthesis of these computational processes aimed at explaining the location of tasks and the appointment of the number of workers per construction site area. The dynamism of this methodology is therefore useful not only in the design phase, but also during the execution and management of the construction site, since it is sensitive to variations, unforeseen events and changes of objective, through continuous and traceable updating of the project database (BIM model).

BACKGROUND

ABOUT ADVANCEMENT OF LEAN CONSTRUCTION

The lean methodology is based globally on the reduction of waste that can be generated along the course of a process. The objective is in optimizing of the chain of labor and the reduction of resources employed to parity of result, more and more current thing in consideration of the current scarcity of energy and raw materials (Carvajal-Arango et al., 2019).

From the point of view of building production, optimizing processes also means taking care of the quality of concrete production operations, with repercussions on safety and quality of working life in general. So (Schimanski et al., 2021) analyses that, in the construction industry, the most widely used lean techniques are Just In Time - JIT, Total Quality Management - TQM and Location Planning System - LPS. In addition, from the experience of the years of the pandemic there is a growing interest in Agile, thanks to the rapid introduction of the techniques of dematerialization of processes even in a very traditional and focused on the real site, such as construction sector is. The growing, spreading of BIM then led to the development of specific prototypes such as KanBIM (Gurevich & Sacks, 2014). The goal of KanBIM is to control the workflow and visualize processes parameters inside a BIM model, where their entities represent the information database of the whole system. However, by analyzing the comparative tests produced on these tools, we can see that the main issue is the link between the BIM entity and the production of the optimized process diagrams according to Lean logic (Babalola et al., 2019).

The advantages of these methodologies, considering the current level of development and definition, concern above all a better control of aspects such as space management, the effectiveness of the logistic chain and an improved responsibility of the technical figures involved in the working phases. From the point of view of the management of workforce, we can see - from the cognitive point of view - a possible drop in attention and operational responsibility on the part of workers, due to the repetitive and constant application of work patterns set by the system. This, combined with a lack of training, can lead to less reactivity and efficiency in case of exposure to unforeseen risky situations (Celik & Gul, 2021).

One of the most common causes of accidents on site is linked to the failure to manage interference, both from a spatial and temporal point of view. The construction site, unlike the industrial production line, is extremely dynamic and susceptible to having work crews interfering in the same area, but with different risks. Furthermore, consider how much the human factor can still influence the risk conditions in the building industry, another factor to be limited with the increase in automation in the building industry, a further reason for encouraging the introduction of industry 4.0 protocols to encourage continuous and constant connection between the forecast/simulation model and the reality of the construction site, with a view to the preventive reduction of overlapping situations. (Pregnolato et al., 2022). A desirable goal is therefore to find a meeting point between human awareness in the management of repetitive actions, and process optimization understood as the systematic adoption of techniques and methods that are easily repeatable by workers, and which can also be transferred to worksite machines that can gradually be inserted into the work site, even as physical support for workers (eg. Exoskeleton) or wearable technologies in general. (Aguirre-Jofré et al., 2021).

The limits of this approach are the cost of installation and management, which are too expensive for small works, and to be applied in socio-economic contexts not technologically developed. Another important limit is the broadband availability, essential to ensure this flow of information. In construction works located in historic contexts, where thick walls or underground areas are present, it is difficult to ensure a complete ICT accessibility. It will be necessary to start thinking about site data networks intended as networks to be installed in parallel to the electrical ones, for making each point reachable by digital devices, also for linking these detailed models as required by the Digital Twin approach.

Agent-Based Model Integration For Overcoming The Limits Of The State Of The Art

A possible limitation of the above simulation models lies in the low weight assigned to the management of the working areas and tasks carried out by the workers, and in general for the management of overlaps. These, in addition to slowing down the working process and therefore the general quality of it, cause inefficiencies for the management of the supply chain, due to a reduced optimization of the spaces and therefore of the temporary storage space of the site.

The goal of an agent system is to predict the emerging behavior of the model (Khodabandelu & Park, 2021). This model is composed of agents, rules, behavior understood as the actions that enable the agent to comply with the rules and goals (Grignard et al., 2022). Of course, agent modelling is not the only way to introduce productivity into the decision-making process, as there are a whole series of methodologies that serve the same purpose, moreover they have already tried and tested in the manufacturing sector and considered for the construction sector such as Discrete Event Simulation - DES and System Dynamics – SD (Lyneis & Ford, 2007). DES and SD follow a top-down approach, in which a system is built at the macro level at the beginning, then hypotheses are proposed, and its validity is measured, which is deeply based on empirical analysis, thus being affected by the implicit knowledge of the technician setting the model parameters (Fortino et al., 2005). Agent modelling follows the bottom-up approach, where the basis is the agents and the choices made to achieve their objectives in a heterogeneous or homogeneous/consequential manner, as is the case when pursuing swarm behavior (Zhang et al., 2019).

One of the fields in which the ABM approach is related to the solution of problems in the multi-options field, due to its ability to adapt the behaviors of the agents according to the different rules and objectives, according to the scenario. This dynamism makes the ABM simulation approach closer to the current building design and production, which is always determined by a constantly evolving context. In fact, while other simulation techniques tend to represent standardized actions in homogeneous contexts, the ABMS allows the modeling of the rules individually, and verifies the behavior of the agent both as a reaction of the individual to external stress, and through the verification of adaptation of the whole system with respect to external stimuli (Mathieu et al., 2018). However, ABM, following a bottom-up approach, can establish the interactive properties and characteristics of agents from the level of simple, reciprocal interactions, and thus produce an emergent result at the macro level. This characteristic makes ABM a preferable solution for the activation of what-if computational processes, without relying heavily on empirical analysis, excessive assumptions or directing the model in a preordained and biased direction (Khodabandelu & Park, 2021).

In conclusion, thanks to the ABM, the management of interferences for safety purposes can be much more accurate since it is effectively linked to dynamic changes in the context, and useful for the continuity checks that must be carried out to verify that the site is compliant with the H&S rules. At the same time, it is possible to increase the reliability of the forecast of the spaces occupied for the storage of materials and the installation of components, with related advantages over the management of the supply chain.

METHODOLOGY

The aim of the research is to set up a methodology potentially able to reduce the uncertainties in building production, above all when given by the lack of knowledge of the positioning of the personnel and of the equipment used. The result is a constant check, conducted by the agent system on the data flow provided by the BIM model, with respect to compliance with the needs of productivity and compliance with safety. Then, it is possible to further improve the synergies between the detailed progress of the works and the evaluation of the interferences of risk prevention. From this point of view, the first phase of the work consists of an accurate modeling of the site and the building, for having a reliable match between the reality and the digital model. (Abune'meh et al., 2016). Therefore, the first phase analyzed concerns the expected modeling specifications, where the level of detail of the BIM elements must follow the overall needs, assuming for the identified purpose an always very high level, bordering on the needs related to facility management. These elements are then managed by a Work Breakdown Structure - WBS, capable of linking the properties of the element with the workings connected to it. Following consolidated workflows, the federated model (i.e. The model includes the various WBSs for the different technical domains), is subjected to clash detections, aimed to filter critical issues in the project right from the start. The positive contribution that the implicit (i.e. Subjective) knowledge of the human designer can give, which includes his evaluations, is not overlooked. These are useful both for the purposes of improving the project being defined, and for training a possible machine learning engine towards more suitable solutions in similar future cases. (Figure 1). Once a BIM model suitable for construction analysis has been got, agent-based simulations can be activated, which will define the number of workers required to perform the planned activities in the respective locations (Antwi-Afari et al., 2018). The location is the functional unit of the construction site, a set of locations encompassing homogeneous work where resources can be allocated. Once the work to be carried out in the locations has been organized, the system automatically starts the verification of the propaedeutic and proximity to the horizontal and vertical communication ways of the construction site, for reducing wasted time and interference that may arise from the mere transit of materials through the site.

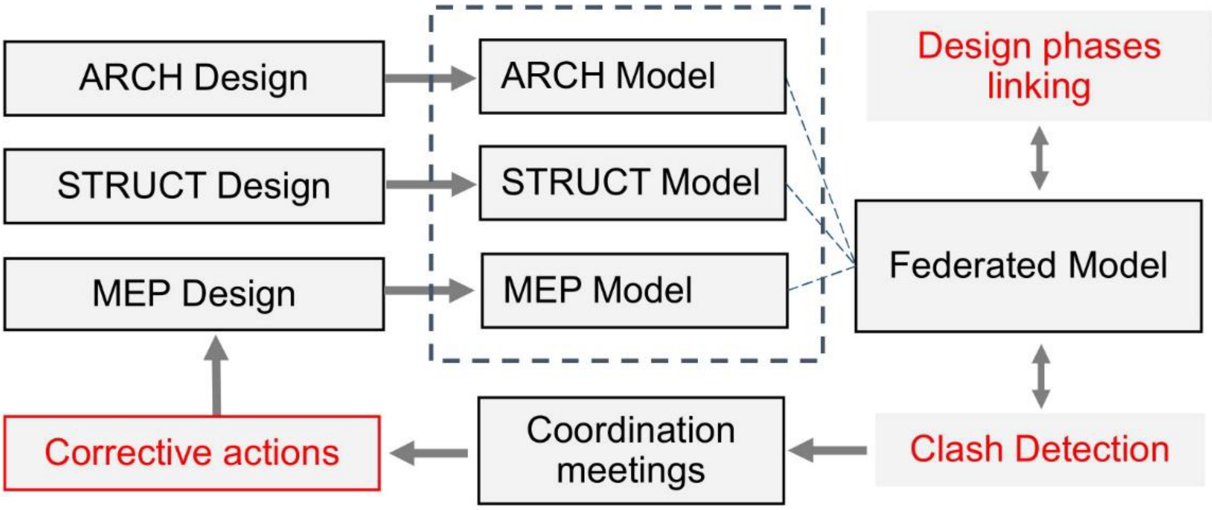

Figure 1: summary of the BIM model checking process.

BIM MODEL VALDATION THROUG MICROSERVICES

This paper describes the methodological approach for a future case study to be applied to a real construction site. The first step consists in importing a BIM model with a minimum LOD of 400, for having a sufficient level of information due to a consistent checking phase, and at the same time enough information to feed the proposed simulation system, or other linked machine learning based tools.

To manage this huge amount of information, often coming from different actors and, above all, subject to numerous updates and alignments during the phases from design to construction, the two approaches of the BPMS protocol can be taken into consideration. The first concerns a centralized orchestrator, where there are a whole series of microservices that gravitate around a centralized management system. The second instead appears as a choreography of microservices where, in a circular and one-way direction, there is a continuous exchange of information where the previous actor updates/modifies the information and sometimes the actions of the predecessor.

The result of the comparison showed that, in this specific case, it was preferable to set up a centralized microservice orchestrator for a matter of scalability of the system and identification of the contribution of the single microservice (Figure 2).

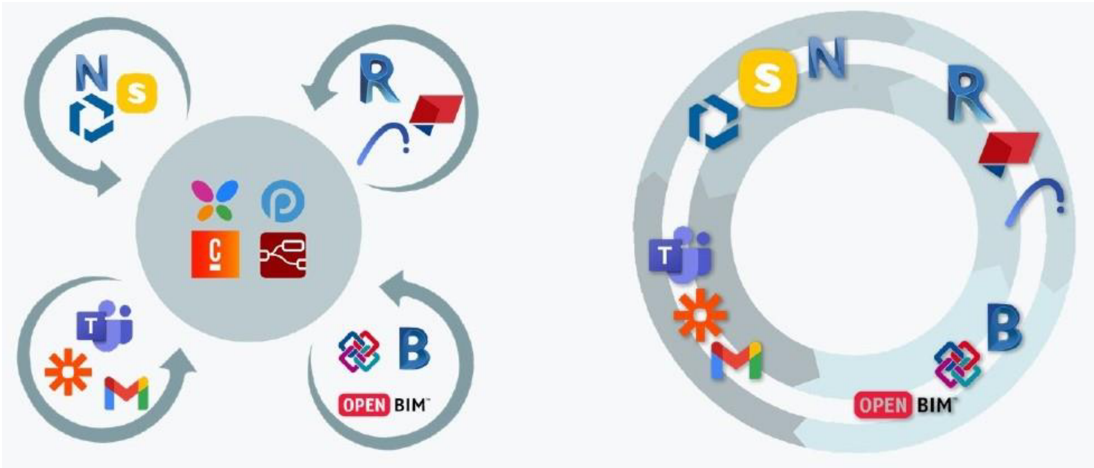

Figure 2: On the Left, the Conceptual Schema of a Centralized Orchestrator; on the Right the Choreography One.

AGENT MODELING FOR THE ASSIGNMENT OF LOCATION AND CREWS

Orchestration using microservices allows you to conduct a whole series of updates, variations, and checks without risking major project inconsistencies. Of particular importance will be the verification of correspondence between BIM elements, possibly updated with respect to all the checks carried out, and the connected work activities, according to the WBS approach.

The analysis of the workings is of particular importance for the subsequent modelling phase of the agents, since they will have to adapt their behavior with respect to the specific rules of the workings, both in terms of productivity and in terms of safety.

Once the modeling of the rules and behavior of the agents has been completed, their activation will be delegated to a Master Actor who, according to the logic of the actors, manages the workflows by activating or not the agents, according to the breakdown into phases envisaged by the WBS. Therefore, we model the WBS themselves as Agencies, i.e. Systems that contain within them other agents that represent simple components and elements. The most important rules regarding the location of the intervention, the productivity of each working team and the need for operating space, and the respect of priorities or the sequence in general of the work activity analysis. The establishment of these rules is decisive for managing the optimization of times and resources, given that a large part of the optimization conditions derives from the possibility of using multiple locations, managing interferences and the possibility of using shared logistic conditions to reduce the areas transit and handling of loads on site, conditions characterized by a high risk of accidents. This activity also helps to correctly evaluate the lost time of transport within the site. The result is the production of a table that summarizes the number of resources to be employed, the location to occupy and the duration of the work. (Figure 3).

Figure 3: The Output of the Agent-based Simulation, Indicating Tasks, Locations and Time Needed.

Once the number of workers has been got from the agent system in relation to the work to be carried out for each location, a new micro-service is activated, aimed at the graphic visualization and verification of interference in relation to the activities expected for each location and the number of workers used. Simple spreadsheets on accessible and widespread formats such as *.xlsx were used to define these graphs. From there, the Location Based Structure is set up, so that the duration of work, the maintenance of the optimal workflow average and any overlaps can be fully visualized.

After an initial series of inferences, the agent system establishes a balance between the number of workers, the duration of the activities and the occupation of the areas. Once this information has been defined, graphically represented according to the standards of the Location Based Structure, in order to verify, also graphically, the existence of overlaps or interferences, as well as the possibility of having the expected number of workers.

To define these graphs and make them as interoperable and accessible to as wide an audience as possible, simple spreadsheets in *.xlsx format were used.

The first result shows the expected number of people, the duration of the work and the teams involved (Figure 4), according to simple straight and oblique lines. This type of scheme is unique for each location, and in any case already guarantees, at a local level, initial checks on compliance with the maximum number of people allowed on site, on the equipment and on the possibility of managing areas for the storage of materials. Once the congruence of the works inserted in the individual areas has been verified, we can enter the result relating to the entire construction site into the system, to have a complete view of the optimized consecutiveness of the works.

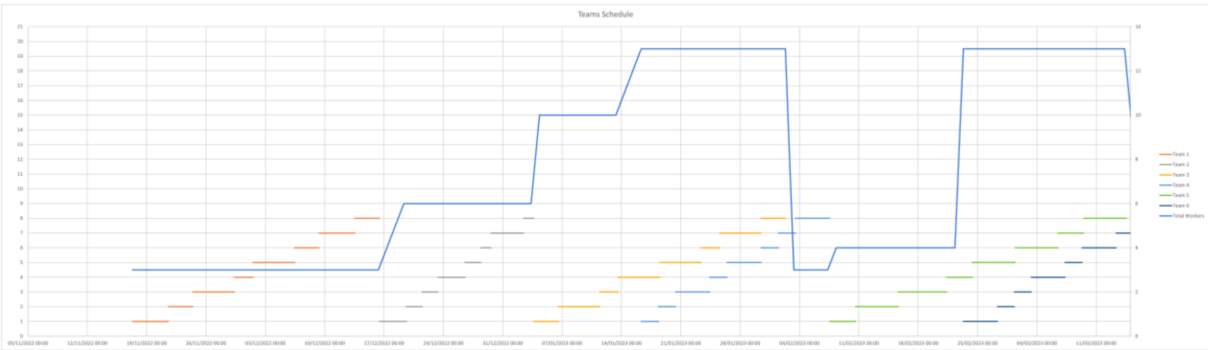

Figure 4: CPG Sample: in Blue the Number of Workers; the Horizontal Lines Describe the Duration of Tasks and the Team Involved. Analysis Conducted for a Single Location.

A further step is the one-to-one link between these results and the BIM model, especially if it is not possible to proceed with the forecasts resulting from the simulation phases.

The objective, through the APIs of the BIM editors used, is to update the simulations on the basis of the information contained in the objects and also the opposite, so as to make the simulation model not only a tool for verifying and organizing the phases of processing, but also a design support, in the sense in which the BIM object can be adapted to the production and safety needs of the construction site..

DISCUSSION

In a first development of this framework, we can observe an underestimation of the productivity reduction factor due to peak occupancy, and an overcrowding in certain areas that are also at high risk, such as in the hypothesis as shown in (fig. 05). Further improvements of this study will keep in analysis, real construction sites and their development compared to forecasting.

We can overcome this type of weakness could through the improvement of the predictive model techniques based on Bayesian statistics. So, in this way will be possible to enhance the correctness of a forecast produced by Bayesian analysis of previous similar cases. These forecasts will be based on expert judgement and the combination with the context. Finally, the future works need to overcome those issues:

- Scalability of the system: considering the large amount of detail required for BIM and agent modelling, there are major limitations regarding the machine's ability to process such large data volumes in a relatively short time. It could be interesting to evaluate the development of digital meta-models, in which will be show representative values of the project, to carry out rapid assessment, creating a new design level named ‘constructive feasibility’.
- Forecast accuracy: to have an adequately accurate forecast model, it is necessary to feed the database of similar events with a good amount of data, as is for the ‘big data’ approach. This consideration may find many practical obstacles, since the construction plans of construction sites, execution methods and metrics of executed projects are sensitive information, proportional to the intended use of the building itself, and therefore problematic to publish. Likewise, it is difficult to create a common data sharing environment from the point of view of the production process of construction companies, which have part of their capitalization and value in the construction and maintenance of best practices and standardized procedures. So, it would be interesting to consider a free digital platform of references in this sense, produced by public institutions that, depending on the type of intervention carried out and the sensitivity of the building, could make available on an open platform with all information necessary to train data libraries dedicated to the construction elements of the building, and to the related agents and rules.
- Auto-generative knowledge: it would also be interesting to gather the experiences gained on the building site itself, and to consider these as a basis to improve the decision-making process for the following construction phases.

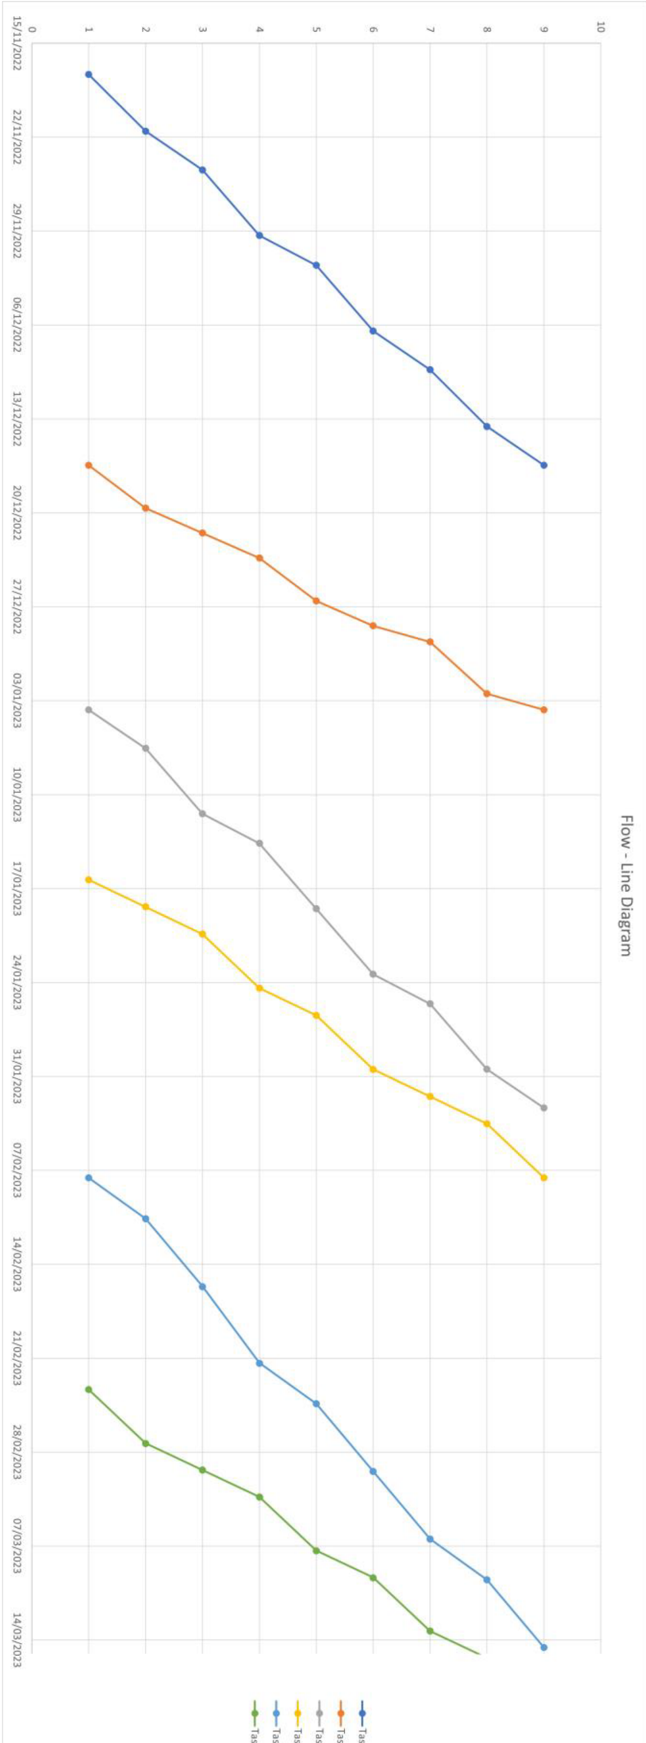

Figure 5: An Overview of the Line of Balance of the Site.

CONCLUSIONS

The proposed methodology takes as its reference the best practices related to lean construction applications, from which derives the conceptualization of CPG. In this management process, the BIM model is the accurate database from which to take and input data following the processing of the ABM simulation results. This information flow, guaranteed by the service orchestrator and managed via APIs, opens interesting perspectives from the point of view of the method's subsequent evolutions. Thus, other micro-services could be added to the workflow, to make the results increasingly accurate, but accepting a reduction in the modelling and simulation execution speed. From the point of view of 4.0 implementation, trusting also in the possibility of having an adequate ICT infrastructure, the possibilities of using wearable technologies connected to the simulation environment could be implemented. This could bring two results. The first one consists of an immediate communication between the system and the worker, who could be warned constantly about the activities to be carried out in the predetermined workplace; the latter instead concerns a continuous collection of data, to create an extensive database for subsequent machine learning applications.

ACKNOWLEDGEMENTS AND FUNDINGS

Case studies and implementations of the proposed methodology were also developed during the 'Construction Site Management' thesis workshop, academic year 2020/21. Authors: Edoardo De Santis (Eng, PhD c), Caterina Spoletini, (Eng, M.Sc.).

USING LOW-CODE AND ARTIFICIAL INTELLIGENCE TO SUPPORT CONTINUOUS IMPROVEMENT IN THE CONSTRUCTION INDUSTRY

Eder Martinez[1] and Diego Cisterna[2]

ABSTRACT

Low-code is a new technology paradigm used to support digitalization in different industries. Nevertheless, there are no studies analyzing the implications of this technology in the construction industry context. Through action research, this paper explores the potential of low-code to support continuous improvement of construction processes. The authors present the development and implementation of a low-code/artificial intelligence (AI)-based solution to automate data processing from paper delivery notes on-site. The as-is process was measured and compared against the low-code/AI powered process to verify efficiency gains. The development process of the digital solution was also analyzed to derive the findings of the study. The implementation of the digital solution resulted in 78% process time savings. The study also reveals the importance of involving people closer to operations in the development process, which resulted in efficient elicitation of requirements and the delivery of a solution meeting the needs of the end users. This paper highlights the potential of low-code productive development practices to support the digitalization in the construction industry. It also enlightens areas for further research and encourages the development of additional case studies to provide evidence of the benefits and limitations of using low-code to support continuous improvement in the construction industry.

KEYWORDS

Low-code, no-code, artificial intelligence, lean construction, continuous improvement

INTRODUCTION

Digitalization and the adoption of construction 4.0 offers the Architecture Engineering and Construction (AEC) industry a great opportunity to improve processes and productivity (Chui & Mischke, 2019). However, the architecture, engineering, and construction (AEC) sector lags behind other industries in terms of digitalization. According to the MGI Industry Digitization Index from 2015, construction was ranked third-to-last, ahead only of agriculture and hunting (Agarwal et al., 2016).

This slow pace of digitalization is usually attributable to systematic industry barriers such as fragmentation, organizational decentralization, and the uniqueness and transience nature of construction projects (Dubois & Gadde, 2002; Hall et al., 2020). In addition to these barriers, it

[1] Professor, School of Architecture, Civil Engineering and Geomatics, University of Applied Sciences and Arts Northwestern Switzerland (FHNW), Hofackerstrasse 30, 4132 Muttenz, Switzerland, eder.martinez@fhnw.ch, orcid.org/0000-0001-7918-9421

[2] Research Fellow. Karlsruhe Institute of Technology (KIT), Institute of Technology and Management in Construction, 76131 Karlsruhe, Germany, diego.cisterna@kit.edu, orcid.org/0000-0003-4282-1141

is widely agreed that the main obstacles to digitalization in construction are not mainly technology-related challenges, but rather insufficient understanding of construction operations (Fenves 1996; Koskela & Kazi, 2003) and the socio-technical environment, which encompasses cultural and human factors relevant to digitalization (Lundberg et al., 2022; Xue et al., 2012) . This lack of understanding translates into a critical disconnection between the requirements of the industry and the way in which technologies are developed and implemented (Arayici et al., 2006).

Xue et al. (2012) acknowledge that despite the efforts put on the development of information technology to improve project performance, practitioners still face several difficulties when bringing it into real-life management and operational processes. It is therefore reasonable to assume that bringing the process of technology development closer to construction operations is particularly relevant to support digitalization and productivity improvement in the construction industry. Bridging technology and operations increases end-user participation in the development process, facilitates the elicitation of requirements and the validation of potential solutions, which in turn helps to ensure that the final solution meets end-user requirements.

An emerging technology paradigm offering opportunities in this area is low-code development (Richardson & Rymer, 2014). Low-code development allows individuals with limited coding skills to develop and implement digital solutions targeted to specific business needs. The potential of low-code lies in its capacity to allow people closer to operations (practitioners or end-users) to find digital solutions to their business challenges. Some authors refer to these individuals as “citizen developers” (Everhard, 2019; Olariu et al. 2016).

Bringing the technology development process closer to operations also aligns with Lean Principles. According to Liker & Meier (2013), from a lean perspective technology has to fit people and the processes they use in order to maximize its value. Furthermore, prior to digitalizing construction processes, it is necessary to assure their stability. Otherwise, digitalization could exacerbate existing problems and introduce new barriers. Stable processes complemented with suitable technology provide an opportunity for developing agile and more efficient information flows (McHugh et al. 2022).

Market and scientific literature forecast that low-code and citizen developers will play a fundamental role in enabling the digitalization of different industries (Prinz et al., 2021). Low-code has been already explored to improve processes in different business scenarios, such as manufacturing and supply chain management. Nevertheless, to the best of the authors knowledge there is no research contextualizing the use of low-code to support digitalization in the construction industry. This paper aims to fill this gap by providing insights about the use of low-code and AI to address challenges in construction processes.

RELATED LITERATURE

LOW-CODE

Low-code is a relatively new development paradigm. The term low-code was introduced by Richardson & Rymer (2014) who argue that it emerged in response to rapidly changing business environments and demands for faster and cheaper software development. Low-code development platforms support fast development of customer-facing applications, requiring minimal hand-coding and enabling productive development practices.

In practical terms, low-code lowers the barriers between software/application requirements and delivery, speeding up the development process and enabling higher customer participation in projects (Richardson & Rymer, 2014). Low-code platform users (citizen developers) use an application modeler with an intuitive graphical interface offering different predefined constructs assisting in the application development process. The user drags and drops different pre-defined constructs in the graphical interface which automatically generate the code in the background based on the choices made by the user. In this way, a user without advanced coding/programming skills can design and deliver fully functional applications or digital solutions without necessarily requiring the support of professional software developers (Sahay et al., 2020).

Some authors, however, argue that more than a disrupting technology, low-code can be considered as the evolution of model-driven engineering and Computer-Aided Software Engineering (CASE) concepts. Some authors even claim that the rise in low-code popularity can be attributable mainly to a rebranding and marketing of its predecessor concepts (Bock & Frank, 2021; Cabot 2020).

Aside from the debate about its roots, low-code ability to enable fast delivery of digital solutions is generating a significant momentum. Forecasts suggest that by 2024, 65% of business applications will be created using some form of low-code technology (Vincent et al., 2019), and the number of citizen developers will eventually surpass that of professional developers (Wong et al., 2019). If these predictions materialize, low-code technology will significantly influence digitalization in different industries and the way in which business processes are designed and run. In fact, the Project Management Institute (PMI) has launched an educational program to prepare the next generation of citizen developers (PMI, 2021). Scientific interest on low-code is also rising (Prinz et al., 2021), with some research projects focusing entirely on preparing future engineers make low-code scalable (e.g., Tisi et al., 2019).

Low-code has already been explored in different industries. Waszkowski (2019), used a low-code platform for automating business processes. The author emphasized that one of the primary advantages of low-code lies in its ability to significantly reduce the time required to transfer requirements from end users to information technology developers. Wolff (2019), described various examples of low-code implementation for digitalizing workflows services and inventory management. The author argued that low-code is especially suitable for manufacturing, given that most engineers who oversee business processes are acquainted with a programming language making the low-code environment relatively familiar to them. Sanchis et al. (2020) assessed the feasibility of using low-code to facilitate digitalization in the manufacturing sector. The authors emphasized that low-code interfaces with Internet of Things (IoT) and Industry 4.0 can greatly simplify the transfer of information and optimize equipment and products across the entire value chain. Wang et al. (2022) used low-code to develop a small-scale Enterprise Resource Planning (ERP) system tailored to the requirements of the context of hydrogen equipment manufacturing. The authors reported the advantages of the low-code-based ERP system compared to the prior semi-manual Microsoft Excel method. They also emphasized the potential of low-code to facilitate innovation and enhance business agility within an organization.

The authors could not identify any documented implementation low-code in the context of construction industry. That is one of the primary contributions to literature of this study.

USE OF AI IN CONSTRUCTION TO EXTRACT INFORMATION FROM DOCUMENTS

Low-code technology is evolving rapidly, and vendors are competing to offer the most intuitive and faster development environment (Vincent et al., 2019). Some vendors are even integrating AI modules into their platforms allowing users to create models to automate tasks such as paper form processing and object detection.

AI-enabled document processing can help reduce the time it takes to manually extract data from documents, while also reducing errors. AI-based document processing is used to scan and interpret documents, extracting the key data points that are needed for further analysis. (Cisterna, Seibel, et al., 2022)

Optical Character Recognition (OCR) and Natural Language Processing (NLP) are two AI technologies that could have a substantial impact in the construction sector (Locatelli et al., 2021; Wolber et al. 2021). OCR technology enables the conversion of scanned or digital images into text that is machine-readable, enabling the automation of human data entry and the digitalization of paper-based operations (Hamad & Kaya, 2016). NLP enables computers to comprehend and analyse human language, enabling them to interpret and process information from unstructured text data. (Indurkhya & Damerau, 2010)

One example of the use of OCR in the construction industry is in the digitalization of contracts and invoices. By utilizing OCR, companies can automatically extract information from these documents and incorporate it into their digital systems, thereby decreasing the need for manual data entry and enhancing accuracy and productivity. This also enables for improved tracking and management of crucial data, such as payment schedules and project deadlines.

NLP can be utilized in numerous ways to enhance construction operations. For example, it can be used to evaluate construction project reports and extract vital information such as status updates, budgets, and resource use. This data can then be used to track project performance and detect possible issues early on, enabling speedier resolution and improved project outcomes. NLP can also be used to automate communication amongst team members, such as informing project managers of potential delays or providing deadline reminders.

Another scenario is the application of NLP to the evaluation of construction site safety reports. By examining these records, construction organizations can find trends and patterns associated with safety events and utilize this data to improve safety processes and reduce the likelihood of accidents.

In conclusion, the employment of OCR and NLP in the construction sector represents a huge opportunity to enhance process efficiency and productivity. These technologies have the potential to make construction projects more streamlined, cost-effective, and secure by automating human operations and extracting important information from data.

RESEARCH METHODOLOGY

The authors used action research. Action research supports addressing practical problem-solving while expanding scientific knowledge based on collaboration of different actors within a mutually accepted ethical framework. The characteristics of action research offer an adequate framework for conducting applied research in the construction industry and foster collaboration between academia and industry practitioners (Azhar et al., 2010).

The authors collaborated with a construction project team in the implementation of a low-code/AI digital solution to address inefficiencies in the process of collecting and processing data contained in paper forms. The authors supported the team in the development process of the digital solution. The as-is process was mapped, timed, and ultimately contrasted with the improved low-code/AI-enabled process to identify the efficiencies that could be achieved through the implementation of the technology. Insights from the site project manager were captured through semi-structured interviews to support the findings of the study.

PROJECT BACKGROUND

The project involves the construction of a large tunnel in Switzerland. The operational challenges are related to a typical situation of manual data processing on construction sites. This process is depicted in Figure 1. For each concrete delivery truck, the construction team receives the corresponding delivery note onsite. Relevant information in the document (e.g., receipt number, type of material, date, quantity, etc.) is manually transferred to a spreadsheet to keep track of materials delivered on-site. The information is then processed to create a dashboard to visualize the information.

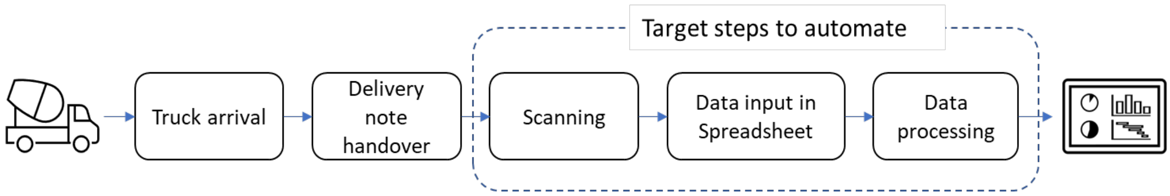

Figure 1: "As-is" Process to Collect and Process Data from Delivery Notes.

This process has several drawbacks. First, the manual transfer of information from the receipt to the spreadsheet is time consuming and prone to errors. People devote daily time to perform this task instead of focusing to deliver value to the project. Second, in many cases the responsible person does not perform the task on a regular basis. This generates a backlog of delivery notes which are not processed baring the project team to have accurate and timely information about the quantity of material received onsite. Although not considered in the scope of the process improvement, the delay in information processing also impacts downstream work. Since there is not an overview of the material received, the finance team is unable to centrally process invoices delaying the payment suppliers. The team aimed to address some of the inefficiencies in the process by leveraging the use of the low-code Microsoft Power Platform. Microsoft Power Platform includes a group of cloud-based applications supporting the automation of business processes and the creation of applications using low-code (Microsoft, 2022). The platform has also available an AI module which support training models to extract information from documents and images.

ARCHITECTURE OF THE SYSTEM AND UPDATED PROCESS

The architecture of the system is depicted in Figure 2. The digital solution leverages the use of the Microsoft AI builder, Power Automate, SharePoint, Excel, and Power BI. In the updated process, the user scans the delivery note and save it in a designated folder in Microsoft SharePoint. This action triggers a digital workflow in Power Automate which recalls an AI model created in Microsoft AI builder. This model is trained to read and extract relevant information from delivery notes. Power Automate then creates a new row with this data in a Microsoft Excel table. In parallel, the workflow triggers an automated confirmation email to the user including relevant information extracted from the document, including the scanned file as attachment for internal archive. Via an automated query, Power BI imports the table, organized the data, and display it based on visuals defined by the team.

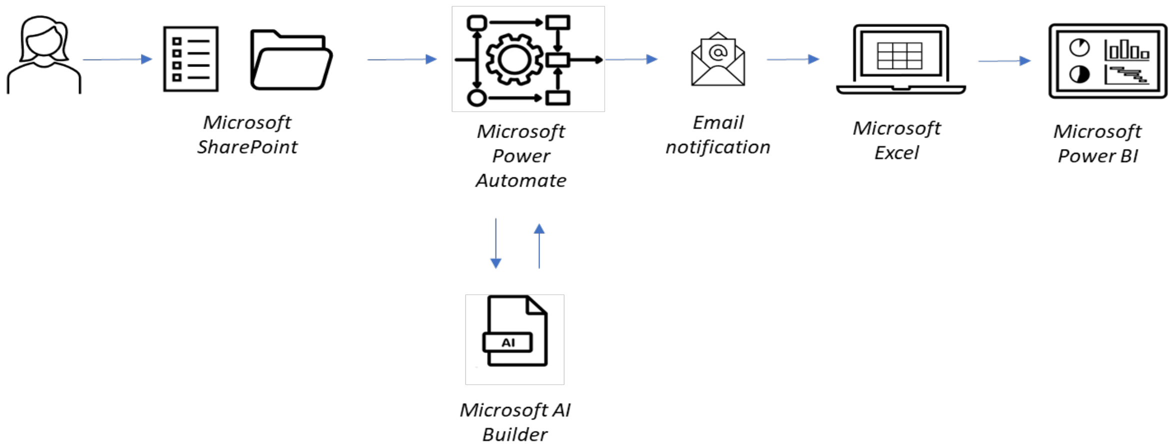

Figure 2: System Architecture.

The first step to develop the solution required training of an AI model able to extract relevant information from scanned delivery notes in .pdf format. For this purpose, the model was trained using 10 standard samples from a specific supplier. This step requires the user indicating manually the areas of the delivery notes where relevant data is located. In our case, we piloted the model using the name of the supplier, receipt number, date of delivery, the type of material delivered and corresponding quantity. After the first rounds with the sample delivery notes, the model provided an indication of the confidence for the different field (Figure 3). The model can be further trained to increase confidence requiring more samples to improve the AI model.

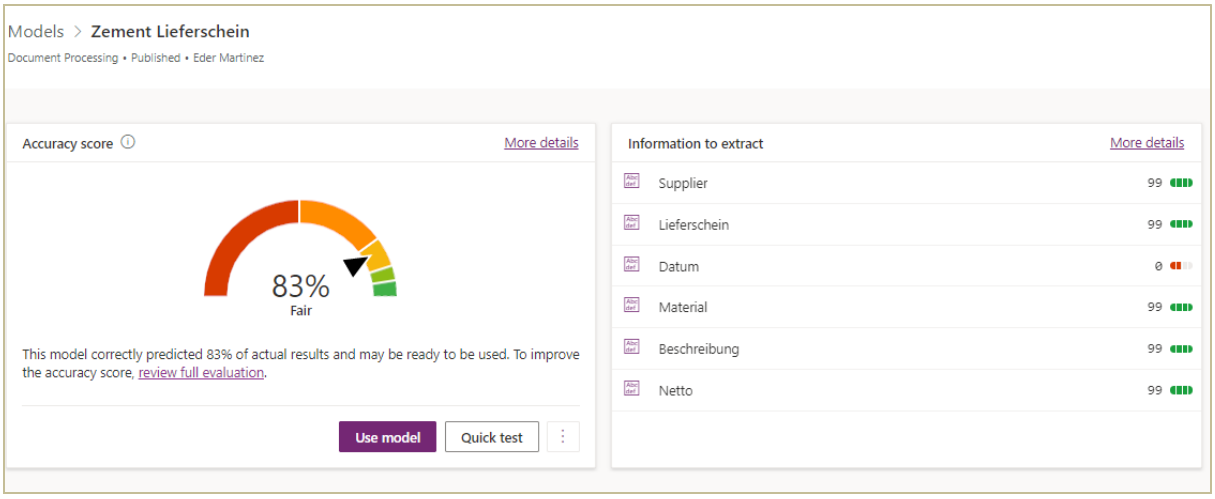

Figure 3: AI Model Accuracy Score.

DIGITALIZED VERSUS TRADITIONAL PROCESS

The new low-code/AI workflow removes several inefficiencies from the original process since the user no longer has to manually type the information in the spreadsheet. On average, the whole process took the user 7 minutes per delivery note. In contrast, the automated workflow takes on average 1.5 minutes, meaning that 5.5 minutes are saved each time the process runs, equivalent to 78% of the original process time.

The digital workflow in Power Automate itself takes in average 25 seconds, varying depending on the quality of the connection onsite and the amount of data in the paper form. For this calculation, we run the workflow 10 times and computed the average. An example of Power Automate workflow timing is depicted in Figure 4.

Furthermore, the digital process discourages producing a backlog of unprocessed delivery notes. Capturing of data, as well as the transformation process required to make information available is triggered as soon as the scanned file is stored in the designated folder. The solution also supports processes downstream since the information is directly made available to the finance department to process related payments.

The time savings may appear marginal when analysing a single process run. Nevertheless, efficiency gains can be scaled up and computed considering the magnitude of the project. It is expected that this project will receive more than 2,000 delivery notes only for this type of material and supplier. This translates into 183 working hours saved for the project. This does not consider other type of delivery notes (materials, equipment, etc.) or potential re-use of the low-code/AI solution in other projects within the organization.

The development process to put this solution together took approximately 1.5 working hours. That includes training the AI model (considering 10 delivery notes) and designing the workflow in Power Automate. This considers a user already familiarized with the Microsoft Power

Platform. For different type of delivery notes (e.g., different layout or supplier), the AI model should be re-trained, but the digital workflow logic could be reused.

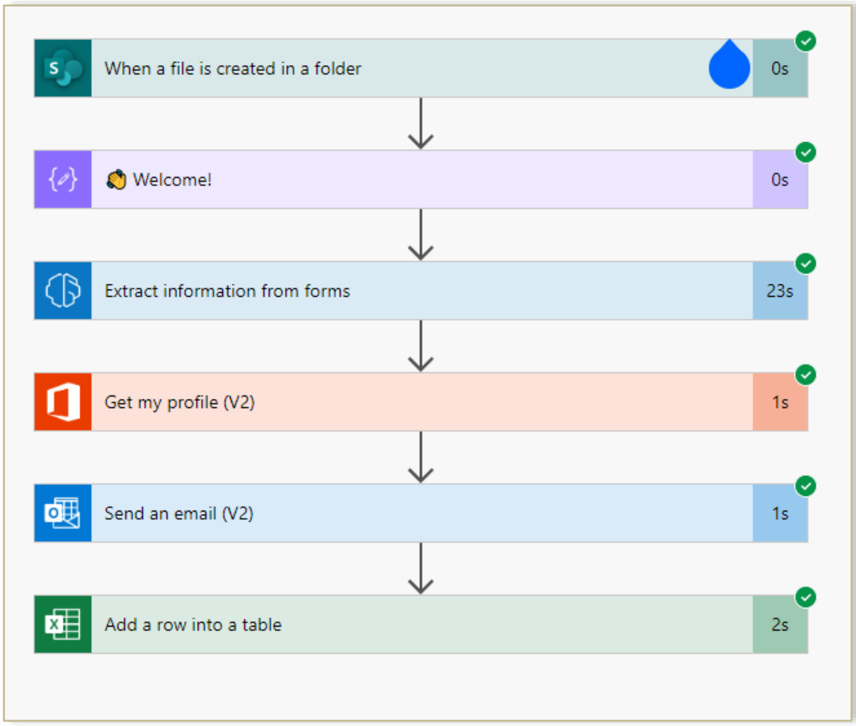

Figure 4: Power Automate Workflow and Duration.

DISCUSSION

THE POTENTIAL OF LOW-CODE IN THE CONSTRUCTION INDUSTRY

This experience demonstrates the potential of low-code and AI to support the digitalization of specific processes in the construction sites. The unique nature of construction results in a variety of specialized processes and procedures, making it challenging to find a ready-made digital solution in the market for those particular cases. Developing a digital solution in the traditional way would arguably require the involvement of information technology experts to support in the development process, which may result costly and time consuming.

With the availability of low-code and AI solutions, people closer to construction operations (acting as citizen developers) can experiment to develop their own applications and digital solutions. Individuals with a closer proximity to operations have a better understanding of end-user pain points, enabling them to efficiently translate requirements into features of the application, resulting in a more streamlined development process. Resulting from this experience, the organization involved in this experience is seeking to find further use cases where the use of low-code can result in increased productivity gains. The authors plan to report on these cases to build up more evidence and knowledge about the use of low-code in the construction industry.

It is reasonable to expect that, like other industries, the use of low-code platforms in the construction industry will grow and become more widespread. This resulting from several factors, including the increasing demand for digital solutions, the need for faster and more efficient construction processes, and the growing recognition of the benefits of low-code platforms. It is also expected that the capabilities of low-code platforms will continue to expand and evolve, enabling the creation of increasingly advanced and complex solutions. This may include the integration of cutting-edge technologies such as artificial intelligence and machine learning, further enhancing the transformative potential of low-code platforms in the construction industry.

In terms of the citizen developer, it is worth to note that the use of low-code also requires certain level of computing knowledge, including data modelling in order to proper delivery an application. Some authors even use the term “low-code” and “no-code" interchangeably (e.g., Hurlburt (2021)) which may be misleading considering the need of minimum computing knowledge to develop applications.

LOW-CODE TECHNOLOGY AND LEAN CONSTRUCTION

Lean construction philosophy seeks to minimize waste of materials, time, and effort to maximize the value delivered to customers (Koskela et al., 2002). In this regard, the use of the low-code/AI solution effectively supported the project team to remove unnecessary work from the process. Along with waste reduction, low-code also supports the team having relevant data available to learn and steer the project. It is known that that construction sites are very rich in terms of data, but most of this data remain analogue and it is barely used for the benefit of the project. By facilitating the data capturing and transformation process, low-code could be an enabler to support projects to better leverage the use of data, facilitating access to relevant Key Performance Indicators supporting the Plan-Do-Check-Act (PDCA) continuous improvement cycle. Our experience indicates that digital solutions or applications developed with low-code platforms do not generate new file types, but rather exploits existing file formats to facilitate interoperability across software. This helps integrate the fragmented software landscape and data silos rather than fragment them further.

Arguably, the type of technology behind the low-code/AI-powered solution described in this study is not ground-breaking. However, the value of the approach lies in the productive development practices that it enables. That is, lowering the technical barriers that allow individuals without advanced coding expertise to create digital workflows to streamline processes and harness the data available on construction sites. This approach provides an ideal environment for project teams to use technology to integrate the project delivery approach (Martinez et al., 2022), supporting both people and processes, in line with the principles of lean construction. (Liker & Meier, 2013).

As per the results of this experience, it is expected that the combination of lean construction and low-code platforms would have a substantial impact on the future of construction projects. The streamlined processes made possible by low-code and the reduction of waste made possible by lean construction are likely to result in quicker project completion times and increased customer satisfaction. This is because of the low-code platform's capacity to simplify data capture and transformation, hence enabling better data-driven decision making. In addition, the low technical barriers of low-code solutions will enable a larger number of individuals to engage in the implementation of technology, thereby contributing to the alignment of technology with lean processes.

Low-code platforms and lean construction are likely to become even more integrated as the construction industry continues to evolve. It is anticipated that the use of AI and other sophisticated technologies in low-code platforms would expand, hence enhancing project efficiency and decreasing waste (Cisterna, Lauble, et al., 2022). Additionally, the use of low-code solutions in construction will continue to expand beyond simple workflows to include complex, data-intensive applications. This includes, for instance, the integration of relational databases such as Microsoft Dataverse, allowing the design of more complex and intensive data models.

INTERFACES TO CONTEMPORARY CONSTRUCTION INDUSTRY TOPICS

While developing and implementing the solution described in this study, the authors also realized interfaces to other contemporary construction industry topics such as Industry 4.0, Building Information Modelling (BIM), and Digital Twin. The data which can be digitalized and processed using low-code/AI could be further exploited and integrated in a larger system. For example, data captured onsite could be linked to the BIM Industry Foundation Classes (IFC) schema to enrich data available in the model. These types of interfaces offer an interesting area for further research considering the novelty of low-code in the construction industry.

LIMITATIONS

The digital solution described in this study was developed using one of the many low-code development platforms currently available in the market. This platform was already embedded in the organizational information technology landscape. As a result, the low-code platform was ready to use, and there was no need to benchmark low-code solutions and spend additional time integrating it into the organization's systems. Although low-code platforms offer similar features, the outcomes of this study could have been influenced by the platform used. In this regard, comparing the suitability of the features of low-code platforms in the context of the construction industry is also an interesting field of study. This paper also describes a single use case. The authors encourage further exploring use cases and research to build up evidence about the benefits and limitations of low-code use in the context of the construction industry.

The solution could have also considered digitalizing delivery notes at the source. That means, requesting the supplier to manage delivery notes digitally, instead of printed. Arguably, this solution requires developing and onboarding suppliers on a shared digital platform. This is an idea to explore in the future. Nevertheless, the capabilities of the low-code platform to handle the requirements of this type of solution were not assessed in this study.

CONCLUSIONS

This paper explored the use of low-code and AI to improve processes in the construction industry context. Low-code enables people with no advanced coding skills to develop and deliver digital solutions to address specific business and operational challenges. This article delves into the potential of low-code technology in facilitating the digitalization of construction-specific processes and promoting lean construction practices in this field.

This study documented the development and implementation of a low-code and AI-powered solution to extract and process data from paper delivery notes, resulting in a 78% process time savings, and the availability of processed digital data related to the process. This experience highlights the importance of the low-code approach, particularly the involvement of individuals with a closer proximity to operations in the development process. This involvement enables the effective elicitation of requirements and their translation into features of the digital solution, ensuring that the result aligns with the process and meets the end-user's needs.

The use of low-code is gaining a tremendous momentum and scientific interest. Since it is a relatively new topic, there is significant room for further research. The authors encourage the development and documentation of additional case studies to build up evidence about the benefits and limitation of using low-code to support continuous improvement in the construction industry context. Additionally, there are several low-code platforms available with different features and capabilities. Further research could involve exploring the relevant requirements of a low-code platform that align with the specifics of the construction industry.

ACKNOWLEDGMENTS

The authors extend their gratitude to the project team participating in this study. Particularly, our acknowledgments go to Julia da Costa de Moraes, who experimented with the low-code platform and offered insightful contributions towards the formation of the study's findings.

UNLEASHING THE POWER OF CHATGPT FOR LEAN CONSTRUCTION: AN EARLY OUTLOOK

Makram Bou Hatoum[1] and Hala Nassereddine[2]

ABSTRACT

Artificial Intelligence (AI) is one of the core technologies that was brought forward by the fourth industrial revolution. This technology is disrupting industries all around the globe, and the construction industry is no exception. Research targeting AI in construction has grown exponentially in the last decade as researchers investigate how to leverage AI across the project lifecycle. With the recent release of ChatGPT, AI research is expected to grow even more as the construction industry navigates this breakthrough and understands its impact.

This paper focuses on AI in the context of Lean Construction and has two main objectives. First, the paper reviews the database for the International Group of Lean Construction (IGLC) to identify AI-related publications, summarize their findings, and detect the research trends. A total of nineteen papers were identified, presenting various theoretical and practical aspects of AI in Lean Construction. Second, the paper provides an early outlook into ChatGPT and experiments with its capabilities through three simple use cases that explore ChatGPT's ability to educate and train on Lean aspects, perform conceptual analysis, and develop Lean applications. The early interaction with ChatGPT showed promising potential for the construction industry with encouraging results that can empower the Lean community.

KEYWORDS

Lean Construction, Artificial Intelligence, ChatGPT, Construction 4.0.

INTRODUCTION

Artificial Intelligence (AI) is a disruptive technology that has the power to revolutionize industries. The concept of AI can date back to the early 1300s (Press, 2016) but its science was officially established in the early 1930s (Ertel, 2017). The term "Artificial Intelligence" was first coined in the year 1955 by McCarthy et al. (1955) "2 month, 10 man study of artificial intelligence" proposal which led to the birth of the AI field in 1956 (McCarthy et al., 2006). The birth was a result of a strong period of technological developments that was accelerated by World War II and the desire to understand and connect the functioning of machines and organic beings (Council of Europe, 2023).

While there is no standardized definition of AI, the notes of 10 U.S. Code § 2358 use the following definitions: "(1) Any artificial system that performs tasks under varying and unpredictable circumstances without significant human oversight, or that can learn from experience and improve performance when exposed to data sets; (2) An artificial system developed in computer software, physical hardware, or another context that solves tasks requiring human-like perception, cognition, planning, learning, communication, or physical

[2] Assistant Professor, Department of Civil Engineering, University of Kentucky, Lexington, KY, USA, hala.nassereddine@uky.edu, orcid.org/0000-0001-7952-5034.

action; (3) An artificial system designed to think or act like a human, including cognitive architectures and neural networks; (4) A set of techniques, including machine learning, that is designed to approximate a cognitive task; and (5) An artificial system designed to act rationally, including an intelligent software agent or embodied robot that achieves goals using perception, planning, reasoning, learning, communicating, decision-making, and acting."

AI AND THE CONSTRUCTION INDUSTRY

The construction industry is no exception to the disruptions caused by AI, a technology that is core to the Construction 4.0 transformation of the industry (Hatoum et al., 2021). A state-of-the-art review by Abioye et al. (2021) on AI in construction showed the valuable contribution of the technology to resource and waste optimization, supply chain management, health and safety analytics, estimation and scheduling, and job creation. The study also highlighted the potential to develop AI-driven contract comprehension, AI-driven audit systems for construction financials, AI-enabled head-mounted displays, voice user interfaces, and deep learning-based project assistive technologies (Abioye et al., 2021). Another study performed by Pan & Zhang, (2021) proposed a futuristic framework for construction engineering and management that builds on AI research and integrates it with other Construction 4.0 technologies such as robotics, AR, VR, IoT, blockchain, 3D printing, and digital twins, to enhance and optimize the design, planning, construction, and operation of projects. The importance of AI has also dubbed it as one of the ten emerging digital technologies in the Architecture, Engineering, Construction, and Operation (AECO) sector, as the interest in AI research has been growing almost exponentially in the past 10 years (Dou et al., 2023). Despite its importance however, major challenges remain at the level of cost, security, talent shortage, computer power requirements, internet connectivity requirements, policies and regulations, as well as ethical and cultural dilemmas (Abioye et al., 2021; Regona et al., 2022).

CHATGPT: AN AI BREAKTHROUGH

The release of ChatGPT in December 2022 has brought major disruptions, as its accessibility and capability prove that "AI is finally mainstream" (Vincent, 2022). ChatGPT is part of the Generative Pre-trained Transformer (GPT) family of languages developed by Open AI "which uses a transformer neural network to generate natural language text" (OpenAI, 2022). The model is trained using Reinforcement Learning from Human Feedback (RLHF), and unlike traditional chatbots, it can "provide answers, solutions, and descriptions to complex questions including potential ways to solve layout problems, write code, and answer optimization queries" (Haque et al., 2022; OpenAI, 2022) It can also remember what the user discussed earlier in the conversation for follow-up questions, refuse inappropriate requests, and question incorrect responses (Haque et al., 2022).

While the technology behind ChatGPT is not new and the model has several shortcomings, its impressive detailed and human-like text has made it a breakthrough in the AI chatbots that were ever released to the public, drawing more than 1 million users in its first five days and crossing the 100 million monthly users in January 2023 (Bæk, 2023) (Baek, 2023).

ChatGPT serves as the greatest example of the "Ready or Not, AI Comes" scenario, where its disruptions were rapidly noted in major aspects and industries (Lock, 2022; Roose, 2022). For example, concerns quickly grew over its effect on academia and research, prompting publishers to create policies on the use of ChatGPT in research articles, and causing universities and schools to constrain its impact on teaching, assignments, and examinations (Lock, 2022; Roose, 2022; Stokel-Walker, 2023).

As for the construction industry, the use of ChatGPT remains in its infant stages as researchers and practitioners are still trying to understand the technology and navigate its capabilities. Early articles by practitioners highlighted ChatGPT's power in helping construction professionals draft ideas, review communications, speed-up information inquiry, suggest solutions in various formats, highlight talking points, create document templates, fill templates with the required information, and automate administrative work (Mitchell, 2023; Sullivan, 2023). Another study conducted by Prieto et al. (2023) investigated the use of ChatGPT for scheduling construction projects. Results showed that while ChatGPT provided a logical sequence of tasks, its thought process behind the schedules was very linear. Not all of the proposed tasks agreed with the scope of work, but conversing with ChatGPT allowed it to correct some of its errors. The authors attributed the reason to the fact that ChatGPT has not been trained for specific construction purposes, making it not aware of all tasks that could be needed for construction. The study concluded that the overall performance was reasonable, the interaction experience with the interface was positive, and the results seem promising if ChatGPT can be further trained on specialized and specific construction project aspects (Prieto et al., 2023). The role of ChatGPT in generating construction schedules was also emphasized by Singh et al. (2023). The study highlighted the potential of ChatGPT as an aid for industry experts to create general project schedules while also acknowledging the tool's limitations in accounting for specific project constraints, risks, and requirements (Singh et al., 2023).

OBJECTIVE AND METHODOLOGY

With the importance of AI to the construction industry and the rise of ChatGPT, the objective of this study is to answer two research questions (RQs):

- ***RQ1.*** How is AI being researched in the context of Lean Construction?
- ***RQ2.*** Can ChatGPT benefit Lean Construction?

To answer RQ1, the database for the International Group of Lean Construction (IGLC) annual conferences was reviewed to identify all AI-related publications. The IGLC database was chosen because of its superior research in the field of Lean Construction and the significant impact of the IGLC annual conferences on the Lean community and the direction of Lean research. All AI-related publications were identified and summarized, and a keyword network was created to detect the general research trends of AI within Lean Construction.

As for RQ2, the authors conducted three simple use cases to experiment with ChatGPT and showcase its potential. The use cases explore ChatGPT's ability to educate and train on Lean aspects, perform conceptual analysis, and develop Lean applications. The use cases provide an early outlook into the capability of the technology and its support to the Lean construction community.

ARTIFICIAL INTELLIGENCE AND LEAN CONSTRUCTION

The first search within the IGLC database for papers that used the term "Artificial Intelligence" in their title, abstract, and/or keywords yielded nine publications. The second search for AI-related terms identified from the first search yielded eleven other publications.

PAPERS WITH DIRECT MENTIONS OF "ARTIFICIAL INTELLIGENCE"

The papers identified in the first search are summarized in Table 1. The nature of the papers varied between theoretical research and practical research. Theoretical research focused on AI's impact on the different Lean aspects like Lean principles and tools (Cisterna et al., 2022) and human-machine interaction (Arroyo et al., 2021), while the practical research utilized AI techniques to develop, verify, and validate AI models for different project purposes such as productivity (Zhao & Chua, 2003), and planning and scheduling (Benjaoran & Dawood, 2005).

A comprehensive keyword network was generated using VOSviewer for the papers as shown in Figure 1. The network aimed to identify the general themes of AI research by clustering the keywords using their association strength and detecting common key terms that

Lean construction researchers use in their papers. Each color in the network represents a specific cluster, and the following trends are identified:

- Commitment, collaboration, and trust are needed for AI to empower digitization through smart data analysis techniques;
- The proper integration of AI and Lean construction can foster a cultural change that embraces continuous improvement;
- Decision-making using AI must adhere to social and ethical principles, and decision-makers should consider and limit AI bias;
- The proposed AI models most used neural networks for multiple project aspects including planning, scheduling, production lines, productivity, and waste;
- Knowledge management was a frequently investigated area where AI techniques such as decision trees, machine learning, data mining, and neural networks were used to analyze data and information and develop knowledge management systems.

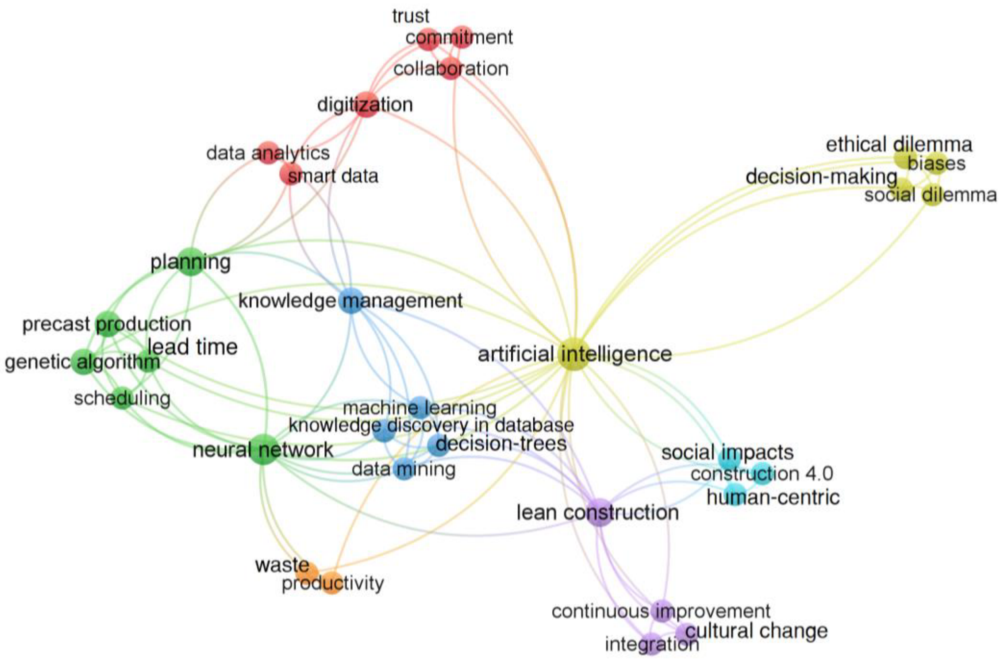

Figure 1: Keyword Network of the IGLC Papers that Used the Term "Artificial Intelligence"

PAPERS WITHOUT DIRECT MENTIONS OF "ARTIFICIAL INTELLIGENCE"

The network in Figure 1 highlighted frequent key terms for different AI techniques used by Lean construction researchers. The key terms include "Neural Networks", "Machine Learning", "Decision Trees", "Genetic Algorithm", "Data Mining", and "Knowledge Discovery". Each of these where used to search the IGLC database for additional AI-related papers, and the search yielded eleven publications that did not appear in Round 1.

The papers are summarized in Table 2. The research was mostly practical in nature with direct applications of multiple AI techniques such as machine learning applications to create information systems (Caldas & Soibelman, 2002), genetic algorithms to reduce inventory (Ko, 2011), and artificial neural networks to benchmark and predict environmental performance indicators (Fernandes et al., 2019). Moreover, some AI techniques were used with common Lean decision-making tools such as genetic algorithms with Analytic Hierarchy Process (Lin, Wang, & Yu, 2009) and graph-based inference with Choosing by Advantages (Haymaker, Chau, & Xie, 2013).

Table 1: Summary of AI-related papers published in IGLC (Round 1)

Paper	Summary
Soibelman & Kim (2000)	Presented a framework required for implementing Knowledge Discovery in Databases (KDD) to uncover new patterns in construction projects by examining extensive project data. The procedure comprises five main stages: identifying issues, preparing data, mining data, analyzing data, and refining the process. The paper also developed a prototype of the KDD system And experimented with it utilizing the Resident Management System database from the US Corps of Engineers.
Benjaoran & Dawood (2003, 2005)	Proposed a system for automatic planning referred to as "artificial intelligence planner (AIP)" to minimize lead time and enhance the scheduling and planning of the precast concrete production process. AIP relies on two AI techniques - genetic algorithm (GA) and artificial neural networks (ANN). The original planner consists of four components that carry out different functions but communicate automatically with each other to achieve the AIP's overall purpose: "the central database, graphic data extractor, processing time estimator, and production planner". The authors followed it up with another paper where they enhanced AIP and presented a case study.
Zhao & Chua (2003)	Utilized a neural network to model the influence of wastes on measured productivity. The study formalized 20 types of waste, then analyzed a total of 75 sets of productivity data collected from formwork crews on multiple projects over 6 months. The model was able to successfully identify the 8 critical wastes affecting productivity and predict on-site performance with very good accuracy.
Oprach et al. (2019)	Focused on understanding the challenges in scheduling construction tasks with smart data and identifying possible solutions using existing applications of AI. The paper suggested three solutions including (i) naming of work packages by clustering with semantic wikis, (Sequential) pattern mining, and data recording with electronic devices; (ii) improvement of activity duration data by recording data with robots and drones and analyzing it with machine learning; and (iii) defining operationally significant locations through using BIM.
Schia et al. (2019)	Researched the successful implementation of digital tools and the understanding of human-machine relationships using literature, a case study, and interviews. The study utilized findings to provide technology, process, and culture factors that can "close the gap between the current and future use of AI in the construction industry" and evaluated the factors on three digital tools – Touchplan, Synchro, and ALICE
Arroyo et al. (2021)	Explored the ethical and social considerations of the AI application to spark discussion on AI within the Lean community. The study presented different examples, opinions, and use cases to elaborate on five main discussion points including (i) verifying the source of data and means of the data collection; (ii) trusting AI decisions; (iii) understanding AI bias; (iv) being cautious of pleasing the algorithm; and (v) understanding the impact on project team motivation and decision-making.
Cisterna et al. (2022)	Investigated the synergies between AI methods and Lean construction techniques where they highlighted two types of synergic interactions – interactions where Lean supports AI processes and interactions where AI supports Lean techniques. Findings were presented in an AI-Driven Construction Improvement Process (CIP) framework in which people were elevated to a pivotal position as a unifying element between the two fields.
Noueihed & Hamzeh (2022)	Explored the social impact of adopting Construction 4.0 technologies and addressed AI as a specific case of these technologies. The study emphasizes the need for human-centric approaches where technologies are means to support people to flourish and succeed, and should not be treated as means for dominancy. The study also highlighted that people should drive the design and implementation of technologies to make sure that "technologies fit their needs and preserve their rights of performing work freely, efficiently, and humanely".

Table 2: Summary of AI-related papers published in IGLC (Round 2)

Paper	Summary
Caldas & Soibelman (2002)	Utilized automated text classification methods to support the "implementation of pull techniques in construction management information systems". The proposed system comprises six main modules namely: "data collection, data conversion, data preparation, dimensionality reduction, learning, and classification". Multiple machine-learning algorithms were used in the learning module including Support Vector Machines. The prototype was created to automate the stages involved in the document classification process and enabled the generation of classification models for projects based on user-defined project components.
Filho et al. (2004)	Analyzed a large data set from a capital facility project to detect common patterns of sequences of non-completed activities. The analysis showed effectiveness in identifying problems in the production workflow and pinpointing relevant events that had not been noticed by the onsite workforce.
Bortolazza, Costa, & Formoso (2005)	Aimed to provide insights into the Last Planner System implementation in Brazil using a quantitative approach. The study aimed to analyze the percentage of plans completed (PPC) data from 115 residential, industrial, and low-income housing projects. The study also utilized data mining techniques including decision trees and neural networks to detect patterns and analyze causes for the non-completion of work packages. The major preliminary reasons indicated that most projects had limited success in the implementation of look-ahead planning.
Wu & Soibelman (2006)	Presented a case study on a novel approach developed by the authors to preprocess and represent network-based work plans from a project control system into abstraction-type descriptions in support of graphical analysis and pattern recognition. The analysis was performed on a Last Planner database of production control from a large capital facility project. The resulting patterns can allow project managers to better understand potential problems and make informed decisions to decrease variability and increase reliability in planning and control.
Srisuwanrat & Ioannou (2007)	Presented a unique investigation of lead-time buffering by focusing on "when to start a production line so that there is no interruption". Two distinct methods of lead-time buffering were investigated – the "sequence step algorithm" (SQS-AL) and the "completed unit algorithm" (CU-AL). The authors employed STROBOSCOPE coupled with a search add-on that utilizes a genetic algorithm (GA). Results showed that incorporating a lead-time buffer leads to improved workflow and greater project profit that vary based on the workflow interruption's penalty cost and indirect cost. The study highlighted the algorithms' advantages as well as limitations "depending on assumptions, simplicity of the simulation model, project characteristics, and uncertainty".
Ko & Wang (2008)	Developed a flow-shop sequencing model to enhance weekly work planning. The model considers production constraints and buffer sizes and uses a genetic algorithm with multiple objectives to explore optimum solutions that minimize both makespan and tardiness penalties.
Lin et al. (2009)	Proposed an integrated model to facilitate the weightings and evaluation of "tenders involved in the best-value contractor selection process". To weight criteria, an adaptive Analytical Hierarchy Process (AHP) was developed using a soft computing scheme and genetic algorithms "to recover the weights of the various criteria based on the derived pairwise weighting matrix". As for tender evaluations, the authors proposed "a bid price evaluation submodel" to handle the quantitative criteria and "a performance-based evaluation submodel" to quantify the anticipated performances of other qualitative criteria for every bidder.

Paper	Summary
Ko (2011)	Developed a framework to reduce the precast fabrication inventory without changing production resources. The framework comprises three components including "(i) a time buffer evaluation is to avoid fabricators losing capacity by considering demand variability; (ii) a due date adjustment to shift the production curve closer to erection dates and reduce inventory; and (iii) a scheduling component that arranges production sequences to achieve multi-objectives using genetic algorithms".
Haymaker et al. (2013)	Leveraged decision models and machine learning to support designers in dealing with decision-making challenges by automatically retrieving pertinent information from prior decisions. The authors employed the Belief Propagation (BP) graph-based inference to "develop a collaborative decision-making model" based on the Choosing by Advantages (CBA) methodology. The paper proposed the CBA-PB algorithm and implemented it to validate its efficiency and effectiveness.
Antunes & Poshdar (2018)	Suggested a theoretical framework to tackle construction production issues through the implementation of "an integrated automatic supervisory control and data acquisition for management and operations". The system is segmented into planning, controlling, executing, and monitoring groups to track the project product as well as production. The system also employed machine learning models that can be trained with input sources from technologies to perform tasks and generate outputs that feed into the system.
Fernandes et al. (2019)	Proposed an equation that "predicts environmental performance indicators based on construction progress". The model was developed via Python and utilized artificial neural networks using a database of 15 construction sites. Three equations were proposed for three environmental indicators – water consumption, energy consumption, and waste generation. The equations can provide managers with a benchmark to establish environmental performance targets and make managerial decisions as the construction progresses.

CHATGPT AND LEAN CONSTRUCTION

To understand how can ChatGPT benefit Lean construction professionals and researchers, the authors performed three simple use cases to experiment with the technology's capabilities.

USE CASE ONE: EDUCATION AND TRAINING

The authors asked ChatGPT to define Lean Construction, list the major concepts and practices, and explain how ChatGPT can support the Lean Construction field. The responses are shown in Figure 2 (Left). The answers provided were both accurate and reliable. The authors also asked ChatGPT to provide the answer to Question 2 (Lean concepts and practices) in the form of an official training document, and ChatGPT changed the entire answer to a professional training template.

USE-CASE TWO: CONCEPTUAL ANALYSIS

The authors provided ChatGPT with a descriptive steel erection process beginning from the time the material was ordered and shipped from the manufacturer, through the construction production process, and ending with the material in its final position in the facility. The process was adopted from the Construction Industry Institute (CII) project RT-191. The authors requested ChatGPT to identify Lean waste and provide solutions, and the responses are shown in Figure 2 (Right). ChatGPT was successfully able to identify five waste types and provide solutions that meet the scope of the process. The answer provided by ChatGPT was very impressive given that ChatGPT was only given a descriptive summary of the process without any quantitative data for further analysis.

Authors: *Define Lean Construction.*
ChatGPT: "Lean construction is a management philosophy and production approach that aims to optimize the design and delivery of construction projects. It is based on the principles of the Toyota Production System, which has been successfully applied in manufacturing and other industries. In construction, the goal of lean construction is to eliminate waste, increase efficiency, and improve overall project performance by involving all members of the construction team in the continuous improvement process. This is accomplished through a series of tools and techniques, including value stream mapping, pull planning, and kaizen events, that help identify and eliminate non-value-adding activities. Lean construction also places a strong emphasis on collaboration and communication between all stakeholders in the project, including owners, designers, contractors, and subcontractors. The focus is on delivering projects that meet the needs of the customer, while also improving quality, reducing costs, and shortening the construction timeline."

Authors: *List the main Lean construction concepts and practices.*
ChatGPT: "The main concepts and practices of lean construction are as follows:
- Elimination of waste: Lean construction aims to eliminate waste in construction processes, including overproduction, waiting, defects, overprocessing, excess inventory, unnecessary motion, unused talent, and production of unnecessary products.
- Continuous improvement: Lean construction is focused on continuous improvement, which involves regularly reviewing and refining construction processes to identify and eliminate waste, and improve efficiency and quality
- Value stream mapping: This involves creating a visual representation of all the activities and processes involved in a construction project, from start to finish, to identify areas for improvement and eliminate waste.
- Just-in-time (JIT) production: JIT production is a key concept in lean construction, and involves producing materials and components just in time for when they are needed on the construction site, reducing the need for storage and inventory.
- Pull production: This involves producing materials and components in response to actual demand, rather than producing ahead of time, to reduce waste and improve efficiency.
- Kaizen: Kaizen is a Japanese term for continuous improvement, and involves regularly reviewing and refining construction processes to eliminate waste and improve quality and efficiency.
- Total productive maintenance (TPM): TPM involves involving all employees in the maintenance of equipment and machinery, to ensure that they are maintained in good condition, and to reduce downtime and waste.
- 5S: 5S is a set of five principles for workplace organization and efficiency, which include sorting, simplifying, sweeping, standardizing, and sustaining.
- Visual management: This involves using visual aids, such as visual schedules and status boards, to communicate project information and improve collaboration and communication.

In summary, these are the main concepts and practices of lean construction, which aim to eliminate waste, improve efficiency and quality, and promote continuous improvement in construction processes."

Authors: *How can ChatGPT support and enhance Lean Construction?*
ChatGPT: "ChatGPT can support and enhance the implementation of lean construction in several ways:
- Education and training: ChatGPT can be used as a virtual assistant to provide education and training to construction professionals on the principles and practices of lean construction. This can help to increase awareness and understanding of lean construction, and promote its adoption in the industry.
- Project management: ChatGPT can assist in the management of construction projects by providing real-time information and support to project teams. For example, it can help with the creation of project schedules, tracking of project progress, and identification of areas for improvement.
- Collaboration and communication: ChatGPT can facilitate collaboration and communication between all stakeholders in a construction project, including owners, designers, contractors, and subcontractors. This can help to promote teamwork, increase transparency, and reduce misunderstandings, which are key components of lean construction.
- Data analysis: ChatGPT can assist in the analysis of data related to construction projects, such as construction schedules, costs, and quality metrics. This can help to identify areas for improvement, and support the implementation of continuous improvement initiatives in the field.
- Knowledge management: ChatGPT can help to centralize and manage knowledge related to lean construction, allowing construction professionals to access and share information, best practices, and lessons learned.

In summary, ChatGPT can be a valuable tool for promoting and enhancing the implementation of lean construction in the construction industry. By providing support for education and training, project management, collaboration and communication, data analysis, and knowledge management, it can help to increase the efficiency and effectiveness of construction projects, and support the continuous improvement of construction processes."

Authors: The following paragraphs describe a structural steel erection process, beginning from the time the material was ordered and shipped from the manufacturer, through the construction production process, and ending with the material in final position in the facility. Information on delivery and handling of the steel joists was obtained from the project manager. Once it arrived onsite, the basic flow of the steel was as follows:
1. After the steel was manufactured, it remained onsite at the manufacturer's warehouse until needed.
2. Each steel shipment consisted of all structural steel members required in one bay. Steel could not be stored onsite in a large material lay-down yard due to safety restrictions. The steel for three to four bays was stored on truck trailers (minus the cab) in the parking lot until needed. It usually remained in the parking lot for one week before being handled again and moved to the second staging area - a small material lay-down area next to the bay being erected.
3. Each load was handled by a heavy-duty forklift. Depending on the steel member type, one to three separate lifting actions were needed by the forklift operator to remove the entire load from the truck bed.
4. The load from the truck was placed on the ground in the same manner as it was on the truck. No shakeout occurred from the truck to the ground.
5. The piles from the truck were organized by member type (columns with columns, trusses with trusses, etc.).
6. Each steel member had a number that correlated to a number on the drawings. Following the placement of each pile on the ground, a ground crewman located the number on each steel piece and related it back to the foreman. This number helped the erection crew foreman with the proper erection sequence.
7. No shakeout occurred after placement on the ground. The crane was required to swing over the material lay-down area in random picks to reach each steel piece. One piece was picked at a time. This created a large material transport time for the crane operator.
8. After the steel members were placed near their respective bay staging areas, the crane moved the girders, bar joists and columns from the staging position to final position in the structure.

Please identify all Lean waste in this procedure and suggest solutions.

ChatGPT: The following are the identified sources of Lean waste in the structural steel erection process:
- Waiting: The steel was stored at the manufacturer's warehouse until needed, and then in the parking lot for one week before being moved to the next staging area, resulting in waiting time for the material to be used.
- Excess Inventory: Steel for three to four bays was stored on truck trailers, creating excess inventory and taking up valuable space.
- Overprocessing: Depending on the steel member type, one to three separate lifting actions were needed by the forklift operator to remove the entire load from the truck bed, leading to overprocessing and increased handling time.
- Unnecessary Motion: The crane was required to swing over the material lay-down area in random picks to reach each steel piece, resulting in unnecessary motion and increased material transport time for the crane operator.
- Unused Talent: The ground crewman who located the numbers on each steel piece was only utilized in the material handling process and not in any other value-adding activities.

To eliminate these wastes, the following solutions can be considered:
- Reduce waiting time: Arrange for just-in-time (JIT) delivery of the steel members, so that they are delivered only when needed on the construction site, reducing the waiting time for the material to be used.
- Minimize excess inventory: Store only the necessary steel members required for the current bay in the parking lot, reducing the amount of excess inventory stored onsite.
- Streamline material handling process: Use equipment and processes that minimize the handling time of the steel members, such as using cranes to remove the entire load from the truck bed in one lift.
- Eliminate unnecessary motion: Arrange the material lay-down area in a way that reduces the movement required by the crane operator to reach each steel piece, such as organizing the piles by member type.
- Utilize all personnel: Encourage the ground crewman to take on additional responsibilities, such as assisting the crane operator, to utilize their full potential and skills.

Figure 2: Use-Case I (Left) and Use-Case II (Right)

USE-CASE THREE: APPLICATIONS DEVELOPMENT

The authors asked ChatGPT to code an application that can help Lean professionals fill in constraint logs. No details, descriptions, or any sort of information were provided for the application. In its reply, ChatGPT acknowledged that it cannot code the entire application, but it can provide a foundation to start developing it. The output resulted in a Graphic User Interface that allows the user to select the constrained type from a dropdown, describe the constraint, and specify its start and end date. Once the user clicks Submit, the input is exported to a text file. The use case showed the creativity of ChatGPT in developing applications. Another interesting aspect of the code is that ChatGPT utilized comments to explain the different sections of the code and their functionalities. This can make it easy for the user to understand the code when implementing and building up on it.

Unfortunately, I am not able to write a complete application for you, as it would require a significant amount of time and resources. However, here is some sample code that demonstrates how you could create a fillable form for constraint logs and track reliable promises in a construction project using the Python programming language:

```
# import necessary libraries
import tkinter as tk
from tkinter import ttk

# create the main window
root = tk.Tk()
root.title("Construction Project Constraint Log")

# create the frame for the constraint log form
frame = ttk.Frame(root, padding="10 10 10 10")
frame.grid(column=0, row=0, sticky="WENS")

# create the form fields
constraint_type = ttk.Combobox(frame, values=["Material", "Labor", "Equipment", "Weather", "Permits"])
constraint_type.grid(column=1, row=0)

constraint_description = ttk.Entry(frame)
constraint_description.grid(column=1, row=1)

start_date = ttk.Entry(frame)
start_date.grid(column=1, row=2)

end_date = ttk.Entry(frame)
end_date.grid(column=1, row=3)

# create the form labels
ttk.Label(frame, text="Constraint Type:").grid(column=0, row=0, sticky="W")
ttk.Label(frame, text="Constraint Description:").grid(column=0, row=1, sticky="W")
ttk.Label(frame, text="Start Date:").grid(column=0, row=2, sticky="W")
ttk.Label(frame, text="End Date:").grid(column=0, row=3, sticky="W")

# create the submit button
submit_button = ttk.Button(frame, text="Submit", command=lambda: log_constraint(constraint_type.get(),
constraint_description.get(), start_date.get(), end_date.get()))
submit_button.grid(column=0, row=4, columnspan=2, pady=10)

# create the function to log the constraint
def log_constraint(constraint_type, constraint_description, start_date, end_date):
  # add the constraint information to the constraint log
  with open("constraint_log.txt", "a") as log_file:
    log_file.write(f"{constraint_type} | {constraint_description} | {start_date} | {end_date}\n")

# run the main loop
root.mainloop()
```

This code creates a GUI application using the tkinter library that allows you to log constraints and track reliable promises in a construction project. The form includes fields for constraint type, constraint description, start date, and end date, and a submit button that adds the constraint information to a text file named constraint_log.txt.

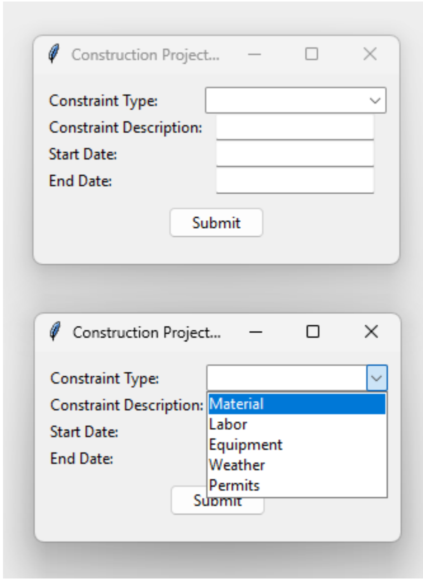

Figure 3: Use-Case III (code on the left and output on the right)

DISCUSSION

The review of the IGLC database on AI-related research showed that the Lean community has been invested in AI as early as the year 2000. Different publications have targeted both practical and theoretical research ranging from developing AI applications and models to understanding the implications of AI on people and Lean culture. With ChatGPT bringing AI to the mainstream, the research of AI within the Lean community is expected to rise even more. ChatGPT shows promising potential, and the three simple use cases presented in this paper showed a glimpse of how capable the technology can be for Lean Construction.

As illustrated in Figure 4, To successfully exploit ChatGPT and upcoming AI disruptions, Lean construction should embrace two types of people: innovators and doubters. On one hand, innovators represent individuals who will adopt ChatGPT early and will be eager to pilot the technology on different Lean aspects. They are often willing to take risks and embrace change, which can lead to new opportunities that leverage ChatGPT and AI in Lean Construction. On the other hand, doubters are individuals who are more cautious and skeptical of AI and ChatGPT. They will often want to understand the potential risks and downsides before embracing new ideas. The presence of both adopters and doubters will thus create a continuous improvement culture, where innovators will bring in new ideas and approaches to solving problems, while the doubters will help ensure that these ideas are thoroughly tested and evaluated before implementation. This interactive dynamic will result in a more thorough and well-informed use of the technology that enables trust, respect for people, adherence to ethical and social principles, and process enhancements.

The biggest threat to technology is resistance, a problem that remains widely common in the construction industry. Once doubters turn into resistors, the continuous improvement cycle of the technology will break as innovators will push ideas and resistors will block them. Thus, the Lean community needs to keep an open mind and embrace its scientific thinking to develop a community of innovators and doubters and exploit the potential of transformative technology.

Moreover, it is also important to acknowledge that AI tools like ChatGPT are still in their early stages of development and, as with any other technology, are expected to evolve and improve over time. Thus, in the meantime, it remains important to utilize the technology as intended, consider its limitations, and verify and validate its output using human intuition, expertise, and available AI content detectors.

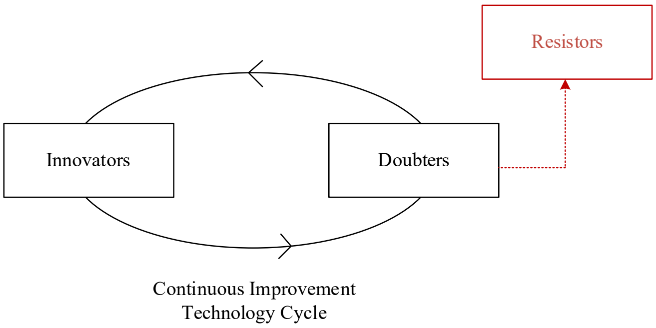

Figure 4: Conceptual Framework that Illustrates Lean and ChatGPT

CONCLUSIONS

This paper explored AI research in Lean Construction and presented preliminary findings on ChatGPT. A review of the IGLC database showed that AI has gained a lot of interest in Lean construction research, while the use cases on ChatGPT showed promising potential for Lean construction. The study however was limited to reviewing IGLC proceedings and performing simple use cases. Further studies can perform systematic literature reviews on other research databases to detect further trends. Future research is also expected to utilize ChatGPT in more complicated use cases that can fully leverage AI capabilities. Finally, in the words of ChatGPT:

Lean construction, so efficient and fast. A building process that's built to last.
With principles to eliminate waste. It aims to make every project great.
Along comes ChatGPT, a tool so bright. Bringing artificial intelligence to the site.
With its vast knowledge, it can assist. Making Lean construction more persistent.
Together they work, as a perfect team. Improving building processes like a dream.
Efficiency and accuracy are their goals. Building better structures for all roles.

LEAN CONSTRUCTION AND BUILDING INFORMATION MODELING (BIM) IN DESIGN MANAGEMENT: SURVEY RESULTS FROM FRENCH COMPANIES

Wassim AlBalkhy[1], Eva Chaize[2], Vincent Morael[3], Zoubeir Lafhaj[4], and Ivanka Iordanova[5]

ABSTRACT

Lean and BIM integration in the design phase may help achieve better design deliverables on the planned time and cost and consistent with the client's needs and requirements. With the absence of enough studies about lean-BIM integration in France, this study reports the results from a survey about lean-BIM integration in French design firms. The results of the study showed that lean is still not routinely adopted in these firms, and more than 95% of the firms do not provide training on lean. The evaluation of lean-BIM integration was neither high nor low; with a mean of 3.73 out of 5.00. Additionally, the results showed that BIM has still not delivered its full potential in the studied firms. The analysis of the results showed also a positive and significant impact of lean-BIM integration on design performance.

KEYWORDS

Lean construction, Building Information Modeling (BIM), Design Management, Construction, Lean construction 4.0, France.

INTRODUCTION

It is widely believed that decisions in the design phase of construction projects result in changes that cannot be adjusted without affecting the time, cost, and/or quality of the project (Haponava & Al-Jibouri, 2009; Sweis et al., 2008). As a result, design management is believed to be a critical factor that affects the success of construction projects (Chaize et al., 2022; Hattab & Hamzeh, 2013).

Design management refers to the planning, organization, and management of processes, people, knowledge, and information flow during the design phase to meet the client's needs and requirements (Herrera et al., 2020, 2021). During this phase, specialists from different disciplines work to translate the value proposition by the clients, meet their expectations, comply with the standards and avoid making errors in the design (Hattab & Hamzeh, 2013; Tauriainen et al., 2016). Nevertheless, achieving all these objectives is still questionable in the presence of weak and traditional design practices (Tauriainen et al., 2016).

Traditional design management can be understood as a linear process that includes a set of tasks done by designers who work fragmentedly to deliver the design based on a predetermined schedule and due dates (Khan & Tzortzopoulos, 2015). In this understanding, collaboration and interrelations between design teams are unappreciated (Tauriainen et al., 2016). It also indicates that design continuous improvement is not the focus. This is due to the understanding that the linear design process helps to achieve higher productivity in design and the iterative approach, which normally contributes to improving value and innovation, is wasteful (Abou-Ibrahim & Hamzeh, 2016; Khan & Tzortzopoulos, 2015). Another consequence of this understanding is the neglect of the flow of information between the right people at the right time, which may result in design errors (Hattab & Hamzeh, 2013).

The presentation of Building Information Modeling (BIM) and lean thinking to design management is expected to solve these problems. The use of BIM offers opportunities to collaboratively work on a "live" version of the design between stakeholders and helps to increase transparency and information flow between all the stakeholders (Hattab & Hamzeh, 2013). The features of BIM allow for achieving numerous improvements in the design phase such as the decline in design errors and clashes, increased visualization, quicker and easier design alternatives, reduced design cycle time, improved coordination, and easier cost estimation (Herrera et al., 2021; Rojas et al., 2019; Tauriainen et al., 2016).

Nevertheless, BIM as a technology is not sufficient to ensure successful design management. Lean construction, with its principles and tools, helps to facilitate the generation of the value of the client and improve the social system during the design process. For instance, the presentation of the Last Planner System (LPS) during the design process can contribute to improving transparency, communication, trust, efficiency, and quality of the design (Chaize et al., 2022; Hamzeh et al., 2009; Khan & Tzortzopoulos, 2015). Big room/iroom/co-location is also effective to increase collaboration, decreasing design errors, and reduce latency in decision-making (Tauriainen et al., 2016) and Design structure matrix (DSM) is helpful to improve planning for the entire design phase (Rosas, 2013).

Therefore, the lean-BIM integration has been topical in many research works and applications (Abou-Ibrahim & Hamzeh, 2016; Bolpagni et al., 2017; Dave et al., 2013; Hattab & Hamzeh, 2013; Herrera et al., 2021; Mollasalehi et al., 2016; Rojas et al., 2019; Sacks et al., 2010; Tauriainen et al., 2016; Uusitalo et al., 2019). In France, a limited number of investigations have been carried out about this integration. Additionally, there is still some missing information about the adoption of both concepts in all phases of the construction despite different calls to adopt them (Chaize et al., 2022; Joblot et al., 2017; PLANBIM, 2022; Tranchant et al., 2017). Additionally, despite the global efforts to study lean-BIM integration, there has still insufficient studies that link between lean-BIM integration and design performance. Aiming at increasing the understanding of lean-BIM integration in France and its impact on design performance, the current study tries to achieve the following two objectives:

1- To investigate the levels of lean and BIM adoption in French design companies.
2- To study the impact of lean-BIM integration of design performance.

RESEARCH METHODOLOGY

To achieve the two objectives of the study, a survey to collected quantitative data was developed based on studies from the literature. The use of survey is very common when the researchers try to get quantitative insights about the personal perceptions and the organizational policies and practices (Albalkhy & Sweis, 2022). The survey included four main sections as follows:

1- Section 1: general information about the company and respondents (three questions; participants' experience, company size, and role in the company).
2- Section 2: was about BIM purposes and uses. This section included 12 questions that were adopted from the studies of Bolpagni et al (2017) and Herrera et al (2021). The

questions were about the experience of BIM adoption and training, purposes of BIM, and frequency of BIM uses on a five-point Likert scale from 1 (refers to never) to 5 (refers to always).

3- Section 3: was about lean principles and tools and was based on lean adoption and training and used tools. The section included three main questions that were adopted from the study of Bolpagni et al (2017).

4- Section 4: was about lean-BIM integration in design and evaluation of design performance. The section was based on eight questions adopted from the studies of Dave et al (2013) and Herrera et al (2021). For the lean-BIM integration, the questions were based on a five-point Likert scale where 1 (refers to never) to 5 (refers to always), while for the performance, the scale was from 1 (refers to strongly disagree) to 5 (strongly agree).

The survey was translated into French and developed using Microsoft forms. It was then distributed using emails and LinkedIn was filled by respondents from design and engineering studies firms in France. The analysis of the results was done using Microsoft Excel 2019.

ANALYSIS OF THE RESULTS

Participants and company profile

49 participants answered the questions of the survey. The analysis of the results showed that the vast majority of the respondents had a long experience in construction design and studies as 40 participants had more than 10 years of experience in the field. The roles of the participants ranged between directors, project managers, BIM managers, heads of departments, architects, engineers, and one lean manager.

Concerning the companies' profile, the participants represented the different sizes of companies as 21 participants were from companies with more than 100 employees, 7 were from companies with 50-100 employees, 13 were from companies with 10-50 employees, and 8 were from companies with less than 10 employees. The participants were also from companies with different areas of work including architecture, public and infrastructure projects, residential and real-estate projects, industrial buildings, commercial buildings, hotels, and renovation projects.

BIM adoption and uses

The responses regarding BIM adoption showed an acceptable range of BIM adoption as most of the participants stated that BIM had been applied in their companies for at least five years (38 respondents). Only one participant in the study stated that BIM was still not adopted in the company. Two other participants stated that BIM was new to their company and its adoption started less than one year ago. 38 respondents (78%) declared that their companies were offering training on BIM.

Regarding the purposes of BIM implementation, architectural purposes (n= 38 respondents), structural (n=25), mechanical (n=25), and plumbing (n=25) works were the most found motives for BIM adoption in the studied companies. BIM was also used to manage and develop electrical works, maintenance and alarm systems, facades, environmental studies, and others.

Concerning the BIM applications in the design phase, Figure 1 shows that 3D coordination (mean=4.16), code validation (mean=3.76), and cost estimation (mean=3.02) are among the most frequent uses of BIM in the studied firms. While 4D planning (mean=1.96) is the least frequent use of BIM.

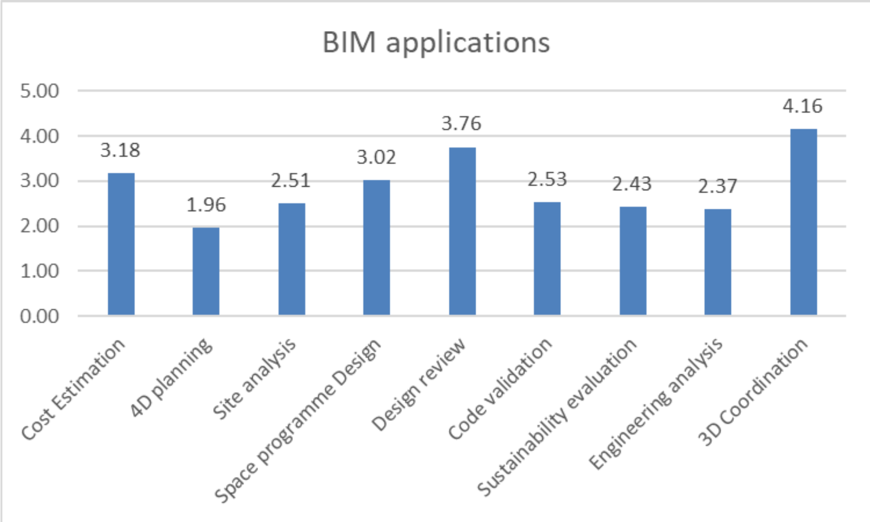

Figure 1: BIM uses in the design phase

Lean adoption and lean tools

The adoption of lean was significantly less in comparison to BIM. This is because only 11 participants (22.45%) stated that lean was adopted in their firms. Among them, only one firm was adopting lean for more than ten years and eight firms were adopting lean for 1-5 years. Additionally, only two participants stated that their companies provide training on lean.

Nevertheless, despite the lack of a declaration of lean as a whole philosophy, some participants believed that their companies use some tools that might facilitate the future implementation of lean. More specifically, as illustrated in Figure 2, the participants showed that the most applied tool/practice is the A3 problem-solving reports (n=13), then Big room or co-location to improve collaborative planning and design (n=12), and then the last planner system (LPS) (n=10). Other tools such as design structure matrix (DSM), plan-do-check-act (PDCA), value stream mapping (VSM), and 5S were less implemented. The least implemented tools/practices were the target value design (TVD), which was implemented by two companies, and the integrated project delivery (IPD), which was implemented by only one company.

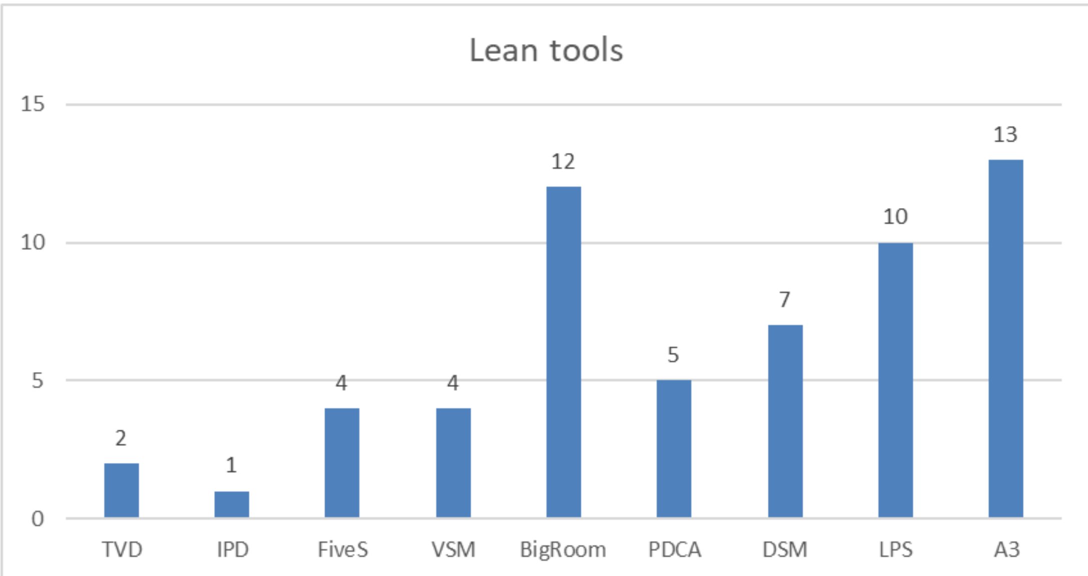

Figure 2: Applied lean tools/practices

Lean-BIM design management

Lean-BIM design management in this study refers to the integration between lean and BIM and the use of BIM models to support lean principles. Table 1 shows that the overall evaluation for lean-BIM integration was neither very high nor low as the mean was 3.73 out of 5.00. The highest evaluation was for the client value (mean= of 3.77), while the lowest was for the early involvement of construction stakeholders (mean= of 3.09). In this regard, it is apparent that other stakeholders (e.g. contractors and suppliers) are not involved early enough before the end of the design phase.

The results also show that design firms try to continuously evaluate and refine the design aiming at satisfying the needs and requirements of the client (mean=3.98). Nevertheless, the use of early BIM models for this purpose is still insufficient (mean=3.55). Concerning BIM as well, BIM models do not seem to be fully implemented to facilitate improving constructability in the later phases (mean=3.29). They are better used for visualization and assessment of design alternatives (mean=3.69) and for collaborative planning among the design teams (mean=3.8).

Table 1: Lean-BIM design management

Dimension	**Item**	**Mean (std. dev)**	**Dimension means (std. dev)**
Client value	Instead of one brief of requirements by the client, the early design is developed iteratively. In each iteration, the requirements of the client are evaluated and the design is refined	3.98 (1.051)	3.77 (1.010)
	BIM models are used to develop the early design to help evaluate the requirements of the client	3.55 (1.385)	
Set-based strategy	Designers consider sets of alternatives from the start of the design process rather than developing one alternative at the beginning	3.65 (1.200)	3.67 (0.927)
	BIM is used to enable rapid visual creation, communication, and assessment of project alternatives	3.69 (1.158)	
Early-involvement of stakeholders	Major project stakeholders (e.g. contractors, suppliers…) are involved early in the design process	2.90 (1.177)	3.09 (1.024)
	BIM models are used in the design phase to help stakeholders plan and construct the building virtually	3.29 (1.275)	
Collaborative planning	BIM models for all design teams can be combined periodically for collaborative working and analysis	3.80 (1.190)	3.64 (0.930)
	The client regularly participates in meetings to support decision-making and problem-solving	3.49 (1.063)	
Overall Mean	**Lean-BIM design**	**3.73 (0.890)**	

Design performance

The analysis of the results showed that the overall performance of the design in the studied firms was neither high nor low as the mean was 3.66 out of 5.00. As shown in Figure 3, the highest evaluation was for the indicators related to the client; specifically, for understanding the needs and requirements (mean=4.22) and then for achieving the client's satisfaction (mean=4.06). As the results showed, participants believed that they could also avoid future change orders (mean=4.04).

The figure also shows that the lowest evaluation was for clash detection (mean=2.76), and then for engaging design teams (mean=3.00), the flexibility of decision-making (mean=3.02), and easiness of dealing with design changes (mean=3.04). The results also showed that delivering the design in compliance with the planned time and budget was not easy (means= 3.10 and 3.18 respectively).

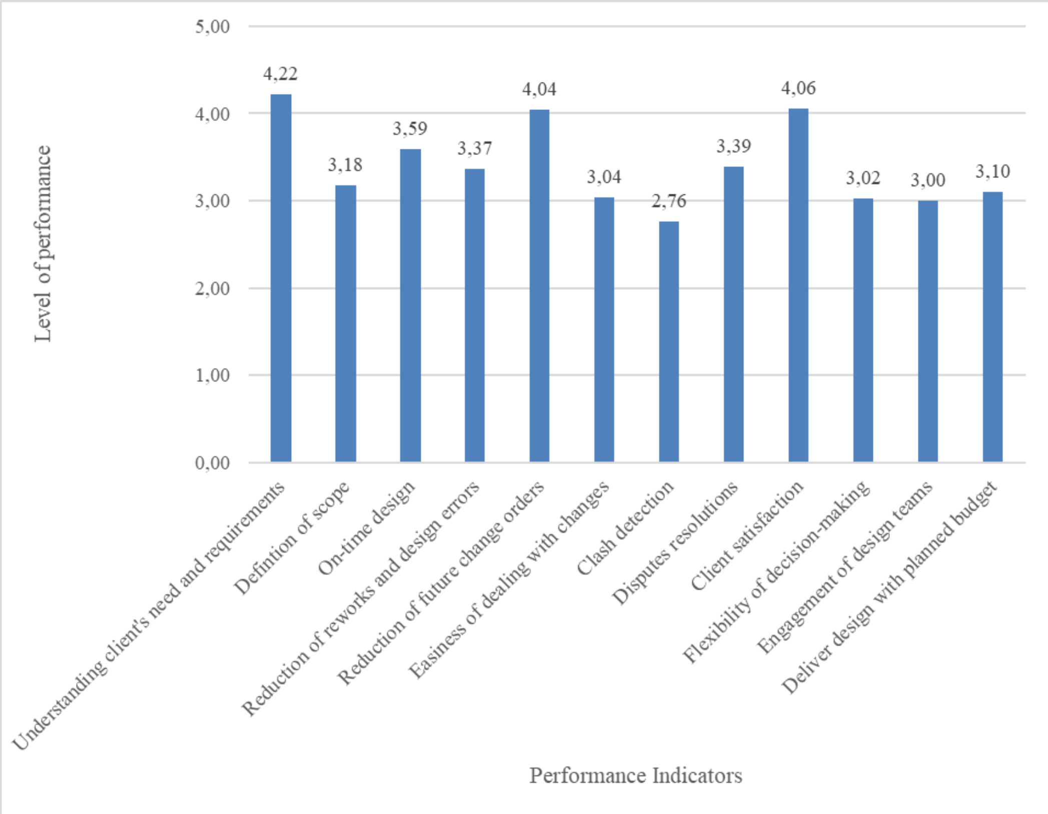

Figure 3: Design performance evaluation

To study the relationship between lean-BIM integration and design performance, a simple linear regression analysis was conducted. The regression test (as shown in Figure 4) revealed that at a significance level of (α=0.050), there is a positive and significant impact (P-value= 0.020) for lean and BIM integration in the design phase on design performance. The coefficient of correlation for the relationship is (r=0.44) and the coefficient of determination is (R-square= 0.194). This means that 19.4% of the change in the design performance can be explained by the change in the lean-BIM integration. Despite the significance of the relationship, it is worth mentioning that the the relationship needs to be investigated and validated using different and larger sample sizes and using other regression analyses.

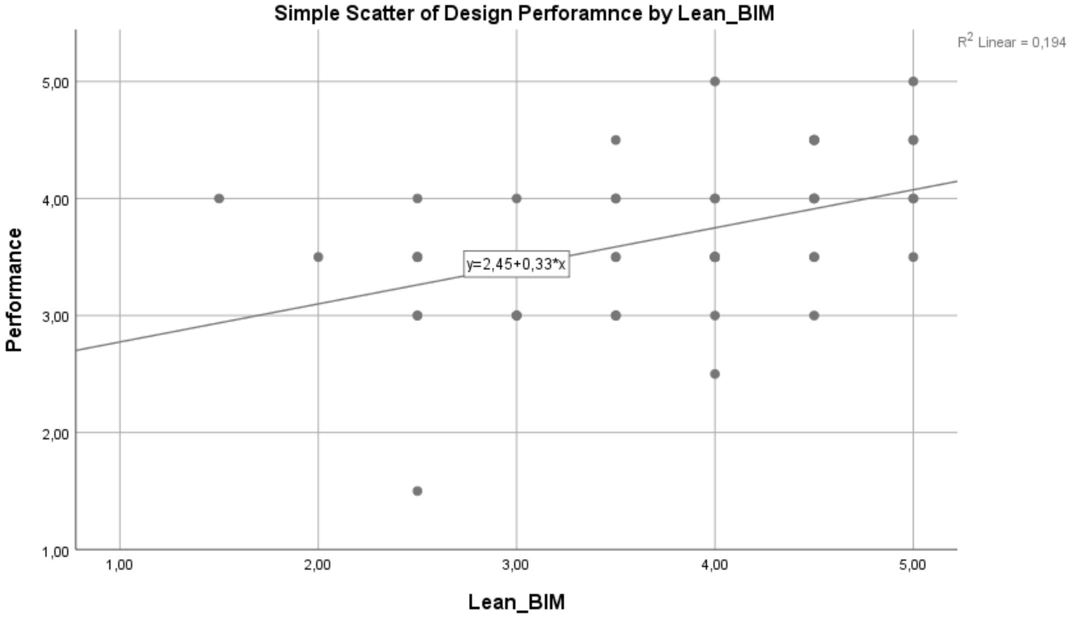

Figure 4: Relationship between Lean-BIM integration and design performance.

DISCUSSION AND CONCLUSIONS

Lean construction and BIM have been considered as two important concepts to create positive changes in the construction industry and along the different phases of construction projects (Sacks et al., 2010). Though, despite the increasing interest in lean and BIM and the numerous efforts to study the synergies between them, the implementation of lean principles jointly with BIM is still overlooked (Likita et al., 2022). Especially in design management (Herrera et al., 2021). Additionally, the levels of lean and BIM adoption are still unknown in different locations around the globe. The current study investigated the levels of lean and BIM adoption in France and the impact of lean-BIM integration on design performance. These objectives were achieved following the analysis of survey results filled by practitioners from different design firms in France.

The analysis of the results showed that BIM is more adopted in the studied firms in comparison to lean. This is unsurprising, especially with the increased interest in BIM due to the recognition of its different benefits and wide implementation around the globe to the limit that it was described as the “biggest change” that happened recently in the AEC industry (Tauriainen et al., 2016). The case for lean is a little bit different. While lean was labeled by some practitioners as the philosophy that can provide “revolutionary” improvements to the AEC sector, its adoption is still facing different barriers among them the lack of awareness and knowledge about it (Albalkhy et al., 2021; Albalkhy & Sweis, 2021). Additionally, for years, BIM has been a mandatory requirement in the construction sector in many countries (Bolpagni et al., 2017; Tranchant et al., 2017), which is not the case of lean despite the different calls and initiatives to increase its adoption.

Despite the greater adoption of BIM, the results of the study showed that it has not delivered its full potential and is not regularly practiced for different purposes in French design firms. More specifically, the results showed that some companies still do not adopt BIM, and others started its adoption less than a year ago. These results are consistent with another study conducted in 2017 about BIM adoption in 206 Small and Medium-Sized companies (SMEs) from the French construction industry that showed BIM adoption was not very high despite increasing (Tranchant et al., 2017). The same study reported complicatedness in the transition toward BIM by the surveyed companies and felt that BIM would not present improvements in terms of cost and time savings for the companies. This might be an explanation for the absence of the full implementation of BIM in the studied firms in this study. Another explanation might be that BIM is not yet a mandatory practice in France.

Concerning lean adoption, the results of the study are consistent with some claims in the literature that lean is not fully or routinely adopted in France (Chaize et al., 2022; Dakhli & Lafhaj, 2017). Nevertheless, due to the lack of studies about the challenges facing lean adoption in France, it is difficult to define the exact reasons behind this result. However, the lack of training on lean in the vast majority of the studied firms might indicate the presence of two serious barriers to adopting lean, which are the lack of support from top management and the lack of skills and knowledge (Albalkhy & Sweis, 2021).

Despite the lack of full implementation or adoption of lean, the current study investigated the presence of some lean tools, as in some cases, these tools might be implemented but without a full adoption of lean. The results showed that co-location or big room and A3 problem-solving are the most adopted tools. This might show some orientation toward collaboration to find solutions for design problems and improve the design. However, the implementation of these tools is only found in around 25% of the companies and there is no evidence that these tools are implemented routinely or perfectly. The lack of lean implementation in the design may cause losses of opportunities to improve trust, communication, collaboration, cost saving, and on-time delivery of the design (Chaize et al., 2022; Khan & Tzortzopoulos, 2015).

Despite the absence of full BIM and lean adoption, the results of the study showed some promising, but not full, results regarding the use of lean-BIM integration in design management. This was due to the acceptable evaluation for the overall lean-BIM integration (mean= 3.73 out of 5.00). This may show the opportunity to benefit from both concepts even if they are not fully adopted to improve the design. The results show that the client value is the most appreciated dimension while considering lean-BIM integration. While studying the design performance, similar results were found as the highest evaluation was for client satisfaction, understanding of the client's needs and requirements, and ability to cope with the changes. This may show an achievement of one of the principles of lean, which is the focus on the client (Albalkhy & Sweis, 2022). However, collaboration is still not enough; may be due to the contracting methods.

Studying the impact of lean-BIM integration showed that the latter significantly affects design performance. This is consistent with many studies in the literature that showed that lean and BIM together can work together to improve design deliverables, achieve higher client satisfaction, improve the quality of the design, and avoid delays (Bolpagni et al., 2017; Herrera et al., 2021; Tauriainen et al., 2016). Nevertheless, due to the small sample size in the study, this result needs to be validated in further investigations and with larger and different samples from different locations around the globe.

The small sample size is one of the limitations of this study, which hinders the full understanding of the overall evaluation of the studied variables. Future work with larger samples is recommended. Additionally, while this study uses the survey to achieve its objectives, further investigations can be conducted using other data collection methods such as interviews and case studies. Finally, while the survey included questions about the adoption of lean tools, further investigations based on the assessment of maturity levels with these tools might be conducted.

The current study aims to provide an understanding of the current situation in terms of lean-BIM integration in France. The results of this study are helpful to provide insights into the needs for these concepts. While lean-BIM integration was found to affect the design performance, this result might be helpful to achieve better design outcomes due to the adoption of lean and BIM. For researchers, the current study tries to fill the gap concerning the limited resources for the joint implementation of lean and BIM, especially in the design phase. The used tool in this study might be applicable in other locations.

LEAN AND INDUSTRY 4.0 IN BRICK MANUFACTURING: A DIGITAL TWIN-BASED VALUE STREAM MAPPING PROPOSED FRAMEWORK

Dorra Karmaoui[1], Wassim AlBalkhy[2], Zoubeir Lafhaj[3], and Christophe Chapiseau[4]

ABSTRACT

As one of the most important industries to face the global housing challenges, brick manufacturing can benefit from the principles of lean and the applications of Industry 4.0 to achieve better organizational, environmental, and operational performance. This study reviews the efforts made on lean-Industry 4.0 integration in brick manufacturing and proposes a framework to support this integration. The proposed framework is based on the use of digital twin (DT) technology to create dynamic and automated Value Stream Mapping (VSM). The proposed framework aims to continuously visualize, monitor, and improve the flow, value creation, and waste elimination in brick production processes. The study also reports the state of the implementation of the framework in a brick company in France as a case study. Validating and testing the framework is possible in different types of manufacturing companies; even out of the brick manufacturing sector.

KEYWORDS

Brick manufacturing, Lean, Industry 4.0, Digital twin (DT), Value stream mapping (VSM), Internet of things (IoT), construction and housing, France.

INTRODUCTION

With roots going back thousands of years ago, brick manufacturing is one of the oldest industries in the world whose products (i.e. bricks) are among the oldest materials used in buildings and remain a basic ingredient in modern construction (Brick Development Association, 2017). Bricks nowadays are used in more than 25% of houses and construction projects (Singh et al., 2021). Therefore, with the exponential global population growth (the global human population increased by one billion people since 2010 to reach 8 billion people in 2022) (United Nations, 2023), brick manufacturing is considered among the most important industries to respond to the increased global housing problems.

Despite its significant role, brick manufacturing is facing numerous challenges. One clear challenge that has received a lot of interest in the last few years is the negative environmental performance of the brick manufacturing process and brick factories. This includes the increased

[4] Factory Director, Briqueteries du Nord (BDN), Lille, France, christophe.chapiseau@bdn.fr

energy consumption, pollutants, CO2 emissions, and large amounts of physical waste (Baude et al., 2021). Another important challenge that received less attention is related to the operational performance and the efficiency of the manufacturing processes while maintaining a high-quality final product. This includes efficiency, lack of adequate funding, lack of skills, poor operational performance, and low productivity and effectiveness (Arevalo-Barrera et al., 2019; Chavez et al., 2019; Utami Handayani et al., 2020).

Similar to any industry, and within the era of digitalization, brick manufacturing has the opportunity to benefit from the applications of the fourth industrial revolution; or what is known more now as "Industry 4.0". Additionally, lean, as a philosophy that has shown noticeable improvements in various industries can help the brick-manufacturing industry to find solutions for the problems it encounters (Aka et al., 2019, 2020; Karmaoui et al., 2022). This study proposes a framework to integrate lean and industry 4.0 in brick manufacturing. The framework was proposed based on studying the case of a French brick factory. More specifically, the proposed framework was built using the integration of digital twin technology to improve the results developed when using the known lean tool; value stream mapping (VSM).

LITERATURE REVIEW

LEAN

The philosophy of lean originated in Japan following the development of the Toyota Production System (TPS). Since the beginning of publications about this philosophy, lean has been understood based on different principles including the identification of value based on the client's needs and requirements, value stream mapping and waste elimination to achieve a better flow of materials and information, establishing pull and producing only what is needed, achieving continuous improvement, and respect for partners and people (Liker, 2004; Womack & Jones, 1996).

With these principles, various lean tools have been presented to improve quality, value generation, resource efficiency, reduction of the environmental impacts of waste, and productivity gains (Hines et al., 2023). Examples of these tools include Just-In-Time (JIT), Value Stream Mapping (VSM), error proofing (Poka-Yoke), Kanban, and others (Valamede & Akkari, 2020). The presentation of these tools in the manufacturing sector, and then in other sectors such as the medical and construction sectors, showed remarkable results regarding quality improvement, cost reduction, time saving, safety conditions, and environmental performance (Albalkhy et al., 2021).

The used tool in this study is the VSM, which is a 2-D map that visualize all the actions in the production line and covers adding-value and non-adding-value activities. Via this 2D visualization of the flow, VSM helps to eliminate waste, streamline work tasks, reduce lead time and costs, and increase productivity quality (Valamede & Akkari, 2020).

INDUSTRY 4.0

Over history, energy sources and disruption in production have been the main reason for moving toward new revolutionary actions in production systems (Dakhli & Lafhaj, 2018; Valamede & Akkari, 2020). These actions started with the mechanization efforts that resulted in the emergence of the steam engine, by which, the first industrial revolution started. The second industrial revolution happened following the increased use of electricity and introduced the principles of mass production. Then, with the development of computerized systems, an automation-based era started as the third revolution. The fourth industrial revolution appeared in 2011 and aimed to apply the principles of robotization, cyber-physical systems (CPS), the internet, smart-oriented technologies, and application in human-machine interaction systems (Hines et al., 2023).

Understanding Industry 4.0 can either be based on the purposes of the application of the new smart technologies or based on the used technologies (Hines et al., 2023). An example of the first classification was that proposed by Tortorella et al (2022), who classified Industry 4.0 into six use categories: "interoperability, virtualization, decentralization, real-time capability, service orientation, and modularity". An example of the technology-based classification was raised by Pagliosa et al (2021) and included the Internet of Things (IoT), Cyber-Physical Systems (CPSs), cloud computing, big data, Digital Twin (DT), Virtual and Augmented Reality (VR and AR), 3D Printing, simulation, and others.

The main used technology in this study is the DT, which can be defined as *"a living model of the physical asset or system, which continually adapts to operational changes based on the collected online data, information, and can forecast the future of the corresponding physical counterpart"* (Qi & Tao, 2018).

LEAN AND INDUSTRY 4.0

The last few years have witnessed several calls to integrate lean and industry 4.0 practices (Hines et al., 2023; Ramadan et al., 2020; Rosin et al., 2020; Sanders et al., 2016; Santos et al., 2021). In some of these calls, lean was considered one of the new principles of industry 4.0 due to the shared objectives with industry 4.0 concerning value creation, modularity, visualization, and service orientation (Albalkhy et al., 2021).

Supporters of the lean-Industry 4.0 integration believe that with the rapid technological advancement, lean alone is not enough, and at the same time, Industry 4.0 alone is not enough as well (Hines et al., 2023; Santos et al., 2021). While Industry 4.0 helps achieve changes in the business model, social level, and technological levels due to the integration of real-time data that can help improve decentralization and rapidness of the decision-making process, it still needs to be integrated with lean to support creating changes on the managerial and organizational level (Santos et al., 2021). Additionally, despite the changes in nature between lean as a low-tech approach that supports standardization and simplicity, and Industry 4.0 as a high-tech that calls for innovation, there are rooms to benefit from their integration and creation of a better flexible system that ensures the rapid reaction to market changes, provide a higher quality of products, and achieve higher customer satisfaction (Hines et al., 2023; Santos et al., 2021).

In their study that was based on the perspectives of 87 academic experts in the field of lean and Industry 4.0, Hines et al (2023) defines lean Industry 4.0 as: *"An innovative socio-technical paradigm that uses both human and artificial intelligence and relies on the strategic, cultural, systems, and tools of Lean as well as the various Industry 4.0 digital technologies continually and discontinuously used to improve both single organizations and their supply chains with a focus on simplifying and managing complexity to benefit the triple bottom line and hence meet specific customer and organizational needs as well as the expectations of employees and wider society".*

LEAN AND INDUSTRY 4.0 IN BRICK MANUFACTURING

Brick manufacturing is characterized as a small-medium enterprises (SMEs)-based industry (Kumar & Sharma, 2021). This type of enterprise has many opportunities to benefit from the adoption of lean Industry 4.0 such as cost reduction, faster growth, and flexibility increase (Elhusseiny & Crispim, 2022). Nevertheless, many barriers hinder this adoption in SMEs. Among them, the lack of financial capabilities, lack of information communication technology (ICT) infrastructure, lack of managerial flexibility and support, fear of change, lack of knowledge, and lack of skilled employees (Agostini & Nosella, 2020; Albalkhy et al., 2021; Albalkhy & Sweis, 2021; Elhusseiny & Crispim, 2022; Kolla et al., 2019). In addition, according to Kolla et al (2019), most of the lean Industry 4.0 frameworks and models are too complex and do not fit the nature of SMEs.

All these barriers might explain the lack of sufficient studies about lean Industry 4.0 adoption in brick manufacturing. During the conduction of the literature review, a limited number of studies were found about both topics. The aims of these studies were the identification and removal of lean wastes in brick manufacturing processes (Aka et al., 2019, 2020; Arevalo-Barrera et al., 2019), identification of possible actions for quality improvement (Cabrera & Oliveros, 2017; Carrero et al., 2021), and design of status analysis system for brick machines using IoT (Xu et al., 2020). This study aims to contribute to the existing literature and propose a lean Industry 4.0 framework that is developed to fit the requirements and nature of brick factories.

RESEARCH METHODS AND PROPOSED FRAMEWORK

The research adopts the case study as the methodology as this approach that is used to generate an in-depth, multi-faceted understanding of a complex issue in its real-life context. The proposed framework followed the conduction of different field investigations in a brick manufacturing factory (will be explained in the case description below).

The proposed framework is based on the use of green-digitalized VSM. The use of VSM provides opportunities to identify production wastes and achieve improvement in the process. VSM can be linked with environmental metrics to identify the existing problems that affect environmental performance (Nguyen & Sharmak, 2022). Normally, VSM is applied on levels; starting with the current VSM, which shows the current situation and the existing bottlenecks and wastes in the process, then the future VSM, which aims to integrate changes in the process to provide improvements and waste elimination, and then, the frequent (normally yearly) VSM that aims to evaluate the progress based on the recommendations of the future VSM. Nevertheless, many SMEs face difficulties in VSM implementation. These difficulties are a result of the reluctance to continuously invest in VSM as a static tool that requires continuous updates (Lu et al., 2021). Therefore, the proposed framework aims to benefit from the advancement of DT and IoT to improve the implementation of VSM.

The selection of DT and IoT was firstly due to their ability to deliver real-time information and connectivity that help achieve continuous monitoring and rapid decision-making to make improvements and optimizations in energy consumption, materials management, process management, and safety (Dardouri et al., 2022; Karmaoui et al., 2022; Lu et al., 2021). The second reason was due to the flexibility of DT systems that can facilitate the application of lean thinking due to the ability to monitor the flow, eliminate waste, and provide visual and real-time access to the management and teams to ensure the continuous improvement and error proofing in the process (Barkokebas et al., 2022; Lu et al., 2021). The third reason was due to the business need of the studied company to deploy DT; similar to what was described by Agrawal et al (2022) as the implementation of DT as a “need pull”.

As shown in Figure 1, the proposed framework is based on two main phases:

- The first phase covers the identification of bottlenecks and wastes in the process. This is based on the use of different data collection methods such as interviews with workers or management staff, surveys, or observations, in addition to the possibility of the use of different types of sensors to collect data about workflow, temperature, humidity, and others. In this phase the current production process can be translated into current VSM using different measures such as cycle time (C/T), change over time (C/O), machine time (M/T), processing time (P/T), and others. Benefiting from the IoT, measures like energy consumption and CO_2 emissions are also possible to be integrated into the VSM. The first phase results in building the virtual model using simulation or software.

- Building the virtual model helps to create a flow of data from the physical model (the production process) to the virtual model. The latter is responsible for processing the data to produce useful information to improve production control and automate decision-making (Agrawal et al., 2022). By making this connection between the physical and virtual models, frequent testing and integration for scenarios and improvements are possible. In this phase, and using the bidirectional data flow between the physical and virtual models, the development of VSM and the monitoring of the production line are done continuously. It is worth mentioning that the second phase is not implemented once. It is continuously implemented aiming at achieving the principle of continuous improvement.

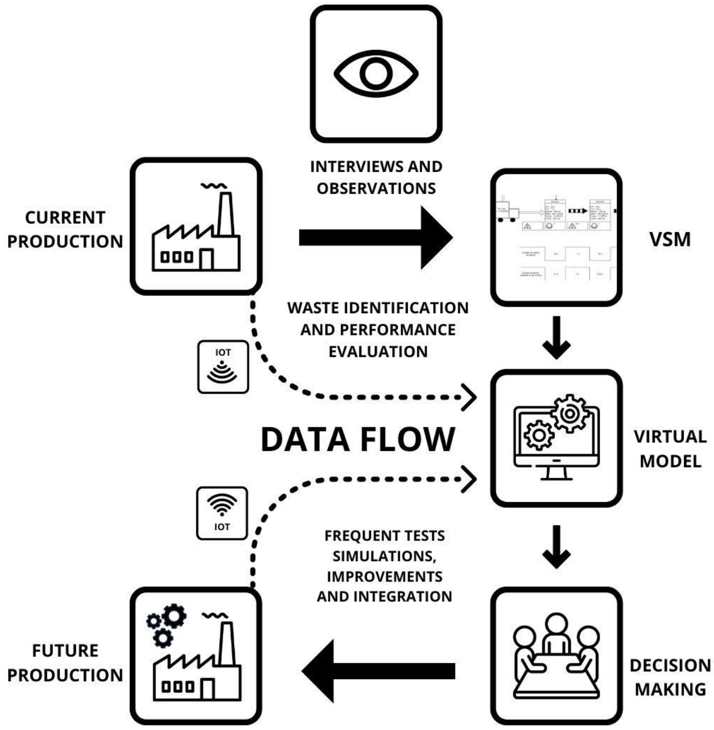

Figure 1: The proposed DT-based VSM framework.

CASE STUDY

CASE DESCRIPTION

Applying the proposed model started in a brick manufacturing company in the North of France. The company, which is a family-based company more than 100 years old and produces different types of clay-based bricks (solid bricks, perforated bricks, and clay brick plates) is a provider of bricks for many projects in France, England, Ireland, and many other locations. Nevertheless, the company faced several challenges during the last few years.

Similar to any company in France, the second largest producer of tiles and brick in Europe (Carole Fossey & Massieu, 2020), the company is experiencing instability in production and an increase in materials prices due to the fluctuated demand due to the impact of the recent war in Ukraine and the pandemic of COVID-19. In addition to the need to deal with the negative environmental and operational performance that results from the levels of pollutants and energy consumption, low machine performance, efficiency rates, strong competition, and skills shortage. Accordingly, to overcome these challenges, the company wanted to adopt lean and industry 4.0 practices to create a flexible, zero-waste, and efficient production line. This paper reports one of the actions taken in this regard.

PROCESS

The process of brick manufacturing in the studied case is shown in Figure 2. In this process, clay is extracted and transported to the production sites and then stored in a warehouse for an average of four weeks. The production starts with the preparation of the brick mixture from the extracted earth and the other raw materials, in particular sand and water. It is first put into dosing devices and then sent to the grinding mill to make the mixture more homogeneous. The material is then conveyed, using a conveyor belt, to a second, more massive aerial dosing unit which mixes a second time and distributes the clay uniformly. Once the mixture reaches the mixer, additional products are added, such as iron oxide and colorants, to give the brick the desired color. The mixture then passes through the extruder, which shreds the clay and compacts it under a vacuum. The strand is then cut with metal wires. After shaping the brick becomes wet and requires drying to remove surface water and reduce its humidity. The firing stage is done in a tunnel kiln that runs on natural gas, with burners and gas injectors. The quality control work is done by hand when the robot unstacks the wagon, so the pace has to be a little slower to give the employees time to spot any non-conforming bricks; stains, cracks, and damaged faces.

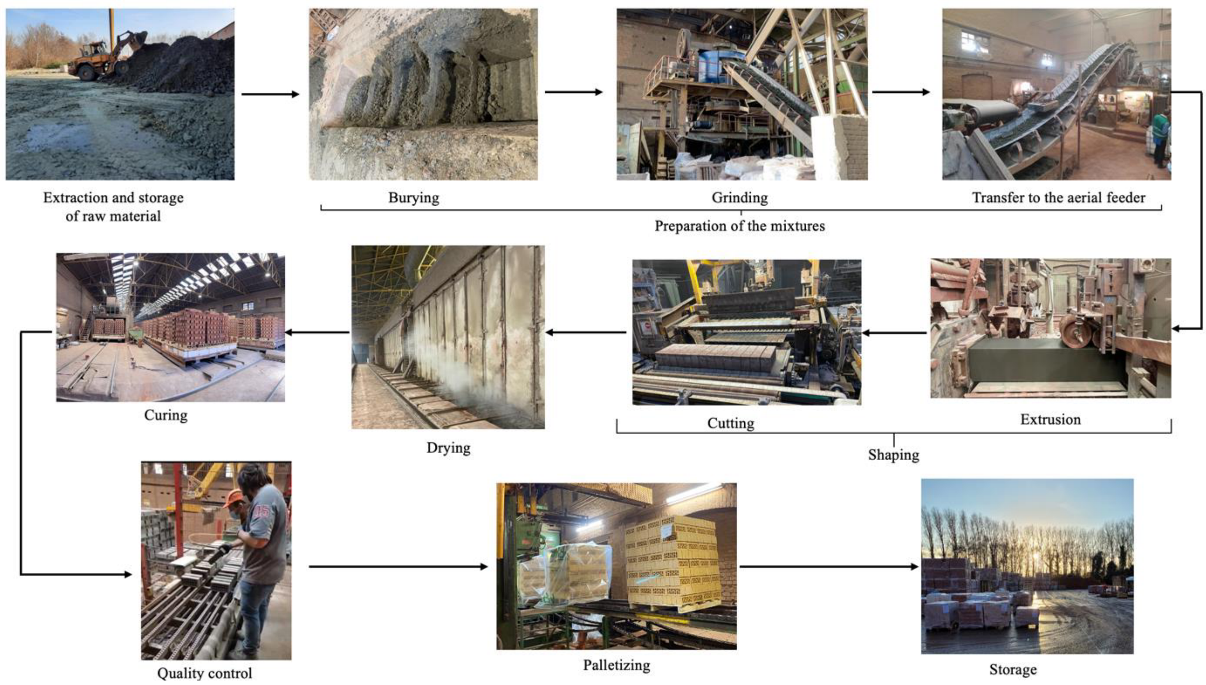

Figure 2: Clay-based brick manufacturing process.

CURRENT VSM AND ENCOUNTERED BOTTLENECKS

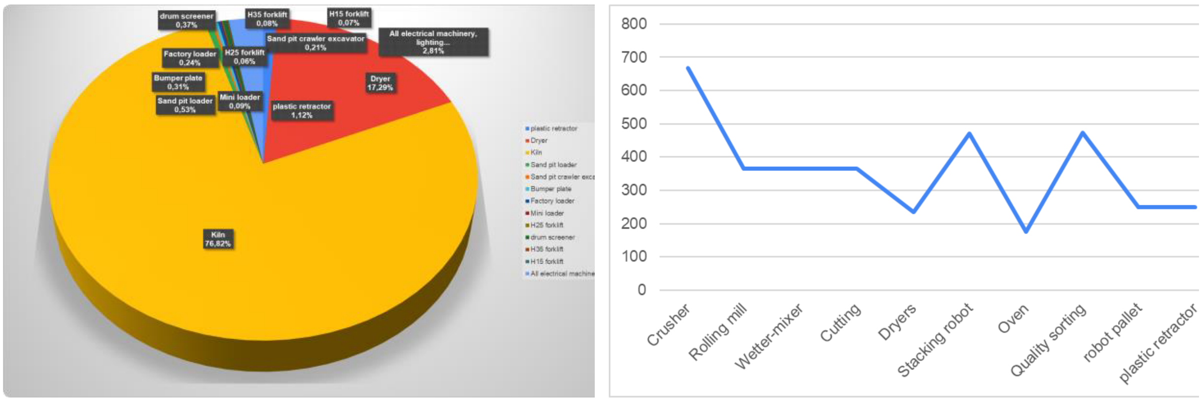
The current VSM was developed following studying the production line. The study covered the red bricks in this phase. Studying the production line was based on a set of observations to identify the different value adding and non-value adding activities and identifying the different phases of production. During these observations, the average time of each phase and at each machine and the bottlenecks in the flow were identified. To confirm the results of the observations with the real situation, the developed VSM was validated through conducting interviews with workers and management staff. Based on the VSM, the total time of non-value-adding activities is 35.5 hours, constituting around 28.4% of the total time in the production process (starting with the arrival of the raw materials and ending with arrival to the storage area). Nevertheless, the efficiency is not optimal as the time spent in the kiln (72 hours) was considered a value-adding activity. This means that neglecting the time needed in the kiln, the percentage of waste in time can reach 67% of the overall process time. In addition to the visualization of the production process and identification of the wasted time, the use of VSM was also helpful to identify the current flow rates, consumed energy, and CO2 emissions in each machine in the process (as shown in Figure 3). This helped to identify the bottlenecks and problems in the process, which can be summarized in:

1) High levels of energy consumption and CO2 emissions in the kiln (the kiln is responsible for more than 75% of CO2 emissions and more than 70% of energy consumption).

2) High levels of defects in different places along the process including for instance defects resulting from bricks falling after getting out from the kiln due to wrong positioning and bricks due to instability of the old wagons.

3) Stoppages in the production line due to some reasons such as fallen bricks in the wagon path, problems in machines, and stoppages due to the cutting machine. The latter is responsible for a lot of stoppages (5-6 times per day) due to frequent failures in the cutting wires, which require their replacement.

4) Levels work-in-progress (WIP), which affects the freedom of movement and creates problems in brick storage.



CO2 emissions per machine | Flow rate in each machine (Kg/min)

Figure 3: Used metrics in the current VSM.

Accordingly, the proposed solutions include:

1) Continuity of the process monitoring to identify the reasons for the wastes in the production process.
2) Apply lean principles and tools such as pull, Just-In-Time (JIT), 5S, and supermarket to eliminate wastes and reduce levels of WIP.
3) Use of IoT to provide alerts when stoppages in the production line happen.
4) Conduct numerical simulations and study the different placement of the bricks in the kiln (so that the heat reaches the brick in the middle of the bottom car faster) which will reduce the firing temperature and the firing time. As a result, trying to improve efficiency and reduce energy consumption and CO2 emissions.
5) Implement predictive maintenance to predict future failures in machines and avoid machines breakdown that would cost productivity loss.

BUILDING DT MODEL AND FUTURE DIRECTIONS

Despite the role that VSM played in identifying problems in the production process, some limitations require the use of more dynamic and digitalized VSM. Firstly, the current VSM is static; therefore, with the stoppages in the production line, its results need to be updated frequently. Secondly, the current VSM was done for only one product in the factory. To apply the principle of leveling (i.e. Heijunka), there is a need for a flexible system that can integrate more than one product; such improvement can be done using DT as stated by Lu (2021). Thirdly, due to the changes in the production line (affected by the stoppages and unexpected events), it is not easy to identify improvements in efficiency and WIP reduction; especially with the presence of workers turnover (Lu et al., 2021), which happens in the studied case. Finally, the use of an interactive model that links the physical process and the digitalized process can provide real-time data and updates about the effectiveness of the changes in the production process (e.g. due to repositioning of bricks in the kiln, changes of current wagons, and predictive maintenance implementation).

Therefore, the work started to build the digital twin model. So far, the team was able to build the 3D model and distribute a set of needed sensors linked with the IoT platform. The 3D model was built using "The 3DEXPERIENCE platform from Dassault Systèmes". The current work covers:

- Building the 3D design and modeling the brick in its different states (as shown in Figure 4-a). Each transformation of the brick corresponds to a visual of the brick, starting with the extracted earth, then the preparation of the earth, the molded, cut, dried, baked, and stored brick
- Building the Manufacturing Bill of Materials (MBOM) (Figure 4-b), which integrates the different 3D models of the brick in the logical order of the manufacturing process.
- Process planning and flow simulation (Figures 4-c), which covers creating workstations consistently with the flow in the original process and linking them to the two previous phases. This step also covers the creation of the workstations, which is a critical step as it allows the definition of the different workstations, the production line as well as the time that the brick spends at this station. In this step, several parameters are defined such as throughput, cycle time, estimated operation time, and the interval between failures and repair time.
- Scenarios testing and monitoring (Figure 4-d): as a result, the digital twin system, presents useful information in the shape of a Gantt Chart about the systems, operation, parts, and resources. The most important criterion is the utilization rate of the systems/machines. This enables checking how the systems are used in the production line, and if a change is made, observing the repercussions on the other systems, especially the storage areas, and checking if this affects the production downstream. An example of the testing of different scenarios was predicting the stoppages of the cutting machine, which as mentioned above, was one of the identified bottlenecks that affect the flow in the process based on the results from the VSM. The machine is made of steel wires that allow cutting the raw brick. However, the process must be stopped manually when the wires break. This leads to other problems that increase the workload and impact the productivity of the company. The digital twin can predict the breakage of a wire and automatically stop the process. For this, it is necessary to implement sensors on the machine (a noise sensor (a microphone), force, and proximity). Thus, the implementation of sensors and alarming system to provide alerts when the machine stopped.
- Building sensors network and connecting the IoT platform with the developed virtual model: to ensure the bidirectional flow of data between the virtual model and physical model, a network of sensors is currently under construction to be connected with the developed virtual model. A complete digital twin should make it possible to monitor the work for each machine of the brick factory and to show their impact on the production line in the event of a problem or modification. Therefore, the built network aims to cover all the production phases and machines that were covered in the virtual model.

DISCUSSION AND CONCLUSIONS

The current study proposed a framework that is based on the integration of lean and Industry 4.0 to improve production performance in brick manufacturing. The proposed framework is based on the use of VSM and digital twin. While the former is well recognized in visualizing and improving flow in manufacturing processes, the latter serves as a supporting tool that aims to maximize the benefits of process mapping. Digital twin is helpful as well in mitigating the impact of the static state of the VSM and continuously providing improvements to the production process. Therefore, the proposed framework goes beyond the use of static tools to visualize the production process and proposes the use of dynamic model that is linked with IoT platform to ensure monitoring the production process, testing different production scenarios, and integrating real-time data to improve predictability, and autonomous and information-based decision-making processes. Additionally, the integrated data from the IoT platform and digital twin is helpful to continuously monitor production and achieve continuous VSM models. As a result, generating greater value for the client, creating stable and smooth flow, and achieving continuous improvement.

The proposed framework is currently implemented in a French brick factory. While the implementation is still in its early phases, the framework has shown some potential to improve predictability, waste elimination, visibility, and decision-making in the factory. Nevertheless, further investigations are needed to validate the framework. Future works can be done based on case studies to modify and test the framework even in other industries. Other research works can investigate the impact of the model on the performance, identify key performance indicators for the framework, or identify the barriers to implementing it.

This study aims to contribute to the ongoing efforts to integrate lean thinking and Industry 4.0 practices aiming at benefiting from the two concepts. In addition, the study serves as a good example of how to improve performance in brick factories in particular and SEMs in general using lean-digitalized models.

COST REDUCTION IN CONSTRUCTION THROUGH PROJECT COMPATIBILITY IN A VIRTUAL PROTOTYPE

Joseph Hakkinen Alves Santos[1] and Camila Campos Goméz Famá[2]

ABSTRACT

The design stage is decisive for the Product Development Process, as it is in this stage that the main guidelines of the projects are defined, which directly affect costs, deadlines and production methods. In this sense, virtual prototypes have been used to approve project alternatives, perform engineering analysis, support production planning and present the product to customers. Thus, they allow the reduction of time and resources in decision-making, in addition to predicting problems that may lead to difficulties in execution. In this context, the research sought to optimize pre-existing projects of a popular standard residence through the development of a virtual prototype through the Autodesk Revit tool where it was possible to reconcile the structural, electrical, hydraulic and architectural projects, in addition to adapting such projects with the construction techniques used by the construction company. In this interactive process, the automatic method of detection of interferences (crash-detection) and the manual were applied, through the contribution of the stakeholders of the work. The estimated direct savings obtained per house built was around BRL 905.00, knowing that this development was a housing complex of 90 houses, a reduction of approximately BRL 81 thousand reais was obtained in total.

KEYWORDS

Lean construction, prototype, BIM.

INTRODUCTION

The building construction process is characterized by a high level of variability, which negatively impacts its performance in terms of time and cost (Cruz et al., 2018). Although the construction industry has made changes and improvements in recent years, there is still a need for changes in both production and product development processes and management processes, since it is still far from being equated to the levels of productivity, quality and efficiency of other industries (Navon and Sacks, 2007, Heigermoser et al., 2019).

Project management during the construction period requires contractors to deal with many uncertain and complex tasks that, in highly interrelated networks of activities carried out by multiple stakeholders, can lead to a tendency to deviate from schedule (Sarhan & Fox, 2012).

Such problems of uncertainty in the production process may occur due to lack of better knowledge of working methods (Howell and Ballard, 1999) as well as design errors and incompatibility of what is planned and really necessary (Li et al., 2008).

[1] Graduate student Civil Engineering Department, Federal University of Campina Grande, Paraíba, Brazil. jhas001@hotmail.com, orcid.org/0009-0003-9161-4189.

[2] Me. civil Engineering, Federal Institute of Paraíba, Paraíba, Brazil. camilafama@yahoo.com.br, orcid.org/0000-0002-7179-9644.

Waly and Thabet (2002) emphasize that these errors and mistakes in the construction planning schedule occur frequently, since their compilation depends largely on the limited knowledge and experience of the project team.

Due to this complexity and the large number of factors involved, Li et al. (2009) says that a major limitation for many projects is the lack of effective computer-aided technology for resource allocation and planning. Therefore, this can be an efficient tool to help project planners.

In this sense, even though it is still considered an industry that is not technologically advanced, scholars have studied topics such as waste reduction, process improvement and virtual information flow in recent decades (Landim et al., 2022).

Given the scenario presented, Bayhan et al (2021) argue that companies that seek to improve their production processes should invest primarily in Lean and BIM, with the aim of reducing waste, such as rework, loss of time and costs.

As stated by Dave et al (2011), there are two categories of problems related to construction: a) problems in the execution of construction processes; and b) problems in product representation. While Lean Construction offers an efficient way to solve issues related to construction processes, BIM helps to solve many problems related to projects (products), providing visualization tools and intelligent models of products based on a virtual platform. BIM functionalities are compatible with Lean Principles and vice versa, providing a synergistic effect.

Because of that, the relation between BIM and Lean have been more developed and different authors have studied the relation between BIM and Lean, identifying positive interactions in their combined use (Hamdi & Leite, 2012; Mandujano, Alarcón, Kunz, & Mourgues, 2016; Sacks et al., 2010).

Lean is a production philosophy that focuses on customer needs, production flow and continuous learning (Huntzinger, 2002). In the construction industry, the lean philosophy has been applied for decades, and due to the special features of the construction industry in relation to factory production, the construction industry has developed its own applications of lean production and lean design.

Building information modeling (BIM) has been recognized as a leading innovation in the construction industry worldwide to improve the productivity capability in this segment (Husain, Razali and Eli, 2018) and can potentially be used with human input to store and structure customer requirements and connect this information to building models to visualize requirements, keep them up-to-date, and perform project evaluation tasks (Jansson, Schade and Olofsson, 2013).

Currently, BIM is one of the most important current approaches to address productivity problems in the construction industry, with an increasing adoption rate in the last years (Peralta and Mourgues, 2022). This high interest can be explained by BIM´s promise of improving the construction performance and efficiency (Azhar, 2011). BIM enables error detection, omissions, and clashes beforehand, which helps reduce waste and makes construction processes more linear (Eldeep et al., 2022).

Crotty (2012) points out that the use of BIM, in addition to enabling the improvement of the quality of project information, the tool also allows establishing mechanisms and procedures for how information is communicated and shared among members of a team.

MacLeamy (2004) also suggests that BIM implementation effort from the early stages of the project causes cost savings with late changes in the product lifecycle. Nevertheless, if BIM is not properly implemented, organizations may incur in additional costs or reductions in efficiency (Chu, Matthews, & Love, 2018). One of the causes for these potential unwanted outcomes is stakeholders without the required capabilities and awareness for the BIM uses in the construction projects (Gu, Singh, Taylor, London & Brankovic, 2008).

Thus, this research sought to reduce execution costs due to errors that occurred during the construction of popular standard residential buildings from a case study using a virtual prototype modelled through the Autodesk Revit tool for project compatibility.

LITERATURE REVIEW

In general, wastes in construction are associated with overproduction, transport and processing of materials, defective products, unnecessary movement of workers, lack or excess inventory, among others (Antunes Junior, 1995).

In this context, Lean techniques supports not only the continuous improvement of the production system by avoiding waste, but also the optimization of the interaction between humans and machines (Cisterna et al., 2022). Lean Construction is the adaptation of Lean principles derived from the Toyota Production System into the construction sector. (Salem et al., 2006).

Today, the application of Lean techniques to construction (Lean Construction) plays a crucial role on many construction sites as with them processes can be stabilized and continuously improved (Cisterna et al., 2022).

According to Sacks et al. (2020), several physical resources (personnel, equipment and materials) interact in construction workflows, many of which are temporary. In addition, construction projects have required the availability of increasingly detailed status information to find and remove constraints, prepare tasks, staff and perform services. Lean principles provide a solid foundation for dealing with these issues; however, their methods require a considerable flow of information and resources, which are difficult to maintain without the support of information technology.

In addition, the elaboration of the projects also has a great impact on the development of the construction. According to Adesse (2006), projects should be considered as the "backbone" of the production process, since design failures are also responsible for negatively affecting the production process.

According to Muller and Saffaro (2011), among the main design flaws stand out: the lack of compatibility between "the functional parts of the building", the lack of detail of the information and the lack of communication between the designers.

These constant design errors bring to light the need to produce more complex and well-designed projects in order to avoid errors and reduce costs. In this sense, the information technologies implemented in engineering and architecture software, enable designer's three-dimensional virtual models of the product, which was previously taken with two-dimensional representation (Muller and Saffaro, 2011).

In this sense, virtual prototypes are fundamental for error checking and continuous project improvements. For Ulrich and Eppinger (2000), prototype can be considered an approximation of the actual product over one or more dimensions of interest. These models are of the physical or analytical (virtual) type, where analytical models can be considered intangible ones, which use computational software for their modelling. This model enables better and faster ways of modifying design at a low cost (Muller and Saffaro, 2011).

In this sense, the BIM philosophy is able to promote harmonization and integration between the areas of architecture, engineering and construction throughout the production of projects. Thus, this tool has great use in the optimization of multidisciplinary projects, bringing an improvement in the quality of products (Miranda and Salvi, 2019).

BIM enables error detection, omissions, and clashes beforehand, which helps reduce waste and makes construction processes more linear (Eldeep et al., 2022).

METHODOLOGY

The method used in this research was Design Science Research (DSR), a method in which it consists of analyzing from various perspectives the conception and execution of projects. The methodology DSR is a research model oriented towards solutions to practical problems in technology and engineering. The process includes identifying the problem, defining objectives, developing artifacts, demonstrating effectiveness, and evaluating results. The aim is to produce useful knowledge to improve practices and decisions in a specific field.

According to Peffers et al. (2007), the DSR process consists of six steps:

Identification of the problem: this first consists of identifying and justifying the research problem, aiming to develop an artifact that can provide an effective solution. The definition of the problem also helps to motivate the researcher and the public, in addition to allowing the understanding of the reasoning involved;

Objectives: this second stage consists of defining objectives for a solution based on the definition of the problem and knowledge of what is possible and feasible. These objectives can be quantitative or qualitative and must be rationally inferred from the problem specification;

Design and development: this third stage consist of designing and developing the artifact to solve the problem. It is necessary to determine the desired functionality of the artifact and its architecture, and create the actual artifact based on the theory applicable to the solution;

Demonstration: in the fourth step, the use of the artifact to solve the problem in question is defined and demonstrated through experimentation, simulation, case study or proof;

Evaluation: The fifth step involves measuring and evaluating how the artifact supports the solution of the problem, comparing the objectives of the solution with the actual observed results of using the artifact in the demonstration.

To ensure a structured and organized approach to the research project, an organization chart was established. This chart served as a visual representation of the hierarchy of tasks and responsibilities, providing clear guidance on the progress of the project. Figure 1 shows the details of the chart, describing the different steps and their respective descriptions. By using this chart as a reference, the research team was able to stay focused and stay on track throughout the project. Additionally, it helped ensure that all team members were aware of their respective roles and responsibilities, promoting efficiency and collaboration.

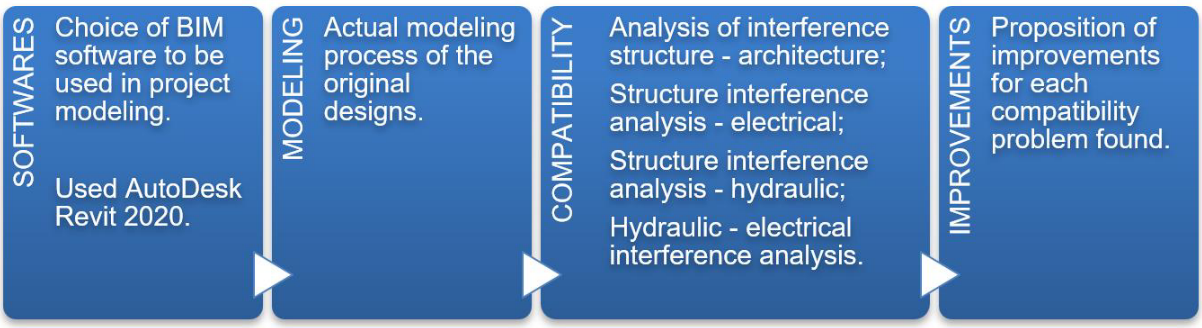

Figure 1: Research organization chart.

Initially, the Autodesk Revit 2020 Educational software was chosen for the modelling of projects, since it had better tools to develop all projects in BIM.

The building in question are houses in the popular standard with 72 m² of built area, replicated in housing estates of multiple units. All the original projects were in the AutoCAD model, BIM modelling started from these projects, according to the architectural plan below (Figure 2).

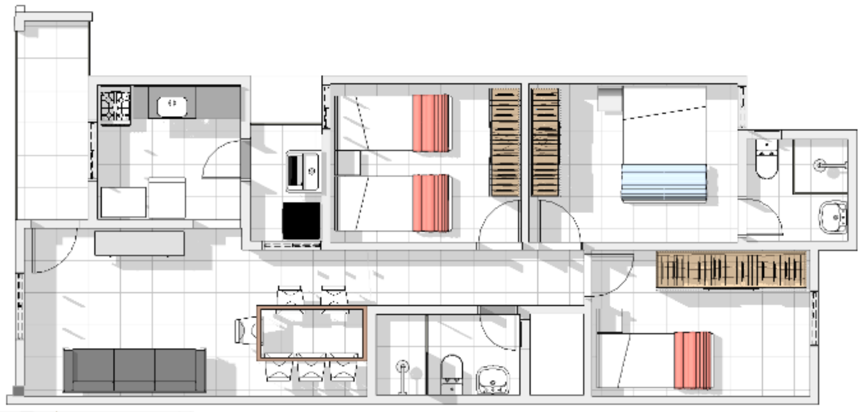

Figure 2: Building layout plan.

After the modelling process of all disciplines, the compatibilizations began. These interactions were done in two ways: manually (based on the authors' experience) and in an automated way (using BIM processes crash-detection). The first structure-architecture analysis aimed to identify differences between the opening spans of doors and windows left in the structural design, when compared to the architect design. This analysis was done manually, verifying point by point of the projects.

The structural-electrical, structural-hydraulic and electrical-hydraulic interactions were made in an automated manner through Revit's own Interference Verification tool. To get to this verification window, we follow the following path:

Collaborate > Coordinate > Interference Verification

Next, the projects that were objectives of identifying interference were selected. In these analyses, we looked for problems of the type contact between structure and electrical or hydraulic elements, or among the elements themselves, which could compromise the execution of the work.

At the end of the interference analysis part, measures of modifications in the projects were proposed in order to optimize the projects as much as possible, reducing costs and facilitating execution.

FINDINGS

From the interactions between structural and architecture, we were able to identify a failure in relation to the dimensions of the doors (Figure 3) and windows (Figure 4).

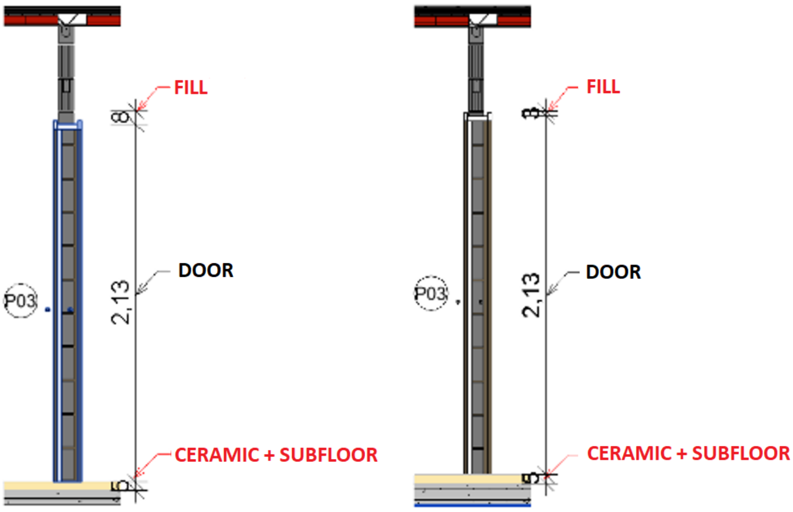

Figure 3: Door before (left) and door after modifications (right).

In the doors, the problem perceived was that: when the floor was executed first, before the structural masonry, the need for a very large filling arose at the top. When this happens, in Brazil, it is common to fill with ceramic bricks, which can generate cracks over time, since this material does not work with the structure. Thus, it was proposed that the floor be executed later than the masonry, thus reducing the upper height of the doors by 5 cm, being now filled only with mortar. This fill was also aligned with the windows.

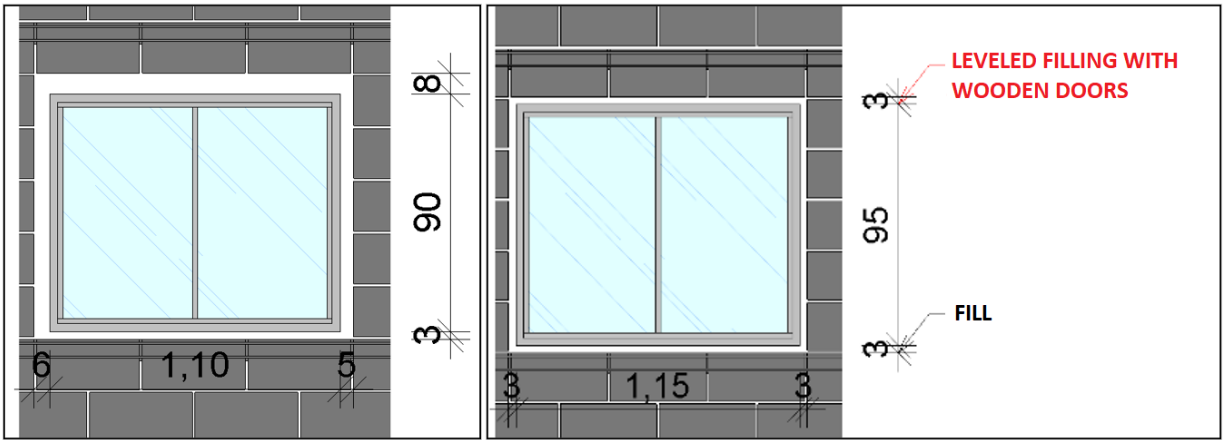

Figure 4: Window before (left) and window after modifications (right).

In this case of the windows, it was identified that they were not aligned with the top of the doors, and for this alignment it would be necessary to increase the frame and leave a mortar fill of 3 cm. Therefore, for the size of the window was increased 5 cm. This problem is related to the modulation of the structure that was made in structural masonry of concrete blocks.

After these modifications, the budget compositions of SINAPI (National System of Survey of Civil Construction Costs and Indexesin Brazil) were applied in order to obtain the final economy of this modification. Each house has 4 windows and 7 doors. The costs obtained after this analysis are shown in Table 1 below.

Table 1: Cost analysis changes in frames

	Windows	Doors
Manpower	BRL 210.00	BRL 370.00
Spared material	BRL 10.00	BRL 10.00
Spent material	- BRL 35.00	- BRL 0.00
TOTAL PER HOUSE	BRL 185.00	BRL 380.00
TOTAL SET 90 HOUSES	BRL 16,650.00	BRL 34,200.00

Another problem identified in this interaction was the lack of alignment between the architecture and the structure. For this, each layer of masonry was modelled, distinguishing the thicknesses of each coating. Thus, it was simpler to align the two projects, and can obtain more trustworthy quantitative (Figure 5).

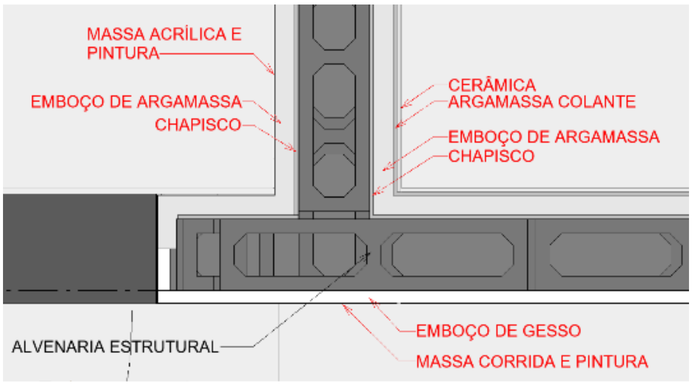

Figure 5: Coating layers of the structure.

Before the electrical-structure interaction, numerous improvements in the project were verified, in agreement with the Brazilian standards in force and the culture of the construction company involved. Figure 6 shows what the project was like before and Figure 7 as the final design resulted after the modifications.

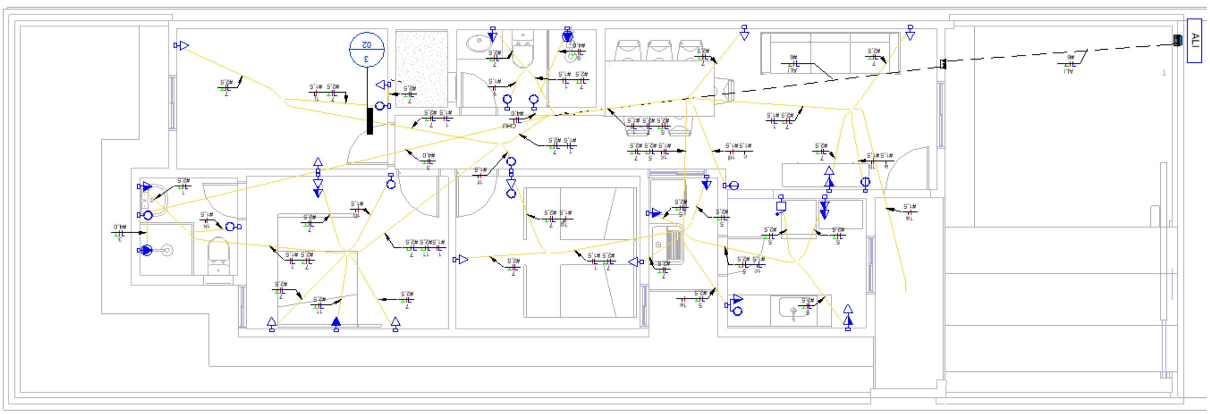

Figure 6: Old electrical design - floor plan. Source: Cipresa, 2018.

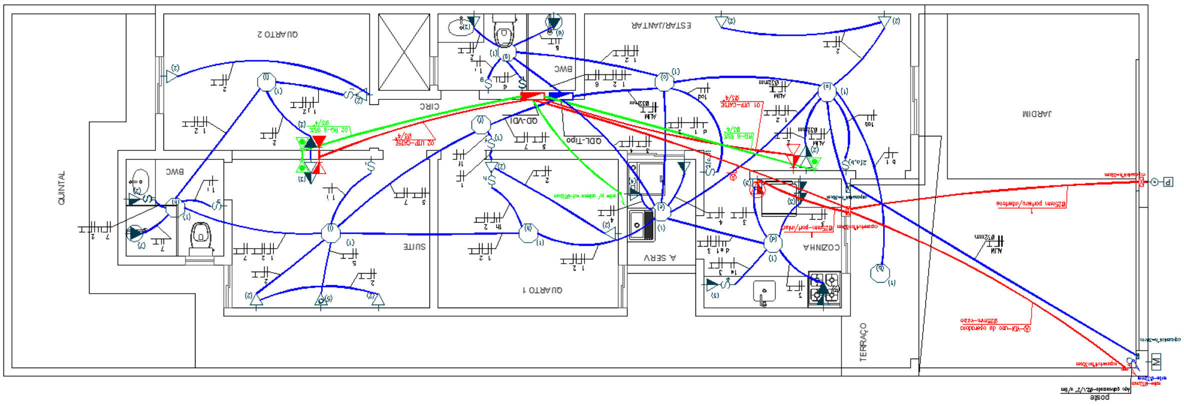

Figure 7: New electrical design - floor plan.

The modifications made in this edition have made the following points:

reduce the route through which the cables passed to power the circuits;

create a separate main power only for the input circuit;

separate the circuit of showers into individual conduits in order to reduce the internal heating of the grouped cables;

create a separate VDI (Virtual Desktop Infrastructure) system with internet input at the front of the residence, and television alimentation by coverage.

By processing the structure-electrical interaction, through crash-detection Revit, it was possible to identify 503 interferences of the structure with the elements of the electrical design. By analysing these interferences, it was possible to see that some 4x2 and 4x4 boxes were not located within the empty blocks. Thus, they were moved to the ideal point as shown in the example in Figure 8.

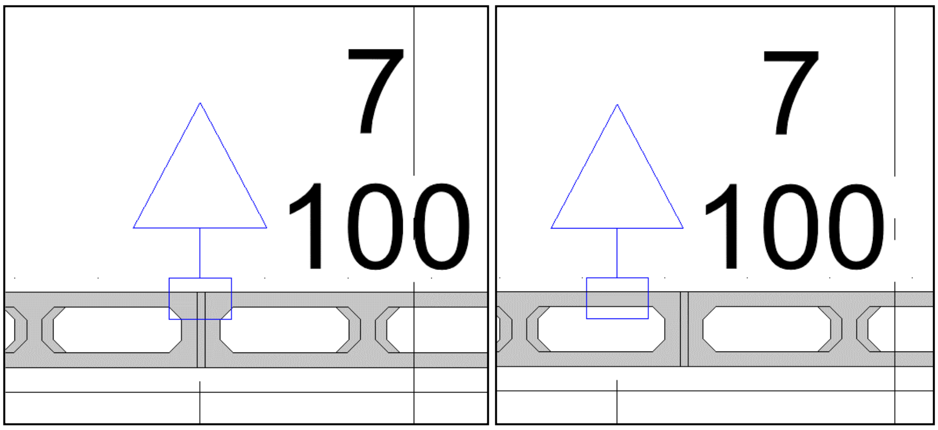

Figure 8: Box 4x2 on the seam of the blocks (left), box repositioned in the empty of the blocks (right).

Other interferences were considered normal, such as conduits passing through the cover slab, since the construction process already uses them in this position.

To verify the costs in this analysis, the fixed amount for labour was used, since the company's culture consisted to pay a single amount per residence to the electrician, and the modifications made would not reduce this service. As for the materials, the base data from SINAPI was also taken for estimated of cost. Based on the modifications made, and comparing the quantity of material before and after, we arrived at the following data (Table 2).

Table 2: Cost analysis changes in electrical design.

	Before	After
Manpower	BRL 900.00	BRL 900.00
Material	BRL 1,800.00	BRL 1,460.00
TOTAL PER HOUSE	BRL 2,700.00	BRL 2,360.00
TOTAL SET 90 HOUSES	BRL 243,000.00	BRL 212,400.00
DIFFERENCE IN VALUES	BRL 30,600.00	

Starting for the hydraulic project, when interacted with the structure, it was possible to identify the pipe connection to structural masonry, which in Brazil is not allowed by the current Norms. In this way, all the pipes were moved out of the masonry. Some connections and pipes were reduced at the request of the builder, so these modifications were not counted as savings due to compatibilizations. The process of compatibilization made it possible to better representation the construction of these elements (Figure 9), so that the gain at execution time becomes almost impossible to quantify.

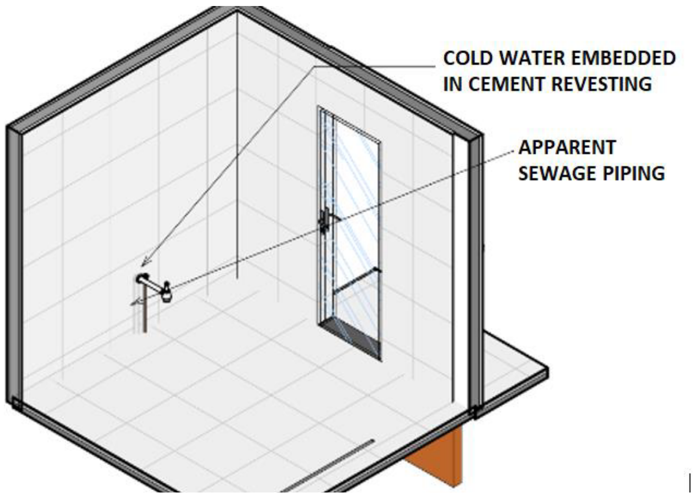

Figure 9: Representation of pipes in the kitchen (example).

The modifications in the hydraulic design were not accounted for, for the reasons mentioned above. Interference analysis was performed between the electrical and hydraulic projects, but no interference was detected. After this step, all representations of all projects were made, now in BIM. These printed and digital projects were made available to the construction team for execution. The 3D visualization of the modelling of this residence can be seen in Figure 10 below.

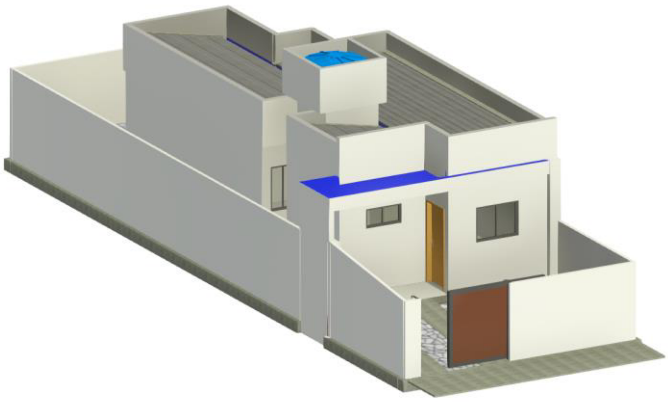

Figure 10: 3D BIM Modelling.

CONCLUSIONS

Modelling in BIM made it possible to explain the construction in a clear and objective way for all the employees involved, bringing with it a rich detailing of information that enabled significant improvements in the old projects of the residences. The joint work of the project team with the construction company's execution team brought greater integration between information, ensuring everyone's participation in the process and reducing future barriers and additional costs at the construction site.

Just relying on automatic compatibility (crash-detection) would not be enough to obtain all the necessary results, since most of the modifications carried out resulted from the construction process. In this way, the active participation of engineers, the master builder and the authors of the paper became essential so that compatibility was carried out properly. Thus, it was possible to ensure that all necessary changes were made and that the final project was completed successfully, without major problems or complications. The integration between professionals and available technologies was essential for the success of the project.

The analysis of the results presented by the BIM modelling process shows the great potential of this methodology to reduce costs in the construction sector. The savings obtained in this specific housing complex of 90 houses represented a final gain of BRL 81,450.00, a significant amount that could be allocated in other areas of the construction. With the implementation of this process, the employees involved were able to obtain greater efficiency and precision in their work, which is essential for the success of any project. It is noteworthy that these savings could be even greater if the project had a larger area or had vertical replication, which reinforces the relevance of this methodology in highly replicable projects.

In addition to the financial benefits, the BIM modelling process also provides significant gains in terms of sustainability and environmental impact. By optimizing the use of resources and reducing waste, the methodology contributes to a more efficient and responsible use of materials, essential for the preservation of the planet. Therefore, the implementation of BIM in construction projects represents not only a financial gain, but also a social and environmental responsibility. This methodology is becoming more and more relevant in the construction sector, and its implementation should be encouraged to promote sustainable development and cost reduction in construction projects.

This type of collaborative approach brings numerous advantages to the construction process, as it allows for the early identification and solution of problems, the elimination of waste and rework, and the maximization of the efficiency of the construction team. In addition, the application of the Lean philosophy in conjunction with BIM technology can result in significant improvements in the quality of the final product, in the reduction of costs and deadlines, and in customer satisfaction.

With this, it is expected that this work can contribute to the dissemination and adoption of more efficient and collaborative practices in civil construction, to the benefit of the entire production chain and, mainly, end users. With the growing demand for more sustainable and efficient construction projects, the Lean philosophy and BIM technology are fundamental tools to achieve these goals, allowing the construction sector to become more competitive and aligned with market trends and demands.

EVALUATING THE USABILITY OF THE LEANBUILD SOFTWARE APPLICATION AFTER THE DESIGN STAGE

Muktari M. Musa[1], Emmanuel I. Daniel[2], Namadi S. Ahmed[3], and Ifeatu C. Enedah[4]

ABSTRACT

Industries are experiencing a new paradigm shift driven by advanced digitalization, automation, smart technologies, and the internet of things. Lean construction (LC) advocates have been promoting the adoption of existing and emerging technologies through Lean construction 4.0 (LC 4.0). This paper presents an opportunity for the adoption of smart digital technologies in the construction industry in the form of "LeanBuild project management software".

This paper aims to evaluate the usability of the LeanBuild software after the design stage of development. This paper evaluated the ease of use and effectiveness, and assessed the comprehensiveness of the software design flow. Focus groups, questionnaire survey and interviews were conducted with industry practitioners, academics, and software/IT professionals.

The results suggest that the incorporation of data privacy and security, modules for designing and tracking modular and off-site construction, tools for calculating carbon footprints and sustainability, and artificial intelligence, will improve its usability and provide more value to end-users. The paper concludes that while the LeanBuild software has some limitations in terms of scope and functions, it is generally easy to use and effective for its intended users. The study provides insights for software developers to design more user-friendly project management software.

KEYWORDS

Lean construction, digitalisation/technology, project management, software usability test.

INTRODUCTION

Industries are experiencing a new paradigm shift as a result of the rapid growth of technology and its applications, tagged the "4th industrial revolution"; this shift is primarily driven by advanced digitalization, increased automation, smart future-oriented technologies, and the internet of things (Hamzeh et al., 2021). The construction industry is not left out in this socio-

economic trend of the fourth industrial revolution as it aims to deploy new information and communication technologies (ICT) (Gimenez et al., 2022).

Consequently, the construction industry is facing a restructuring crisis that is based on rethinking and focusing on reforming current production processes and workflows to improve both the production process and the product. The crisis has been facilitated by advances in information technology, which have been promoted as the primary enabler of process reengineering in the construction industry (Gimenez et al., 2022; Love et al., 1996).

There has been a strong advocate for the adoption of existing and emerging technologies as the architecture, engineering, and construction (AEC) sector is yet to fully profit from the established and emerging technologies that characterize the fourth industrial revolution. (Sawhney & Odeh, 2020; Hamzeh et al., 2021, Li et al., 2012). To this end Hamzeh et al., (2021) proposed a change to Lean Construction 4.0 with a focus on maintaining the people-processes-technology synergies between production management theory and digital/smart technology. LC 4.0 is the integration of digital technologies into the construction process (Hamzeh et al., 2021).

Studies have shown a low level of innovation, a lack of collaboration, and limited knowledge sharing in the construction industry (Musa et al., 2019, Alashwal et al., 2011, Ahmed et al., 2017, Xue et al. 2014). The studies noted that investment in Research and development (R&D) and intangible assets (such as new processes) is low (Egan, 1998) due to uncertain demand for new goods, limited collaboration (Musa et al., 2019, Namadi et al., 2017), and low transfer of technology from academia to industry. However, recently, there has been a strong interest to harness the power of innovation through the adoption of digital/smart technologies in LC community. The growth of automated construction is gaining traction as a radical new way of adopting digital tools and technologies

Although many innovative solutions are already being applied on a small scale albeit in few countries, yet the industry still needs large-scale applications or better adaptation of current technological developments. As LC 4.0 advocates for the integration of ICT in the construction industry, it is worth noting that transforming the current construction business model would be difficult without the adoption of innovations, technologies, and techniques by all construction stakeholders. The introduction of new technologies, almost always has an influence, whether favourable or unfavourable. The use of Target Value Delivery (TVD) in many projects throughout the world has had a wide-ranging influence on various parts of those projects (Musa, et al., 2016).

TVD as a Lean practise can serve as a strategic pathway for adopting LC, to eliminate waste and satisfy clients' expectations (Musa, 2019, Musa, & Pasquire, 2020). TVD is an innovation that aims to create value for the stakeholders by reducing waste and ensuring all aspects of the construction process are carried out with the stakeholder's agreed targets in mind; cost, quality, standards, time, and stakeholders' value (Musa, 2019).

This paper presents one of the opportunities for the adoption of smart digital technologies in the construction industry in the form of software, "the LeanBuild project management software." The software aimed to manage various types of projects and is currently being developed and digitized from a framework that emulates TVD principles and values called Framework for Implementing Target Value Delivery (FFITVD). The concept involves the development and deployment of computer software. Presently, the discovery phase of the software development has been concluded. The discovery phase is an important stage in the software development process, during which the goals, objectives, and requirements of the project are identified and defined (Khalimonchuk, 2022). All the necessary software requirements for each project phase, from initiation to closing were considered, and TVD and the traditional construction approach were integrated into the user interface designs. Thus, this necessitate the need to measure the degree of effectiveness and acceptance of the software designs.

RESEARCH GAPS

Despite the growing interest in adopting digital technologies in the construction industry, there is still a lack of large-scale applications or better adaptation of current technological developments. Additionally, while many usability evaluations are conducted at the later stage of the software development process, some researchers have suggested that issues surrounding the ease of use of software should be addressed as early as possible, because such issues are considerably cheaper to rectify early in the development cycle (Hornbæk et al. 2007). However, identifying such issues early is difficult in today's software development practice since usability testing is typically segregated from core software development operations. Lárusdóttir (2011) argued that usability evaluation is essential for ensuring that software applications are effective and easy to use for their intended users and that it should be an integral part of the software development process. Finally, although there is various project management software available currently, many are limited in the area of covering the complete lifecycle of a typical construction project.

AIM AND OBJECTIVES

The paper aims to evaluate the usability of the LeanBuild software application after the design stage of development.

a) To review the literature on current project management software
b) To identify the most common usability problems experienced by users of project management software after the design stage of development.
c) To determine the ease of use and effectiveness of the LeanBuild software application for its intended users after the design stage of development
d) To determine the comprehensiveness of the LeanBuild software design flow

LITERATURE REVIEW

LEAN CONSTRUCTION TO LEAN CONSTRUCTION 4.0

LC is a concept that originated in the manufacturing industry and has been adopted and adapted for use in the construction industry (Koskela, 2000; Musa, 2019; and Daniel, 2017). LC aims to optimize resources, reduce waste, and improve the overall efficiency of construction projects (Musa 2019; Daniel 2017). As an adaptation of Lean production, LC is the application of Lean thinking to the design and production (or delivery, in general) of capital projects (or projects, in general) (Musa 2019).

In construction, the Lean approach has been applied to a wide range of processes, including project design and planning, construction management, and commissioning. Studies have shown that the implementation of LC can lead to significant improvements in the efficiency and quality of construction projects. The development of new digital technologies and the widespread use of the Internet of Things (IoT) has led to the transition from LC to LC 4.0 (Hamzeh et al., 2021). LC 4.0 aims to increase the efficiency and productivity of construction projects while reducing waste and improving quality by leveraging the power of digital technologies. This is achieved by leveraging the data and connectivity provided by digital technologies to better manage the construction process, from design to construction to commissioning and maintenance (Hamzeh et al., 2021).

Some of the major differences between LC and LC 4.0 are the emphasis on data-driven decision-making and the use of digital technologies. LC 4.0 also emphasizes the use of virtual and augmented reality technologies to improve the design and planning processes. This allows for better visualization of the construction process and helps identify potential problems before construction begins.

PROJECT MANAGEMENT AND PROJECT MANAGEMENT SOFTWARE

Project management is the process of planning, organizing, and managing the resources, tasks, and schedules of a project to achieve a specific goal or objective (Project Management Institute, 2017). It involves several activities, including defining the scope and objectives of the project, creating a project plan, identifying and allocating resources, tracking progress and performance, and communicating with stakeholders (Project Management Institute, 2017, Harold, 2017). The goal of project management is to deliver a successful project within the agreed-upon time, budget, and quality constraints (Philpotts, 1996). Effective project management requires the ability to identify and manage risks, as well as the ability to adapt to changing circumstances and requirements (Project Management Institute, 2017). Project management can be aided by the use of tools and software, such as project management software and project management methodologies, such as Agile or Waterfall (Project Management Institute, 2017, Harold, 2017).

Project management software is a digital tool that helps organizations initiate, plan, execute, monitor/control and close projects effectively (Project Management Institute, 2017). There has been a significant increase in the use of project management software in recent years, as it provides numerous benefits over traditional methods of project management. The most common features of current project management software include task management, time tracking, resource allocation, collaboration, project planning, and project reporting (Hoban, 2023). These features help project managers to break down complex projects into manageable tasks, allocate resources and time, communicate effectively with project stakeholders, and track project progress.

However, the current project management software market is highly competitive, and there are a large number of options available, each with different strengths and weaknesses. Choosing the right project management software can be a challenge, and it is important for organizations to carefully consider their specific needs and requirements. As project management software continues to evolve, it will likely become an increasingly essential tool for organizations looking to improve project outcomes. Several challenges have been identified with current project management software, including complexity, limited scope, limited customization, lack of integration, limited access, and concerns about data security and privacy (Goncalves, 2018). The LeanBuild software, which is currently under development, seeking to address these challenges. Despite the availability and implementation of various new and innovative construction technologies, including software, over the past four decades, the construction industry has made slow progress in improving efficiency, due to limited adoption of new technologies among other reasons (Li et al., 2012, McKinsey & Company, 2020).

USABILITY TESTING

Software usability evaluation is the process of evaluating the ease of use and effectiveness of a software application by testing it with a representative sample of users (Lárusdóttir 2011, Dillon 2015, Bruun and Stage 2015). It is an important aspect of software development because it helps ensure that the software is effective and easy to use for its intended users. There are a variety of tools and techniques that can be used to evaluate software functionality and identify opportunities for improvement. These include:

a. Usability testing: This is a method in which users are observed as they complete tasks with the software and data is collected on their performance. This can help identify problems or issues that users encounter when using the software and provide insights into ways to improve the efficiency of the software (Moran, 2019).
b. Heuristic evaluation: This method involves having a small group of experts review the software and identify any issues based on established principles of usability. This can provide valuable insights into the functionality of the software but may be limited in its

ability to capture the perspectives and experiences of a representative sample of users (Ssemugabi & Villiers, 2010).

c. Expert review: This method involves having a single expert review the software and identify usability issues. This can be a useful technique for identifying specific usability issues, but may not provide a comprehensive view of the usability of the software (Harley, 2018).
d. User experience (UX) evaluation: this is a more comprehensive approach to evaluating software usability that takes into account the overall user experience of the software, including factors such as user satisfaction, functionality, and effectiveness (Kaisa and Virpi, 2008).

Studies have shown that early usability testing is a key factor in determining whether a software will be designed with users in mind or not (Lárusdóttir 2011). Users are more likely to adopt and continue using software that is easy to use and effective for their needs. User interface design, plays a crucial role in determining the efficiency of the software. A well-designed user interface can make the software easier to use and more intuitive, while a poorly designed user interface can make the software confusing and frustrating to use. All these are dependent on early usability testing.

METHODOLOGY

The research methodology adopted for this study is a combination of qualitative and quantitative methods. Integrating the two methodologies will not only give various viewpoints on the study's research aim and objectives, but it will also improve the quality and depth of the entire research process and findings (Bouma 2000).

The usability testing was carried out in the United Kingdom and Nigeria and the process included focus groups discussion, questionnaires and interviews. It has been argued that the focus group approach is a quick and inexpensive way to get information from experts and users. It can give content-rich, qualitative data and highlight findings that would be difficult or expensive to get using other approaches (Kontio, et al., 2004).

Focus group discussions: Three sets of focus group discussions (one face-to-face and two online/virtual focus group discussions) were held with a total of 33 participants to gather qualitative data about the usability of the software application. The focus group discussions were used to obtain the participants' opinions, preferences, and experiences with the software design. The focus groups aimed to understand how users interact with the software, identify areas for improvement, and gather suggestions for enhancements. By having a group of participants, the focus group discussions allowed for a more interactive and dynamic discussion, encouraging the exchange of ideas and opinions. Holding both face-to-face and online/virtual focus groups allowed the researchers to reach a wider range of participants, and gather data from both in-person and remote users.

Questionnaire survey: The questionnaire survey was used to gather data in a structured and standardized format. The questionnaire survey consisted of a set of questions aimed at gathering feedback and opinions on various aspects of the software's usability, such as ease of use, functionality, and overall satisfaction. The questionnaire survey was conducted using SurveyMonkey, a widely used online survey tool. 29 out of 33 professionals (97%) who participated in the focus group filled out the online questionnaire survey.

Interviews: The interviews were conducted to gather more in-depth and personalized feedback from the participants. Interviews were conducted with about 16 out of the 33 participants in the focus groups. The interviews were recorded with the consent of the interviewees and then transcribed for analysis.

The literature review reveals that previous research has explored various methods to conduct usability testing, including focus groups, interviews, and questionnaires. For instance, Kontio's (2001) study on software engineering risk management utilized interviews to gather information on risk management practices. Similarly, Lehtola, et al., (2004) study on requirements prioritization challenges utilized a questionnaire to collect data from software professionals. Furthermore, Sunikka's (2004) study on the usability evaluation of the Helsinki School of Economics website used a combination of usability tests, interviews, and questionnaires to gather data from users. Therefore, in line with these previous studies, the current study adopts a mixed-methods approach to conduct usability testing. The use of these methods enables a comprehensive understanding of the usability of the software, from both user and expert perspectives, and can inform possible reviews of the user interface (UI) before commencing the development of the software.

The participants in the study included industry practitioners, academics, and software/Information Technology (IT) professionals, providing a diverse range of perspectives and feedback. By combining these different methods, the researchers aim to gather a comprehensive understanding of the usability of the LeanBuild software application and to identify opportunities for improvement.

The responses obtained from the participants (both the focus group, questionnaire and interview) were analysed using descriptive analysis. Inferential statistics were not conducted because the sample size is very small and the purpose of the survey was not for generalisation, but basically to rate the respondents' opinions on the factors of the software.

RESULTS AND DISCUSSION

The section presents the analysis and discussion of the results obtained from this study.

ANALYSIS OF RESPONDENTS

The questionnaire results provide some useful information about the background and experience of the respondents, as well as their familiarity with the internet and software tools, particularly project management software.

The respondents' professional backgrounds and years of experience are presented in table 1.

Table 1: Participants' Professional backgrounds and years of experience

Professional background	% of Respondent	Years of Experience	% of Respondent
Industry Practitioners	72%	Not more than 5 years	21%
Academics	14%	5 to 10 years	17%
Software/IT Professional	14%	10 to 15 years	38%
		More than 15 years	24%

The respondents include industry practitioners, academics and software/IT professionals. In terms of experience, the results indicate that the respondents are fairly evenly distributed across different levels of experience. This suggests that the views and insights of the respondents may be representative of a diverse range of career stages and backgrounds.

The results also indicate that all the respondents have an appreciable knowledge of the internet and the use of software, which is an important factor in conducting online surveys and using software tools for project management. However, it's notable that only 41% of the respondents have used project management software before, which suggests that some respondents may be less familiar with this type of tool and may need additional guidance or training in its use.

COMMON USABILITY PROBLEMS EXPERIENCED BY USERS OF PROJECT MANAGEMENT SOFTWARE

Based on the survey and interview results, it is clear that data privacy and security are major concerns for end users. Approximately 83% of the participants recommended that data must be controlled by subscribing organizations to ensure data privacy and security. This indicates that data privacy and security should be a top priority when developing software. To address this concern, the development team would focus on incorporating top-notch security features into the software to ensure the end-users data is secure and protected.

According to the feedback received from the questionnaire, participants suggested that the software should include a budget approval process and a disbursement process. This would enable project managers to track and manage project costs more effectively. This will ensure that budget limits are not exceeded. Another issue raised was that the software should be more colourful and visually appealing. Some respondent noted that the software's current interface is more academic than practical, which could lead to less user engagement. This concern highlights the need for the software to be designed with the end-users in mind, making the interface more visually appealing, and enhancing user experience (Lárusdóttir, 2011).

Additionally, the survey and interview results indicated that there is a need for the software to offer more features and functionalities. Participants noted that the current design of the software has a limited scope and function, which can limit its usability. To address this concern, the development team would consider adding more features and functionalities to the software to provide more value to the end users.

THE COMPREHENSIVENESS OF THE LEANBUILD SOFTWARE DESIGN FLOW

The questionnaire results suggest that a large majority of the respondents (86%) agree that the documents listed on the project initiation homepage are comprehensive enough to initiate a project, while 14% neither agree nor disagree. This indicates that most of the respondents perceive the listed documents as sufficient for initiating a project. To ensure the comprehensiveness of the documents listed, the researchers compared the listed documents against established best practices and standards for project initiation to determine their adequacy and completeness.

The questionnaire results show that a significant majority of the respondents (83%) agree that the documents listed on the project planning page are all the documents needed for the scope management planning of a project. However, 17% of the respondents neither agree nor disagree, which suggests that they may have some uncertainty or lack of clarity about the completeness of the listed documents. One possible explanation for the disagreement or uncertainty among the respondents could be that they have different levels of experience or expertise in project management or scope management, which may influence their perception of what documents are needed for effective planning. A respondent suggested the addition of an accounting interface and project responsibility flow to the software.

In the case of the cost planning sheet, the majority of the respondents (79%) agree that it represents the standard bill of quantities for a typical construction project. However, a notable percentage (14%) disagreed with this statement, while a smaller percentage (7%) were undecided. Respondents suggested providing a feature for budget approvals, cash flow, and disbursement to manage and control costs. Regarding the TVD user interface, the results indicate that a significant majority of the respondents (86%) agreed that it captures the detailed working principles of TVD. However, a smaller percentage (14%) were undecided. The majority of the respondents (69%) agreed that the TVD "set targets" interface covers all the typical project constraints, while a significant percentage (28%) were undecided. This suggests that some respondents may not have a clear understanding of TVD principles and its associated constraints, or may need more information to fully evaluate the "set targets" interface. Further clarification and explanation may be needed to ensure that all respondents have a common understanding of TVD and its associated constraints.

In regards to the execution page user interface, a large majority of the respondents (89%) agreed that it captures all the necessary activities for the execution stage of a typical project, while a smaller percentage (11%) were undecided. This suggests that the majority of respondents perceive the interface as comprehensive enough for the execution stage of a typical project. The respondents suggested the addition of task flow and project report interface.

Similarly, for the control schedule page user interface, a significant majority of the respondents (86%) agreed that it captures all the necessary elements for controlling the schedule of a typical project, while a smaller percentage (11%) were undecided, and a very small percentage (3%) disagreed. This indicates that the majority of respondents perceive the interface as sufficient for controlling the schedule of a typical project, but some may have reservations or uncertainty about the completeness of the interface.

Results also show that all respondents agreed that the construction project data model is well represented in the user interface (UI). This is a positive finding that indicates that the UI is effective in presenting the data model to the users (Hornbæk, et al., 2007).

The Ease of Use and Effectiveness of the Leanbuild Software

The questionnaire results indicate that the majority of respondents find the user interface of various project management software clear, easy to understand and implement. Specifically, 93% agreed that the layout of the project initiation homepage and the project planning user interface is clear and easy to understand. Furthermore, 96% agreed that the labels and instructions for using these pages are clear and concise. Regarding the appropriateness of the visual elements used in the user interface, most respondents agreed with the project initiation homepage (75%) and the project planning user interface (81%). However, some respondents (17%) were undecided about the appropriateness of the visual elements used in the initiation homepage UI. This means there is still room for improvement (Dillon, 2014).

Similarly, the cost planning sheet user interface, Set Target user interface, and the execution stage user interface are also clear and easy to understand, with over 90% agreement. Some respondents were undecided about some aspects of the UI, such as the visual elements used in the project planning UI (15%) and the labels and instructions for using the software (15%).

However, when it comes to the design of the UI, the results were somewhat mixed (Bruun, and Stage, 2015). While most respondents found the colours, fonts, and other visual elements used in the project initiation homepage UI to be appropriate, only 75% agreed that they were appropriate for the project planning UI.

This survey result shows that the majority of participants (77%) gave a score of 8 or higher on the recommendation scale, indicating that they are likely to recommend the software to a friend or colleague. 42% of participants gave the highest score of 10, indicating that they are extremely likely to recommend the software. 8% gave a score of 9, which is still a high score. 35% of participants gave a score of 8, which is a somewhat likely score. Finally, 15% of participants gave a score of 7, which is a neutral score indicating that they might recommend the software but with some hesitation.

Overall, the results suggest that the UI is effective in presenting the construction project data model, and the labels and instructions are clear and concise (Bruun, and Stage, 2015). However, some improvements may be necessary for the design of the UI to ensure that it is visually appealing and appropriate for all users.

FINDINGS AND RECOMMENDATIONS FROM INTERVIEWS

The interview results provide valuable feedback and suggestions for improving the LeanBuild software. The figure 1 shows the various suggestions and number of interviewee that made the recommendation.

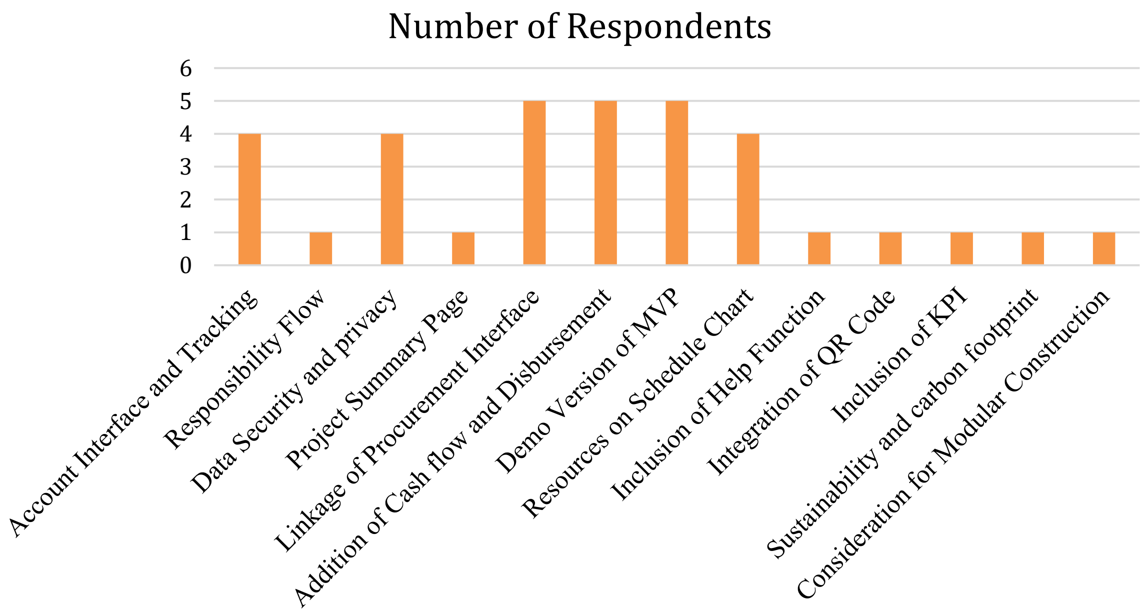

Figure 1: Suggestions and Number of Respondents that Made the Recommendation

Figure 1 shows the recommendations for improving the LeanBuild software. Some of the key suggestions include adding an account interface and tracking feature, defining responsibility flow and linking line management to activities, capturing variation of material and material diversion, providing budget approvals, cash flow, and disbursement, and offering a demonstration version of the software. The respondents also suggested the addition of resources to the schedule tracking chart to show the volume of resources required, and making the Gantt chart flexible enough to accommodate changes. Also the software should include a help function and screen guide; and integrate Building Information Modeling (BIM), Microsoft Project files, QR Codes for inventory management, Key Performance Indicators (KPIs), Artificial Intelligence (AI), sustainability and carbon footprints measurement (Sawhney and Odeh, 2020). The respondents also recommended that a provision should be made to capture the variation of material, and linkage of activities on the procurement interface. Finally, they suggested incorporating the features that support emerging trends in off-site and modular construction. The interview feedback has helped to validate the findings of the focus group and questionnaire survey. It also provides valuable insights into improving the LeanBuild software, and incorporating the suggestions provided would enhance the software's overall effectiveness and user experience.

CONCLUSIONS

The study evaluated the usability of the LeanBuild software application after the design stage of software development. Literature on current project management software was reviewed and the most common usability problems were identified. Attempt was made to determine the comprehensiveness of the design flow, the ease of use and effectiveness of the LeanBuild software application.

The research adopted a hybrid of qualitative and quantitative methodologies which include focus groups, questionnaires, and interviews. Integrating the two techniques not only provided different perspectives on the study's research aim and objectives, it also increased the overall quality and depth of the research process and findings. The study participants/respondents include industry practitioners, academics and software/IT professionals – as such views and insights of the respondents represents diverse range of career stages and backgrounds.

The results show that data privacy and security are important to end-users, and that the software should include a budget approval and a disbursement process. There were also suggestions for additional features, such as an accounting interface and project responsibility flow. The majority of respondents perceive the designed user interface to be sufficient and comprehensive for initiating, planning, executing, monitoring & controlling, and closing a typical project. Overall, respondents find the user interface of the project management software clear, easy to understand, and implement. The majority of participants have a positive view of the LeanBuild software and are likely to recommend it to others, which is a good sign for the software's success.

The implication of this research for researchers and software developers is that the paper has established that it is possible and better to identify usability issues early by conducting early usability test after the design stage. The limitation of the study includes small sample size and limited generalizability. Finally, the paper presented a digital technology that construction experts have been advocating for. This digital technology is a project management software that covers the complete lifecycle of a typical construction project. And also incorporated TVD and traditional construction methodology. The paper has also demonstrated that it is advantageous to conduct early usability test after the design stage of the software development cycle.

ENVIRONMENTAL IMPROVEMENTS FOR RENOVATION WORK USING LASER SCRAPING

Kaori Nagai[1], Motoki Imazeki[2], Yasuaki Kaneko[3], and Yuuki Kawai[4]

ABSTRACT

Construction sites in general are in environments where noise, vibration, and dust including. Especially in renovation and demolition works, concrete cutting, drilling, and scraping require not only loud noise, vibration, and dust, but also long hours of reaction force from the workers to use the machinery. Robotization has progressed in recent years and the environment for workers is improving, but the working environment in general sites where robots are difficult to install remains a challenge.

This study aims to develop a method to improve the noise and other working environments of refurbishment works. This paper describes the results of a feasibility study on a laser scraping method to reduce noise in the renovation of infrastructure facilities around residential suburban areas.

The results show that thin cement adhering to the rebar can be removed by the low power laser. Furthermore, a comparison of the noise level with conventional methods on site confirmed the superiority of laser scraping. This result indicates, in terms of lean construction, will reduce waste and improve the quality of the site.

KEYWORDS

Renovation, Environment, Sustainability, Concrete, Laser.

INTRODUCTION

Concrete structures built during the period of high economic growth are aging, and deterioration phenomena such as cracking, floating, and peeling are becoming apparent. There are various methods for repairing and renovating deteriorated concrete structures, and appropriate methods are selected according to the deterioration phenomena and surrounding environment. In the sectional repair method, one of the repair methods for concrete structures, the process starts with concrete removal, followed by reinforcement cleaning, corrosion protection, and sectional repair. It has been reported that the quality of the surface of the reinforcement after reinforcement cleaning affects the performance after repair (Kunieda 2010).

For example, in sectional repair work of concrete structures, concrete removal is performed using water jets or similar tools, and it is necessary to completely remove the mortar adhering to the reinforcement using tools such as jet chisels. At that time, it has been reported that incomplete removal can cause re-corrosion of the reinforcement (Watanabe et al. 2013).

In conventional reinforcement scraping, jet chisels and cup brushes are used to remove cement paste adhering to the reinforcement. Miyamoto (1973) reported that there is noise and vibration of 80 dB or more at 30 m from the work point in on-site concrete demolition work. In particular, sufficient consideration is required for elevated roads passing through residential areas in urban areas. Jet chisel work is essential due to the increasing number of infrastructure rehabilitation projects. This operation is one of the most difficult tasks to manage the process because of the limited working hours due to the loud noise. However, although some tools have been developed for scraping or chipping concrete, they have little effect on noise reduction. Therefore, we focused on laser technology as a new means of rebar cleaning that can reduce the burden on the work environment.

In recent years, laser technology has been considered for its applicability as a new surface treatment method for removing rust from metal material surfaces and has been implemented as laser cleaning work. Shirakawa et al. (2005) conducted an experiment to remove rust from iron towers using a 280W YAG laser. As a result, it was reported that laser cleaning improved adhesion of paint compared to cleaning with a metal brush. Hino et al (2018) reported that cleaning of metal materials is possible for various types of dirt by using a 3 kW YAG laser. In addition, Nishihara et al (2019) cleaning of molds is performed using a 70W fiber laser to remove dirt and oil from metal surfaces. Zhihu Zhou et al. (2023) have also explained the mechanism of laser cleaning and confirmed its effectiveness for cleaning metal and non-metal materials. Matsui (2003) reported the superiority of using lasers for graffiti removal on concrete. Although research on rust and paint film removal from metal substrates has been conducted in this way, no research has been conducted on the removal of cement materials adhering to steels.

In the philosophy of lean construction (Koskela 1997), this research is a development that will improve the quality of construction and the environment of on-site cleaning work. In this study, the research is aimed to develop a low-vibration, low-noise, low-dust, and reactionless method that can remove 1mm thick concrete scraping to reinforcing bars after the concrete is removing and red rust remaining after removal. The experiment is to use a portable laser of 200W and less for use at construction sites. This report describes the results of basic and applied experiments on the laser cleaning method using an understanding of the thermal effects of mortar, laboratory tests, and trial construction at actual sites.

MECHANISM OF LASER SCRAPING

The principle of laser scraping is shown in Figure 1. Laser scraping works by utilizing the ablation that occurs during laser irradiation. This involves instantaneously decomposing substances adhering to the surface layer of the irradiated area with laser light, and evaporating and sublimating them in the process while removing the target substance as long as it continues to absorb the energy of the laser in combination with the micro shock waves generated.

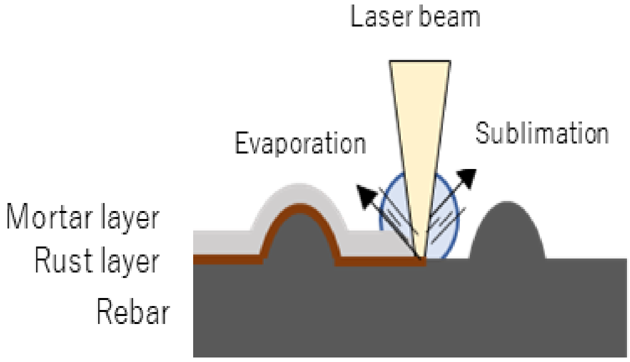

Figure 1: Laser scraping diagram

In this study, the test is tried with a low-power laser to remove 1 mm of cement without affecting the rebar. As shown in Figure 1, efficient irradiation can be achieved by using a galvanometer mirror to scan the laser light at high speed on substances adhering to the surface layer. At this time, the laser energy density that causes ablation of the target material must always be higher than the energy density that causes ablation of the base material. This allows only the target material to undergo ablation without affecting the base material, making it possible to remove only the target substance.

LASER IRRADIATION EXPERIMENT

PURPOSE OF EXPERIMENT

This experiment verifies the removal performance using 100W lasers, based on the results of an experiment using mortar plates, to select laser irradiation conditions assuming a construction site.

CONDITION OF EXPERIMENT

The specimen is shown in Figure 2 and the irradiation range is shown in Figure 3. Assuming a structure such as a bridge, the specimen consisted of five D16 rebar's crossed at intervals of 130 mm and covered with 1 to 2.5 mm of mortar. The mortar adhered to the specimen was a premix TDR mortar (Hirama 2006) except for the vinylon fibers, and the external dimensions of the specimen were 950 x 950 mm. This mortar is repair materials for concrete structures.

Figure 2: The specimen

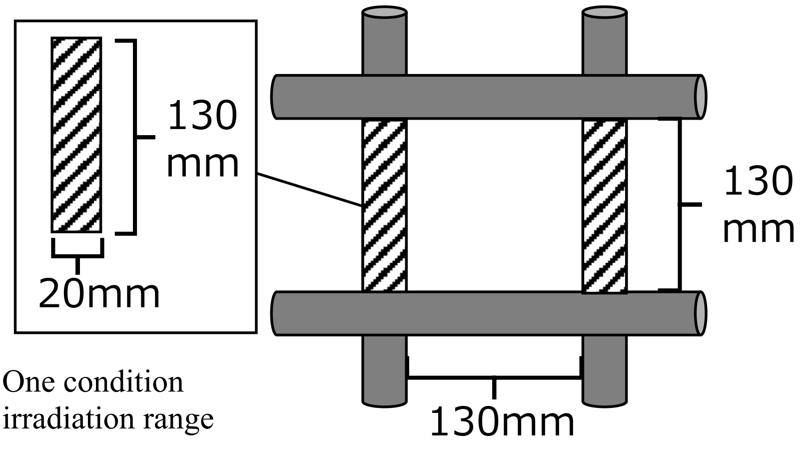

Figure 3: Laser Irradiation area

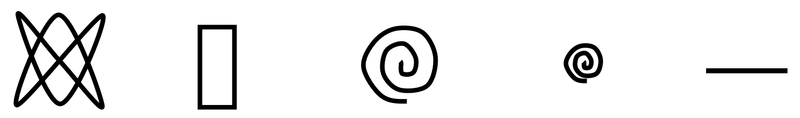
EXPERIMENTAL METHODS

Irradiation conditions are shown in Table 1 and scanning geometry in Table 2. Among the irradiation conditions, the frequency was selected from the preliminary experiments to have high removal performance. In addition, the laser beam was scanned and irradiated to each shape to improve the removal efficiency. An irradiation schematic is shown in Figure 4.

Table 1: Laser Irradiation Condition

Power (W)	Mode	Frequency (kHz)	Irradiation Speed (mm/s)	Irradiation time (s)	Focus distance (mm)
100	パルス	70	0.3 0.6 0.9 1.2 1.5	180	163

Table 2: Scanning Geometry



Lissajous	Rectangle	Spiral-L	Spiral-S	Beeline

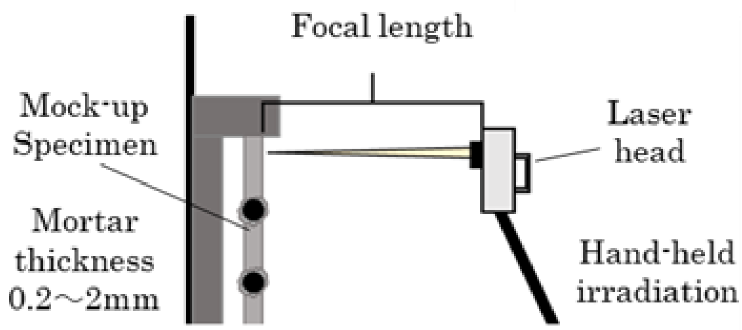


Figure 4: Laser irradiation schematic diagram

EVALUATION METHODS

Surface observation: Mortar and rust residues were visually checked after laser irradiation.

Removal rate: The removal rate was calculated from the images of the specimen after irradiation and after the use of a cup brush, using processing software to determine the evaluation area and the area of mortar removed.

Working time: The time required for the work was measured at two levels: the time required for laser irradiation alone, and the total time required for cup brush removal as a secondary process for the remaining areas. In the cup brush removal process, the completion of mortar and rust removal was visually determined.

RESULTS OF EXPERIMENT

The results of the removal performance under different laser irradiation conditions are shown in Figure 5. The graphs compare the results of the 100 W results of this experiment with data from the author's previous studies conducted using a 200 W fiber laser (Imazeki 2022). It was found that the removal rate of the 100W laser was lower than that of the 200W laser under all conditions when using the laser alone. However, when a cup brush was used after irradiation with both the 100W and 200W lasers, almost the same level of removal rate was achieved. Considering that the mortar thickness of the mock-up created in this study ranged from 1mm to 2.5mm, it can be inferred that even 1mm thick mortar, which was the original target, could be removed using the laser alone, and thicker mortars could also be weakened by the heat generated by the laser. Furthermore, each laser machine used in this study had a different spot diameter, with the spot of the 100W laser being smaller. This factor may have contributed to the ability to weaken the mortar by achieving a similar power density as the 200W laser.

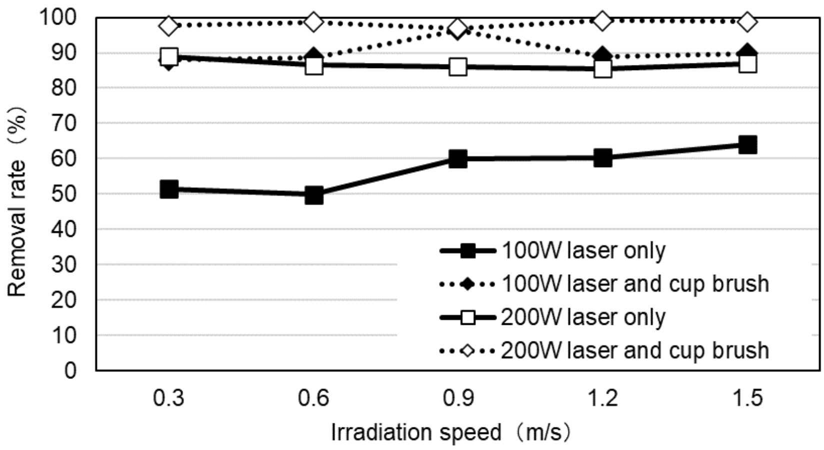

Figure 5: Comparison of removal performance

A comparison of scanning geometries is shown in Figure 6. In this experiment, a change in the removal rate after each operation was observed depending on the scanning geometry. The two types of spiral shapes tended to have higher removal rates, with the Spiral-S with a smaller diameter showing higher removal rates. The high removal rate of the spiral shape was also observed even when a cup brush was used, indicating that, among the scanning shapes, the spiral shape was more prone to heat accumulation in the center of the mortar because the laser beam was irradiated from the center towards the outside.

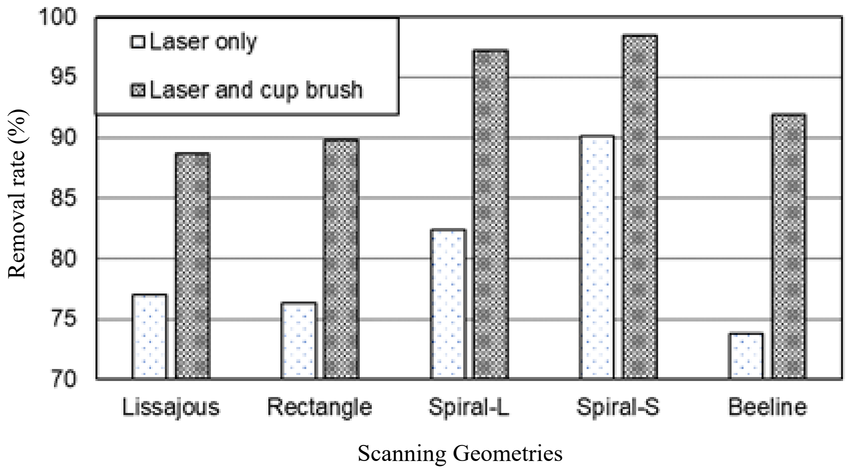

Figure 6: Comparison of scanning shapes

According to brittleness of the mortar. Furthermore, the maximum removal rate was 98.5% when the cup brush was used in combination with the laser beam, indicating the potential of laser scraping even with the 100 W laser, which is low power.

ON-SITE TESTS

TEST OVERVIEW

The field test construction location is shown in Figure 7. The construction site was the overhang of the slab on which the sectional repair was being constructed, in a space surrounded by a light-emitting soundproofing sheet. The concrete removal was completed and the rebar was exposed before the cleaning work was carried out. The rebar in question was φ13 round steel. For the test construction, one condition of laser irradiation was applied to one span (150 mm) of the assembled rebar.

The laser irradiation conditions were as follows: frequency 70 kHz, focal length 163 mm, irradiation speed 10 m/s, and two types of spirals with different irradiation diameters as the scanning shape. The irradiation time was not decided beforehand and was carried out at the discretion of the laser irradiation operator. As a comparison, a conventional cleaning method using a jet tool and a cup brush was also carried out. The end point of the cleaning work using the tools was determined at the operator's discretion.

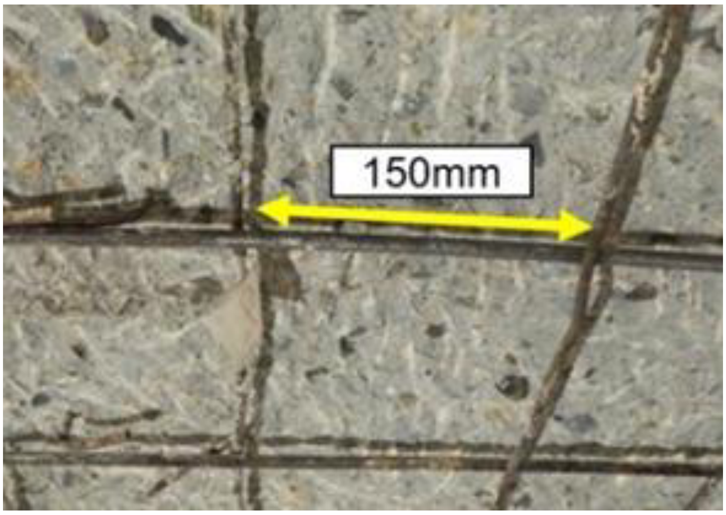

Figure 7: Irradiation area of on-site demonstration test

EVALUATION METHODS

The surface condition was checked when laser irradiation and cup brushes were used. The evaluation was based on the surface finish and compared with the conventional method.

The time required for laser irradiation and the time required to clean the surface using tools were measured using a stopwatch. Only the working time was measured and the comparison was made without including the time required for changing tools.

Measurements were taken using a digital dust meter (S) to measure the amount of dust prior to the cleaning work, during laser irradiation, jet chisels and cup brush application for 2 minutes. The average value of the measured dust amount was organized as a relative index with the dust amount before the installation set as 1.

Measurements were taken during each operation using an ordinary sound level meter (manufactured by Company R), and the measured values were expressed as equivalent noise level Leq (dB). Dust and noise were measured at a distance of 2 m from the workers.

RESULTS OF ON-SITE TESTS

Figure 8 shows the condition of the surface during the field test installation and Figure 9 shows the condition before and after scraping. As in the verification of the mock-up specimen, the laser irradiation was able to remove rust and thin mortar, but not all mortar could be removed by laser irradiation alone. However, by using a cup brush to clean the surface after laser irradiation, it was possible to achieve a finish comparable to that of the conventional method (combination of jet chisels and cup brush).

Figure 8: On-site demonstration test situation

Before scraping.	
After laser irradiation	
After laser irradiation and cup brush work	

Figure 9: On-site rebar before and after scraping work

The working time per unit length is shown in Figure 10. The conditions in which laser irradiation was carried out increased the time required to clean the rebar compared to the conventional method. However, the time required for cup-brushing work was similar for all conditions.

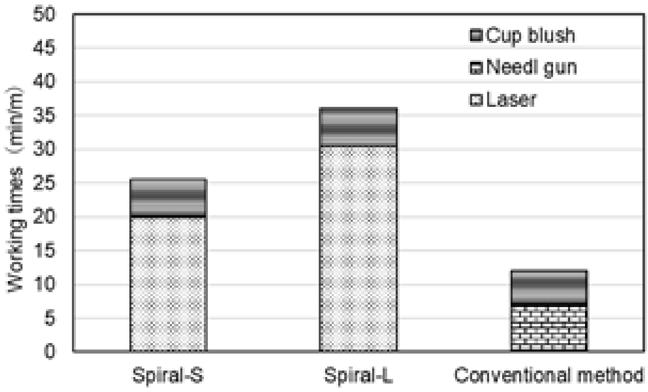

Figure 10: The results of Working times

The results of the dust measurements are shown in Figure 11. The objective of this experiment was to confirm the relative dust reduction effect. For this reason, the relative dust amount was organized as the dust amount before the construction (initial value) was set to 1.

It was confirmed that the amount of dust during laser irradiation was approximately 1/4 of that of a cup brush and 1/10 of that of a jet chisels, and that dust could be reduced significantly compared to the conventional method.

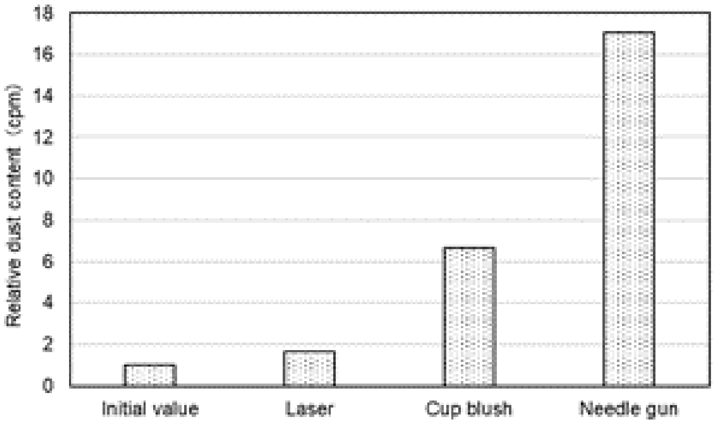

Figure 11: The results of dust measurement

The results of noise measurements are shown in Figure 12. The initial equivalent noise level during on-site work was 64.1 dB. The noise levels during each operation were 66.6 dB for laser irradiation, 92.6 dB for cup brush operation and 96.3 dB for jet tagger operation, and the equivalent noise levels for laser irradiation only were approximately 3/4 and 2/3 of those for cup brush and jet tagger respectively. The equivalent noise level during laser irradiation was similar to the initial value, confirming that laser scraping is less noisy than the conventional method.

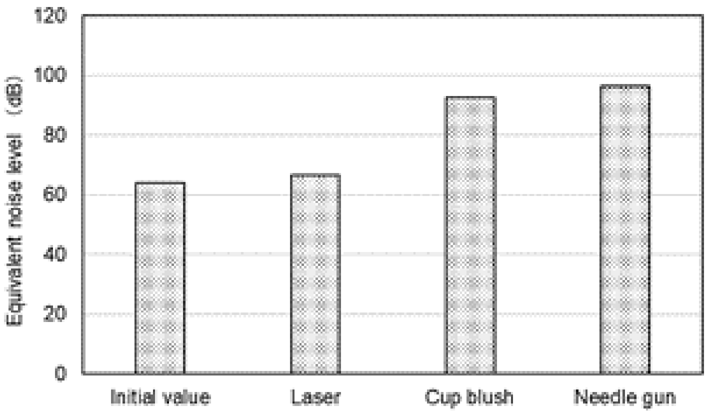

Figure 12: The results of noise measurement

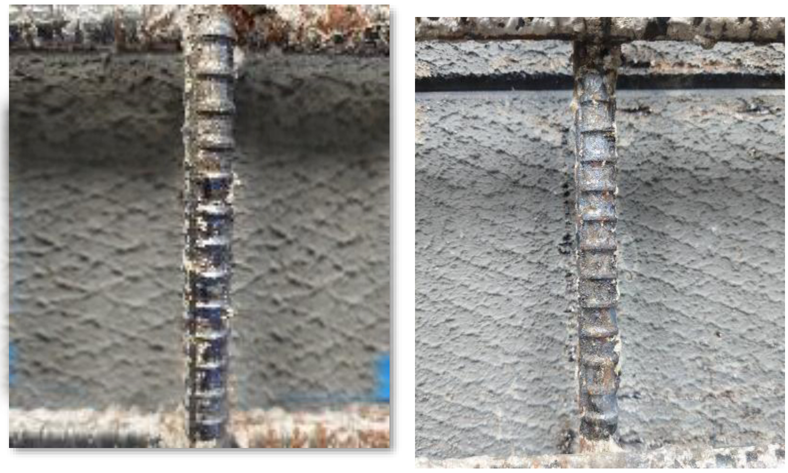
DISCUSSION AND FUTURE ISSUES

KAIZEN OF SCRAPING WORK BY LASER

In this study, we confirmed that it was possible to use a 100W low-power laser on two types of materials: thin cement layers and rust (Figure 13). Previous studies have mostly focused on the removal of paint or rust from iron plates, where the materials were single and several hundred micrometers thick.

In laser processing of concrete, it has been reported that it vitrifies due to high temperature at 3kW or more (B. Tirumala Rao et all 2005). On the other hand, if the exposure time is short even at high power, the thermal influence on the material is small, and it has been reported that holes can be made in concrete (Nagai et al, 2018). In addition, the possibility of chipping the surface of concrete with about 500W has been reported (Kamata et al, 1996). From these results, since the target of this study is a thin cement layer, it was thought that cement could be made brittle with low power and it was possible to demonstrate it.

This development can contribute to the improvement and quality enhancement of lean construction sites. The work time for digging in renovation projects can be long depending on the site conditions, or limited by noise problems. However, this development makes it possible to plan work hours. Furthermore, it is effective in reducing power consumption on site by making it smaller and simplifying its handling. Future research should be conducted to further reduce working hours.



200W Laser 100W Laser

Figure 13: Compare of 200W Laser and 100W Laser

IMPROVEMENT OF WORK ENVIRONMENT

As a result of our examination of noise, vibration, and reaction force issues at construction sites, we have found that laser construction reduces noise problems and allows for renovation work to proceed in environments such as urban areas and near hospitals. Furthermore, the work environment for workers is clearly improved, and the use of non-reactive non-vibration scraping construction can contribute to reducing the burden on workers.

In the future, we believe that incorporating robots will lead to further improvements in the work situation.

REDUCTION OF GLOBAL ENVIRONMENTAL IMPACT

As a result of field tests, it was confirmed that the amount of dust generated is almost negligible. This is due to sublimation by laser. In mechanical processing such as water jetting and sandblasting, a large amount of water and sand is used, resulting in a large amount of dust and an increase in waste materials. These problems can be improved by using lasers.

In the future, further environmental improvements can be expected by suctioning the small amount of dust generated.

CONCLUSION

It was confirmed that mortar and red rust as thick as 1 mm could be removed even with a low level of laser irradiation of 100 W. Furthermore, for mortar thicker than 1 mm, the heat from the laser irradiation tended to weaken the mortar in a short time, reducing the cup brushing time. In the field, the combination of laser cleaning and cup brushing was found to provide removal performance comparable to conventional methods without the noise and vibration. This method was found to be effective in improving the environment for workers and excellent in areas where noise and dust control measures are difficult to implement.

A FUZZY FRAMEWORK FOR CONTRACTOR SELECTION ON IPD PROJECTS

Zeina Malaeb[1], Mohamed ElMenshawy[2], Anas Badreddine[3], Omar Azakir[4], and Farook Hamzeh[5]

ABSTRACT

The construction industry is characterized by complexity, budget and schedule overruns, quality and safety problems, and increased claims and disputes. To successfully manage the inherent complexity of construction projects, optimal contractor selection is integral for project success. Choosing the best-fit contractor is especially important in Integrated Project Delivery (IPD), since this procurement route relies heavily on the efficient collaboration of project stakeholders and necessitates trust to guarantee successful outcomes. However, the numerous methods and tools for contractor selection in the literature target traditional delivery routes and are unsuitable for IPD, considering the latter's distinct features and stakeholder roles. As such, owners transitioning to IPD do not fully understand the requirements for optimal contractor selection, which jeopardizes the success of IPD projects. To address this need, this paper conducts a comprehensive literature review and investigates twelve unique IPD case studies to identify contractor selection criteria important to IPD. The paper presents a decision-making framework for contractor selection in IPD projects, using the Fuzzy Inference System (FIS), that provides an indication of the best-fit contractor for the IPD project. This research fills a significant gap in the literature by providing a tool to assist IPD practitioners to select the right contractor.

Contractor selection, fuzzy inference system (FIS), integrated project delivery (IPD), qualification-based selection, multi-criteria decision-making (MCDM) tool

INTRODUCTION

The construction industry is characterized by complexity, budget and schedule overruns, quality and safety problems, and increased claims and disputes (Singh and Tiong, 2005). Since construction projects heavily rely on the interaction and collaboration of different parties (El-Sayegh et al., 2021), and since contractors play a major role on such projects, it is widely agreed that optimal contractor selection is integral to manage the inherent complexity of these projects (Mousakhani et al., 2018). Accordingly, having the right contractor on board is critical to determining project success or failure (Vardin et al., 2021) as appointing the most suitable

contractor is a prerequisite for successful project outcomes (Fong and Choi, 2000; Jafari, 2013; Zhang et al., 2016). Furthermore, Kog and Yaman (2014) underline the importance of having a strong and steady relationship between the client and the contractor to achieve project goals. On the other hand, inappropriate contractor selection leads to bad quality works (Alptekin and Alptekin, 2017), delays, cost overruns, poor performance, accidents, bankruptcy, disputes (Abdul Razak et al., 2021), and project failure in terms of quality, cost, and time (Mousakhani et al., 2018).

"Integrated Project Delivery (IPD) is a project delivery approach that integrates people, systems, business structures and practices into a process that collaboratively harnesses the talents and insights of all participants to optimize project results, increase value to the owner, reduce waste, and maximize efficiency through all phases of design, fabrication, and construction" (AIA, 2007). Considering the unique characteristics of IPD and its reliance on the efficient integration and collaboration of project stakeholders, it is crucial to select suitable project participants with shared goals and established trust and cooperation to guarantee the successful implementation of integrated projects (Zhang et al., 2016). In this regard, selecting a project team that collaborates efficiently has been identified as a prerequisite to effective IPD implementation (Townes et al., 2015). Therefore, it can be argued that appropriate contractor selection for IPD projects is of even greater importance than for other traditional project delivery routes.

While numerous studies in the literature attempt to propose methods for contractor selection for traditional delivery routes, these traditional practices and selection methods are not suitable for IPD projects (Zhang et al., 2016; Townes et al., 2015). Zhang et al. (2016) emphasize that different criteria and techniques must be considered when selecting contractors for IPD projects, since this delivery route has distinct features and imposes different roles and obligations on the participants. Nevertheless, there is a lack of studies on IPD party selection, and the existing literature fails to sufficiently investigate how IPD contractors should be assessed and compared (Townes et al., 2015). Furthermore, an investigation of the contractor selection process in twelve IPD projects published by the AIA "IPD Case Study Matrix" in 2012 reveals that, while certain IPD-related criteria are considered, there is no standardized or published decision-making framework utilized for this process. Due to the present state of knowledge, project owners transitioning to IPD do not fully understand the requirements for selecting an optimal contractor for this delivery route, which jeopardizes project success (Townes et al., 2015). Therefore, considering the established importance of appropriate contractor selection for construction projects in general, and IPD in specific, and considering that the traditional selection methods and criteria are not suitable for IPD, there is a clear need to establish a framework for contractor selection on IPD projects.

This paper conducts a comprehensive literature review to identify the criteria used for the assessment and selection of contractors for construction projects. In addition, the paper further investigates twelve unique cases of IPD projects, published by the AIA, to identify IPD-specific criteria utilized in this process. Ultimately, the objective of the paper is to develop a decision-making framework for contractor selection in IPD projects that utilizes the user's rating of the identified criteria as inputs and provides, as an output, an indication of the best-fit contractor for the IPD project at hand. This research fills a significant gap in the literature by providing criteria and a framework for evaluating and selecting contractors on IPD projects. The proposed framework can be customized according to the stakeholders' needs and preferences on the specific project it is applied to. This decision-making tool will assist practitioners entering IPD projects in selecting the right contractor to optimize the chances of project success.

METHODOLOGY

The methodology of the paper followed the below 5 steps.

1. Identification of Contractor Selection Criteria for Construction Projects: A systematic literature review was conducted, based on the guidelines by Hong et al. (2012), to identify the criteria for contractor selection on construction projects, with a specific focus on IPD projects. Accordingly, the authors performed a selective search to find articles with the following phrases in subjects, titles, keywords or abstracts: contractor selection “and/or” criteria, factors, frameworks, IPD, and methods. The abstracts of the articles were then reviewed in detail to assess their relevance and criteria were identified from the research.
2. Identification of Contractor Selection Criteria for IPD Projects: Subsequently, the authors studied and analyzed twelve cases of IPD projects published by AIA IPD Case Study Matrix (2012) to establish a stronger understanding of the process of contractor selection in real IPD projects. From these cases, further criteria relevant to contractor selection were identified.
3. Filtering, Sorting, and Grouping the Established Criteria: Next, the factors identified from the first two steps were analyzed, filtered by removing redundancies, grouped into sub-factors, and organized under a hierarchy to prepare for the execution of the FIS modeling.
4. Constructing the Rubric for Measuring the Factor Input: A rubric was developed to maintain consistency in rating the metrics. The rubric describes the input degrees of each factor in practical terms.
5. Modeling Using Fuzzy Inference Systems (FIS): The framework is constructed using FIS, which was chosen due to (1) its ability to manage and represent qualitative factors, considering that certain factors identified for IPD contractor selection are qualitative in nature, and (2) its capacity to account for the vagueness and uncertainty of decision-makers (Hellmann 2001). The MATLAB Fuzzy Logic Designer Toolbox is used to construct the model and the Mamdani style is adopted for “being intuitive, having widespread acceptance, and well-suited to human input” (Gunduz et al. 2015). Using the Mamdani style, membership functions are assigned trapezoidal and triangular shapes, ‘if … then’ rules are applied, and the output is evaluated by calculating the centroid of the aggregated shape. For simplicity, the authors assumed a set of base rules and a standard template for the membership function applied to all factors, based on the model proposed by ElBeltagi et al. (2011). Nevertheless, when applying the tool to a specific case study, the rules and functions can be easily calibrated based on the expert opinions of the project stakeholders, which can be obtained through surveys or interviews. The FIS involves 3 stages, Fuzzification, Fuzzy Inference, and Defuzzification and follows the below steps:
    1. The user provides a crisp input by choosing a rating between 0 and 10 as per the rubric developed in Step 4.
    2. Fuzzification: Using membership functions, the input is converted to fuzzy sets.
    3. Fuzzy Inference: The fuzzy inference or the rules that determine the outcome of the outputs are applied. Each rule generates a fuzzy set which is then aggregated for the next step.
    4. Defuzzification: Using output membership functions, the sets are defuzzified after aggregating the fuzzy sets.
    5. The user then receives the final output which is a crisp result. This is an indicator of the “contractor score” on the IPD project.

LITERATURE REVIEW

The selection of the optimal construction contractor is considered the most important responsibility of the owner as this decision directly impacts project performance and outcomes (Mousakhani et al., 2018). While, traditionally, contractors were selected on a lowest-bid basis, studies have found this method to detrimentally affect project outcomes in terms of time, cost, quality, and disputes (Cheaitou et al., 2019). Therefore, contractor selection methods were developed to include multiple criteria additional to cost and utilized various multi-criteria decision-making (MCDM) techniques (Cheng et al., 2020). To this end, Sigh and Tiong (2005) presented a fuzzy model to assess the contractor's capacity to deliver a project meeting the owner's requirements and applied the tool to choose between 4 contractors. Doloi (2009) analyzed contractor prequalification criteria to determine their influence on project success. The author performed a factor analysis on 43 influencing technical attributes and extracted 7 factors that impact performance. The results show that project success in terms of cost, quality, and time is significantly influenced by a number of factors, including time in business, technical proficiency, history of success, working capital, and work methods. Jafari (2013) used the quality function deployment (QFD) method for contractor prequalification, considering both the owner's requirements and the contractor's qualifications. Marzouk et al. (2013) categorized factors influencing contractor selection into 10 main criteria and 46 sub-criteria, including cost, experience, time, safety, insurance, disputes, and risk avoidance, among others, and isolated the most important ones based on statistical analysis using surveys. Moreover, Kog and Yaman (2014) developed a multiagent system-based model to prequalify contractors. However, this was only suitable for traditional design-bid-build projects and excluded other delivery routes. Liu et al. (2015) identified several essential criteria to consider in assessing contractors, based on two-stage partial least squares path modeling. In their contractor selection method research, Mousakhani et al. (2018) used a risk-oriented approach to identify contractor selection factors and evaluated them using AHP. To select the best contractor for public construction projects, Cheng et al. (2020) proposed a Bayesian fuzzy prospect model, based on probability and utility multiplied relation. Further, to overcome the deficits of lowest bid selection, Vardin et al. (2021) used Fuzzy-VIKOR and the best-worst method to develop a contractor selection framework.

While these studies, in their selection of criteria and development of decision-making models, appear to be comprehensive, they are all related to traditional procurement routes and are not sufficient for IPD. In fact, existing studies do not adequately investigate how IPD contractors should be compared and selected (Townes et al., 2015). Nevertheless, certain researchers attempted to reduce this gap by providing insight and recommendations on the matter. As such, Rahman and Kumaraswamy's (2005) recommended pre-selection workshops for short-listed teams to select relationally integrated teams. Similarly, Dossick et al. (2013) described the adoption of 2-hour workshops in an IPD case study that involved 4 shortlisted teams who engaged in a unique proposal process. Townes et al. (2015) investigated a case study to comprehend the means and process of contractor selection on IPD projects, and detailed the different stages that took place, including the submission of proposals prepared by self-selected multidisciplinary teams and the use of pre-selection workshops for team evaluation. They described that the owner's assessment of the shortlisted teams relied on the IPD workshops and interviews conducted, which were useful for the observance and evaluation of IPD team selection criteria, including intangibles qualifications, such as collaborative performance. However, they did not provide the method for rating the criteria nor the decision-making tool used to this end. On the other hand, based on the inter-organizational transactive memory system (I-TMS), which is "a collaborative cognition division system that forms when multiple organizations cooperate with each other", Zhang et al. (2016) developed a method for selecting IPD contractors. Using this system, all IPD stakeholders rate the transactive memory of others across three main factors: specialization, credibility, and coordination, and the appropriate combination of IPD parties is evaluated using social network analysis (SNA). This technique is a relational-based framework that considers trust and collaboration, being factors integral to IPD. Nevertheless, a strict prerequisite to its adoption is that project participants possess previous, shared memories or experiences of cooperation, which limits the application of the framework. Accordingly, there remains a need to propose an objective MCDM framework to evaluate contractors on IPD projects without the limitation of previous relationships between the parties, which is the main contribution of this paper.

CASE STUDY ANALYSIS

The 2012 AIA IPD Case Study Matrix provides detailed project information and firm selection strategies for 12 unique IPD projects (AIA 2012). Figure 1 presents the contractor and/or subcontractor selection processes and methods used in those case studies. Two out of the twelve case studies had no published information on the party selection processes and therefore were excluded.

1 [Cathedral Hill Hospital]

- The Contractor was selected based on (1) familiarity with IPD and lean construction and (2) previous history/relationship with the owner, who was also keen on IPD.
- Subcontractors were pre-qualified, then pre-qualified firms submitted RFP, then shortlisted firms were interviewed. Among the considered criteria for subcontractor selection were (1) experience with IPD and (2) willingness to be part of IPD and (3) willingness to collaborate.

2 [MERCY Master Plan Facility Remodel]

- RFQ were sent to contractors and considered the following criteria: general company information, regional experience, healthcare experience, and IPD knowledge and experience. A scorecard was used to evaluate RFQ to shortlist firms, who were then interviewed on subjects, including: relational aspects of project delivery, budgeting process, and logistical strategies specific to healthcare and IPD environments. The selected contractor had shared project experience with the architect.
- Subcontractors were pre-qualified based on positive past work experience with the contractor. Then pre-qualified firms submitted RFP on experience with IPD, experience with other technologies that would be used on the project, and financial background. Finally, shortlisted firms were interviewed.

3 [Lawrence and Schiller Remodel]

- Contractor selection was based on (1) previous relationship with owner and (2) interest in IPD.
- Subcontractor selection was based on expertise, past experience, and trust.

4 [Edith Green Wendell Wyatt Federal Building]

- Public RFP were sent to contractors inviting them to attend a project workshop. Then, 13 contractors met with owner in "Early Exchange Meetings" to discuss project requirements, including project history, design aims, and constraints regarding time, cost, and site. The IPD process was a main topic discussed as applicants were made aware of the necessity to support a collaborative approach. Final contractor selection relied on their qualifications, past performance, key personnel, conceptual cost estimate and pricing for design phase services.

5 [Autodesk Inc.]

- RFP were issued to select an already established team of architect and contractor. The RFP expressed the owner's targets regarding scope, cost, sustainability, and type of agreement. The architect and contractor were selected on the basis of qualifications, understanding of the local market, BIM and LEED experience, and willingness to abide by a "true" IPD agreement.

6 [Sutter Health Fairfield Medical Office Building]

- At the owner's request, the architect met with the contractor to investigate the fit and alignment of their cultures. They met and found it was a good fit. The companies had past experience working together on traditional projects in the Midwest.

7 [Cardinal Glennon Children Hospital]

- The owner decided to adopt IPD after the commencement of the design stage, once the architect, engineer, and contractor were on board. The owner, architect and contractor had previous work experience and relationships.

8 [Encircle Health Ambulatory Care Center]

- Selected the contractor based on (1) the owner's previous experience with the contractor and the (2) the contractor's previous experience with IPD.
- Subcontractor selection was based on price, personnel qualifications, and previous work with the contractor.

9 [Walter Cronkite School of Journalism]

- Public RFQ were issued to select an already established team of architect and contractor, purely based on qualifications. Around 15 responses were received and 3 teams were shortlisted, based on past experience with public entities, familiarity with the type of project, and the prospect of working well together.

10 [USCF Mission Bay Medical Center]

- The owner adopted a best value selection process, developing a questionnaire that allows the selection of contractors based on experience and expertise and not on the lowest price.
- Subcontractor selection followed best value selection based on the quality of experience. The expectations for teams, relative to IPD principles, were listed as part of the bid documents. Criteria were specified to support IPD goals, whereby heavy weight was given to collaborative experience.

Figure 1: Contractor and Subcontractor Selection Processes and Criteria in 12 IPD Case Studies

Analyzing the selection methods on these projects, it is apparent that most projects adopted requirements particular to the IPD procurement route. For instance, on projects 1,2,8, and 10, owners focused on the contractors' knowledge and experience with IPD as a criterion in the selection process. Moreover, on projects 1,3,4, and 5, all bidders were made aware of the IPD form of delivery and contract to be signed and therefore the selected bidder would have expressed their willingness to sign and take part in a "true" IPD agreement. Additionally, on certain projects, bidders' experience with implementing lean (project 1) and Revit/BIM (projects 2 and 5), which are operational principles and systems integral to IPD, were specified. It is worth noting that a recurrent factor adopted across several projects was the previous relationships of the parties, owner, architect, and contractor, be it on IPD or traditional projects (projects 1,2,3,7, and 8). Finally, another unique criterion in selecting contractors for IPD was the contractor's compatibility with the architect and the prospect of positive collaboration between the parties (projects 5,6, and 9). In fact, this is not usually considered in traditional delivery routes but is especially important in IPD in the presence of a multi-party agreement establishing an official relationship between the contractor and the architect and with the requirement for high levels of communication and collaboration between those two parties on IPD projects. From these studies, the authors well able to identify and translate certain factors of importance in contractor selection used in the above IPD projects into IPD-specific criteria to be included in the proposed decision-making tool, as presented in Table 1.

Table 1: Criteria obtained from IPD Case Studies

No	Criterion	Case Study
1	Previous implementation of lean in contractor's organization	1
2	Knowledge and experience with IPD	1-2-8-10
3	Willingness to be part of IPD and sign "true" IPD agreement	1-3-4-5
4	Systems and technologies that are integral to IPD (e.g. BIM, Revit)	2-5
5	Successful previous relationship with owner/architect/contractor	1-2-3-7-8
6	Compatibility of contractor and architect	5-6-9

Notwithstanding, it is apparent that none of the case studies present a comprehensive contractor selection procedure specific to IPD nor an official decision-making tool for choosing the most appropriate contractor based on a scientific method and an inclusive list of criteria. Rather, it would appear that criteria for qualification-based contractor selection in traditional delivery routes were considered, while adding certain requirements related to IPD. Moreover, the majority of the projects adopted an interview process whereby the bidders' compatibility with IPD was assessed, but again without providing the method for evaluating and ranking the bidders. In any case, if any decision-making tool was used, there are no official publications in the literature detailing the basis of the same to advise on the optimum process for IPD contractor selection.

RESULTS AND DISCUSSION

PRESENTATION OF THE IDENTIFIED FACTORS

After conducting the systematic review, a total of 42 factors were identified, filtered, and organized into four categories: Technical Qualifications (14), Past Experience and History (16), Financial Qualifications (5), and IPD Qualifications (7).

PRESENTATION OF FINAL HIERARCHY OF CRITERIA

Subsequently, the 42 identified factors are organized under the four-level hierarchy presented in Figure 2 below.

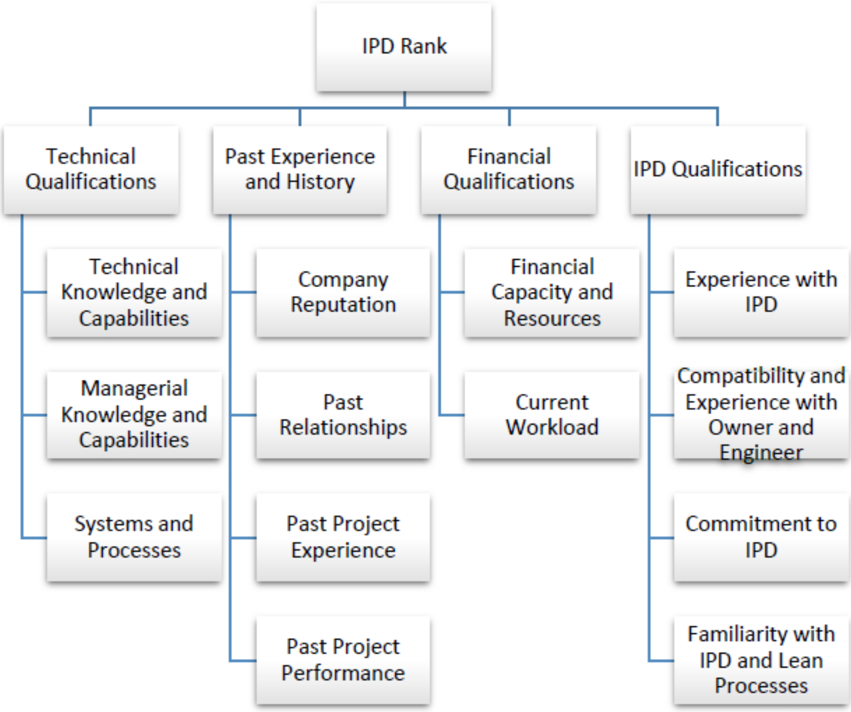

Figure 2: Hierarchy of Factors

PRESENTATION OF THE FUZZY DECISION-MAKING TOOL AND RUBRIC

The development of the fuzzy inference system relies on specifying the inputs and outputs of the model. In this paper, the output is the IPD rank, and the inputs are several factors that contribute to this rank. A membership function must be defined for every factor. After identifying those membership functions, the factors of the lowest level are rated by the user, using the rubric, to identify the final output score, representing the contractor's IPD rank. The forthcoming sections will discuss the developed model in detail.

Using the developed rubric, the users input a rating from '0' to '10' of each lower-level factor, where '0' represents a minimum rating and '10' represents a maximum rating.

Input and Output Factors

The model is a multi-level hierarchy, where the first level in the hierarchy is the major goal itself, the IPD Rank. The second level presents the main categories that contribute to the score of the IPD Rank. Finally, the third level, which is the lowest level, defines the sub-factors.

To use the tool, the following steps are followed: (1) the user inputs the rating of the third-level factors using the developed rubric (2) next, fuzzy calculations are applied in order to obtain the ratings for the level 2 factors, which will be the outputs from the level 3 calculations and (3) finally, the ratings of the level 2 factors are used as input to calculate the rating of the level 1 factor, which represents the IPD rank. As such, this model could be described as an aggregated tree, in which the output of a function is used as an input of another function to get the output of the final goal.

Membership Functions and Rules

After conducting an extensive literature review, the authors implemented the most commonly utilized membership functions: low, medium, and high. Furthermore, the membership functions were represented by trapezoidal and triangular functions, trapezoidal functions for both low and high membership functions and the triangular function for the medium membership functions. Fuzzy logic allows the overlapping between different functions so that each score/rating might be represented by membership in two functions, which is the core benefit behind choosing this method. The parameters of the membership functions have been set with the following values, representing the span of the functions, low [0 0 2 4], medium [2 5 8], and high [6 9 10 10].

The subsequent step is identifying the different scenarios, or rules, that might occur in evaluating the output. The number of different scenarios is based on the number of factors and the number of membership functions. So, in the case of a category that has 4 sub-factors, each having 3 membership functions, the total number of rules required is MF^SF (i.e., 4^3=64 rules). Overall, 227 rules were defined for the entire model.

CONCLUSION AND FUTURE RESEARCH

This research provides a practical tool for owners to select the most suitable contractor for an IPD project. This research adds to the body of knowledge by providing a metric to the decision maker so that he/she can have a better understanding of the requirements for contractor selection in IPD to optimize successful project outcomes. The developed framework facilitates the selection of the appropriate contractor for the IPD project at hand, considering a rounded classification of criteria along IPD-specific requirements. The benefit of the tool is in its flexibility, as it is suitable for use on any project since its main membership functions and rules can be adjusted as required using the input of project stakeholders. Nevertheless, it was apparent from the investigated IPD case studies that an interview process is essential, whereby the owner and the architect met with the bidders to assess several qualitative factors such as the "willingness to collaborate", "team chemistry" and the "compatibility of the cultures". Therefore, the authors suggest that this tool be used not as a replacement but rather to supplement the interview process. For instance, one potential application is applying the tool as a pre-qualification step to filter contractors prior to the interview process. For future work, a more comprehensive model can be developed that considers additional factors, which would benefit from the input of construction professionals in validating the identified factors and contributing to the development of new factors. Another opportunity is the framework's application to a case study after calibrating the membership functions and rules through input gathered from project stakeholders and experts.

LIFE CYCLE COST AND VALUE OF NORWEGIAN SPORTS FACILITIES

Johan C. Ørke[1], Tobias O. Malvik[2], Olav Torp[3], and Terje K. Fossheim[4]

ABSTRACT

Sports facilities are built to create value for owners and users. In the front end, it is crucial to make decisions based on information about the Life Cycle Cost (LCC) and the possible benefits of the facility. This paper aims to create knowledge about the relationship between the value and LCC of sports facilities. This has been done through literature review, document studies, and workshops.

The construction costs have been compared to the operation and maintenance (OM) costs for 11 sports halls. The results show a ratio between OM and construction costs between 0,1 and 3,7. Diverse aspects could explain this, such as the lack of a standard model for what to include in the OM costs and volunteer work with planning, and OM not counted.

Planning in sports facilities construction often relies on volunteers from the sports clubs, leading to a lack of competence and resources to implement value-centered approaches like the Lean Construction methodology. This paper shows that it is challenging to quantify the value generated by sports facilities, and value is highly dependent on perspective. There is a need for a more systematic way to evaluate the OM cost and the value generated by the sports facilities.

KEYWORDS

Life cycle cost, value generation, lean construction, sports facilities

INTRODUCTION

Projects are generated to create value for owners and users. Diverse types of buildings will contribute to value in various ways. When deciding to start a project, the value and cost must be considered (Ballard & Morris, 2010). In the front end, estimated costs for planning and constructing a facility are often based on the cost of previous projects (Barakchi et al., 2017). Operation and Maintenance (OM) costs should also be considered in the big decisions during the front-end phase. As decision basis for the final decision to finance a project, it is crucial to estimate the Life Cycle Cost (LCC) of the facility, comprising the planning and construction costs, cost of operation and management of the facility, and operation cost of the activity at the facility (e.g., cost of running the hospital activity) (Evans et al., 2004). The LCC, together with an estimate of the value created by the activity in the facility, is important to make the right decision. Life-cycle costs comprise all the expenses incurred during the lifetime of the product, work, or service to have an overview of the complete cost picture.

Sylte et al. (2017) assessed factors affecting the investment cost of a sports hall and created awareness about these factors to help the future implementation of sports halls. Little research has been found about the size of facility management costs and the relationship between construction costs and operation and maintenance costs. Research shows that due to the gain in health effects, the benefits of sports facilities are three times the construction costs (Strøm et al., 2022). Compared to general building projects, some additional aspects that need to be addressed when constructing sports facilities are under consideration. This includes concerns about a country's vision and objectives for sports and activity in society. However, sports involve a vast pool of conflicting perspectives and stakeholders, e.g., different sports federations, sports clubs, varying levels of knowledge, resources, and financial strength. The different perspectives affect the perception of value and the motivation for value delivery. Also, there is often some amount of voluntary work related to the planning and constructing of sports facilities. So, what reflections do you need to do to create value at sports facilities?

This research aims to elucidate and increase our knowledge about the relationship between sports facilities' construction costs, operation and maintenance costs, and the value generated by them. The following research questions are defined:

- RQ 1: How do the construction costs correlate with the operation and maintenance costs in sports facilities?
- RQ 2: What are vital value considerations when constructing a sports facility?

The study is limited to Norwegian sports facilities. In Norway, many sports facilities are built, with a total building cost of about 500 million USD per year (Sylte et al., 2017). Gaming funds, which is profit from the National Lottery of Norway, partly fund the facilities. The Norwegian government owns the National Lottery, and the gaming funds are distributed by the Norwegian Ministry of Culture and Equality (Norwegian Ministry of Culture and Equality, 2022). The average funding from gaming funds is around 20%. The rest is financed by the municipality, the sports club, sponsors, etc.

METHOD

To answer the research questions, we conducted a literature and document study. In addition, we participated in a workshop organized by the Norwegian Olympic and Paralympic Committee and Confederation of Sports (NIF), where all the sports federations in Norway were represented. In the literature study, we used the databases Oria (Norwegian University of Science and Technology's online university library) and Google Scholar, searching for combinations of "cost, "Life Cycle Cost," "value/benefits," and "sports facilities." Not much relevant literature was found covering the cost, LCC, or value of sports facilities, but we found some literature covering other types of facilities. We reviewed the top 50 hits in the searches to identify relevant literature sources.

The data in the document study is collected from the Norwegian web page www.godeidrettsanlegg.no (Gode idrettsanlegg, 2023). "Gode idrettsanlegg" (GIA) can be translated to "Excellent Sports Facilities." The Centre for Sports Facilities and Technology (SIAT) at the Norwegian University of Science and Technology (NTNU), NIF, and the Norwegian Ministry of Culture and Equality finance this web page. Its purpose is to contribute to high-quality sports facilities' building and operation. The web page intends to publish articles, news, information about sports facilities, and tools and guides for successful sports facilities. Notably, "Excellent Sports Facilities" also publishes and presents model sports facilities (MSF). These MSFs are facilities that stand out as exemplary, for instance, in terms of cost, effectiveness, use, innovation, or cooperation between sports. The MSFs are recommended to GIA by the national sports federations to ensure that the best sports facilities from the different sports become MSFs.

Among the data obtained about the MSFs are the construction cost, the operation and maintenance cost, and the facility area. As a result, GIA holds cost data for many MSFs.

PROCESSING OF DATA

The study has investigated the indoor sports hall facility category, as this category receives most government funding through gaming funds (Norwegian Ministry of Culture and Equality, 2021). The MSFs included in this study are categorized as indoor sports halls by GIA. When conducting this study, we have not further assessed which MSFs can be classified as indoor sports halls. As an example, gymnastics facilities are not counted as indoor sports halls, while indoor sports halls containing gymnastics facilities, among other facilities, are included.

GIA does not obtain information about when the model sports facilities were completed during the completion year, so all construction costs are set to December of the completion year when indexing. This assumption will probably not impact the result significantly, considering the limitations of the data.

The cost data from GIA are given in NOK but are presented in USD for this paper. The exchange rate fluctuates around 10 NOK per USD, so for simplicity, we are using an exchange rate of 1 USD = 10 NOK for all data in this paper.

TOOLS

The collected data were systemized and analyzed in Microsoft Excel. The indexed construction cost is based on Statistics Norway's construction cost index for residential buildings (Statistics Norway, 2023). The chosen index and inputs are considered the most representative.

LIMITATIONS

The collected data has some inconsistency. The information was not easily comparable as different people gathered the information at different times and from various sources. Also, as the data was not initially collected for research purposes, there has been a lack of consistency in how data was gathered. We left out several facilities due to the need for more consistency in the data. However, this ultimately led to more consistent results for comparison.

THEORY

LIFE CYCLE COST IN CONSTRUCTION

A project goes through different stages, from initiation, design, and execution to operation. Project costs are estimated during project planning through these phases (Westkämper et al., 2001). The cost estimates are used as a part of the decision basis at decision gates in the project. Costs related to planning, design, and construction are estimated, often using analog estimation in the early stages of the project (Barakchi et al., 2017). The costs of similar previously built buildings per m2 gross area are often used for estimation.

To make informed project decisions, the focus should be on Life Cycle Costs (LCC), not only construction costs. An LCC calculation considers all costs for a product or service during its life cycle (Miske, 2010). The aim of using LCC is to evaluate the cost-effectiveness of alternative design strategies by considering the potential initial and operational costs incurred over a specified period (Sadliwala & Gogate, 2022). The use of LCC has over 50 years of history and can reasonably estimate the total cost of ownership of construction assets (Sadliwala & Gogate, 2022). Despite its proven utility, successful application and diffusion within the construction domain are scarcely seen (Manewa et al., 2021). According to Sadliwala and Gogate (2022), there needs to be more data available for implementing LCC in construction. Costs of the life cycle should include at least three groups of costs (Miske, 2010): 1) costs for the acquisition of the building, 2) costs for the use of the building, and 3) costs for the deconstruction of the building.

The cost of building procurement includes all planning, design, and construction expenses. The Norwegian standard NS3453 states what costs should be included in a cost estimate for a building (Standard Norge, 2016). Included should be all the costs related to the building, installations (e.g., electrical, HVAC, etc.), outdoor works, general expenses (planning costs, design costs, project management costs), special costs (plot costs, VAT, furniture, etc.), expected additions and project owner reserves. Final costs should count all the costs related to the building according to the NS3453 and will also include the impact of the uncertainties and use of contingencies. For sports facilities, Sylte et al. (2017) show a variation in construction costs for sports halls, where costs depend on the project delivery model, location, project ownership, and whether the sports hall is part of a school project. By monitoring the construction costs of sports halls in Norway, SIAT has discovered that these costs have grown over time (Sylte et al., 2017).

According to the International Facilities Management Association (IFMA), the costs for the use of a building, the *facility management costs*, or operation and maintenance costs (OM) used as an expression in this paper is associated with a maintenance cost, replacement cost, janitorial cost, cost of moves, indirect cost, utility cost, life safety cost, support and project costs (security, space planning, and employee amenities), and financial indicators (lease, fixed assets, and operation, among others) (Islam et al., 2019; IFMA, 2023).

Lee (2012) shows that multiple studies investigated the ratio of relative costs in owning and using a commercial office building. With a construction cost of 1, Evans et al. (2004) found operation and maintenance (OM) costs to be 5 over the lifespan of the building, while Hughes et al. (2004) found the ratio to be 0,4, and Ive (2006) found the ratio to be 1. The business operation costs are shown to be considerably higher, from 200 (Evans et al., 2004), 12 (Hughes et al., 2004), and 15 (Ive, 2006) times the construction costs.

VALUE GENERATION

Values and Value

A value focus is essential in Lean theory. The report from Lauri Koskela from 1992 was, in his effort to conceptualize the Lean production philosophy for construction, one of the first to emphasize how important customer value is in construction projects (Koskela, 1992; as cited in Tillmann & Miron, 2020). In the Transformation-Flow-Value generation (TFV) theory, eliminating non-value-adding activities (waste) is the main principle for the flow view. The value generation view is about creating value for the customer by fulfilling requirements, with the principle of eliminating value loss (achieved value compared with the best possible value) (Koskela, 2000).

There is ambiguity related to the term *value*. Due to the lack of a commonly accepted definition, the concept of value is associated with some confusion. As a response, a comprehensive definition of the value term for a Lean Construction context was presented by Drevland et al. (2018) through nine tenets. In this definition, they maintain that values (plural) and value (singular) differ. Values are essential for guiding someone's evaluative judgment. In contrast, value is the outcome of an evaluative judgment based on knowledge and driven by values. Similarly, Tillmann & Miron (2020, p. 107) state that "values are related to core beliefs, morals, and ideas, while perceived value is related to a judgment of an object by a subject."

Organizational values possess several values that make up a value system. These characteristics make it difficult to isolate for analysis. This contrasts with personal values, which are values possessed at an individual level and are, therefore, easier to isolate (Schwartz, 1992; as cited in Bourne & Jenkins, 2013).

According to Aadland and Askeland (2019), values create the intentional basis for actions, the direction for actions, and the basis for interpretation in evaluating actions. This ultimately means that all actions are based on values. There is a saying that every well-written villain is a hero of their own story (Vogler, 1992). All actions – good or "evil" - are first and foremost based on the practitioner's perspective, who performs actions based on their values.

The core principles of Lean Construction are adapted from production theory. The ultimate goal of LC can be described as generating value for the customer and avoiding non-value-adding activities (i.e., waste) (e.g., Koskela, 2000; Bertelsen, 2001; Tillmann & Miron, 2020). Woodruff (1997) argues that, when generating customer value, one takes the perspective of an organization's customers by delivering a product based on the customer's needs. Projects, however, are complex one-off events characterized by multi-stakeholder environments. Thus, multiple perspectives exist (Tillmann & Miron, 2020). So, who is the customer in a construction project? The term *customer* is closely related to what is referred to as a *stakeholder* in project management literature and may refer to everyone affected by the project, not only the paying customer (Drevland & Tillmann, 2018). Based on the stakeholder typology from Mitchell et al. (1997), Drevland and Tillmann (2018) identify four *definitive* stakeholders, i.e., stakeholders possessing all three stakeholder attributes in a project (power to impose, legitimacy, and urgency): the owner, the designer, the builders, and the society at large.

With the condition that projects are systems for value delivery, Drevland and Tillmann (2018) explore the question of whom value should be delivered to in a project and that the question is a matter of value philosophy. They argue that the key to deciding whose value matters lies in understanding the motivation for the value delivery and identifying three causes for value delivery:

- **Transactional motivation:** Centers around a formal transaction between two or more parties.
- **Selfish motivation:** Any action a party takes to exploit contractual ambiguities, motivated by greed, self-preservation, or interest in maintaining a good relationship or reputation for future business.
- **Altruistic motivation:** Delivering value, not by formal transactions or for egoistic reasons, but for altruistic reasons. Corporate Social Responsibility, for instance.

The definitive stakeholders will always matter, and their motivation is mainly transactional. Value delivery is based on selfish or altruistic motives when going beyond formal contracts and regulatory constraints.

A cost-benefit analysis contributes to a solid, transparent, and comparable decision basis for politicians and other decision-makers when evaluating different concepts (DFØ, 2018)– highlighting the effects of alternative solutions before a decision makes it easier to choose the best solution for society. When performing cost-benefit analyses, the benefits and the costs must be quantified. Not much is written about quantifying the value of the benefits of sports facilities other than by (Strøm et al., 2022). They claim that the health gained from sports facilities is three times the cost.

FINDINGS

CONSTRUCTION COSTS CONCERNING OPERATION COSTS OF SPORTS FACILITIES

The research is based on the facilities presented in Table. The facilities are, as accounted for, indoor sports halls. They generally consist of a multi-purpose court intended for basketball, handball, and volleyball but are also usable for other sports, such as futsal and floorball. Further, some facilities have separate rooms or courts for other sports, such as archery, gymnastics, sport climbing, table tennis, fitness, spinning, dancing, and fencing. In addition, the facilities offer wardrobes, toilets, common areas, spectator stands, conference rooms, and kiosks.

The different projects, their construction cost, operation and maintenance (OM) cost, usable floor area (m^2), and construction cost per m^2 are given in TableTable 1. The construction costs vary from approximately 6 to 47 million USD. The operation and maintenance costs range from about 65 000 to 880 000 USD per year. The construction cost per m^2 is divided by usable floor area, which was found to be the best representative area in a sports hall. The costs for deconstructing the facilities are non-existing and, therefore, not included in the study.

Table 1: Data from the MSFs

Facility Name	Indexed construction cost [USD]	OM cost [USD/year]	Usable floor area [m²]	Construction cost per m² [USD/ m²]
Utleirahallen	9 019 144	265 000	3 580	2 519
Hønefoss Arena	14 192 361	100 000	12 000	1 183
Sjulhustunet	24 164 973	200 000	7 700	3 151
Harestua Arena	16 863 992	210 000	4 700	3 588
Lislebyhallen	15 518 750	64 252	3 460	4 485
Bugårdshallen og Sandefjord bueskytterhall	6 188 621	455 179	8 283	1 238
ROS Arena	8 975 165	230 000	3 500	2 564

VALUE IN NORWEGIAN SPORTS

To answer what they value in Norwegian sports, we have done a document study on reports from NIF. The findings we present are valued from the top level in Norwegian sports. However, as there are many sports organizations to satisfy, it must be acknowledged that the wide variety of sports leads to many different perspectives that need to be pleased in the construction of sports facilities. In 2019, NIF collaborated with the sports federations in Norway and committed to a set of goals, strategies, and measures for the future. These decisions were presented in two reports, one for constructing sports facilities (NIF, 2019a) and one for sports policies (NIF, 2019b). The reports represent a shared understanding and agreement on which direction sports policies and sports facility construction should take in Norway. The intention was to agree on a set of goals, strategies, and measures to guide the sports federations when they make their own strategic decisions. NIF aims to work for equal opportunities for all to perform sports after their own needs and desires without being victims of unreasonable discrimination (NIF, 2019b). A strategy for achieving this purpose is presented with a vision, business idea, strategic efforts, overall objectives, and fundamental choices. These are given below.

- **Vision** – "Sporting joy for all."
- **Mission** – "Everyone should experience sports, coping, and development in the safe and sound sporting community."
- **Strategic efforts** – A set of strategic priorities for the coming years.

  - Lifelong sports – work for an inclusive and diverse community with outstanding quality to facilitate everyone to be a part of a sports community for as long as they want to.
  - Better sports teams – work for democratic, open, and honest organizations, where voluntary work, which is at the core of many sports teams, should be experienced as a safe and meaningful community.
  - More and better sports facilities – build sports facilities where desired activities can be performed. More predictable economics and environmental efforts during the whole life cycle of a sports facility.
  - Better elite sports – Norway should have world-class athletes and teams. More efforts in helping young talents reach the highest levels.
- **Overall objectives –** "Get more people involved – for longer" and "More new medals."
- **Fundamental choices –** A set of organization- and activity values to guide and improve the sports' work in the coming years.
  - Playful – A sports community where playful curiosity is not neglected.
  - Ambitious – Ambitions about development in sports and organizations for a better society.
  - Honest – Fair play. E.g., no cheating, corruption, or drug use, and equal competition conditions.
  - Inclusive – A community where everyone is seen, feels safe and cares for each other. A community where everyone feels joy and can participate on their level. Everyone is worth the same.

The overall intention for Norwegian sports is to make society better. Thus, it cannot be isolated from the society it is a part of (NIF, 2019b). This means facilitating activities in sports federations but also activities outside the federations' core affairs. In summary, the intention is to create a physically active society with a community sharing excellent sports values. Integrating the sustainability goals from United Nations (2023) is an essential part of this strategy. In collaboration with the sports federations, NIF launched a sustainability strategy based on the UN sustainability goals (NIF, 2023). They decided on five prioritized focus areas anchored in the abovementioned goals, strategies, and measures. The focus areas and associated sustainability goals are presented below:

1. Lifelong sporting joy and healthy sports (SG 3 – Good health and well-being)
2. Inclusiveness, diversity, and equality in sports (SG 5 – Gender equality & SG 10 – Reduced inequalities)
3. Ethical and forward-looking development (SG 17 – Partnerships for the goals)
4. Responsible use of resources (SG 12 – Responsible consumption and production & SG 13 – Climate action)
5. Green sports facilities (SG 12 – Responsible consumption and production & SG 13 – Climate action)

DISCUSSION

The first research question was, "How do the construction costs correlate with the operating expenses in sports facilities?". The construction costs in the study vary from 1200 USD/m^2 usable floor area to 4 500 USD/m^2. We see that still considering sports halls for similar activities, the costs vary a lot. This was also shown by (Sylte et al., 2017), who explained these variations by different project delivery systems, location, project ownership, and whether the sports hall is part of a school project. What is included in the construction costs is well defined by the Norwegian Standard (NS3453), but this standard is not consistently used when cost information is provided. This may impact the findings. For instance, it varies whether buying the plot is included (sometimes the plot is given by the municipality for free), and the amount of outdoor work varies. The same goes for the ground conditions. Further, the degree of precision and rounding differs between different MSF cost data. Lastly, as construction costs lack dating, we assumed that the cost is the final cost for the project owner at completion.

When it comes to the correlation between the operation and maintenance costs (OM) and the construction costs, the results are presented in Figure 1. Figure 1 displays a correlation between the construction and the OM costs but also offers a considerable variation in annual operation costs vs. construction costs. Through previous research, Lee (2012) shows that total OM costs over the lifespan of a building compared to the construction costs vary from 0,4 to 5 times the construction cost. Using a lifespan of 50 years and a discount rate of 4 % (DFØ, 2018), the average ratio of OM costs compared to construction costs is 0,4. The ratio varies from 0,1 to 1,6. Considering without discount rate, the average ratio of OM costs compared to construction costs is 1,0, from 0,2 to 3,7. We see a lower ratio of OM compared to construction costs for some of the sports halls than the findings in Lee (2012). However, we can see findings at the same level, depending on the assumptions used to calculate the ratio. One explanation for the variations could be that it is not very well defined for sports halls what to include in the operation and maintenance costs. For instance, OM cost may be given for the specific part or the whole facility.

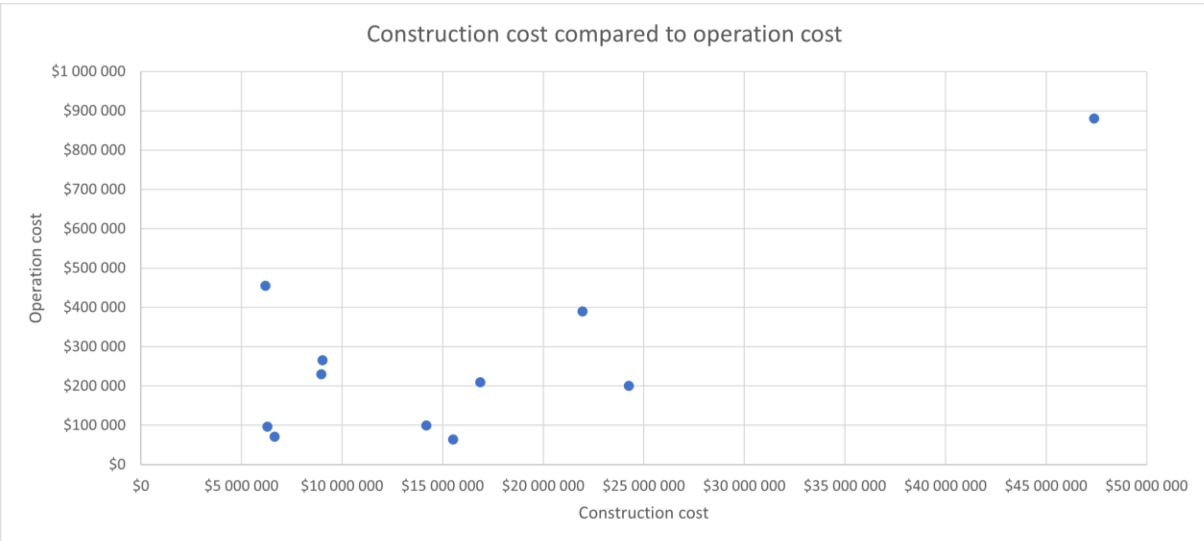

Figure 1: Construction Cost Compared to Operation and Maintenance Cost.

Furthermore, OM cost may be given with or without interest and amortization, value-added tax, or insurance. The complexity of the OM costs is also increased because many sports facilities are operated and maintained partly by the municipality and partly by the sports club. As a result, the OM costs are spread over multiple budgets, decreasing the probability of correct amounts being provided to GIA. The International Facilities Management Association (IFMA, 2023) has defined what to include in facility management costs, where the following should be included; maintenance, replacements, janitorial, cost of moves, indirect cost, utility cost, life safety cost, support and project costs, and financial costs. More unity should be implemented in sports halls regarding what to include in the OM costs.

The motivation for value generation in sports facilities depends on the perspective. Even though the sports federations cooperated with NIF to create a set of overall goals, strategies, and measures, as well as a plan for sustainable efforts, their different perspectives will affect their perception of value. Thus, the motivation for value delivery is effectively affected.

Transactional motivation: The Norwegian Olympic and Paralympic Committee and Confederation of Sports is Norway's largest voluntary organization (NIF, 2019b). Voluntary work is the cornerstone of Norwegian sports and hereby of planning, constructing, and operating sports facilities. The sports club must rely heavily on volunteers to get the work done, especially during planning and operating the facility. Sometimes also during construction, but professional contractors most often do construction with a contract with the actual municipality or sports club. Often the sports clubs manage the project execution themselves, as they are the facility owners. Consequently, this leads to variations in knowledge and experience in planning, design, and construction, depending on whether a person with construction competence is privately volunteering for a particular club. Some municipalities offer free use of the sports halls for the sports clubs; some sports clubs need to pay. An important observation is that not paying for the construction will influence users' or clubs' relations to requirements and cost.

Selfish motivation: The value delivered in sports facilities depends on the stakeholder perspective – any sports federation like to see its sport lifted to appease current members and attract new members. Sports federations might, for instance, compete for governmental funding to build a sports facility or to optimize a shared sports facility for their sport. They might have contrasting perceptions of how the space is best utilized. This can lead to one of the federations exploiting an unclear situation to generate value for their activity at the expense of other sports or activities. In those cases, the sports federation does not necessarily have bad intentions but rather a selfish motivation for value delivery. Still, such an opportunistic value approach might neglect an opportunity for a more holistic approach that could generate more value for the overall purpose of Norwegian sports, as stated in the vision and strategies from NIF.

Another question that needs answering is if mass sports or elite sports are prioritized at the sports facility. Mass sports and elite sports may have conflicting perspectives. Some sports teams have athletes competing at both the elite level and amateur or mass sports level. The Norwegian football club Rosenborg, playing at an elite level, used known Lean principles to create value for the local community. They assisted local football clubs at the mass sports level with funding and competence, intending to help them develop the next local superstar to play for Rosenborg (Malvik, 2022). In this case, the end goal shows signs of selfish motivation. However, the cause was also charitable. Value for elite sports clubs like Rosenborg is usually to win trophies and entertain the local community, which is easier to achieve by using talented (local) players. Moreover, the value of local sports clubs is to facilitate higher participation and be an arena for development and growth.

Altruistic motivation: As mentioned above, NIF is Norway's largest voluntary organization. There is much altruism tied to this voluntarism. Planning and construction of sports facilities often depend on club members or other interested people's voluntary spirit. In Norway, this is most visible on the mass sports level through sports club members or parents of members selling cake or toilet paper. However, it can also be seen at the elite sport level. For instance, supporters make supporter effects (tifos, mosaics, flags, etc.) or songs for their teams' home matches. One extreme example of voluntary work in elite sport is the German football club Union Berlin's supporters, who spent their free time and holidays working on a new modern stadium after the German Football Federation (DFB) threatened to close their old stadium for not meeting the security requirements. In total, 1600 volunteers put in an estimated 90 000 hours of work to save the club 2 million euros in construction costs (Hessler, 2009). The close-knit sports community fortified the already unique supporter culture in and around the club. It shows that even the construction of sports facilities can bring value to society through shared altruism and voluntary work.

Besides comprehensive efforts from NIF to facilitate sustainable endeavors in the construction of sports facilities, there is also demands from the government and the general public. Still, projects are not imposed a sustainable strategy, and the actual implementation of a sustainable approach is a matter for the owners of the sports facilities (usually the sports teams). Thus, the effort put into sustainability is tied to altruistic motivation. Generating value for the user is an elementary component of a sustainable strategy (Malvik et al., 2021). Therefore, a sustainability strategy is inevitably interrelated with value generation. One should ensure that the sports facility covers the needs and requirements put forward by the user and is aligned with the values NIF presents in its vision and strategies.

Strøm et al. (2022) show that the benefits of sports facilities are three times the investment costs, where health effects are counted. We have shown that sports facilities give different types of value or benefits. To do a quantitative cost-benefit analysis, we need to be able to quantify the facilities' value or benefit. The values pointed out above are not easily quantifiable. This is a central challenge when identifying the ratio between sports facilities' value and LCC.

CONCLUSION

This research is aimed to increase the knowledge about the relationship between the Life Cycle Cost of sports facilities and the value the facilities generate. We have investigated the relationship between construction costs, operation and maintenance costs, and value generated by the sports facilities by looking at sports halls.

Regarding the cost of sports halls, both the construction cost and the operation and maintenance costs vary greatly. Also, the ratio between the OM costs over the lifespan of the buildings and the construction costs varies from 0,1 to 3,7, depending on assumptions in the model. How to calculate the construction costs follow a Norwegian standard, while what to include in the OM cost is not standardized. A standard for what to include in OM cost needs to be developed. When much of the work in sports facilities is done by volunteers, it will still be unclear how to count it in a model elucidating LCC.

Diverse types of value are discussed regarding the value the sports facilities generate. A vital issue is that it is not easy to quantify the value generated by a sports facility. The value depends on your perspective if you are the owner, designer, builder, or the society at large. For sports facilities, the owner is most often the sports clubs or the municipality. Transactional motivation is, of course, necessary for the municipality or the sports club due to what often is limited funding. But stakeholders in sports clubs are highly driven by selfish motivation. Decisions during planning and construction are much driven by selfish motivation. However, we also see a lot of altruistically motivated actions in work with sports facilities at any level through the immense amount of volunteer work.

Some attempts are made to identify the cost-benefit ratio of sports facilities. However, more defined rules about estimating construction costs, quantifying operation and maintenance costs, and quantifying value must be in place. A recommendation for further work is to make a standard for what to include in the OM costs. Also, methods need to be developed to standardize what value parameters to include and how to quantify them.

IPD EN FRANCE: IS IT LEGAL?

Emna Attouri[1], Alan Mossman[2], Laetitia Fehlmann[3], Ian Heptinstall[4], and Laure Ducoulombier[5]

ABSTRACT

Normal design and construction creates poor project outcomes and low productivity. Integrated Project Delivery (IPD) was introduced as a response to these and other shortcomings. Despite the advantages this method provides, IPD is not used in France. This paper discusses different interpretations of French procurement legislation and regulations. French procurement legislation is based on the *European Directive 2014/24/EU on public procurement*. Based on the way the Directive is understood in other EU countries this paper suggests that there is no legal reason why IPD cannot be used for both public and private construction in France. Some will doubtless suggest that this needs testing in the courts before they will risk using it. Limitations of this paper are that it is based on the opinion of a single French construction lawyer and observation of what happens in other EU countries. The implications of this paper for public and private sector clients in France are that they can consider using IPD for more complex projects in their portfolio; for practitioners it is a signal that they can start to learn how to deliver projects using IPD and Target Value Delivery (TVD); for francophone scholars there are whole new areas for research.

KEYWORDS

Integrated project delivery, collaborative contracting, legal barriers, habit barriers, system change.

INTRODUCTION

As elsewhere, construction is very important for the French economy. *As elsewhere,* construction in France is dominated by “*normal*” construction procurement using bilateral, transactional and adversarial contracts. *As elsewhere*, this approach to construction procurement does not deliver what customers want (Barbosa et al, 2017; Egan, 1998).

Construction clients want projects delivered on time, on budget with full scope (Mossman & Ramalingam, 2021). As elsewhere, construction clients in France rarely get this level of service from *normal* construction.

Normal construction systematically separates design from production. The construction sector is the only major industrial sector where this still happens. The result is that designers lack good cost information during the design process and frequently produce designs that are difficult to build. This frequently means that designs need to be reworked (de-scoped) to meet the client cost criterion and to make the project more buildable. This separation often creates

claims, conflicts, mistakes, costly corrections (rework), and delays. As construction projects become more complex, there are increasing schedule and cost pressures and a growing quest for sustainability and quality. These pressures, the fragmentation of the construction sector and the adversarial relationships that flow from the use of *normal* bilateral, transactional and adversarial contracts put the people involved under significant stress.

IPD can address the problems listed above (Ashcraft, 2022). IPD is a relatively recent way to procure construction based on a relational contract. Only construction customers (clients) can choose to procure in this way.

Most adults in France, as elsewhere, have experience of relational contracts (they signed up to one when they got married). Relational contracts for construction have existed since 1992 in UK, since 1997 in Australia and since 2004 in the USA (Mossman, 2023). In France, this type of contract is not widely known in construction, perhaps because of the language differences.

Some people see barriers to the use of IPD. Since research has been done on IPD application elsewhere, the purpose of this paper is to understand what, if any, legal obstacles there are to the use of IPD in France.

Following the method section, this paper introduces IPD and its key elements and then discusses the potential legal barriers to its adoption by French construction customers.

The research question answered in this study is: *Can public and/or private sector construction customers use IPD (relational) contracts to procure construction in France?*

METHOD

The research method used in this paper is a literature review of IPD and its main characteristics. Then, one of the authors, an experienced construction lawyer reviews a representative IPD contract to identify the legal challenges in France. Her opinion is then challenged by other authors with knowledge of the use of relational contracts in other EU countries that have adopted the same EU Directive (EU 2014) in their own legal code and are already using relational contracts for construction. A content analysis of the French legislation was carried out to answer the concerns raised by the construction lawyer.

LITERATURE REVIEW

The use of collaborative/relational contracting to improve the performance of construction type projects came to prominence in the 1990s in the UK process industries. It built on the previous ideas of partnering by incorporating them into a contractual agreement. Known as *project alliancing*, by the early 2000s its use had spread to the public sector in Australia and from there to Finland in the 2010s. The term IPD emerged in the US in the early 2000s during initiatives to address poor project outcomes of *normal* construction methods – they fail to deliver projects to cost, schedule, and quality (Ashcraft, 2022). To overcome these limitations, Will Lichtig created a multiparty agreement, the *Integrated Form of Agreement* (IFoA) (Lichtig, 2006) for Sutter Health. The IFoA requires key delivery partners to pool their proposed profit *at risk*, jointly manage the project through consensus, and use lean processes during design and construction. In 2007, an American Institute of Architects, California Council group named this approach *Integrated Project Delivery* (IPD) (AIA CC 2007). IPD is an approach to agreements and processes for design and construction (Zhang & Chen, 2010).

IPD developed in the US within the Lean Construction community as a holistic approach to both contracting and to delivering projects. This paper is only looking at the narrower procurement/contracting aspects, making IPD the same as *project alliancing*.

IPD is now seen as a method with the potential to revolutionize project delivery. While *normal* delivery methods are based on transactional contracts, IPD is generally based on a single relational contract. "*Relational*" because consideration is given to the quality of relationships and processes, not just to the end product (Roy et al., 2018). It is a project delivery approach that integrates people, systems, business structures and practices into an innovative process that collaboratively harnesses the talents and insights of all participants to reduce waste and optimize efficiency through all phases of design, fabrication, and construction (AIA CC 2014).

Different organizations approach IPD differently. There are, however, consistent similarities that have been found within most IPD projects and definitions. At core, an integrated team jointly develops project targets, makes decisions by mutual consensus and shares the risks and rewards for achieving them (Azhar et al., 2014).

IPD uses relational contracts — ideally a single agreement that all key participants sign including, at least, the client, lead designer and lead builder. Specialist trades and specialist designers are often added to the contract when they are in a position to significantly affect the project outcome. Use of these relational contracts is common in Australia, New Zealand, the US (Gokhale, 2011) and more recently in Canada and Finland. Clients in other countries are catching on.

For this paper, we use the elements of IPD defined by Rubel and his colleagues from The American Institute of Architects California Council in the second AIA CC report on IPD (AIA CC, 2014). These are listed in Table 1.

Table 1: Main elements of IPD (AIA CC 2014)

Structural elements		**Behavioural elements**
Business model	**Contract structure**	**Enabling behaviours**
Profit separated from cost	Early involvement of key participants	Optimize the whole, not the parts
Costs guaranteed to completion	Jointly developed and validated targets/goals	Trust
Limited entitlement to change orders	Shared risk/reward, based on project outcomes	Integration of information, people, and systems
Profit based on agreed project outcomes	Joint project control and decision-making	Continuous improvement/ learning
	Reduced liability among risk/ reward members	Appropriate use of technology
		Collaboration

Different definitions and widely varying approaches and sophistication levels mean that the term "IPD" is used to describe different contract arrangements and team processes (Kent and Becerik-Gerber, 2010). Other characteristics of IPD are mentioned in other studies. For example, Cohen (2010) mentions the use of a multiparty contract and collaborative decision making. Others write about the use of Target Value Delivery (TVD) and designing to cost. Table shows the frequency of each characteristic observed in different studies defining the delivery method reviewed by Barutha (2018).

Table 2: Literature review of commercial IPD characteristics listed (Barutha, 2018)

	(Kent & Becerik-Gerber, 2010)	**(Ashcraft, 2012)**	**(NASFA, 2010)**	**(Lahdenperä, 2012)**	**(Cohen, 2010)**
Early involvement of key participants	x	x	x	x	x
Shared risk and reward	x	x	x	x	x
Collaborative decision making and control		x	x	x	x

Jointly developed and validated targets		x	x	x	x
Liability waivers among key participants		x	x	x	x
Multi-party agreement	x			x	x

Both Tables 1 and 2 reflect IPD's origins in the lean construction community in the US. Lean methods are integrated into the contracts and/or the execution strategies.

IPD is designed to increase collaboration, align the interests of different stakeholders, and encourage actions that add value to the project. It uses a relational structure with shared risk and reward to create a system that enables and supports collaboration. Delivery partners are generally bound together with a multiparty agreement that includes at least the client, the lead designer, and the lead builder. Key consultants and trades can also be included in the agreement (Fischer et al., 2017). An IPD agreement places authority within the team (which includes the client). Projects are jointly managed so that shared risk is balanced with joint production control so that work is more likely to flow. IPD requires jointly made and validated decisions which enable the team to stay aligned to the project targets. It generally limits liability among delivery partners which enables them to share information in a secure way. In contrast, *normal* construction agreements are made independently between two parties at a time and focus on transferring risks. It discourages behaviours that create value for the client but are not required (or rewarded) by the contract, and results in siloed working, protective and defensive behaviour, keeping information close.

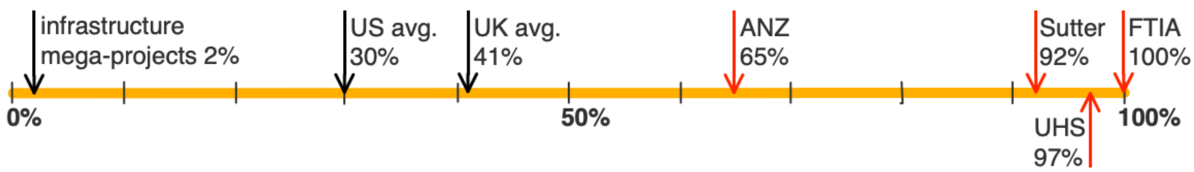

Figure 1: Percentage of projects delivered on-time *and* on-budget. All the projects at the right-hand end – ANZ, Sutter, UHS and FTIA – are IPD or *project alliances*. *Sources*[6]

As Figure 1 and Ashcraft (2022, Table 2) demonstrate, IPD has shown a positive effect on cost, schedule, quality and team morale; researchers have shown IPD projects to be significantly less expensive than Construction Management at Risk and Design-Build comparisons; others found significantly higher satisfaction with IPD on cost, schedule, and quality than other delivery systems; 86% of IPD projects reported an increase in the profit pool as performance exceeded initial expectations; pair-wise studies found that IPD is statistically superior in some aspects, although the specific benefits differed among studies (though some dispute this finding); in other research, IPD projects outscored other project delivery systems and a model using characteristics correlated with project success has predicted better outcomes using IPD for complex projects (Ashcraft, 2022; Cheng et al., 2015; Walker, Harley and Mills 2015).

Though IPD is not yet widely used, it is known as an efficient construction project delivery method. A study, led by Kent and Becerik-Gerber (2010), surveyed several owners, contractors

[6] **infrastructure mega-projects**: on time *or* on budget – Companies public annual report; HIS Herold Global Projects Database, press release 19 Nov 2013 widely quoted; **USA avg**: Construction Industry Institute 2012 Sample of 957 projects avg. US$65m; **UK Avg:** calculated from 2020 Glenigan data for all Non–Housing Construction; **ANZ**: 61 Australian and New Zealand Alliance Projects, 85% on- or below budget, 76% on-time or better, limited use of *lean* thinking. (Walker, Harley and Mills 2015); **Sutter**: 24 projects 2007-19 worth $4.7bn. Overall, 5% under budget with no scope compromises; **UHS** (United Healthcare Services)**:** 40 IPD Projects completed 2007-14 in USA, US$2m-150m (Seed 2014); **FTIA** (Finnish Transportation Infrastructure Agency)**:** 10 IPD projects 2011-22 avg. value €81m.

and designers and revealed that fewer change orders, cost savings, and shorter schedules were listed as the most beneficial aspects of IPD compared to other delivery methods. In addition, case studies of completed IPD projects show the successes realized by project stakeholders.

Companies in the French construction sector are now waking up to the possibility that IPD can help to align the interests of clients, designers and constructors and simulate the collaboration and litigation free characteristics of a single organization (Thomsen et al, 2009).

IPD incentivises delivery partners to collaborate and look out for the interests and success of both the project and of other delivery partners.

KEY ELEMENTS OF IPD

For most people in the construction sector, there is no clear understanding of what's involved in IPD (Kent and Becerik-Gerber, 2010). That is still the case. The following section is a short brief for those not familiar with it.

SELECTING DELIVERY PARTNERS

Construction clients select their delivery partners for IPD projects in a variety of ways.

In the private sector it is not uncommon for the client to select either the designer or the constructor first, to agree the profit that organisation wishes to make on the project and then for the two of them to identify a lead constructor or designer that they can work with and agree with that organisation the profit they want to earn from the project. This snowball type process continues until all the key delivery partners are selected. Key delivery partners are those that can seriously affect the success or failure of the project. This method is not generally possible in the public sector unless it is associated with appropriate open competition.

In the French public sector, as in most parts of the world, it is necessary to organise an open competition where the selection criteria are known from the outset – in Europe they are included in the advertisement published in OJEU, the Official Journal of the European Union. This is the first step in the procurement process.

Finnish public sector IPD projects are procured in this way using a model developed with and for public sector clients in Australia (Ross, 2003) and selection is usually based 60% on quality criteria and 40% on cost. The cost assessment uses the amount of profit that the bidder wants to make from the project and the schedule of rates that they will use to recover their direct production costs and project related overhead during both design and construction. The Finns are clear that having the right people in the project team is vital. They recognise that at the start they don't know exactly what they want to do. According to Finnish construction lawyer, Juha Virolainen, they work to select the *people* who can create the most advantageous project. When selecting partner companies, they are most interested in the people who will represent that company, their IPD experience, their relevant construction experience and their professional skills. "We [assess] skills with case examples or questions. Only named key personnel can participate in these workshops, case examples and *exams*, so the company's best writers cannot answer for them" (personal interview & email with one of the authors).

Finnish procurement law is based on European Directive 2014/24/EU on public procurement (EU 2014) and, as Virolainen pointed out, there is no requirement in the directive for the whole project cost to be known in order to make a selection[7]. French procurement law is based on the same directive. If the Finnish public sector is allowed to procure in this way, why shouldn't French public sector clients be allowed to operate in this way too?

[7] As one author of this paper has pointed out, in 'normal' construction the acceptance of the lowest bid does not mean that the final cost is known at the time of selection either. As noted above, the successful bidder is likely to be looking for opportunities for change orders and claims to increase both the cost and the profit on the project.

AGREEING COST

In *normal* construction the customer pays the contractual price for the work (the agreed tender price + any agreed or awarded claims). This generally means that doing more work creates a bigger profit for the constructors. This leads constructors to bid low and increase the cost during the project at every opportunity through change orders and claims. Once in contract, the actual cost is generally irrelevant!

IPD projects use *target costing*. Target costing shifts production cost from a fixed to a variable amount with profit and market price established upfront (Tillmann et al., 2017). If delivery partners reduce the amount they spend on staff time, materials, etc., (their production costs) their profit increases. This incentive aligns the interests of the designers and constructors with those of the customer (to build a project that meets the requirements of the customer and end-users within their budget). This helps the customer have greater cost certainty while enabling the delivery team to increase their margins.

Many IPD projects include Key Performance Indicators/Key Result Areas (KPI/KRA) that affect the size of the incentive/profit pool.

Normal construction:

Price = Agreed tender price (incl profit) + agreed/awarded claims

IPD Target Costing:

Profit = % of ((Agreed Cost – Actual Cost of work) + KPI/KRA ±bonuses)

Before starting an IPD procurement process the construction client prepares a business case for the facility they are considering. The business case includes information about the economic and other benefits to the client organisation of the proposed facility as well as a review of how much the organisation is willing to pay to acquire those benefits. Once the business case is clear, the client goes to the market to find delivery partners with whom they can work to deliver the facility. Delivery partners are chosen using several criteria which generally include a schedule of rates for members of staff and the profit they expect to earn from the project if it is successful.

Once the key delivery partners are selected and they agree the basic principles of the IPD contract, it is possible to move to the next phase – getting agreement about how much it is likely to cost to deliver the full scope requested by the client within the client's timeframe. This cost – the *Target Cost* – is agreed in a process called *Validation* (Grau et al., 2021). Additional delivery partners may be added to the relational contract during this process as they are identified and selected. The conceptual estimates of cost are made by the constructors who are expected to deliver the project to the price they have estimated.

The delivery team then designs both the facility and the delivery system so that the scope requested by the client is delivered within the time and agreed Target Cost using the Target Value Design (TVD) process (Tillmann et al., 2017). Using TVD requires the delivery partners to design to cost. The estimated future cost is calculated on a regular basis, generally twice a month, so that the delivery team are quickly able to see the effect of their decisions on the anticipated profit that they will make.

How Are Delivery Partners Paid for Their Work?

Delivery partner		*profit ++*	*proportion*
Designer	D	75,000	10.73%
Builder	B	205,000	29.33%
Structural Eng	S	15,000	2.15%
Services Eng	S	20,000	2.86%
Mechanical	M	55,000	7.87%
Electrical	E	38,000	5.44%
Plumbing	P	27,000	3.86%
Groundworker	G	42,000	6.01%
Security	S	15,000	2.15%
Mechanical C	MC	120,000	17.17%
Electrical C	EC	87,000	12.45%
	total	**699,000**	100%

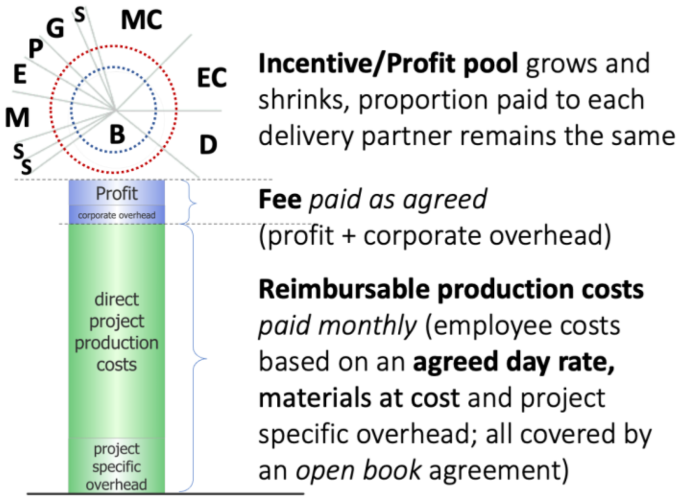

Figure 2: How do delivery partners get paid? Project production cost payments and incentive pool (= fee) Source: Mossman with permission; image derived from Ross (2003), Wilson (2014), Morwood, Scott and Pitcher (2008) and Fischer et al (2017)

Figure 2 shows how much profit the delivery partners to a relational contract have agreed (left hand side). The total is poured into an incentive/profit pool (the fee) and the delivery partners agree that each will receive that percentage from the pool no matter how large or small the pool is at the end of the project. So, the mechanical contractor (MC) for example will receive 17.17% of the profit pool at the end of the project. If the delivery team are successful in keeping the reimbursable costs (green bar) below the total agreed with the customer, some of the saving will be added to the project pool and the remaining saving will go to the customer. The contract may also include additions to – or deductions from – the incentive pools that depend on how well the delivery partners have addressed the client's KRA and/or KPI.

If the reimbursable costs exceed the total agreed with the client, the profit pool related to the project costs will shrink. Most clients recognise that if they wish to retain the project team as *advocates for the project,* they need to ensure that delivery partners do not make a loss. What this means is that the delivery partners may make no profit (the pain), but all their costs will be reimbursed and the customer will pay anything over and above the reimbursable cost plus fee agreed at the start of the project. So far as the authors are aware, this has only happened once.

How Are Payments Agreed?

Figure 3 shows the process flow of a typical IPD project using TVD. Notice that the key project delivery team members are assembled from the beginning (1). They first work together to agree each party's production cost rates, project specific overheads and fee (profit + corporate overhead at risk). Agreement of the contract terms and conditions is the first step in validation (2) – these discussions help to build the team while building a foundation for understanding the business case and the *Conditions of Satisfaction* for the project. The key task in validation is to establish if the project can be delivered within the budget and timescale requested by the customer. If they feel it can be, there are final negotiations on the contract terms and conditions, schedule, the people who will be involved, hours teams will spend in the co-location space, and risk/reward arrangements so that these can be included in the contract.

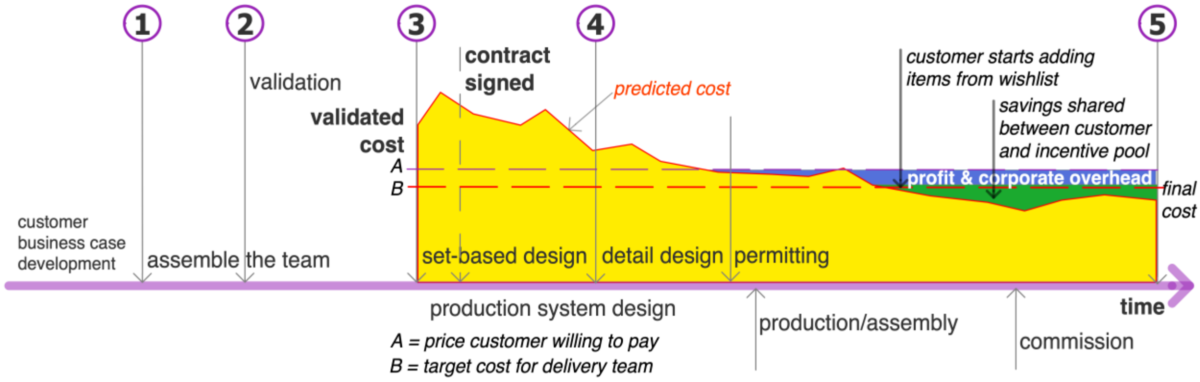

Figure 3: TVD process flow (Mossman with permission)

They work collaboratively from (3) to deliver the project. Project cost is regularly tracked and the total estimated cost is updated every 2 to 4 weeks. Because the constructors are already members of the delivery team, it is they who provide the cost estimates; they have *skin in the game* and is it in their interest to produce the best possible estimate they can. Their estimates may be reviewed by cost consultants. As details of the design become clearer the estimates become more and more accurate and monies that may have been initially allocated to contingency diminish. The predicted cost between (3) and (5) generally falls. At some point the predicted cost generally falls below the total price the customer wants to pay (A) and there is then *some* money in the profit pool to be shared between the delivery partners. When the predicted cost falls below the allowable target cost (B) some of the savings made are added to the incentive/profit pool. Some customers use the savings that they receive to buy additional scope from their *Wish List*. This additional scope adds to the funds in the profit pool.

ARE THERE LEGAL BARRIERS TO USING IPD IN FRANCE?

In this section, potential legal barriers to implement IPD in France are presented for both public and private sector based on the contract review done by one of the authors, a construction lawyer.

There are no legal obstacles to the private sector using IPD.

The principles on which an IPD contract is based (payment terms, limitation of builder and designer liability, early termination of contract) do not contravene the rules of public policy applicable to private contracts under French law.

The Public Procurement Code (*Code de la Commande Publique*, "the Code") requires, with some exceptions, the use of competitive procedures for the award of a public contract. Article L.2152-7 of the Code requires the contracting authority to award the contract to the tenderer who has "*submitted **the most economically advantageous tender"*** on the basis of one or more precise objectives linked to the subject of the contract or its performance conditions.

Art. R.2152-7 states: "*In order to award the contract to the tenderer or, where applicable, to the tenderers who have submitted the most economically advantageous tender, the purchaser shall base himself either 1) on a single criterion which may be (a) the price, provided that the sole object of the contract is the purchase of standardised services or supplies whose quality cannot be varied from one operator to another (b) The cost determined according to an overall approach which may be based on the life cycle cost defined in Article R. 2152-9. Or 2) on a number of non-discriminatory criteria linked to the subject-matter of the contract or its performance conditions, including the cost criterion and one or more other criteria including qualitative, environmental, or social aspects*. [...] " (Légifrance, 2023)

It follows from the above that the cost criterion must necessarily be considered for the award of a public contract. This criterion is important, but it rarely represents more than 50% of the overall assessment score. The notions of "price" and "cost" are not defined in the Code. Almost all public design and build contracts are awarded based on a global and, often, fixed price.

On the day an IPD contract is signed, the programme has not been decided and the overall price is neither determined nor determinable. These elements are defined by mutual agreement between the delivery partners during the *validation* phase and become part of the contract during the early part of the design phase provided the total price is within the client's budget.

The only financial information generally communicated to, and agreed with, the client by delivery partners prior to the start of the validation phase is the hourly or daily rates for the people who will do the work and the amount of profit and corporate overhead (the **fee** in Figure 2) to be earned if the project is delivered successfully.

RESULTS AND DISCUSSION

There appears to be no legal barrier to the private sector using relational procurement in France. The private sector is not subject to the Code. Private clients have the option to a) Negotiate with delivery partners that it has chosen and conclude a contract by mutual agreement, or b) Set up a competitive process based on freely defined criteria. Both can be used with IPD contracts.

Is there a legal barrier for the public sector?

The Code requires selection based on competition and allows for decisions based on a balance of criteria that must include some element of cost - there is an acceptance that the financial criterion can be weighted below 50%. When using the Competitive Dialogue and Innovation Partnership procedures, the Code requires the use of cost rather than price (Art. R.2152-8). The EU 'competitive dialogue' and 'innovation partnership' procedures are two of the EU procurement procedures suitable for use with IPD. A third approach the 'negotiated' procedure has been used to procure public sector construction works in Finland since 2011 (Lahdenperä, 2013). This also demonstrates the feasibility of using the IPD contract approach in compliance with EU Procurement Regulations (EU 2014), which are the basis of the French Code[8].

IPD delivery partners are selected using competitive criteria: e.g. competence, capability and experience as well as price/cost. Can the financial requirement of the code be satisfied by the potential delivery partners' schedules of rates and the amount of profit and corporate overhead that they expect to earn (the **fee** in Figure 2) if the project is completed successfully?

The legal advice received suggests that the available financial information (Schedule of rates and expected fee) is insufficient to enable the client to assess the price or cost criterion within the meaning of Art. R.2152-7 (see above) of the Code. Yet the Code Art. R.2112-6 makes it clear that the inability to determine a final project price is not an obstacle to public procurement, nor is the use of defined unit rates and unknown quantities. In Art. R.2152-9 and -10, the Code gives an example of a cost criterion – lifecycle cost. This includes elements that are unknowable at the time of the contract. The requirements for such a criterion are that it is non-discriminatory, clearly defined and objectively verifiable.

Art. R.2112-6 of the code allows for unit-rate reimbursable contracts. This suggests that the inability to determine a final project price is not an obstacle to public procurement, nor is the use of defined unit rates and unknown quantities.

Despite this, the legal author feels that the use of an IPD contract in the public sector will be difficult to reconcile with the competitive tendering procedures imposed by the Public Procurement Code. That constitutes a barrier to public sector IPD implementation.

Two of the other authors believe that the legal author's interpretation of the law is influenced by her experience of the *normal* way of doing things – the Design-Bid-Build, DBB way. In the DBB way there is an agreed sum for the completion of the project written into the contract.

[8] Although the Finnish use of IPD pre-dates the current version of the EU procurement regulations (EU 2014), the procurement procedure they used (the 'negotiated procedure') was established in earlier versions of the EU procurement regulations and continued in the 2014 version.

It can be argued that when a DBB, contract is signed the final cost is not known. There is an agreed sum for the completion of the project, but almost all construction using DBB costs more than the agreed sum (claims) or delivers a reduced scope. With IPD, clients often spend less than the agreed cost and get greater scope than anticipated. Which of those procurement routes is more *economically advantageous*?

Many government lawyers and many who procure construction for public sector organisations are likely to interpret the code in the same way as the legal author. What this suggests is that the interpretation of the code needs further opinions. Some will doubtless suggest that this needs testing in the courts before they will risk using it. They might have a long wait. An Australian review of AU$43bn worth of projects found zero AU$ spent on dispute resolution (Victoria, 2009)

IPD is a *system change* in construction procurement. As a system change, it requires new thinking habits, new concepts and new language (e.g. *delivery partner* or *trade partner* instead of (sub-)contractor, tier 1-n, etc.). It is difficult, even impossible, to do IPD with a mindset from *normal* construction. These are reasons why it is often difficult for people embedded in *normal* construction to understand what is involved in IPD.

As clearly illustrated in Figure 1, data from IPD-type contracts suggest most contracts complete on or under the target cost and on or ahead of time – the opposite of the outcomes of *normal* contracts (Cheng et al., 2015; Walker, Harley and Mills, 2015). This data also suggests that IPD is more likely to be the *most economically advantageous* procurement route for any public-sector client *provided* they can be sufficiently involved in the management of their projects. Active client engagement in IPD helps to increase the chances of success (Seed, 2022).

CONCLUSIONS

This study aims to identify the legal barriers in adopting Integrated Project Delivery in the French context. First, the challenges that construction sector is facing are highlighted to show the need for an alternative delivery model. Then the main IPD main characteristics are presented. The third part of this paper focuses on the legal – and related – barriers to IPD adoption in both public and private sector.

There are no legal obstacles to the private sector using IPD. The barriers that exist are in the mind and are related to habitual ways of thinking about project delivery.

The review has also demonstrated that the principles on which an IPD contract is based (payment terms, limitation of builder and designer liability, early termination of contract) do not contravene the rules of public policy applicable to private contracts under French law.

The Public Procurement Code requires selection of “the most economically advantageous” offer based on advertised and non-discriminatory criteria that can be qualitative (such as competence, capability and experience) as well as price/cost. In *normal* construction this is often interpreted as the *lowest bidder* even though that is rarely the price finally paid.

IPD uses value-driven selection criteria incompatible with the idea of the lowest bidder. IPD is a system change in construction procurement that requires different thinking and different concepts. It is as if *normal* construction is from Mars and IPD is from Venus.

There is nothing in the Public Procurement Code that requires public sector clients to procure lowest bidders. Over two decades of experience with IPD and similar approaches suggests that *active* clients using a relational contracting approach can provide the *most (economically) advantageous* project outcomes for all stakeholders.

Despite that, our lawyer’s interpretation of the Public Procurement Code is likely to be widely shared in the public sector and beyond. This, if nothing else, will make it difficult for many involved in public sector construction to consider using IPD.

There are barriers to IPD adoption by organisations in the public sector — it seems clear that they are unlikely to be legal – they may be based on old (*normal*) thinking habits and assumptions.

OPPORTUNITIES FOR FURTHER RESEARCH

It will be useful to have:

- Further opinions from other lawyers
- Opinions about alternative relational contracts
- A discussion of relational contract theory in the context of the French legal system may help in this discussion. French and Anglo-Saxon legal systems are different.
- A discussion of cultural and behavioural barriers to IPD in the French context.

STRATEGIC PARTNERSHIPS – BEST PRACTICE ACROSS NORWAY AND DENMARK

Sigurd B. Paulsen[1], Atle Engebø[2], Morten S. Jensen[3], Rolf Simonsen[4], and Ola Lædre[5]

ABSTRACT

In recent years, the concept of strategic partnerships has gained attention in the Norwegian and Danish construction industry. As a project delivery method, strategic partnerships share similarities with the Lean project delivery perspective and Integrated Project Delivery (IPD) as they all seek to achieve more collaborative projects. In this paper we will compare strategic partnerships, strategic partnering and IPD based on literature reviews and experiences from recent strategic partnerships and strategic partnering in Norway and Denmark. The paper explains strategic partnerships and partnering by structuring it according to three essential Lean Construction (LC) elements: Commercial, organizational, and operating system.

A combination of literature review and document study was used for data collection. Also, online meetings with all authors participating were completed to discuss and analyse data.

Experiences from a Norwegian case study and Denmark points to several success criteria that are crucial for the success of long-term collaboration, such as multi-project framework agreement, keeping the same people, and support from the management. Some of the success criteria stem from IPD and others might also be a positive application for IPD.

KEYWORDS

Strategic partnerships, Strategic partnering, IPD, lean construction, collaboration.

INTRODUCTION

Bennett and Jayes (1995) defined partnering as a management methodology used to achieve increased value and productivity in the construction industry. The concept of partnering focuses on improving cooperation between the parties involved (Lahdenperä, 2012). This paper divides partnering into three categories: Project partnering, strategic partnering and strategic partnerships. The former is a collaboration between a client and a delivery team (Architects, designers and main contractor) that are specific to a particular project (Lahdenperä, 2012). With strategic partnering, a delivery team collaborate on more than one project, but a separate contract for each specific project (Paulsen et al., 2022). However, with a strategic partnership, a client offers a portfolio of upcoming projects over several years in a single package to a delivery team (Værdibyg and Rebus 2021a). Research from Denmark and Norway shows great potential when implementing strategic partnering and strategic partnerships in the construction industry (Gottlieb et al. 2020; Paulsen et al. 2022; Værdibyg and Rebus 2021a; b). In Denmark,

they have moved from project partnering to a focus on strategic partnerships with long-term contracts whereas in Norway the recent focus has been on strategic partnering. Thus, the Danish approach goes more in the direction of a programme perspective where a group of related projects are aligned and coordinated to achieve benefits that are not possible when projects are managed individually (Shehu and Akintoye 2009).

This paper has structured strategic partnership into three elements: Commercial, organizational, and operating system, based on the LC triangle described by Ballard (2012). All three elements in the LC triangle are crucial to achieving a successful strategic partnership. Partnering as a project delivery method shares similarities with the Lean perspective as they both use contractual-, organisational-, and cultural elements to achieve a collaborative project (Falch et al., 2020). Since strategic partnering is an extension of traditional partnering, the similarities with the Lean perspective are even higher for strategic partnering (Paulsen et al. 2022). The reason is that, over a more extended period, companies can eliminate problems and ensure ongoing improvement through a more open and frequent exchange of information (Shimizu and Cardoso, 2002). Thus, strategic partnerships and strategic partnering can reduce waste and increase value in construction projects. Also, strategic partnering shares similarities with IPD as they accommodate the construction industry´s need for more efficient collaboration between project participants (Lahdenperä, 2012).

This study aims to identify improvements in current strategic partnering and strategic partnerships. The target group for this study is researchers and construction practitioners who want to develop strategic partnerships. Previous research shows positive effects from strategic partnering in Norway (Paulsen et al. 2022), strategic partnerships in Denmark, (Værdibyg and Rebus 2021a; b) and IPD (AIA 2007; Fischer et al. 2017). However, no one has yet compared the similarities, the differences, or whether the different approaches can learn something from each other. Therefore, this paper seeks to answer the following research questions:

1. What can be learned from the different approaches to strategic partnerships in Norway and Denmark?
2. What is needed to achieve a successful strategic partnership?

METHODOLOGY

This paper reports our exploratory approach towards creating a more coherent view of the concept of strategic partnerships from a lean construction perspective and in the context of the Norwegian and Danish AEC industry. The research idea stemmed from a case study by Paulsen et al. (2022) presented at IGLC 2022, which to the authors' knowledge is the only case study of strategic partnering from Norway. The case study included four school building projects where the same contractor and design company had partnered up four times from 2014 to 2022. Fifteen interviews were conducted and supplemented by a document study of the respective tendering documents, the contracts and meeting minutes from the four projects. The interviews were semi-structured, meaning that they followed a standardized interview guide (Blumberg et al. 2014). The informants all had key roles in the projects. For example, the project manager, design manager and Processing supervisor were interviewed. These people were involved in all four projects. The study design followed the prescriptions of Yin's (2014) case study approach.

To anchor the empirical insight and to ensure relevance to lean construction, a literature review was conducted. The initial review was carried out primo 2022 by searching in the databases Scopus, Google Scholar and Oria. The latter is the Norwegian universities' library database. The literature survey was supplemented with new searches ultimo 2022, to clarify improvements to strategic partnering. The existing documentation from studies on strategic partnering is scarce, especially in the context of lean construction theory and IPD. However, qualitative methods are well-suited for explorative purposes (Thagaard, 2018). Consequently, it was decided to carry out a continuation of the initial research work based on feedback gained at IGLC 2022. Particularly, contact was made with the Danish NGO "Værdibyg" (The Value Creating Construction Process). Strategic Partnership has gained a foothold in Denmark. Empirical experiences are well documented in guidelines and research reports. A natural continuation of our work on the theme was therefore to compare Norwegian and Danish experiences and then draw the lines to the principles of IPD and Lean philosophy.

To corroborate the findings from the Norwegian case study documented by Paulsen et al. (2022) it was decided to carry out an in-depth document study as data collection methodology. Through Værdibyg the following documents for the in-depth document study were identified:

- Strategic Partnerships - From Idea to Contract.
- Strategic Partnerships - Implementation of the Collaboration.
- Long-term strategic collaboration in the construction industry.
- Strategic Partnerships in the Municipality of Copenhagen.
- Experiences and Facts about Strategic Partnerships.

The documents were analyzed using a qualitative approach where the findings from the selected documents were categorized according to the LC Triangle. According to Bowen (2009), this form of document analysis could be defined as a systematic procedure for reviewing or evaluating documents to create or obtain empirical data. The use of the predetermined categories given by the LC triangle made the analysis an iterative process.

In sum, we report from an exploratory comparison between how strategic partnering/partnership is practised and perceived in Norway and Denmark through the lens of lean construction theory. The study is limited to a single Norwegian case whose empirical findings are compared to the Danish practice described in selected guidelines and research reports. Although the study is limited to this geographical location, we believe that there are general learning points here that are interesting for Lean Practitioners.

THEORETICAL FRAMEWORK

A core principle for Lean project delivery is described using the LC triangle, which describes the three fundamental elements in all project delivery methods: Commercial, organizational and operating system (Ballard, 2012; Howell, 2011; Thomsen et al., 2010). Lean project delivery seeks to align all project parties to achieve a collaborative project organization with available contractual elements and create a project culture for delivering value (Falch et al., 2020).

Construction projects can be delivered through various delivery methods, ranging from traditional design–bid–build (DBB) to more integrated forms such as partnering, Lean Project Delivery System (LPDS) and IPD. The project delivery method dictates how the project team engages, how different parties get involved, and the means used (Engebø et al., 2021). Other examples of project delivery methods for single collaborative processes are Partnering, Integrated Project Delivery, Alliancing, Relational contracting, and Relationship-based procurement (e.g., Engebø et al. 2020). These methods have both similarities and differences. Nyström (2005) applied Ludwig Wittgenstein's idea of family resemblance to conclude that trust and mutual understanding are necessary components in every partnering project (similarities), while there are components that vary from project to project (differences). However, this paper focuses on so-called collaborative project delivery methods across several projects that seek to integrate and align the parties early, i.e., already in the planning phase.

LPDS AND IPD

The LPDS is a delivery system in which the project team helps clients and customers (beneficiaries) to decide what they want (Ballard 2000; Khanzode et al. 2005). Ballard (2000) describes LPDS as a "project-based production system" because it is a temporary production system. LPDS contains five project phases: Project definition, lean design, lean supply, lean assembly, and use. Each phase also contains three project steps. The phases are interconnected to the next one through a common project step. Therefore, each project phase is influenced by the previous phase and has an impact on the following phase (Ballard 2000). In contrast to traditional project delivery systems, LPDS questions at the very beginning of the project what needs to be done and who is responsible for the task. Compared to traditional project delivery like DBB, LPDS explicitly shows the relations and dependencies between the different phases through a construction project, which are often ignored (Ballard 2000; Nguyen et al. 2008).

IPD (as described by i.e., Fischer et al. (2017)) is a project delivery method that integrates people, systems, organizations, and practices into a single collaborative process. The aim is to optimize results and value to the owner, reduce waste and maximize efficiency through all phases of the project (AIA 2007; Dargham et al. 2019). Lahdenperä (2012) describes that an IPD contract is a multi-party contract between several actors, and for example not only between the client and the contractor. Multiparty contracts are not common within what has traditionally been called partnering (Lahdenperä, 2012). Contractually, IPD differs from strategic partnership. Collaboration with the client and application of Lean tools is also common in IPD projects (Fischer et al., 2017). Research on the IPD shows benefits linked to risk sharing, improved productivity, and increased quality of work (AIA, 2007).

STRATEGIC PARTNERSHIPS/ PARTNERING IN A LEAN PERSPECTIVE

Partnering as a project delivery method shares similarities with the Lean perspective as they both use contractual-, organisational-, and cultural elements to achieve a collaborative project (Falch et al., 2020). Since strategic partnering and strategic partnerships in several ways are an extension of project partnering, the similarities with the Lean perspective are even higher (Paulsen et al. 2022). The reason is that companies in the long run can eliminate many of their problems and ensure ongoing improvement through a more open, frequent, and accurate exchange of information (Shimizu and Cardoso, 2002). Thus, strategic partnering as a project delivery method can both reduce waste and increase value in construction projects. Even if the Lean Construction concepts are more related to firms, they can be extended to the organization level (Shimizu and Cardoso, 2002), as in this paper.

Sundquist et al. (2018)'s study points out research gaps regarding the actual features of strategic partnering. From a Lean perspective, IPD has, in recent years, been given more attention than strategic partnering (see for example, Dargham et al. 2019; Simonsen et al. 2019). Part of the explanation probably lies in the fact that IPD projects are more linked to the use of LC tools and BIM, compared to partnering (Lahdenperä 2012). However, IPD shares similarities with strategic partnering as they accommodate the construction industry´s need for more efficient collaboration between project participants (Lahdenperä, 2012). Therefore, this paper is placing strategic partnering in a setting of IPD`s basic structure. Howell (1999) has said that "Partnering can be a solution to the failure of central control to manage production in conditions of high uncertainty and complexity". If this is true, strategic partnering can be a way to get Lean issues effectively into companies.

FINDINGS

This section presents results related to the research questions and the LC triangle.

STRATEGIC PARTNERING IN THE NORWEGIAN CASE STUDY

Commercial

In this particular case, the contractor entered a contract with the client, and the contractor had contracts with a design company and an architect company. The delivery team implemented strategic partnering as an informal agreement and separate contracts were signed for each project. The client is not included in the partnering collaboration. Because of the informal agreement and separate contracts, the Norwegian case study showed that such long-term collaborations entail a degree of uncertainty. First, it is difficult to predict which future projects will be put out to tender, and second, there will always be uncertainty about whether the tendering competition will be won. Also, it was found that several partnering elements were stipulated in the contracts to improve the collaboration from project to project. The most important were start-up seminars, team-building activities, open book, and joint meetings with the client and users. However, no contractual incentives were used between the parties (Paulsen et al., 2022). A fixed-price contract is most common, which means that the client relinquished the risk related to the cost of the projects to the delivery team.

Organizational

Full delivery team (architects, designers, and main contractor) are included. The parties use a collaborative project delivery method with early contractor involvement, project hotels and BIM as digital collaboration tools. The interviews showed that keeping the same key personnel was a strategic aim from the beginning of the strategic partnership. For example, the project manager and the design manager were the same person in all four projects (Paulsen et al., 2022).

The delivery team focused on becoming more productive, and results from the case study showed that they managed to increase productivity and recurring effects from project to project. However, the recurring effects were not as significant as hoped because keeping the same people from project to project is challenging. External factors such as the client were one of the reasons why it was challenging to keep the same people through the strategic partnership, among other things due to political decisions which led to postponements. Also, the client's indecision negatively affects the strategic partnership. Therefore, an insight from the Norwegian case study, showed that external factors such as the client could significantly influence the relationship between the parties in the delivery team (Paulsen et al., 2022).

Operating system

There were three main reasons why the delivery team implemented strategic partnering: 1) They had some prior positive partnering experiences from other projects, 2) together, they believed they could form a competitive team that would stand a better chance at winning tendering competitions, and 3) the desire to achieve a repetition effect. The informants from the case study describe that the relations at the individual level developed well and that people have built close ties across the companies. The professional collaboration also led to improved productivity and increased quality of the work. Another positive effect documented was the delivery team`s strong performance in the tender competitions. Their strategic partnering collaboration was crucial to the team winning four school projects in a row, the informants said. However, the case study showed that sustained strategic partnering over time creates tension between the organizations, due to economic conflicts (Paulsen et al., 2022).

The case study showed that the delivery team agreed that they should have been better at continuously evaluating the collaboration during the strategic partnership. They also acknowledge that they failed to eliminate problems. As a result, the same problems recur in all four projects. Another characteristic worth noting was that no formal organizational agreement was drawn, making the intention and commitment purely relational (Paulsen et al., 2022).

Strategic Partnerships in Denmark

The first strategic partnerships in Denmark were established in 2016. The earliest strategic partnerships were inspired by cases from UK and Sweden (Kadefors et al., 2013), and alliancing in Finland (Lahdenperä, 2012). There are currently nine active strategic partnerships with a combined expected value of approximately three billion euro (Frederiksen and Johansen, 2022).

Commercial

In the Danish construction sector, a strategic partnership is defined as a long-term collaboration between a client and a delivery team on a collective project portfolio (Værdibyg and Rebus, 2021a). The clients from the nine active strategic partnerships are four municipalities, three social housing companies, one region and one governmental. the type of projects are schools, daycare centers and social housing. All the nine active delivery teams include at least one contractor as well as an architect and the designers. The partnership agreement between the client and the delivery team is typically based on a framework agreement, where the contractor is fronting a consortium. That means that new contracts can be assigned to the partnership without separate tenders on an ongoing basis over the contract period. The long-term aim of the collaboration is to provide the opportunity for the client and the delivery team to build an organization across the companies involved and to work with the development, innovation and optimization of solutions and processes.

For previous strategic partnerships, the contract period has been four years, but projects initiated within the four years can be carried out and completed subsequently so that the partnerships' tasks extend beyond four years. In most of the Danish strategic partnerships, there has been no guarantee of a minimum volume of tasks and in their set-up, they have chosen that both the client and the delivery team can stop the collaboration at any time. None of the nine partnerships has used this opportunity yet. The tender documentation has often contained a risk model that defines the distribution of risk between the parties. For delivery teams, it has been a challenge to create a common business model and to share responsibilities and risks in a collective setup. Many of the Danish partnerships have a risk pool for unforeseen expenses and improvements. A partnership is about having an interest and insight into each other's basis for decision-making and risk elements, and thus it is appropriate that people do not try to place responsibility on one party alone. Often in the partnerships, everyone is willing to jointly manage the risks of the projects and discuss how to handle matters when faced with an incident or uncertainty. It can be risks regarding quantities, design errors or execution risks, where the parties can agree on how to best solve it overall (Værdibyg and Rebus, 2021a; b).

Organizational

The tender process has primarily been based on qualitative evaluation criteria. Often, the client has conducted a market dialogue in advance to ensure that there is a market for a partnership. This has also been an early warning to the companies, who then began teaming up with collaborators they would submit a bid with. The tender documentation often contains a description of the client's organisation, decision-making processes, and business processes. The partnerships have in most cases used the standard documents and agreements of the Danish construction industry as a basis for the projects. The experiences show that it is important that each company are willing to enter a value-based collaboration. All parties must have strong managerial support for entering a strategic collaboration.

In strategic partnerships, the delivery team has close collaboration with the client. In the contractual agreements, there are defined common goals and values as well as the team uses "open books" for pricing the construction costs of the projects. Furthermore, the experience is, that keeping the same personnel for several projects produces positive effects, such as repetition effect and better cooperation (Frederiksen and Johansen, 2022; Værdibyg and Rebus, 2021b). Also, many of the strategic partnerships become so close, that they begin to work as a uniform company with people being employed (and laid off) directly to the strategic partnership.

Operating System

Once the strategic partnership has been formalized between the client and the delivery team, there has been a great deal of work in establishing the collaboration and getting the many organizations involved into a position to act as a single partnership. Most of the strategic partnerships have a joint project office to support the common culture. To ensure the necessary managerial attention and decision-making power in the strategic partnership, a joint organization has been established in all strategic partnerships between the client and the delivery team. Often as a three-part management structure: 1) steering committee, 2) operational management, and 3) project management. The steering committee handles the strategic management of the partnership and can be compared to the board in a large corporation. The operational management handles the day-to-day management of the partnership and can be compared to an executive board. The strategic partnerships consist of key persons from 3-5 of the central actors in the partnership. The specific work of developing and implementing the individual projects in the portfolio takes place at the project management level.

The project portfolio is planned to suit both the client and the delivery team. The client has the primary responsibility for the management of the project pipeline, while the responsibility for the management of the ongoing project portfolio lies jointly with the operational management. The projects that are chosen to be completed in the partnership are implemented in several phases that often are divided into the following steps: 0) Clarification of needs, 1) planning, 2) project proposals and pricing, and 3) design, execution and handover. The long-term collaboration and repetition in projects and processes have given greater budgetary security, fewer conflicts, no expenses for lawyers, better delivery on time, and better quality for both the client and the delivery team. With many projects in the portfolio, there has been an improvement in processes and cooperation and the parties have gained a closer relationship and a deeper understanding of each other. This is, among other aspects, caused by keeping the same personnel for several projects with ongoing relations and collaboration between persons from different companies (Gottlieb et al., 2020). In the next phase of strategic partnerships in Denmark, there has been a much larger focus on sustainability and the delivery team's ability to prove the construction project to be cheaper than "traditional" projects.

Figure 1 summarizes the similarities and differences between IPD, Norwegian strategic partnering and Danish strategic partnerships in a Wittgenstein family-resemblance sunflower model. The figure is inspired by Nyström (2005).

DISCUSSION

In this section, the authors will discuss similarities, differences, or whether the different approaches can learn something from each other. The discussion is based on the findings presented in the results section. Table 1 shows a summary of the key findings of this study.

Table 1: Key findings. Strategic partnering and strategic partnerships in a setting of IPD.

Elements	Norway	Denmark	IPD
Commercial:			
Design-build	x	x	
Multi-party contract			x
Framework agreement		x	
Ability to win projects	x		
Risk Sharing		x	x

Increased quality of the work	x	x	x
Collaboration with the client		x	x
Application of Lean tools			x

DIFFERENT APPROACHES TO STRATEGIC PARTNERSHIPS

Commercial

Both in Norway and Denmark, the client entered a design-build contract with the contractor, while the contractor had contracts with designers and architects. Since the client was not part of the strategic partnership, a multi-party contract was not entered into as in IPD projects. In Denmark, the legal basis for the partnership agreement between the client and the delivery team is typically based on a framework agreement. With the Danish approach, the delivery team doesn't need to worry about which future projects. However, with the Norwegian approach, the delivery team depends on the local business environment, local economy, and government regulations to get new projects. In the public domain, it seems like the biggest barriers to strategic partnering lie in the lack of opportunity to manage projects at a portfolio level. This is mainly because public clients are given a mandate and funding for individual projects. The second barrier is the law on public procurement, which sets requirements for the contracting process. Thus, most strategic partnering will take place in the value chain under the client. The Danish model facilitates continuous evaluation of the collaboration during the strategic partnership. With the Norwegian approach, it is uncertain whether the parties will collaborate on future projects. Nevertheless, the results show that strategic partnering in Norway gives a competitive advantage when it comes to winning projects, while it is still unclear whether strategic partnerships in Denmark do the same. In some of the strategic partnerships In Denmark, there are internal agreements of shared risk between the companies in the partnership. This allows the delivery team to focus their energy on quick solutions rather than on placing risk, blame and responsibility for errors. This approach is also highlighted as part of the simple framework of IPD projects (Fischer et al., 2014).

Organizational

In all collaborative project delivery methods included in this paper, there is a predetermined delivery team who tries to win projects together. An advantage of strategic partnership and strategic partnering, which IPD does not necessarily have, is that the delivery team can use the same people in several projects. Both results from Norway and Denmark show that keeping the same personnel for several projects produces positive effects, such as the repetition effect. However, In the Norwegian case projects, the repetition effects were not as significant as hoped because keeping the same people from project to project is challenging. External factors such as the client were one of the reasons why it was challenging to keep the same people. The chance of this happening is perhaps less with strategic partnerships in Denmark, since the client has a larger share of the risk, compared with the Norwegian approach. Also, Fischer (2017) has pointed out that keeping the same people is a challenge for IPD projects, but on a project level.

As the strategic partnerships in Denmark are rather large contracts all the companies in the partnership have a special focus on the work they do within the partnership. Therefore, there is also a willingness from top management to get the partnership to work as an efficient entity as this is the best way to get profits and to get more work within the framework agreement. However, in the Norwegian case projects, it was identified lack of support from the management. The consequence was that the delivery team did not continuously evaluate the collaboration during the strategic partnership and the same problems recur in all projects.

Operating system

Results from Norway and Denmark show that the relational collaboration between the people within the delivery team has positive effects on the professional collaboration. Research and experiences suggest that strategic partnerships and strategic partnering lead to improved productivity and increased quality of work. From the Norwegian case study, the informants describe that there has been a good development of relationships at the individual level across the companies. However, at the company level, the Norwegian case study showed that a negative relationship was developed due to financial and contractual conditions. In Denmark, on the other hand, such problems have been avoided because the strategic partnerships have a joint project office to support the common culture. Also, to ensure the necessary managerial attention and decision-making power, it is common to establish a joint organization. With IPD, such problems are also less likely because it is a multi-party contract which means that all parties are more dependent on each other to achieve the project goals. Therefore, the overall assessment shows that the Danish approach and IPD makes the parties work more towards the same goals, while the parties in Norway are more concerned with their profits.

Success Criteria for Strategic Partnerships

Our comparisons across both existing research and the experiences from Norway and Denmark point to several key activities or criteria that are crucial for the success of long-term collaboration in either strategic partnering or strategic partnerships. Some of these stems from IPD and others might also be a positive application for IPD projects.

Opportunity to win more contracts

The setup of a strategic partnership or an ongoing strategic partnering across several projects helps optimise the internal processes and this will make the partnership able to give better bids to other construction jobs with other clients offering an experienced and united team with optimised delivery processes. This will most often result in both better quality and lower prices (or more accurate prices) in new tenders.

Long-term, multi-project framework agreement

A portfolio of projects as opposed to single project contracts gives the possibility and project volume to invest in the shared organizational setup as well as benefitting from both the repetition of processes and the long-term relations across the participating companies and employees. This also provides the foundation for a shared learning organization with a solid basis for the application of Lean tools across different projects. The learning and application of

Lean tools result in better project delivery and productivity. Based on our research we cannot say how long the contracts should be. Four years may be a suitable length with the opportunity to renew the contract if all parties are interested in continuing.

Keeping the same people across projects

The multi-project contracts of strategic partnerships allow keeping the same people from different companies together for several projects, something which both enriches the projects as well as employee satisfaction and long-time employment.

Risk sharing

By sharing risk between the companies, the focus is on solving problems rather than placing or avoiding blame. This keeps participants aligned in the shared goals of delivering good projects.

Support from the management

Larger contracts seem to attract more attention from top management which also gives the benefit of easier access to company support in case of problems within the strategic partnership.

Collaboration with the client

For multi-project contracts it is possible to have a closer collaboration with the client to solve the projects in unison as they come. This also calls for an engaged and active client that can be part of the partnership and assign managerial resources permanently to the partnership projects to make good and quick decisions that keep the projects running and on target.

CONCLUSIONS

In this paper, a study was conducted to research different approaches to strategic partnerships. A comparison between IPD and Lean construction was also made to examine the differences. Therefore, this paper has placed strategic partnerships in a setting of Lean philosophy to see if strategic partnership can be a solution to the failure of central control to manage production in conditions of high uncertainty and complexity. As the study only emphasized strategic partnerships in Norway and Denmark, the results should not be viewed as a generalization of the phenomena. Instead, this study may provide deeper insight into the phenomena and be of value to those considering strategic partnership. In addition, this paper can contribute to the theory of strategic partnership, especially from a lean perspective.

Figure 1 summarized the differences between IPD, Norwegian strategic partnering and Danish strategic partnerships. The Danish approach facilitates continuous evaluation of collaboration during the strategic partnership to a larger extent than in Norwegian strategic partnering projects. The risk sharing between companies and support from the management in the strategic partnerships in Denmark gives advantages to the delivery team related to finding quick solution rather than on placing risks and continuously evaluating the collaboration. Also, if the client is more involved in the collaboration, results from Denmark and IPD shows that the parties work more towards the same goals, compared with Norwegian strategic partnering.

Experiences from Norway and Denmark point to several success criteria that are crucial for the success of long-term collaboration, such as multi-project framework agreement, keeping the same people, and support from the management. Some of the success criteria stem from IPD and others might also be a positive application for IPD projects, like the opportunity to win more contracts and get people to collaborate on multiple projects.

There is still a lack of proof of how well strategic partnership is working in practice. For example, more quantitative research is needed to measure quantifiable performance data such as productivity and quality. Therefore, more case studies and interdisciplinary research are needed to further clarify improvements.

INTEGRATED PROJECT DELIVERY (IPD) FOR HEALTHCARE PROJECTS: A COMPANY-SPECIFIC ANALYSIS

A.S. Hanna[1], Z. Zhu[2], and J.T. Morrison[3]

ABSTRACT

Organizations are increasingly looking to Integrated Project Delivery (IPD) to provide leaner and more successful projects in their construction efforts. Of particular interest is IPD in the healthcare sector, which has a higher instance of megaprojects and a higher overall level of complexity and risk. Therefore, the risk-sharing model espoused by IPD is more attractive than conventional delivery like Design-Bid-Build (DBB) or Construction Manager At-Risk (CMR).

A major contractor worked with the researchers to evaluate its performance on two recent healthcare projects on which it deployed IPD techniques as the first step in a potential organizational shift to the IPD paradigm. Eleven projects were collected – the two IPD projects as well as nine similar projects delivered under CMR within the last five years. These were compared to twenty healthcare projects completed by other firms in terms of eighteen key performance metrics.

Logically, lean ideals native to IPD led to better performance in several metrics; particularly those that have been previously identified as strongly correlated with project success such as cost and schedule growth, as well as in overall project performance in terms of the Project Performance Index (PPI). Buoyed by strong results, the company intends to continue with IPD.

KEYWORDS

Integrated project delivery (IPD), lean construction, process, project delivery systems, project performance

INTRODUCTION

It is an indisputable fact that healthcare construction in the United States will continue to experience increases in demand over the next several decades. For proof of this sustained increase, one needs to look no further than a U.S. Census Bureau forecast. Vespa et al. found that in the year 2020, it was estimated that 56.1 million individuals (or roughly 17% of the population) were over the age of 65, but by 2060, these numbers are due to increase to 94.7 million and 23%, respectively (2020). Therefore, it is unsurprising that inpatient care days in hospitals and medical facilities are forecast to outpace population growth by 22% by 2050 (Pallin et al, 2014). It is thus logical that U.S. construction spending in the healthcare sector

[2] M.A. Mortenson Associate Professor, Program in Construction Engineering and Management, University of Wisconsin, Madison, USA, zzhu286@wisc.edu orcid.org/0000-0002-4554-1770

[3] Project Management Consultant, Hanna Consulting Group, Middleton, Wisconsin, USA, john.morrison@wisc.edu, orcid.org/ 0000-0002-4741-2091

increased from $42 million per month in January 2013 to $55.7 million in January 2023, an increase of 32% in a decade (Federal Reserve Bank of St. Louis, 2023).

Accordingly, there are an increased number of firms seeking to enter the healthcare construction space and/or improve their existing practice in that area. It was forecast that construction firms that work in the healthcare space should continue to enjoy "growth in revenue, profit, and backlog," given that supply-chain issues and inflationary pressures have not slowed the rate of healthcare construction executed or planned, characteristic of the sector's historical steadiness even through economic uncertainty (Obando, 2022).

One such firm, a top-twenty contractor in the United States as reported by the Engineering News-Record (ENR), has a large and successful healthcare construction practice but had only just begun to implement integrated project delivery (IPD) on healthcare-sector projects[4]. This is in line with previous research: an American Institute of Architects (AIA) survey in 2011 found that a much higher percentage of its members reported "awareness" (83%) or demonstrated an "understanding" of the IPD system (40%) than had ever executed a project under that model (13%) (AIA Center for Integrated Practice, 2012).

The low industry penetration of IPD is due to various entrenched obstacles. As was found by Fish, the three principal obstacles to IPD adoption are unfamiliarity with or unavailability of suitable contract documents for the requisite multiparty agreements, lack of available insurance products in the marketplace that are appropriate for the risk-sharing paradigm, and difficulty aligning the project team to the necessary culture of facilitation (Fish, 2011). Building upon this work, Kahavandi et al. identified that contractual challenges were the most significant, followed by environmental factors (including legislative obstacles and insurance product availability) (2019).

Beyond these enumerated obstacles, there is another perception-related barrier to IPD use. While volumes have been written extolling the virtues of lean construction by academia, and IPD, some research has argued that IPD has almost become overexposed and that the industry-wide publicity of IPD leads to inflated expectations, becoming in fact a further obstacle to adoption (Bilbo et al, 2014).

Given that major contracting firms of the type which engaged the researchers for this investigation are exceptionally risk-averse and can be opposed to sharing information to the degree that IPD requires, leaders of change who were internal proponents of IPD needed to present a quantitative-based analysis of the pilot projects' performance to help make their case and overcome the obstacles previously noted (Zachariah & Goldsmith, 2022). Thus, the researchers were engaged by the company to perform such an analysis.

OBJECTIVES AND SCOPE

In order to assist the company in its analysis of its IPD pilot efforts, the following research objectives were set forth: 1) understand what performance metrics had the most impact on the key stakeholders in the company; 2) quantify those performance metrics for the IPD pilot projects as well as other comparable projects within the company's portfolio delivered by other methods; 3) compare the company's performance under both IPD and non-IPD delivery models to the industry at large; 4) present results in a clear and engaging way; and 5) create a process that could be repeatable at other companies, thus generating a benefit to the healthcare construction sector at large as it seeks to become leaner and incorporate IPD more significantly.

Throughout this paper, IPD is used not only to represent the delivery system but also as a shorthand for the lean techniques and practices that are inherent to it. This is because it is difficult to realize the desired benefits of IPD without embracing and implementing lean practices. The Construction Industry Institute (CII)'s research team DCC-06, led by Hanna,

[4] To protect confidentiality, the firm in question will not be named, but will be referred to as 'the company' throughout.

noted that the use of lean techniques was a key concept imperative to an IPD deployment (Hanna & Morrison, 2021).

RESEARCH METHOD

The study presented herein was conducted in four principal phases, as presented in Figure 1. Each phase is characterized in detail in the following sections.

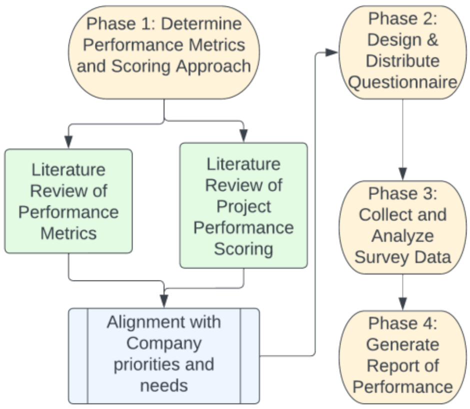

Figure 1: Research Method Overview

LITERATURE REVIEW AND METRIC/SCORING SELECTION

PROJECT PERFORMANCE METRIC SELECTION

There is a significant body of work in project performance analysis which contains a variety of different scoring systems and performance metrics to compare projects. The general chronology of project delivery systems both over time (in terms of adoption) and effectiveness (in terms of project performance) proceeds from Design-Bid-Build (DBB) to CMR, then to Design-Build (DB)[5] and culminates with IPD (Ibrahim & Hanna, 2019).

To determine what performance metrics to utilize in their analysis, the researchers worked closely with representatives from the company to assess what metrics informed their operating decisions. Particularly useful in this discussion was the work of Iskandar et al., who performed a healthcare-focused quantitative analysis of project performance. Among the most significant metrics identified by the Iskandar study were: design quality (as measured by requests for information (RFI) per million dollars), construction speed, schedule growth and cost growth (Iskandar et al. 2019). However, Iskandar did not compare projects through the lens of project delivery systems.

Similarly, Labib performed a two-part model development on a dataset composed of state-financed projects, which included a high percentage of institutional work. Labib's model formulation was based on eight metrics, and had among the most robust validation process in the literature (Labib, 2019).

Per the method agreed upon by the researchers with the company, the company reviewed the performance metrics to assess which could reasonably be tracked by their project staff, and which were of import to their decision-making. The resultant eighteen metrics, divided into eight holistic areas, that were selected from the literature and augmented by the company's business intelligence needs are presented in Table 1, below, alongside definitions thereof which serve to ensure an understanding of the metrics in use by the reader and to improve the portability of the approach to other companies who might wish to perform a similar analysis.

[5] DB is occasionally interchangeably referred to as Engineer-Procure-Construct (EPC).

Table 1: Selected Performance Metrics

Area	Metric and Type		Definition/Formula
Communication	RFI per $1M	Ratio	$\frac{\text{Number of Project RFI}}{\text{Project Cost in Millions}}$
	RFI processing time	Number	Count of days between submission of an RFI and a resolution
Change Management	Change order processing time	Number	Count of days between submission of a change order and a resolution
	Absolute Value of % Change	Ratio	$\frac{\text{Absolute Change Amount}}{\text{Project Total Cost}}$
	Specific Factor-Related % Change[6]	Ratio	$\frac{\text{Change Amount due to Factor}}{\text{Project Total Cost}}$
Business	Company Image	Scale	5-point Likert scale[7]
Quality	Project System Quality	Scale	5-point Likert scale
	Punchlist items per $1M	Ratio	$\frac{\text{Count of Punchlist Items}}{\text{Project Total Cost}}$
Safety	OSHA Recordable Rate[8]	Ratio	$\frac{(\text{OSHA Recordable Injuries}) * (200{,}000)}{\text{Total Project Work Hours}}$
Cost	Construction Cost Growth	%	$\left(\frac{\text{Actual cost} - \text{Initial estimated cost}}{\text{Initial estimated cost}}\right) * 100$
	Budget Factor	Ratio	$\frac{\text{Actual cost}}{\text{Initial estimated cost+Cost of approved changes}}$
Schedule	Construction Speed (ft^2/Day)	Ratio	$\frac{\text{Construction ft}^2}{\text{Construction Duration (Days)}}$
	Schedule growth	%	$\left(\frac{\text{Actual duration}-\text{Target duration}}{\text{Target duration}}\right) * 100$
	Schedule intensity ($/Day)	Ratio	$\frac{\text{Final Construction Cost}}{\text{Construction Duration}}$
Labour Productivity	Work Value per Labour Cost	Ratio	$\frac{\text{Sell Value of Self} - \text{Performed Work}}{\text{Self} - \text{Performed Labour Cost}}$

PROJECT PERFORMANCE SCORING METHOD

In selecting a scoring tool to use here, one must consider that IPD is a more recent iteration in construction, which disqualifies from consideration the notable preceding work of Konchar and Sanvido (1998), Ibbs (2003), Rojas & Kell (2008), and Sullivan et al. (2017) among others which did not consider IPD. Additionally, while these studies and the general body of literature of which they are representative have done a great deal to advance the operational understanding of PDS in the industry, there is another factor by which this effort was constrained: many previously published works include a great deal of analysis and/or quantification of performance metrics, but lack a unifying method or standardization approach

[6] Three versions of this metric were assessed: Program-related, Design-related, and Quality-related percent change, bringing the total to 18.

[7] All 'scale' metrics were of interest to the company but are not used for quantitative analysis due to their qualitative nature.

[8] While safety is of paramount importance to the construction industry at large and to the company in question, previous research has found that safety is largely ingrained in company culture to the point where it is independent of PDS (Hanna & Morrison, 2021). As such, safety factors were gathered but are not assessed or reported.

by which a project's performance can be distilled into a single number. This is an attractive proposition for industry professionals, as it more easily facilitates the comparison of projects to each other and makes for simpler reporting to leadership. Standardization also facilitates a more ready comparison of projects in a like-to-like fashion.

Therefore, the preceding work the authors could consider for application in this effort consists of work published largely since 2016 which considered IPD. The work fitting this description which was considered included El Asmar et al. (2016), Ibrahim et al. (2018) and the combination of Labib (2019) and Hanna & Morrison (2021).

Among El Asmar et al.'s most notable research contributions were their observation that there was a significant gap in the literature - a single, comprehensive metric to assess project performance did not yet exist - and their creation of the Project Quarterback Rating (PQR) to begin addressing it (2016). The PQR was comprised of 23 individual metrics within seven holistic performance areas, namely: customer relations, safety, schedule, cost, quality, financial performance, and communication (El Asmar et al. 2016). However, while IPD was included by the El Asmar study, only 35 projects in total were considered, and IPD was at the time "emerging" by the study's own admission (El Asmar et al. 2016). Furthermore, the El Asmar study was based in part upon subjective weights (i.e. opinion based) which reduce its accuracy as compared to more recent efforts.

Ibrahim et al. reported in the Construction Research Congress a robust investigation of 12 performance metrics in six areas, considering IPD alongside DBB, DB, and CMR, but the focus of the study was not on a distillation of this analysis into the kind of single numeric score the researchers and the company were seeking (Ibrahim et al. 2018).

The researchers had previously reviewed with the company the Project Performance Index (PPI) which was developed by Labib. However, the original work of Labib was based on a dataset that, while it contained numerous institutional projects that are comparable to healthcare-sector work, did not contain IPD projects (Labib, 2019). Enter the work of Hanna & Morrison, which validated the applicability of Labib's model on IPD projects in the course of their own development of the Project Performance Score (PPS) for downstream and chemical construction, another industry sector that has a comparable level of complexity to healthcare sector work (2021).

Thus, given that the PPI model was developed on a large dataset of projects (189) and on a variety of institutional projects (correctional facilities, medical research, military installations, engineering science labs, etc.), and that its merit was validated on IPD projects by a separate effort, the researchers and company agreed to use the PPI model (Labib, 2019; Hanna & Morrison, 2021).

The Project Performance Index

Labib's PPI score is as follows (2019):

$$\begin{aligned} PPI\ =& -1.101 \times RFI\ processing\ time - 0.219\ \times Percentage\ change \\ & -0.241 \times Schedule\ growth\ - 0.022 \times Schedule\ factor \\ & -0.014\ \times Number\ of\ RFIs\ per\ millionUSD + 0.011 \times Construction\ speed \\ & +0.67 \end{aligned} \quad \text{(Eq. 1)}$$

An astute reader will note that this equation does not utilize all 15 factors that were previously identified. This is because while all performance metrics identified were relevant to the company's operations and business intelligence needs, not all of them have been found to correlate to project performance, and some (such as company image) are not true quantitative metrics as defined in Table 1 previously. Therefore, they are not weighted or used to calculate the PPI here.

Adding further value to the company's efforts, the PPI score can be scaled into a numeric value between MinR (1) and MaxR (10), which creates a useful and intuitive shorthand for project performance comparison as shown in Equation 2 (Labib, 2019).

$$PPI_{scaled} = \frac{(PPI - PPI_{Min})*(MaxR - MinR)}{PPI_{Max} - PPI_{Min}} + MinR \quad \text{(Eq. 2)}$$

DATA COLLECTION AND CHARACTERISTICS

After the target performance metrics and project scoring strategy had been agreed to, the researchers worked with the company to design a questionnaire that could be circulated to collect the data needed for analysis. The questionnaire was structured to align with similar data collection vehicles that have been used by the researchers over the last decade, to ensure a uniform dataset from which informed and accurate comparisons can be drawn. The questionnaire includes thirteen sections, as follows: Project Characteristics (I), Special Conditions (II), Prefabrication Usage (III), Contracting Strategy/PDS (IV), performance data for communication, change, quality, safety, cost, schedule, labor, and business (V-XII) and contact information for required follow-up questions (XIII). For brevity, the survey is not included in its entirety in this paper. The survey was distributed to the company's corporate offices in major markets across the midwestern United States, from which eleven medical sector projects were gathered. A further twenty healthcare specific projects were supplied from project data maintained at the University of Wisconsin - Madison to provide a database from which to comparatively evaluate PDS performance. Project data from the assembled dataset were plotted using the boxplot, a common statistical tool.

DATA CHARACTERISTICS

The eleven company projects and twenty industry projects that were analysed in this effort were executed between 2007 and 2021 in all cases, and specifically within 2017-2021 for the company's projects. The company data consisted of two IPD projects from their pilot work with the delivery system and nine CMR projects. The industry data consisted of seven IPD projects, and nine CMR projects. While the company did not directly deliver any projects under DBB, the researchers also included four such projects as an additional comparison since the data was available. All datapoints were from projects completed in the United States, with the largest share of projects being completed in Wisconsin (18). Other states represented in the data by multiple projects included Missouri (3), Minnesota (2), Illinois (2), and Florida (2).

The cost data in these projects were standardized for time and location using the RSMeans 2021 historical cost indexes and city cost indices. The reference location and year in this study are Chicago and 2021, respectively. The standardized cost of the projects ranged from $3 million to $661 million with an average of $152 million.

RESULTS AND DISCUSSION

The thirty-one assembled projects were first characterized in terms of key characteristics (cost, location, delivery system, etc.). Then, the projects were analyzed by delivery system chosen and scored using the previously provided PPI equations, as well as for each of the eighteen performance metrics. The PPI scores and a selection of the performance metrics will be presented in this section for comparison and discussion. In each box plot in this section, the result of the pertinent equation defined in Table 1, previously, is plotted on the Y axis. Further, in each case the company's specific project data will be presented in light grey and on the right-hand side of the comparison, while the industry data will be presented in dark grey and on the left.

COST PERFORMANCE EVALUATION AND COMPARISON

The two metrics used to measure cost performance were cost growth and project budget factor. It should be noted that one of the company projects did not report cost data sufficient for analysis and was therefore excluded. Thus, only 30 projects are assessed here. Figures 2 and 3 present the box plots for each of the cost metrics.

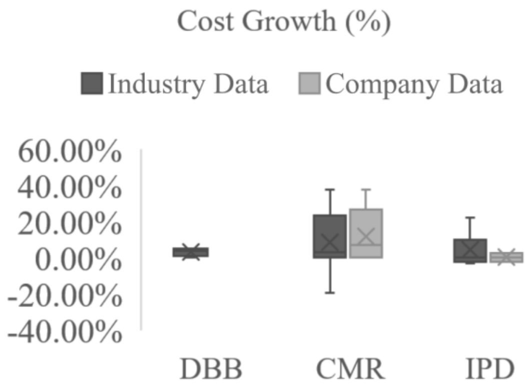

Figure 2: Cost Growth Performance

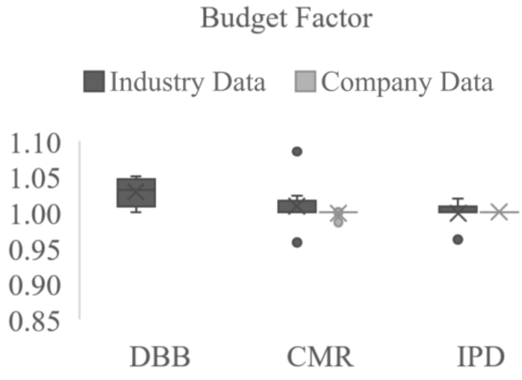

Figure 3: Budget Factor Performance

It is apparent that the projects delivered under CMR by both the company and the industry at large have higher cost growth and a higher budget factor than those delivered under IPD. In comparison to the industry at large, the company's CMR projects have both a higher mean and higher range in cost growth. This implies that the company tended to experience higher actual cost than baseline estimates. However, the same CMR projects had a budget factor quite close to 1, which implies that the majority of the cost growth percentage was due to approved change orders, rather than any degree of poor project performance. By considering these metrics in tandem, the company can ascertain a more impactful picture of its performance than by considering either alone. On the IPD projects that were examined, the company's cost growth was 0%, outpacing the industry data's (4.23%).

SCHEDULE PERFORMANCE EVALUATION AND COMPARISON

Figures 4 and 5, below, present schedule performance as measured by schedule intensity, and construction speed. All projects in the dataset reported sufficient information to be included in the schedule analysis. However, it was found that the company experienced negligeable schedule growth on all its reported projects, indicative of strong operational practice. Thus, the value of visualizing schedule growth for comparison is limited, and the figure is omitted.

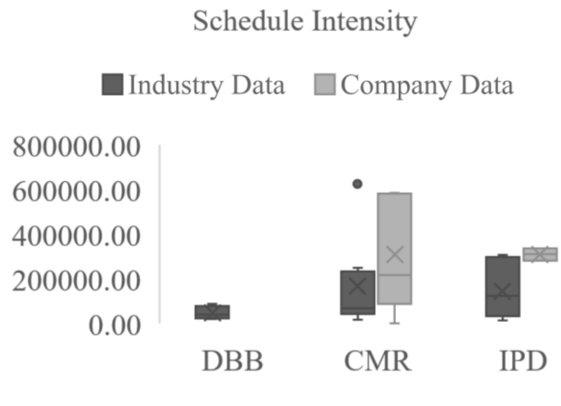

Figure 4: Schedule Intensity Performance

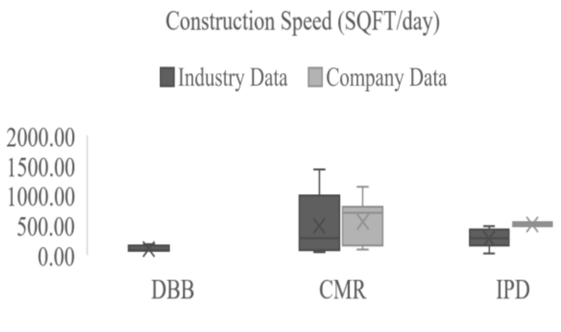

Figure 5: Construction Speed Performance

Both the company's CMR projects and those of the industry at large slightly outperformed IPD projects in terms of construction speed. Additionally, the company's projects under both delivery systems were faster (in terms of construction speed) and more intense than the average. This speaks to corporate culture and project approach in addition to PDS selection.

Encouragingly, the company saw little-to-no schedule growth, regardless of delivery method (the industry by contrast experienced 19.2% schedule growth in CMR and 14.2% in IPD).

CHANGE MANAGEMENT PERFORMANCE EVALUATION AND COMPARISON

Change management was measured in terms of three metrics: change order processing time, absolute project percent change, and percent change ascribable to program, design, or quality. The company's IPD projects experience no change due to design or quality, vastly outperforming both their own CMR projects and the industry at large. However, the specific reason-related percent change comparison is not reported as individual figures for brevity.

Change order processing time, shown in Figure 7, is presented on a 7 point scale: 1 (1-7 days), 2 (8-14 days), 3 (15-21 days), 4 (22-28 days), 5 (29-35 days), 6 (36-42 days), and 7 (greater than 42 days).

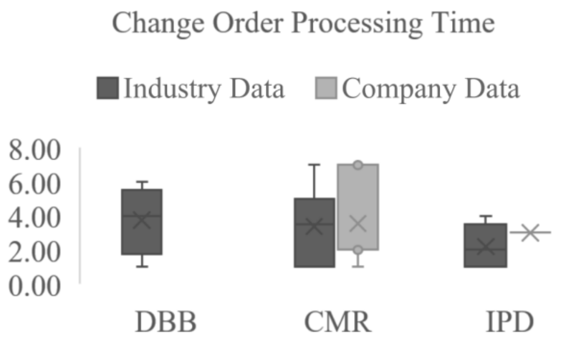

Figure 6: Change Order Processing Time Performance

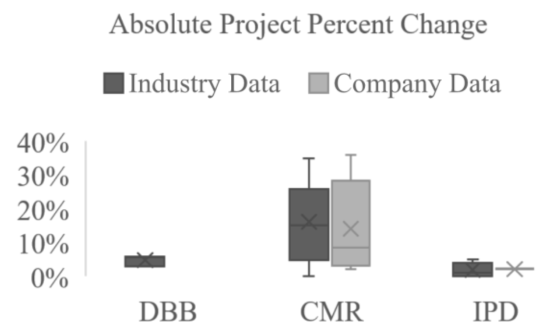

Figure 7: Absolute Project Percent Change Performance

As is evident, the company experienced higher change order processing time for both CMR and IPD than the industry at large. However, it should be noted that change order processing time is frequently beyond the control of the contractor directly. IPD projects for both the company and the industry experienced a lower volume of percent change, as shown in Fig. 7.

COMMUNICATION AND DESIGN QUALITY EVALUATION AND COMPARISON

Similarly to the presentation of change order processing time in the preceding section, RFI processing time is presented on a five-point scale: 1 (1-7 days), 2 (8-14), 3 (15-21), 4 (22-28), and 5 (29-35 days). DBB, as would be expected, has the highest number of RFI per million dollars on average, followed by CMR and IPD, indicative of the increased coordination and design quality that IPD can produce due to more collaboration among the project team and an incentive of a shared risk pool. The company specifically saw higher numbers of RFI per million dollars than the industry at large, and a more variable processing time under IPD.

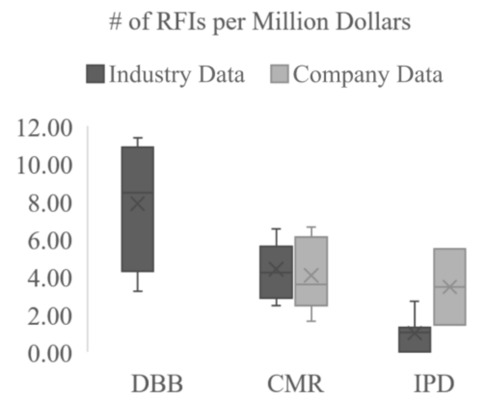

Figure 8: # of RFIs per Million Dollars Performance

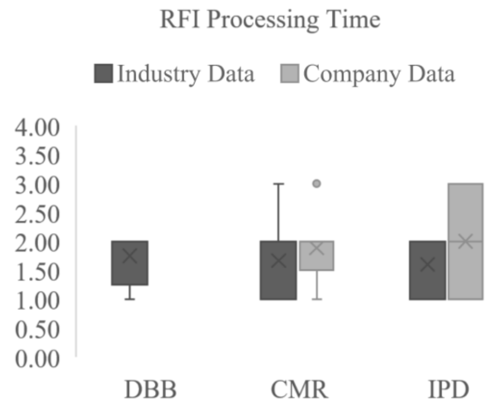

Figure 9: RFI Processing Time Performance

PPI PERFORMANCE EVALUATION AND COMPARISON

The PPI scores from 22 projects[9] were calculated, scaled, and then compared. The results are shown in Figure 18. The performance ranges of the CMR and IPD projects are close. However, the average scaled PPI score of the CMR projects is lower than the IPD projects in general. The company outperformed the rest of the industry in terms of both CMR and IPD projects.

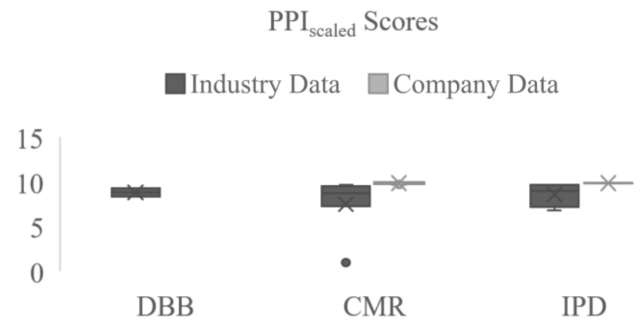

Figure 10: PPI Scoring Performance

DISCUSSION OF RESULTS

The overall performance of IPD projects scored better on the PPI than other delivery systems for both the company's IPD pilot projects and the industry project data. Additionally, IPD was the best-performing on average in terms of: Punchlist items per \$1M, RFI per \$1M, Quality-Related Percent Change, Design-Related Percent Change, Change Order Processing Time, Absolute Project Percent Change, Schedule Growth, Cost Growth, and Budget Factor. This amounts to 64% (9/14) of the assessed metrics (recall that the qualitative metrics, as well as safety, are not differentiators between PDS). The company's consistently better performance than the industry on both IPD and CMR projects is not solely due to the delivery system. The company is a recognized leader in CMR delivery and as such is and was able to realize exceptional performance under that system. This performance is in part due to lean practices that are embedded in the company's culture include use of Building Information Modelling (BIM), the Last Planner system, the Big Room, and others. The researchers believe the company was thus more 'IPD-ready' than it had previously thought and was hence able to realize the benefits that research has long shown IPD can deliver effectively. However, that is not to discount the ability of IPD's risk-sharing, incentivization of collaboration, and multiparty

[9] Sufficent data to calculate the PPI was only available from 22 projects: 2 (9%) DBB, 14 (64%) CMR, and 6 (27%) IPD projects.

strategy to improve communication, design quality, and performance, as was seen in the more expedient processing of changes and reduced amount of overall project change and requests for information, among other performance indicators. The key understanding is that IPD and lean are tied together – lean theory and practice facilitates organizational paradigm shifts, while the IPD system provides an avenue to utilize those lean tools and practices in pursuit of a shared project goal.

LIMITATIONS

As this study was a case-study type examination of a specific company's transition into IPD, it necessarily collected new data only from one company. However, this methodology can be easily adapted to other company-specific examinations, and over time an understanding could be built of the industry's transitions to IPD. For such an investigation to occur, it is likely based on previous work (Hanna & Morrison 2021, Ibrahim et al. 2020, Labib 2019, Antoine et al. 2018) that closer to 100 datapoints would be needed.

Furthermore, this study focused on healthcare sector projects. As a result, findings about the relative performance of the PDS in question may not directly translate to other industry sectors. Again, however, the methodology is sound enough to be applied to other sectors should further researchers wish to do so.

CONCLUSIONS

Thirty-one construction projects from within the healthcare sector were analyzed to assess the performance of a major contractor's transition to IPD in their work. Eleven projects from the contractor were collected (including the two initial IPD pilot efforts) and twenty were supplied from institutional data held by the researchers. Eighteen performance metrics were identified, and fourteen of them were used for comparison (safety, project system quality, and business image were excluded – safety due to its lack of correlation with PDS as defined by previous research, and the other two exclusions due to the structure of the metric being qualitative in nature and therefore ill-suited for comparisons of this type).

The areas in which IPD was the superior performer are logical, given the priority that this lean delivery system places on communication, coordination, change management, scope management, and quality. Specifically, it was found that IPD was the best performing PDS in terms of RFI per million dollars, as well as punch-list items per million dollars, percent change, and change order processing time as compared to CMR. DBB, while included for referential comparison, was not representative, as the company examined did not use the DBB PDS.

Moreover, this paper presents an easy-to-adopt framework for other companies wishing to develop report cards on their IPD efforts to utilize as part of their project scoring. The Project Performance Index (PPI) allows for disparate projects to be compared within a company and across the industry. As an ancillary benefit, performing this type of analysis will encourage contractors to begin tracking more project data (if they do not do so already) which will improve their own outcomes and allow for more detailed research in the future.

Most importantly, the researchers were gratified that the results of this comparative effort included an enthusiastic reception to the IPD pilot projects the company had embarked upon and an intention to pursue more work with this contracting strategy in the future. Given that contractors must be selective about what they bid on, identifying IPD as a differentiator that points toward a more successful project is a valuable insight for this contractor and for other industry practitioners, who can easily apply this method to assess and monitor their own IPD implementation efforts.

COLLABORATIVE DIALOGUE DURING THE PRE-TENDERING PHASE TO MAXIMIZE PROJECT VALUE GENERATION

Valeria Vecchio[1], Abbey Dale Abellanosa[2], Bernadette Konwat[3], Yu Wei[4], and Farook Hamzeh[5]

ABSTRACT

The construction industry has widely adopted traditional project delivery methods, such as design-bid-build, to develop conventional construction projects, where only one main contractor is granted the project contract. Selecting only one main contractor for the project results in the waste of valuable ideas coming from the rest of the bidders who participated in the tendering process but did not win the bid. These ideas, coming from the contractors that lost the bid, are usually not considered during the project execution, even though they could increase the value of a project, shorten the schedule, and reduce costs. As an alternative to solve the current gap of lost creativity and ideas coming from contractors that were not awarded the project contract, this study will explore the workarounds to promote partnership between key stakeholders during the pre-tendering phase by involving multiple contractors instead of a single construction project, to develop innovative ideas that could maximize the value of a construction project. The importance of collaboration and co-creation of value is widely emphasized in lean construction. Experts in the construction industry with a background in collaborative delivery were surveyed and interviewed to understand their opinion on the proposed topic. The experts from both backgrounds concluded that involving multiple contractors instead of just one main contractor is a feasible idea, but it will take effort from all the stakeholders to compromise on this type of agreement. The benefits and constraints of implementing collaborative dialogue are further discussed in the following sections of this study.

KEYWORDS

Value generation, project definition phase, key stakeholder engagement, procurement strategy

INTRODUCTION

Traditionally, the construction industry strives to deliver a construction project that complies with a pre-established schedule at the lowest cost possible. Current practices such as Lowest-Cost Procurement and Design-Bid-Build allow the owner to select a single contractor based

only on the total cost of the proposal, which leads the client to choose the lowest-cost option out of all the bidders, without considering important aspects such as qualifications, quality, and added value for a project (Nguyen et al., 2018). In addition, the competitive nature of the current procurement methods, where only a single contractor is granted the contract, results in wasted creativity and a lack of innovative ideas from other bidders that could have added significant value to the proposed project, but will not be applied since these contractors were not awarded with the contract.

Recently, the construction industry is leaning towards a more collaborative work strategy (Mosey, 2019), where methodologies such as Design-Build (DB) and Integrated Project Delivery (IPD) are being implemented (Maturana et al., 2004; Tillmann et al., 2017). Procurement strategies like Best Value (BV) and Competitive Dialogue (CD) allow the owner to select a contractor based mainly on proposals that could add value to the project. However, this does not solve the wasted creativity issue that results from choosing only one contractor and not using the innovative ideas coming from other contractors.

As an alternative to resolving the previously mentioned gap, this study proposes the idea of a collaborative dialogue where multiple contractors can be involved in one single project. This would be achievable by combining the BV and CD into a single collaborative procurement. The methodology would follow an initial pre-selection phase that would allow the client to choose the contractor that best aligns with the project they want to develop. After the pre-selection, the owner would have a dialogue with the pre-selected contractors to allow the flow of ideas between stakeholders to improve the current project design and share suggestions that could add more value to the construction before the execution (Wondimu et al., 2018). The several contractors would be compensated just for passing to the dialogue phase, and in case they offer ideas that add value to the project, they would be compensated for them or even hired as consultants for the project, working collaboratively with the awarded contractor. The early contractor involvement (ECI) and flow of ideas between different professionals would open a space for innovation that could lead to cost and time-efficient projects (Nygård et al., 2019; Tillmann et al., 2017). Moreover, advantages and disadvantages of collaborative dialogue are explored through expert interview that is discussed in the results and discussion section.

LITERATURE REVIEW

The procurement phase in construction is defined as a pre-tendering stage in which roles, risks, and responsibilities are identified and assigned among all construction project stakeholders (Ying et al., 2021). The chosen procurement strategy specifies how the interested parties will collaborate to meet the client's specifications regarding a construction project (Wondimu et al., 2018).

Traditionally, the Lowest-Bid Procurement has been selected as the most popular option to choose the AEC team. In the Lowest-Bid alternative, the client selects the contractor based only on the total cost of the proposal, which leads the client to choose the lowest-cost option out of all the bidders (Nguyen et al., 2018). The procurement method has the benefit of allowing the owner of the project to choose the most economical option out of all the bids, but it overlooks important aspects such as the qualifications of the personnel, and the quality of the product, and might lead to conflict due to misalignment of interests and the lack of a clear definition of what value is for the client and the contractor (Nguyen et al., 2018). The last two effects usually make the project prone to suffering schedule delays and cost overruns project (Wondimu et al., 2018). Multiple studies suggest that collaborative approaches such Target Value Design (TVD) and Integrated Project Delivery (IPD), as alternative to the traditional tendering methods, can be integrated into the procurement phase to meet the needs of the project (Mosey, 2019; Musa & Pasquire, 2020; Whelton et al., 2004).

To reduce the chances of misaligned interests and effectively define value as the main objective of a construction project, an alternative to Lowest-Bid Procurement has been developed, known as BV (Nguyen et al., 2018). This procurement method attempts to choose the best AEC team based on what the client considers to add value to the project rather than the low price of the proposals (Ying et al., 2021). Moreover, BV procurement allows for the early involvement of the contractor in a public construction project (Nygård et al., 2019). The procurement method has commonly been used to minimize the involvement of the client during the design and execution phases of the project since the contractor is considered the expert and the only member capable of making decisions related to the development of the construction project (Wondimu et al., 2018). Multiple studies have reported (Lesjø et al., 2019; Nygård et al., 2019; Tillmann et al., 2017; Whelton et al., 2004; Wondimu et al., 2018) that, even though BV focuses on ensuring both value and lower costs before construction starts, there is still conflict and misalignment between the owner and the contractor about these aspects during the execution phase of the project. Furthermore, misalignments of commercial incentives in AEC projects can be avoided if participants select trusted and competent members; business models and key performance metrics is communicated well; stick around to adapt towards the principles of IPD and TVD; ensure that participants are adequately trained in lean construction; and adequate resources to implement IPD and TVD systems (Do et al., 2015).

Ying et al. (2021) conducted qualitative research on BV procurement in New Zealand, interviewing project managers, designers, engineers, and procurement specialists to explore ways to increase innovation and improve the system. The results suggest that innovation can be achieved by promoting a mindset shift among stakeholders and enhancing communication and collaboration throughout the procurement process to achieve the common goal of creating a project with the best value for the client. On a different study, Malvik et al. (2021) evaluated the performance of Best Value (BV) procurement in a public highway construction project, using Integrated Project Delivery (IPD) as the project delivery method. The study attempted to combine BV and Target Value Design (TVD) to improve collaboration among stakeholders. However, the results showed that a lack of transparency in managing the bill of quantities (BOQ) by the contractor and a lack of shared responsibilities during decision-making created conflicts and hindered efficient collaboration between the client and contractor. Since collaboration seems to be one of the root problems during the procurement phase, even with more progressive methods such as BV, other alternatives have been developed to stimulate shared responsibilities and the flow of ideas among interested parties to create a more valuable project.

CD is a procurement approach where the client narrows down potential bidders through pre-qualification, allowing for dialogue and idea exchange to optimize the project and gain more value before officially choosing the contractor (Wondimu et al., 2018). Both Best Value (BV) and CD consider value and price while selecting the AEC team, but CD allows the client to discuss ideas with multiple contractors before deciding on the best option, while BV only clarifies the project's scope and work strategy after selecting a single contractor (Wondimu et al., 2018). Both CD and BP procurement approaches were compared to each other during a research study where the participants of two different highway construction projects in Norway applied both procurement methods to improve the collaboration between client and contractor (Wondimu et al., 2018). The study included face-to-face interviews with executive managers from both sides of the contractual agreement. The results proved that BV and CD allow space for ECI thus, improved collaboration can be achieved in the two procurement strategies (Wondimu et al., 2018). However, pre-selection and dialogue in CD are time-consuming but increase the likelihood of selecting a contractor offering the best value, and optimize the project's original concept (Wondimu et al., 2018).

Wondimu et al. (2018) in essence considered that the key to improving collaboration between the stakeholders of a project stands in the pre-qualification and dialogue steps that are part of the CD. The pre-selection phase allows the client to choose the contractor that best aligns with the project they want to develop, and the dialogue phase allows the flow of ideas between the client, several contractors, and other interested parties to improve the current project design and share suggestions that could add more value to the construction before the execution (Wondimu et al., 2018). Currently, CD only chooses one of the interviewed contractors from the short-list as the construction manager for the project, but an alternative to increase even more collaboration in DB projects and reduce the waste of time for the contractors that were not selected includes that the client compensates the contractors that were selected for the short-list for their participation while hiring contractors with clever ideas for the project as consultants. The disadvantage of this alternative is that it implies additional costs for the client, but the advantage is that there is a possibility that each interviewed contractor comes up with an idea good enough to significantly improve the design and execution strategies for the project, which will result in a more valuable project by including collaboration from all the stakeholders (Wondimu et al., 2018). Although the previously mentioned studies provided valuable information about collaborative procurement, none of the studies addressed how the relationship between multiple contractors would work in a collaborative procurement scenario. Further studies need to be conducted to test this theory, which will be the focus of research for the present paper.

METHODOLOGY

A comprehensive review of previous literature and studies on different procurement methods and project delivery methods will be done to identify the criteria and methods used during the pre-tendering phase and contractor prequalification. The literature review will be used to develop theoretical background on the topic and explore the current problems and issues faced in the current industry methods. Backward and forward snowballing methods will be used to not miss out on both new and old reference papers (Lesjø et al., 2019).

The research method was a mixed-method approach of quantitative and qualitative data collection (Roopa & Rani, 2012). A survey questionnaire was developed and sent to professionals in the AEC industry and gathered data from over 50 respondents. The respondents needed to have at least 5 years of experience, be actively working in the construction industry and needed to have a basic knowledge of collaborative project delivery methods. The respondents must be working under these construction disciplines: design architects, engineering consultants, contractors, and subcontractors. Respondents were from different countries such as Canada, Singapore, the Philippines, and Egypt. The questionnaire was formulated using close-ended questions where respondents were limited to a fixed set of responses and scales are closed-ended.

Lastly, to validate the survey results, interviews were conducted with 2 experts on the collaborative delivery approach and best value practices in the industry. The first interviewee is an experienced land developer in Canada and the second is a construction veteran in the Philippines. Interviews conducted were done through in-depth semi-structured interviews via video conferencing and are recorded and transcribed. A concurrent triangulation strategy is used to compare the survey results and interview responses gathered to determine any confirmation or disconfirmation. This approach will be used to first provide quantitative statistical data and then validate or invalidate based on the quantitative interview.

SURVEY RESULTS

A total of 57 respondents were gathered. Out of the 57 respondents, 43.9% are from the main contractor background, 33.3% are from the Architect/Engineer/Consultant side, 12.3% are owners/developer experts, and 10.5% of the respondents are subcontractors. The distribution of respondents' years of experience is shown in Figure 1. This figure tells us that there are more professionals who have relatively less years of experience. The respondents' work experience in the industry ranges from 5 to 50 years and the designations were owners, architects, project engineers, planning engineers, M&E coordinators, quantity surveyors/estimators, associate directors, and directors, vice presidents, and senior project managers.

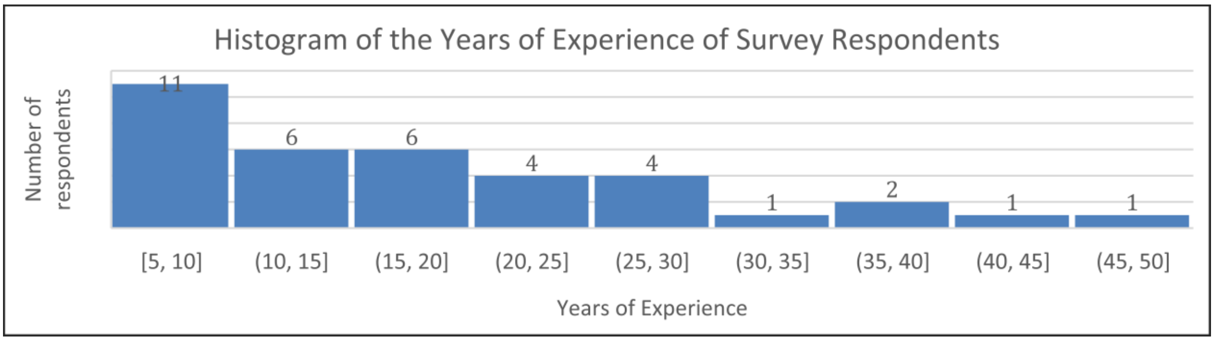

Figure 1: Histogram of the Years of Experience of Survey Respondents

The survey started with questions regarding the role, position, and years of experience of the respondents in the construction sector. By asking these questions, it was easier to identify if the respondents met the criteria to be qualified as participants in the present study. After the introductory questions, participants were asked about their previous experience in collaborative procurement (working with several stakeholders during the pre-tendering phase). The results showed that most of the respondents have experience in collaborative procurement (71.9%) and only 28.1% have not experienced collaboration during this phase of the project. Likewise, 61.4% agreed that collaboration during the pre-tendering phase improves the selection of the AEC (Architect, Engineer, and Contractor) while only a small percentage disagreed (1%). More than 90% of the respondents also agreed that collaborative procurement improves the overall delivery of the project, not only during the pre-tendering phase.

The survey was then divided into two sections, questions about collaborative procurement from the owner's point of view and then from the contractor's point of view. The objective behind this idea was to allow all the participants, regardless of their role within the industry, to think of how collaborative procurement would work from two different perspectives. Some of the questions were designed to be yes/no questions, while others provided additional space for the participants to give their input on the information they were being asked about.

GENERAL PERSPECTIVE

As a more general question, the respondents were asked to rank on a scale of 1 to 5, how hard they think the collaboration or cooperation during the pre-tendering phase could be; with 1 being very easy and 5 as very hard and almost impossible. Only 7% of the respondents believe that it would be almost impossible, and about 52.6% of them believe it to be just at the halfway point, not too easy and not too hard. A summary of the result is shown in Figure 2. Regardless of their role in a project, 96.5% of the surveyed respondents believe that having a dialogue about possible optimal solutions for a project, instead of just a clarification phase before signing the contract, would reduce the chances of conflicts between stakeholders and add more value to the project.

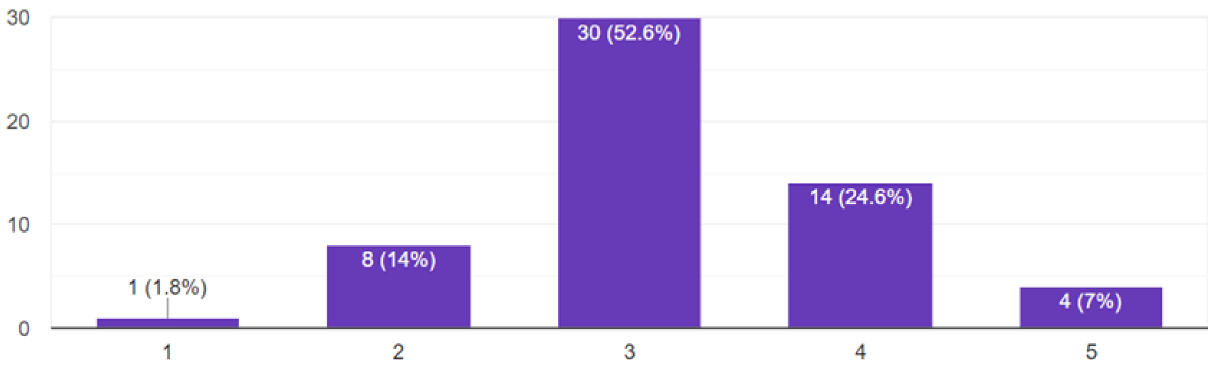

Figure 2: How Hard to Implement Collaboration (1 very easy and 5 very hard)

Owner's Perspective

From the owner's point of view, the results show that almost 90% of the respondents are willing to have a dialogue with several contractors before choosing the most suitable team for the project. However, one respondent highlighted that he will either go with the contractors he is most familiar with or with contractors recommended by people he trusts or from people in his circle. Similarly, if an idea comes from a contractor, who will not be the awarded contractor of the project, 87% of the respondents will consider using the idea if it adds value to the project, but only 63% of the participants are willing to pay for the idea. About 26% of the respondents do not agree to pay for the idea obtained from other contractors and the rest highlighted that it will depend on other factors to be considered such as the cost of the idea, if it is proprietary or not, and if it is an innovation or just an industry standard.

In addition, most of the respondents (74%) are willing to hire the contractors, who were not awarded the project but contributed value-adding ideas, as consultants for the project. However, some participants believe that not all contractors with brilliant ideas can execute their theory properly and that their performance would depend on the scope of the project.

Contractor's Perspective

On the other hand, from the contractor's perspective, almost all (94.7%) of the respondents are willing to have a dialogue or discussion with the owner before signing the contract, despite not being certain about their future participation in the project. The survey results indicate that most of the contractors, 86%, do not get any form of compensation from the owner for losing a bid. The participants manifested, from the contractor's point of view, that 93% of them are willing to participate in the bid process knowing that there will be compensation for participating and giving value-adding ideas to the project. Moreover, 65% of the participants are also willing to be hired as consultants for the project despite not being awarded the contract.

INTERVIEW RESULTS

To validate the results from the survey, and based on the responses of the participants, two interviews were arranged to ask more questions about collaborative procurement, one with a Developer/Owner expert and another one with an experienced Contractor. Some of the questions were the same as the ones provided in the survey, but the interview experience allowed more space for short explanations after every question. In addition, the interviewers were asked about their opinion on the advantages and disadvantages of paying multiple contractors, who were not granted the contract award, for their value-added ideas, and we also asked the experts about their input in hiring several contractors as consultants for a project.

EXPERT VALIDATION (OWNER / DEVELOPER)

The first interviewed expert works as a Vice-President of Development in Edmonton, Canada. He reviews and takes a lead in design directions, manages approvals with the city of Edmonton, and oversees the Construction Managers' work on several projects. He has over 20 years of experience working in the construction industry.

When asked about the popularity of collaborative project delivery, the expert mentioned that there has been an increased interest in this type of delivery method in the last four years due to its economical effectiveness and cooperation between stakeholders throughout the design and execution phases of a project. He mentioned that he had experienced the successful results of collaborative projects himself when his company was able to save $300,000 because of collaborative meetings, where all the stakeholders were able to participate in the decision-making process of a water project after a conflict with one of the suppliers of a pipeline had arisen.

When choosing an AEC team during collaborative procurement, the expert highlighted that he would feel more comfortable working under this type of procurement with a contractor he has previously worked with and has known for many years. In case he is required to seek a new contractor, he would set up an interview to get to know the contractor on a personal level and would do a background check to verify the level of expertise of the contractor and his availability to handle the costs and risks related to the scope of a project.

When asked if he had previously used input ideas of different contractors on a construction project without granting them the contract, the expert said that he had done it before, but not without compensating them for their input. He mentioned that he has hired other contractors, different from the main contractor, as consultants for his projects.

The interview was finalized with advantages, disadvantages, and recommendations about paying different contractors for their ideas and hiring them as consultants, instead of just having one contractor for a project. Among the advantages, the expert mentioned that collaborative procurement has proven to be economically efficient, and the teamwork environment makes the project an enjoyable social experience. When asked about the disadvantages, he mentioned that the relationship between contractors is extremely competitive, and it would be very difficult to make them work together as a team, since conflicts and disputes between them would be very likely to occur. One of the recommendations he suggested is to make the stakeholders and different contractors share what is known as the profits and risk pool. This means that the contractors should be rewarded proportionally for their involvement in a project and the profitability of their ideas. Similarly, in case of financial losses, contractors should take accountability for their actions based on their level of involvement in the event.

EXPERT VALIDATION (CONTRACTOR)

The second interviewed expert has over 40 years of work experience in design, construction, risk management, and project management. He was the former President and CEO of a major construction company in the Philippines specializing in industrial, infrastructure, and specialty works. He is currently the President and CEO of another construction company specializing in mid to high-rise commercial and residential buildings.

Through his work experience, he pioneered early contractor engagement in Philippine power plant projects. He explained that by engaging contractors early, they did not need to wait for drawings to be prepared which saves the total project duration by almost 2 months. Projects were approached like an open book and other stakeholders were treated as partners. However, there will still be a consultant engaged to do the checking and inspection. Every stakeholder shares the risk of quantities but there is also a guaranteed margin of around 15% to 20%, discussed and agreed upon before the collaboration.

When asked what type of projects are more suitable for collaborative delivery, he mentioned that in the Philippines, most PPP projects are already engaging early contractor involvement. Owners now do not go for bidding because, from the time the project is conceptualised, the approvals almost take 3 years. Aside from PPP projects, there is still much hesitancy in collaborative projects, mostly due to owners rather than contractors. From a contractor's point of view, there is no loss in being engaged early because it entails the assurance of a project.

Collaborative procurement has advantages such as saving time and costs for the owner. He explained that contractors can provide more options to the owner, not only based on cost but also on choosing the better methodology. Methodology drives the price. Some designers design specifications that are not available or feasible. By engaging the contractor early on, specifications can be agreed upon with the owner and there will be fewer variations when the project starts.

In another follow-up question, he asked a contractor if he would be willing and if it is possible to collaborate with another main contractor. He agreed it is possible and that they have done it before. They had a previous joint venture with 2 other biggest contractors in the Philippines. "We derive strengths where we are weak", he quoted. In previous experience, since his company is good in electromechanical works, but another main contractor is good with civil works, they collaborated and had a successful project.

The interviewers then asked how tough will introducing collaborative procurement and project delivery be, especially since traditional contracts are competitive instead. Usually, when the competitors rely on a subcontractor to do the work, it means it is not their core competency. Instead of you winning alone, you can suggest joining together, sharing the loss and profit. That is where consortiums come in. However, this can only happen with "mature" contractors. "If you want us to be stronger than the rest, let us combine forces and bring value in different ways", he quoted.

Regarding compensation for contractors contributing ideas, there should be reasonable compensation depending on the level of engagement. If they cannot add value to the contractor company, it is better to accept the compensation rather than join the project and contribute to the waste. According to him, the biggest challenge in this type of delivery is getting the owner to participate willingly in this kind of collaboration and early contractor engagement. If the client is willing to do it and the contract agreement is fair, the contractors will always want to do the work.

To wrap up his final thoughts, he concluded by highlighting that the more owners and contractors adopt the idea, the more benefits they will reap on time and costs and there will be fewer issues, disputes, and arbitrations. Arbitrations put a stop to the beneficial use of the projects. People can do more important things than attend to disputes. If the big industry players will start to adopt this kind of procurement, the advantages are very clear, it saves time and cost. If there is mutual trust, we can eliminate cheating and corruption which is rampant in the construction industry in any country. To be able to do repeat engagements, one cannot cheat. It has more advantages than disadvantages. Once more people accept the idea and become more open to exploring it, they will realize it is all advantageous rather than disadvantageous.

RESULTS AND DISCUSSION

Both the survey questionnaire and the interview results exhibit that there has been an increased popularity of collaborative procurement in recent years. Though this collaborative procurement comes with its own advantages and disadvantages as summarized in Table 1. The results from the survey questionnaire showed that there is a high willingness from contractors and owners to engage in a dialogue before awarding a contract, to discuss project ideas, and elevate the relationship to a more personal level to increase trust among the involved stakeholders, an indispensable element in collaborative projects. Moreover, the survey shows that owners are open to having a dialogue with multiple contractors and using their ideas if it is considered that would add value to the project, even though the ideas are not coming from the awarded contractor.

Table 1: Summary of Advantages and Disadvantages of Collaborative Procurement

Advantages	Disadvantages
Share technical best practices between the owner, designer, and contractor.	The contractor becomes involved in the project before it has been designed in detail and may not provide an accurate price for the construction works.
The earlier the contractor is identified, the greater the potential benefits the contractor can bring to the project.	Traditional contracts generally provide elements of transparency and competition. In early contractor engagement, other contractor bidders could lose interest in the project since the early-engaged contractor will have a competitive advantage.
Well-defined scope of work and target price at completion of conceptual design and fewer potential scope gaps	Conflicts and disputes may occur if there are too many experts in the project.
Owner, designer, and contractor collaborate to achieve goals on overall project cost & schedule; less risk of claims and variation orders from the contractor.	Some great ideas during the pre-tendering phase cannot be executed well.

As supported by experts' personal experience, collaborative procurement was also sought to be both cost and time-efficient and contributed greatly to the success of projects. These findings are in support of the ideas for collaborative procurement under lean construction theory as discussed in the studies of Gomes & Tzortzopoulos (2020) and Malvik (2022). The challenge, based on the owner's point of view, contractors are the ones who may not be willing to participate in early collaboration, which was the opposite of the contractor's point of view. Contrary to owners' belief, contractors consider that there is no loss in being engaged early in the procurement phase because it ensures that they would be part of the construction project. Study results also show that there is no problem with contractors working with multiple other contractors. However, due to the culture of competition in the construction industry, conflicts between multiple contractors during execution are likely to occur. This would represent a challenge for collaborative procurement in the present practice in construction.

Some suggestions from the owner and contractor's perspective are to share profits and risks between stakeholders, follow an open-book accounting format, and offer a guaranteed margin to the contractor for their involvement or consideration in a project. In addition, hiring other contractors, different from the awarded contractor, as consultants or paying them for their ideas have been done before and is possible if it gives benefits to both parties. Contractors are willing to contribute their ideas early in the project planning phase if they will be well compensated for their value-adding ideas. Compensation should be proportional to the level of involvement and application of the ideas of the contractors because some ideas cannot be executed well.

CONCLUSION

Collaborative procurement can only be achieved if all the stakeholders work together towards accomplishing the objective of adding value to a project. Following lean principles is key to ensure an efficient collaboration between stakeholders towards a common goal. Project owners could be initially hesitant to reward multiple contractors for their bidding participation and valuable ideas since it represents a financial increase in the overall project cost. However, financial compensation motivates stakeholders to work as a team and create beneficial ideas for the projects to achieve a common goal. Antagonistic behaviors within the project team should be avoided, and conflicts should be resolved with the sole purpose of optimization and continues improvement, which are essential lean principles. Additionally, the early involvement of the partners in selection process increases the chances of building a well-functioning team (Tillmann et al., 2022). Early stakeholders' involvement provides the opportunity to work on the expected project quality through open and continuous communication, resulting in lower costs and a reduced schedule for a construction project.

In conclusion, collaboration and early contractor involvement are dependent on the accurate application of lean principles for the method to work. Stakeholders are required to work as a team to increase innovation and efficiency in construction projects. Including key participants of the project in the early design phase results in shared knowledge and continuous improvement, reducing the occurrence of common mistakes during the project execution phase, such as the case of project delays. Each participant is rewarded for their value-added ideas, which motivates contribution and flow of ideas within the team.

As demonstrated in this study, owners, A/E, contractors, and other trade partners are mostly open to the idea of collaboration in the pre-tendering phase to improve value during the execution of the project, as it is already a technique that has been widely used in many countries. The method still needs improvement, but industry practitioners who have already experienced this kind of collaboration consider the method as time efficient. The interest in collaborative procurement could further increase if proper compensation, proportional to the ideas contributed by the contractors/trade partners, is stipulated before the bidding for a construction project. This study mentions that trust between contractors could be a difficult aspect to resolve during collaborative procurement.

Further research should be conducted to investigate solutions to this problem. Additional research could evaluate the impact of applying open book approaches for collaborative procurement and alternative methods to deal with conflict between stakeholders in case of a collaborative contract. Moreover, evaluating contract pricing for added value for ideas is an area that could benefit from further research. Research on this topic could explore ways to incentivize contractors to offer innovative and value-adding ideas by incorporating performance-based incentives in the contract pricing. This could include mechanisms to measure and compensate for the added value generated by these ideas, such as a share of the cost savings or additional revenue generated.

TOWARDS A FLOW-BASED DISRUPTION METRIC: A CASE STUDY

Eran Haronian[1] and Shmuel Korb[2]

ABSTRACT

Construction projects are inherently ad-hoc, meaning if disruptions arise, it can be hard to quantify the impact of the “damage” that has been done to the cost or timeline as a result of the disruption, as there isn’t necessarily a nominal steady-state condition to compare it to. In this paper, we present a case study of an infrastructure construction project that was beset by over a hundred documented disruptions due to a politically charged project that had ongoing, active attempts to interfere. Traditional approaches to quantifying the impact of disruptions presume there is a baseline against which the disruptions can be compared, which is not the case in a unstable project. Also, they are inherently “transformation” in their approach, whereas a Lean Construction approach would recognize the importance of taking a more holistic view incorporating elements of Flow and Value. A WIP-based metric of the project outcome, called “WIP-Time” is proposed and assessed in the context of the case study.

KEYWORDS

Disruption analysis, Transformation-Flow-Value theory, contract disputes, production control

INTRODUCTION

Construction projects have long suffered from inefficiencies, leading to cost overruns and schedule delays (Egan 1998). When problems occur, project stakeholders (owners, project managers, contractors) naturally want to understand their nature, so that responsibility can be apportioned and parties “made whole” through compensation. To this end, the Society of Construction Law (SCL) publishes a “Delay and Disruption Protocol” (Society of Construction Law 2017) that is a widely-used framework for mediating disputes between the parties that may arise due to deviations from the agreed project scope.

The SCL defines a disruption as “a disturbance, hindrance or interruption to a Contractor’s normal working methods, resulting in lower efficiency” (Society of Construction Law 2017). Disruptions are distinct from delays, though the two are linked and often lead one to the other. In this approach, disruption events are identified and quantified, using methods like the “measured mile analysis” (Ibbs and Liu 2005). In a measured mile analysis, periods of undisrupted work (the eponymous “measured mile”) are compared to those suffering disruptions to assess the impact of the disruption event on the productivity of the work.

Underlying the measured mile analysis (and the other methods proposed by the SCL) is a transformation-centric paradigm. In Koskela’s Transformation-Flow-Value theory (Koskela 2000), there are different approaches to conceptualizing and understanding production, of which the transformation approach is but one. The Delay and Disruption Protocol makes frequent references to work efficiency, lost productivity, and analyzing direct and indirect costs. All of these clearly indicate that they are solely focused on the actions of transforming the raw

materials into finished products, which in turn implies they are not taking into account the Flow (how the products flow through the production system) or Value (how the value is created for the end customer, and conversely which elements do not add value and thus are waste) approaches.

In this paper, we present a case study of a project that had over a hundred disruptions, as well as a preliminary metric based on integrating Work In Progress (WIP) in order to assess the impact of the disruptions on the flow of the project and the capability of the project to generate the planned value. While there are Lean-related metrics that have made great improvements upon metrics like the measured mile, such as the Percent Plan Complete (PPC), used in the Last Planner System to evaluate the ability of the team to meet their weekly commitments (Ballard 2000), or the Construction Flow Index (CFI), which quantifies the quality of the production flow (Sacks et al. 2017), these were not found to adequately address the need of quantifying the impacts of disruptions on the project outcome.

PROJECT BACKGROUND

The case study project is a linear infrastructure project (a new rail line) that expands over 20 km, with a cost scope of US$200 million. The general work sequence for the project is presented in Figure 1. In the first stage, structural linear elements such as retaining walls were built (tasks A, B, and C in Figure 1) in parallel with the construction of structural elements in particular locations, such as bridges and tunnels (tasks D and E). After the structural elements, the superstructure of the transportation infrastructure was built (task F), followed by systems and finishes (task G), and handovers (task H). From an engineering point of view, this project was not particularly innovative.

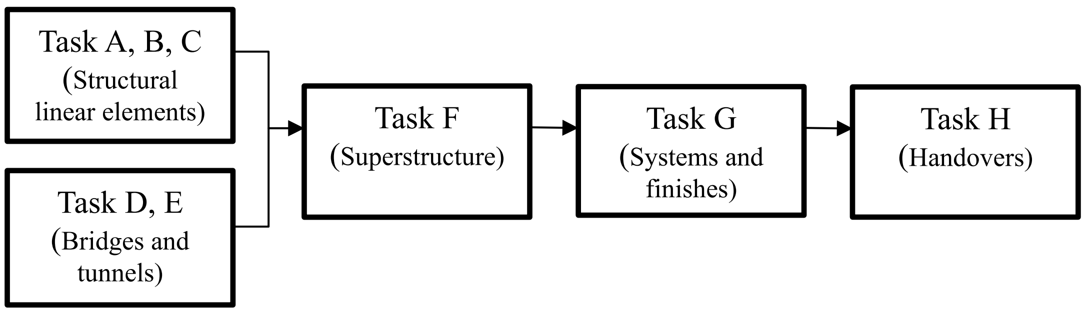

Figure 1: Process sequence for the infrastructure project

While this sequence seems fairly straight-forward, in practice, the project was subject to over one hundred documented disruption events in less than a year. These disturbance events were all caused by external parties, who were attempting to actively interfere with the project. The project was politically controversial, leading to objections, and it became a lightning rod of sorts through which political frustrations were vented through attacks on the project.

The disruption events recorded by the contractor, and categorized based on which type of "waste" (Ohno 1988) they caused:

- Disruptions leading to re-work: damages were caused to the product, as a result trades were required to return to previously-completed sites to perform repair or do the work again. For example, off-road vehicles were driven over graded substrates that had been smoothed and awaiting the next course. The tracks left by the vehicles meant the material had to be re-graded, effectively doing the work again. In other instances, sewage was routed into the work sites, which required drying them out and possibly disposing of contaminated materials.

- Disruptions leading to waiting and transportation: materials (such as steel) and equipment (such as concrete forms) were stolen. As a result, the workers would have to wait for a renewed supply, either from external suppliers or by additional transportation on of the materials within the project (and given the 20km extent of this linear project, this could be quite far).
- Disruptions leading to movement: in general, as WIP levels increased due to the disruptions preventing the closing out of work areas, trades were required to move back and forth from one location to another as they addressed the problem areas. In addition, due to damages to access roads to the site, work trades were sometimes required to travel via alternate (longer) routes. Finally, the project sites were used as illegal dumping sites for construction and other wastes, requiring the removal of more than a hundred thousand cubic meters of waste that had been deposited on the work sites.

While individual disruptions (like theft) might not be clearly political, their high rate of incidence relative to other similar projects made it clear that there was additional motivation beyond random opportunism. The impact of all of these disruptions was to greatly delay the completion of the project tasks, and as a result the entire project suffered, as well. Figure 2 and Figure 3 show the time-location diagrams of one section of the project, with each task shown as a diagonal line. Note that a time-location diagram, which is common in infrastructure projects, has swapped axes from a Line-of-Balance chart (Kenley and Seppänen 2010): time is on the y axis, progressing downwards, and the project locations are on the x axis. The actual project delivery took significantly longer for all tasks to be completed, due to the multitude of disruption events. In Figure 3, the disruptions events for 2022 are shown as small stars (those from earlier in the project were not sufficiently recorded), 120 disruptions in all during the period of a year. As the project (railway construction) was well-understood and relatively routine, it was clear that the disruptions were the cause of the delays, particularly when compared with similar projects that were not subject to the same barrage of disruptions.

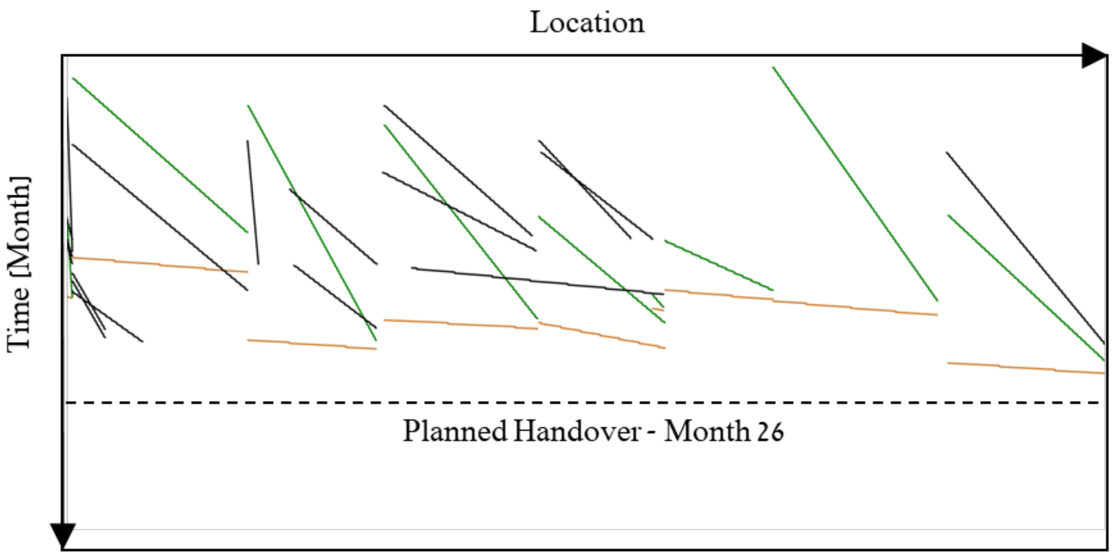

Figure 2: Time-location diagram of the planned schedule for one section of the project

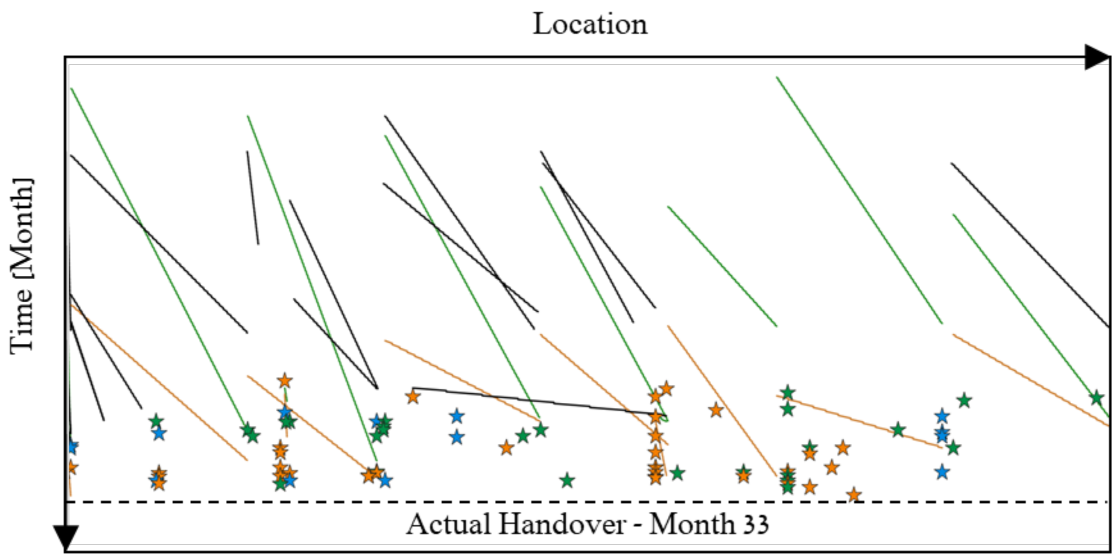

Figure 3: Time-location diagram of the actual schedule for one section of the project, including the 2022 disruption events (show as stars)

A FLOW-BASED METRIC

LIMITATIONS OF EXISTING APPROACHES

As mentioned above, each of the disruption events was documented, using the SCL approach of trying to quantize the financial damage caused by each of the disruptions. For example, in the case of stolen material, the replacement cost of the material would be presented, or in the case of damage, the cost of the workers' time to repair the damage. But a harder question to answer remains what the impact on the overall project is of each individual disruption event.

For example, the missing material could mean that the work for a particular segment of the work would not be able to commence. So either the workers would be underutilized, or they might engage in "making do" (Koskela 2004), which could lead to further waste. And when the material does arrive, the tradespeople have to be scheduled away from what they were supposed to be doing at that point to return to the newly-arrive material.

One approach for trying to address this problem is reductionist in nature: for each disruption event, create an estimate of the delay caused by that one disruption. In the case of rework, how much time will it take to perform that rework. Or in the case of stolen material, how long will it take to source a replacement and have it delivered. Then, the time-impact of each individual event on the critical path can be assessed, enabling the quantification of the total time impact of all the events on the project duration.

This thinking is behind the approach suggested by the SCL, which recommends constructing a "Baseline", "Impacted", and "Accelerated" timeline for the project. The baseline is the plan, prior to any of the disruptions. The impacted timeline is calculated according to the critical path and reflects the total impact of all the individual events. And the accelerated timeline is what the contractor is capable of achieving (or has in practice achieved) if they work hard and bring on additional resources.

But a reductionist approach is flawed in this scenario, since it assumes that the individual disruptions and delays are sufficiently independent events (especially if they are not on the critical path). In practice, any construction project is a tightly coupled network, invalidating that assumption. A piecemeal approach to time delays doesn't necessarily reflect the system-wide impact of the total sum of the disruptions; in this case the whole is different than the sum of its parts. Even the necessity of starting tasks, then stopping when disruptions arise, then starting again can have costs, as fragmented work carries the cost of task switching.

A New Metric

To that end, a new metric was developed, that incorporates the Flow and Value approaches that are distinct from a pure-Transformation approach. The metric is based on an analysis of the level of Work in Progress (WIP) over the lifetime of the project.

As Little's Law (Hopp and Spearman 2011) describes, WIP is directly related to production throughput and the cycle time of products leaving the system. WIP has long been a focus of Lean thinkers, as WIP is inventory, which is a form of waste (Ohno 1988). Early pilgrims to Toyota factories described what we now call Lean as "Just in Time" production, as their attention was drawn to the low levels of WIP in the production system. In the world of software, the "Kanban" approach seeks to limit the WIP of work tasks, under the understanding that this will inherently improve the throughput of individual tasks.

In construction, particularly linear infrastructure projects, the concept of how to measure WIP is a bit more amorphous and up to the discretion of a planner. A unit of work might be a sub-area of a building, or a room, or in the case of a new road, a "roadel"(Haronian and Sacks 2020). The important aspect is not finding a globally accepted definition of what the "unit" is as much as being mindful of what is appropriate for the project in question and then studiously tracking the level of WIP throughout the lifetime of the project.

In the case study project, WIP was defined as sections of the train tracks of roughly equal length. Due to the differences in the nature of the different tasks, the WIP was defined differently for each.

The graphs in Figure 5 show the levels of WIP of the tasks over the lifetime of the project, both Planned and Actual. The WIP is the amount of "open" work areas, either according to the original plan or those that the contractor had to leave “open” due to the ongoing disruption events. The disruptions prevented the contractor from completing the works as planned and closing out work areas, leaving the WIP high. Trades were often forced to move the work teams among the various areas to address the problems as they appeared. Keeping many work areas open at the same time (high WIP levels) increased costs due to excess transportation of materials, equipment and tools, costs of damages, repair costs, and so on. In other words, WIP is both a waste and it leads to the other wastes, an insight as old as Lean itself.

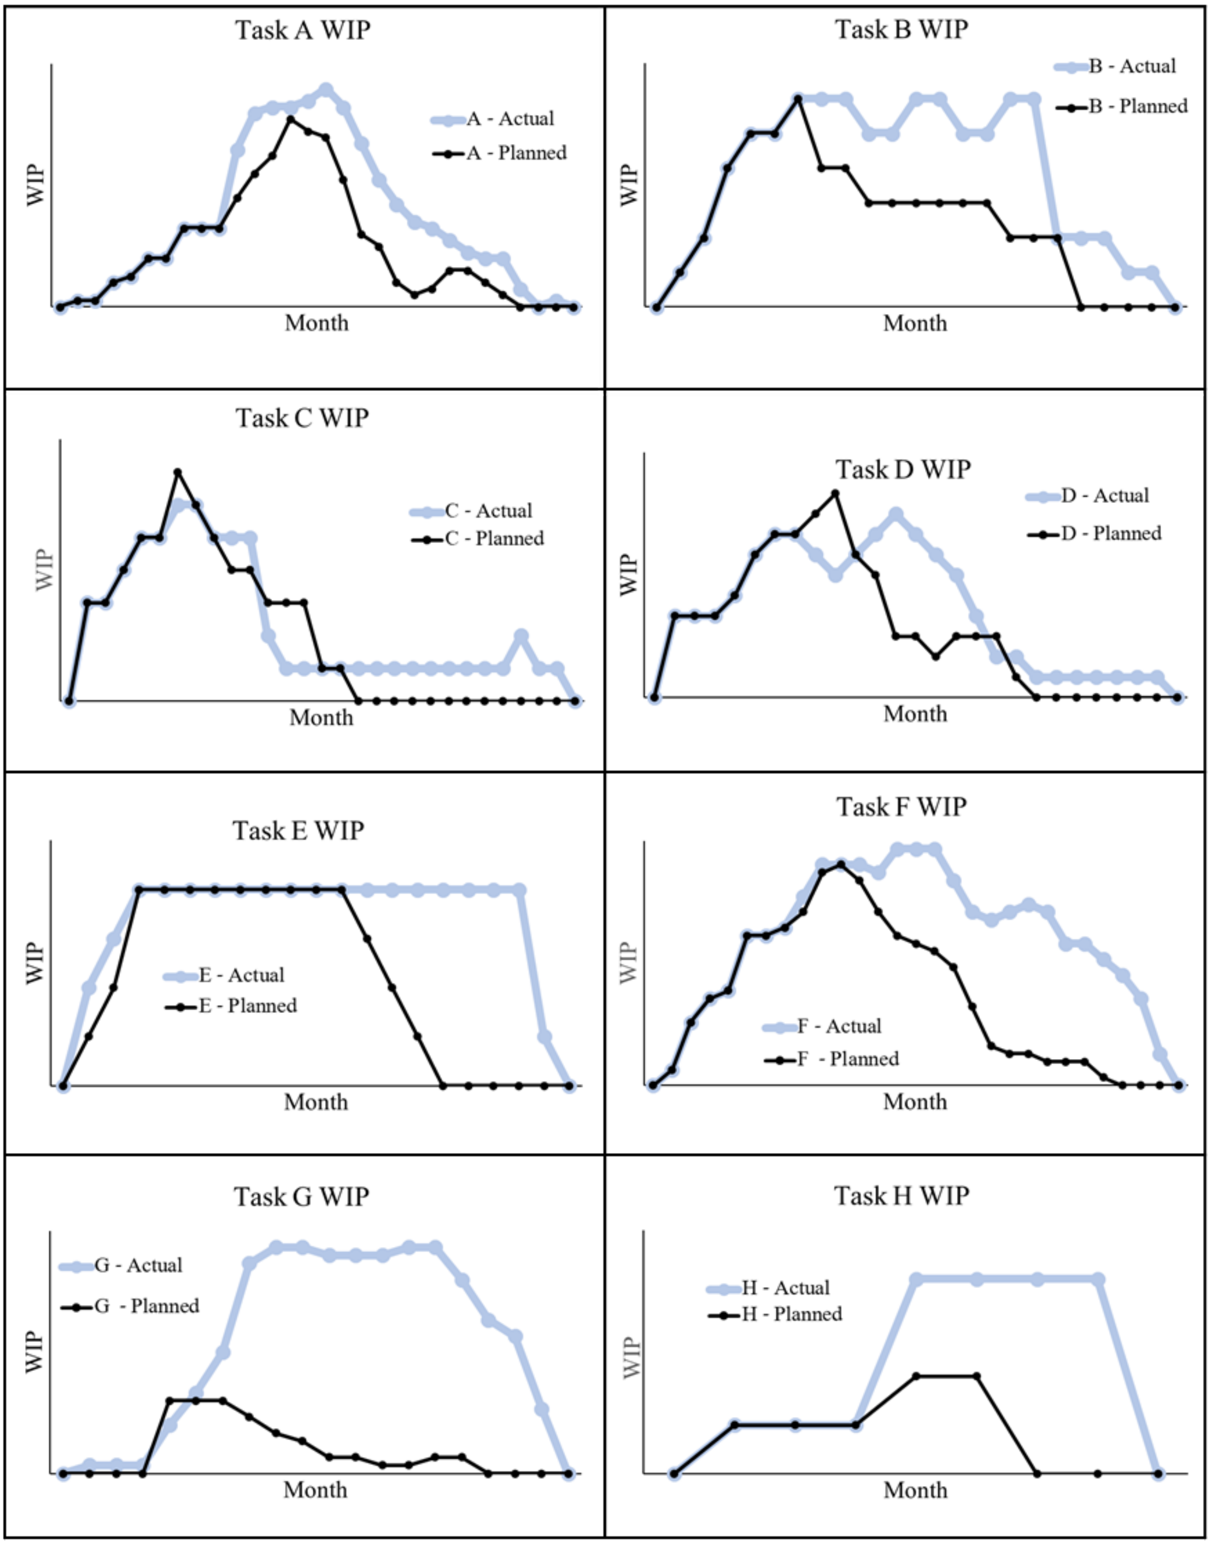

Figure 5: Planned versus Actual WIP for Each of the Tasks, over the Course of the Project

The proposed new metric integrates the WIP curve over the lifetime of the project, and compares the planned versus actual. In other words, the area under each of the curves, which has units of "WIP * time." For each time interval, the open WIP is summed, for both the plan and the actual. This metric is useful because it provides a concrete, flow-based measure of how the disruptions to the flow are leading to work areas that can't be close out and which continue to "gather" wastes. The metric is easy to compute (in this case, merely counting the number of open units each month) but also connects directly to the overall efficiency and effectiveness of the production system, in light of the disruptions.

RESULTS

For the case study, the new metric (WIP-Time) is shown in Table 2.

In this project, the WIP (and in turn the metric) was broken down by task, instead of looking at the WIP for the entire project all together. The reason this was done was in order to increase the fidelity of the measure. The WIP for the entire project jumps quickly to 100% and then stays there until the end of the project timeline, which means that the WIP-Time metric at the level of the project devolves into a proxy for the project timeline (both planned and actual). The project timeline, which a useful outcome measure, is less focused on the quality of the Flow. As the main goal of the proposed metric seeks to measure, in order to derive use from this indicator, it was computed at the task level.

Table 2: WIP-Time metric for each of the project tasks

Task	Planned WIP-Time (Unit-Months)	Actual WIP-Time (Unit-Months)	% Overrun
A	289	425	47%
B	55	87	58%
C	57	66	16%
D	90	113	26%
E	45	70	56%
F	318	533	68%
G	53	321	506%
H	7	19	171%

As can be seen, the WIP-Time overrun ranges from a modest 16% up to 506%. The latter was for Task G, which included laying the communication systems infrastructure for the trains. This was very precise and sensitive work, which was particularly vulnerable to interference and damage, as the disrupters soon learned. This was part of the reason that the WIP was planned to be so low, but in practice, the workers found it difficult to close out the work areas for this task.

In this case study, the metric has been deployed at project completion, as part of the efforts to quantify the scope of the disruptions that caused financial damage to the contractor. But it could also be deployed as a "live" metric, where the numbers are updated weekly or monthly throughout the project lifespan, to draw attention to the problem areas of the project where flow is currently suffering the worst.

CONCLUSIONS

This work presents a preliminary analysis for the impact of disruptions on production flow in construction projects. The proposed analysis and "WIP-Time" metric, as demonstrated on the case study, enables the evaluation of the impact of disruption events on production flow, as reflected by basic production parameters, for each type of activity and trade. The new metric has the advantage of simplicity of calculation while simultaneously connecting directly to the quality of the project value creation. The findings align with what was reported by the construction team on site, indicating that the disruptions prevented the completion of tasks and location handovers, forcing redundant movement, and making the work plans unreliable. The analysis presented in this paper is contrary to the traditional evaluation methods that view production exclusively through a "transformation" lens, without addressing aspects of production flow. The findings provide motivation for further work required to formulate a systematic methodology for evaluating the impact of disturbances on the production flow.

While this project was unique in the political landscape that it was developed and deployed in, there are other scenarios where there may be a number of disruptions, such as other parts of the world with political instability. But any project has disruptions and delays, even if not so many or from inimical third parties, and a proper measure of Flow can serve them, as well.

A large limitation of the work is the open question about the accuracy of the plan. Since the plan is the basis for comparison with the actual outcome of the project, if it is incorrect, then the metric in turn may be equally divorced from reality. Yet in the case of linear infrastructure projects, which tend to have more benchmarks and fewer engineering "surprises", it is possible that the planning is more accurate. Also, a flow metric such as this one does not apportion "blame" in the sense that the metric itself is agnostic as to the cause of the poor flow, be they external disturbances (as in this case study) or internal mismanagement or poor decision making.

Future work is required to turn this general metric into one that can be more directly translatable into financial terms, since as described above, it can be hard to put a monetary figure on poor flow. Likewise, it would be beneficial if the impact of external disruption events could be teased out from those of internal problems (i.e. inefficiencies that are due to or the fault of the project management/execution). And while this case study was a retrospective, the proposed metric could be deployed as a "live" measure of project performance in an ongoing project, with the impacts of its implementation being studied.

Another tack is to examine how worker morale due to a large number of disruptions can impact the project flow, as this project definitely struggled with a demoralizing effect in the face of repeated and ongoing interferences to the work, which took a toll on the workforce.

Ultimately, a Flow-based approach to measuring projects will have benefits, as the metric will in turn bring the focus of project management to the impact on the flow of the evolving nature of the project.

PROCUREMENT OF COLLABORATIVE PROJECT TEAMS – A LITERATURE STUDY

Trond Bølviken[1], Una Obiose Kriston Nwajei[2], and Magnus Mikael Hellström[3]

ABSTRACT

In construction the procurement phase is the connection between the definition phase and execution. Thereby it establishes crucial preconditions for success (or failure) in execution by establishing a shift from competition to collaboration as the fundamental logic in the relationship between customer and supplier. The paradox of the procurement of projects in general and collaborative projects in particular is its aim of establishing collaboration through means of competition.

The paper presents a literature study of methods used in the client's procurement of teams in collaborative project delivery models such as Integrated Project Delivery (IPD), Alliancing and others. Five procurement methods are identified: Direct Negotiations (DN), Team-Based Procurement (TBP), dual Target Outturn Cost (dTUC), Competitive Dialogue (CD) and Best Value Procurement (BVP). Three methods for comparing alternatives are also identified: Weight Rating Calculating (WRC), Best Value Selection (BVS) and Choosing by Advantage (CBA).

The paper discusses public procurement, procuring the team in one or several steps, early or late setting of targets related to Target Value Design (TVD), the use of qualitative and quantitative evaluation, the need to adjust the procurement method, and the need for information and training. The possibility of procurement based on design solution is also presented.

KEYWORDS

Alliancing, Collaborative contracts, Integrated Project Delivery, Procurement, Relational.

INTRODUCTION

Construction is a commercial activity (business) and, as such consists of customers (buyers) and suppliers (sellers). A construction project consists of chains of customers and suppliers where most suppliers also have sub-suppliers for whom they are customers and side-suppliers for whom they are not. In the relationship between customer and supplier, the customer is the principal, defining if, what, how, and when to buy; in contrast, the supplier is an agent supplying something (information, a production process, or a physical thing) to the principal and acting on the order and behalf of the principal (Eisenhardt, 1989). In the construction industry, the customer, initiating and buying the entire project is often referred to as the client, while the parties using the constructed object (the clients of the client) are often referred to as end-users.

The relationship between customer/buyer/principal and supplier/seller/agent undergoes three generic phases. In the first initial phase, often referred to as the definition phase, the customer defines if, what, how, and when to buy. He/she acts on their own behalf and has not entered a commercial relationship with the supplier, who holds no formal or binding position (although he/she might of course try to promote himself to the customer). The second phase establishes the formal and binding relationship between the customer and the supplier. The customer decides from whom he/she will procure, and the commercial terms are agreed between the parties. Taking the customer's perspective, we will refer to this as the procurement[4] phase. In the third phase, execution, the delivery takes place.

By passing on the need and intents of the customer to the supplier, the procurement phase is the connection between the definition phase and execution. Thereby it establishes crucial preconditions for success (or failure) in execution. It also establishes a fundamental shift from competition to collaboration as the fundamental logic in the relationship. By competition, we mean that the customer, in one form or another uses the presence of competing suppliers to gain an advantage for himself, while the suppliers try to exploit their strengths. Procurement occurs in a market where the parties look after their own commercial interests. This is done through different forms of direct and indirect competition. By direct competition, we refer to competitive tendering and parallel negotiations, and by indirect competition, we refer to the option for the customer to terminate exclusive negotiations and contact an alternative supplier. Through the procurement phase, the competitive relationship between the customer and several potential suppliers is replaced with an exclusive relationship between the client and the one chosen supplier for the execution phase. This makes collaboration between the two a fundamental requirement in the relationship within the execution phase (even though there will also be conflicting issues and a need for control)[5].

It is, however, commonly agreed that the levels of conflict are often too high and value creation too low in construction. Both public and private clients have traditionally, to a large degree, used transactional contracts awarded by low-bid tendering, taking only price into consideration. These traditional project delivery models have been seen as a major obstacle to improvement and have resulted in an increasing interest in the development of new collaborative project delivery models, such as Integrated Project Delivery (IPD). They are all based on relational contracting (Nwajei, 2021)[6] and aim at high levels of collaboration and the elimination or reduction of the principal-agent problem (Nwajei et al., 2022).

The reasoning above leads us to the formulation of the fundamental paradox of the procurement of projects in general and collaborative projects in particular: it aims at establishing collaboration through means of competition. A good start is often crucial for the success of a project, as in the expression “well begun is half done”. This is the reason why, according to Klakegg et al. (2021), procurement is one of the key elements that constitute a

[4] In their book *Collaborative Project Procurement Arrangements* Walker & Lloyd-Walker (2015) use the term procurement in a different way, referring to Project Procurement Arrangements and Relationship-Based Procurement (RBP), what we would call Project Delivery Models and Collaborative Project Delivery Models (Nwajei et al. 2022). In this paper we see the procurement process as consisting of three phases: 1. the design of the process. 2. the procurement process, (identifying and comparing alternatives and their differentiating features), leading up to 3. the actual procurement (the decision of whom to engage and the closing of the agreement which the chosen party). Our paper is related to phases 1 & 2 as the specific phase by which the relationship between the client and his supplier(s) is established.

[5] This balance and the fact that the parties must pursue both the interests of the other party and the interests of their own, is called the principal-agent problem and is the topic of agency theory (Eisenhardt, K. M. (1989). Agency theory: An assessment and review. *Academy of Management review, 14*(1), 57-74.

[6] In literature and different parts of the world, variants of these models are named Integrated Project Delivery (IPD), Partnering, Alliancing, Lean Project Delivery, Collaborative Contracting, Relational Contracting, and probably others. The differences between these variants are not the topic of this paper, and we will for ease refer to them all as IPD.

project delivery model. Lahdenperä (2012) describes a need to balance between early collaboration and competitive tension. One of the key issues in agency theory is the risk of adverse selection of a supplier (agent) (Eisenhardt, 1989).We could therefore expect the new collaborative project delivery models to have a high emphasis on how to approach procurement, that is, how to carry out the competitive selection of the team in a way that, instead of hindering, facilitates collaboration in the execution phase. This turns out not always to be the case. Research has to a large degree, focused on the collaborative processes in the execution phase, typically through observation of case projects. Nwajei (2021) points out that gaps exist from the limited empirical evidence on this subject and suggests further empirical examination of procurement and its effect on the relationship between the parties. Nwajei et al. (2022) summarise how the central components of collaborative project delivery models are described in literature and find that the selection and formation of the team is addressed as one of the fundamental functions of IPD in only two out of eight referred articles.

This lack of attention leaves researchers with limited overview of the procurement methods used and hardly any knowledge of the consequences of the different procurement methods both for the procurement and subsequent development and execution phases. This paper is part of a Ph.D. research project addressing these questions through understanding how IPD projects are, could, and should be procured. The paper presents the results of the first step: a study of how procurement is described in existing IPD-related literature. First, we describe the method used in the study. Then we present and discuss the identified procurement methods related to IPD. The goal is primarily to identify and give an overview of the methods, not to discuss their pros and cons.[7] The second step will be to expand and include empirical data in a journal article that will address the paradox of IPD procurement.

METHOD

The paper presents the results of a systematic literature review, of the procurement of a team in IPD contracting in construction. The review is based on Booth et al. (2016) guide to conducting a systematic and rigorous process and is in accordance with PRISMA reporting standards.

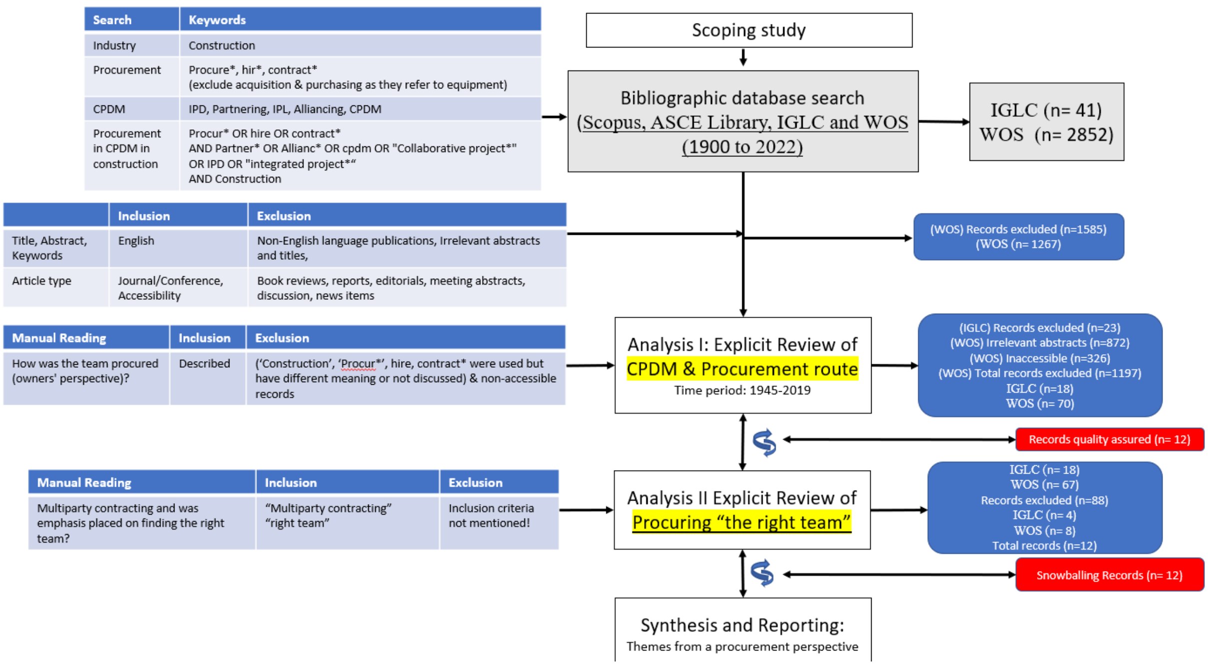

Figure 1: Flow chart of the literature search

[7] Walker & Lloyd-Walker (2015) discuss pros and cons regarding some of the procurement methods we identify in this paper.

This search, see Figure 1, followed the following steps: 1. A systematic search in scientific databases, and 2. Snowballing from identified articles in combination with direct mail to some of the main contributors to the IPD literature asking about the literature on procurement of IPD they may be acquainted with.

SELECTING JOURNALS AND PAPERS

The review involved searching for 'peer-reviewed journals' in the World of Science database (WOS) and the International Group for Lean Construction database (IGLC) from 1900 to June 2022. A total of 2852 articles from WOS and 41 articles from IGLC were identified that had abstracts, title and keywords containing: 'Construction' in combination with: 'Procure*' OR, 'hir*' OR 'contract*' OR 'IPD' OR 'Partnering' OR 'IPL', 'Alliancing' OR 'CPDM' as shown in the flow chart, Figure. 1.

The search results were cleaned, excluding false positives (literature on a different or unrelated topic), non-English language publications, book reviews, reports, editorials, meeting abstracts, discussions, and news items, (WOS = 1585, IGLC = 0). Second stage cleaning, checking the title, abstract, keywords, and, if necessary, the full publication, identified irrelevant abstracts (WOS = 872, IGLC = 23) and inaccessible articles (WOS = 326, IGLC = 0). Articles were rejected if one of the words 'procure', 'hire' or 'contract' was used in a different meaning or not discussed.

Third-stage cleaning validated the efficacy of the exclusion criteria by double-checking the results resulting in 12 new admissions to WOS articles. Further cleaning reduced 100 articles to 85 articles (67 WOS and 18 IGLC), by examining the significance of the articles in discussing 'procuring the right team'.[8] Subsequently, this number (85) was further reduced to 24 articles by only retaining articles relevant to multiparty contracting (IPD, alliancing, consortium or multiparty contracting').

In line with the approach taken by Booth et al. (2016), the quality of the articles was appraised. Therefore, articles and publications not included as part of the search were instead used as a starting point for additional citation searches (snowballing). In total, we ended up using a total of 24 documents (articles, handbooks/guides and books), of which 8 came from the WOS search, 4 from the IGLC search and 12 were snowballed documents.

PATTERN OF PUBLICATIONS

Compared to the total amount of publications on IPD, the number of publications addressing IPD procurement is limited, figure 2. Guide/handbooks and were the most useful sources of information figure 3. The publications on IPD procurement typically describe one or more procurement methods; some also give advice. However, only very few discuss the consequences of the different procurement methods for the procurement process itself. More important than the effect on the procurement process is the effect on the subsequent development and execution phases, and as a result, for project success and outcome. We have, in our search, found no publications discussing this and no publication giving an overview similar to the one we present in this paper.

[8] After the search, we analysed the papers categorically into descriptive (describing how IPD teams are procured) and prescriptive (giving advice and describing how IPD teams should or could be procured). This turned out to be unsatisfactory, the reason being that some papers contained a mix of the two, while in other cases it was somewhat unclear to what degree the presentation actually was descriptive or prescriptive. We have, therefore, not included the coding in the presentation of the search.

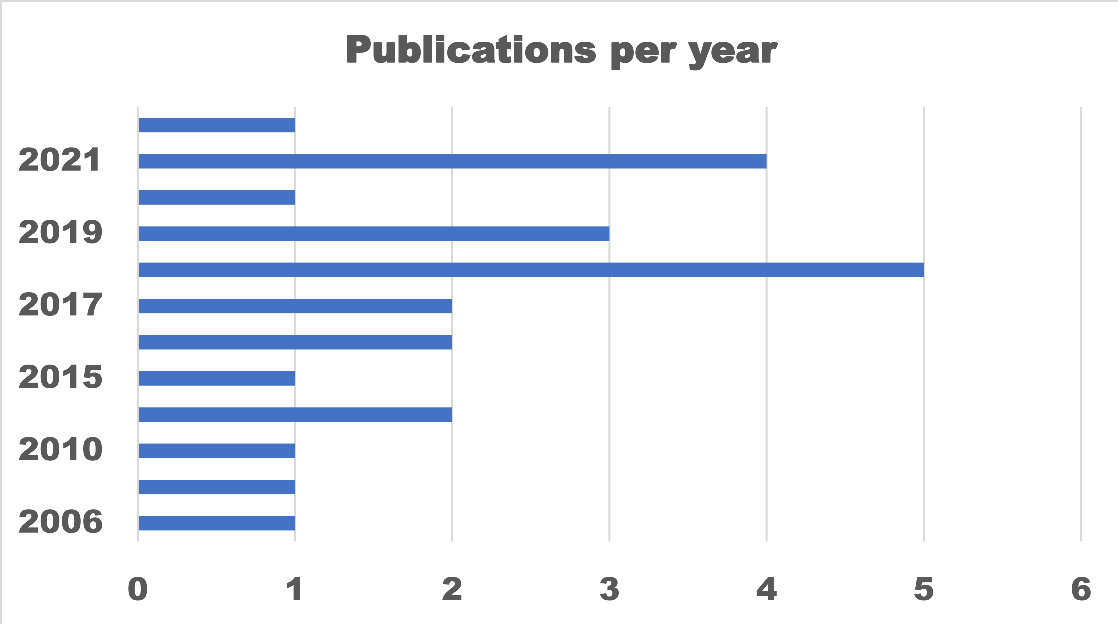

Figure 2: Number of publications per year from the identified literature

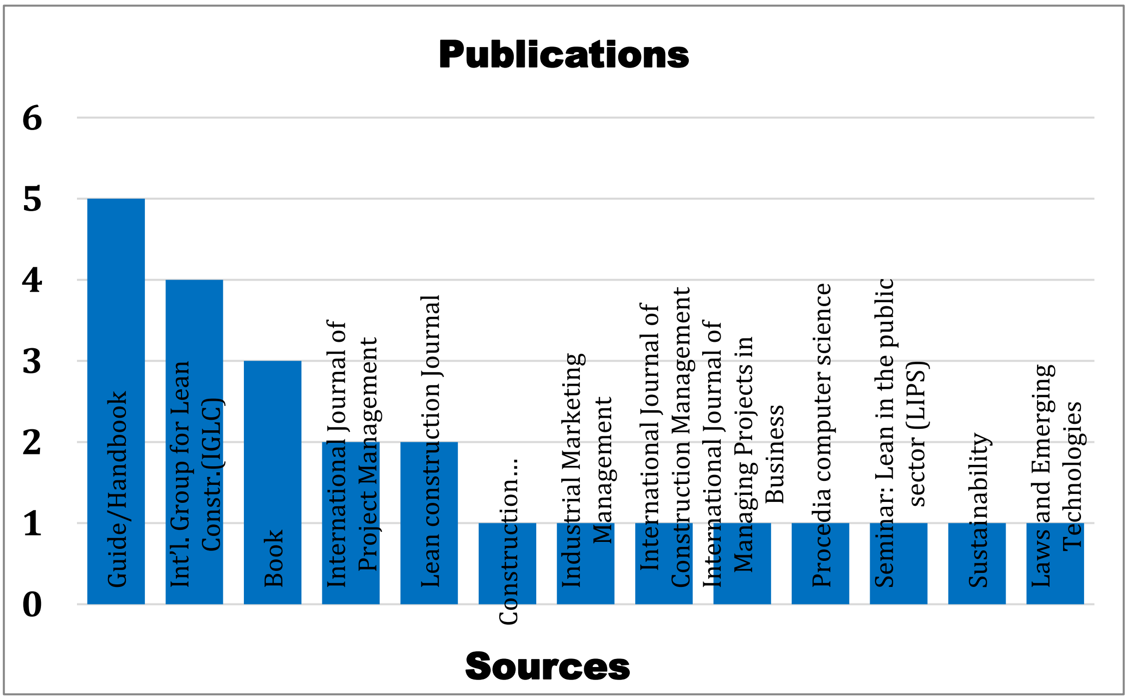

Figure 3: Number of reference sources from the identified publications

PROCUREMENT METHODS

In general, a project proposal might address the following components: solution, process, team, price, and commercial arrangements (Department-of-infrastructure-and-regional-development, 2015). Several authors emphasise that collaborative project delivery models like IPD cannot be based on price alone and require a procurement process based on competence, qualifications, and (product and process) value (e.g. (Heidemann & Gehbauer, 2010; Lahdenperä, 2012; Mesa et al., 2019; Schöttle et al., 2015). According to the Department-of-infrastructure-and-regional-development (2015), a selection process that optimises the opportunity for innovation and differentiation between the proponents should result in better Value for Money (VfM) for the client.

All procurement methods identified in our literature search evaluate the team using techniques like interviews and workshops. In addition to the team, price, or value (related to product or process) other factors are taken into consideration in several of the methods. We have found no example of procurement methods related to IPD focusing only on price or value.

DIRECT NEGOTIATIONS

Some clients might have established relations with design and construction companies they prefer to work with. Crespin-Mazet et al. (2015) refer to this as “relational congruence in the project network”. When this is the case, the client might, instead of evaluating several companies, simply choose to enter into direct negotiations with their preferred partner (Allison et al., 2018; Crespin-Mazet et al., 2015).

TEAM-BASED PROCUREMENT

Several authors (e.g. (Allison et al., 2018; Department-of-infrastructure-and-regional-development, 2015; Fischer et al., 2017; Frydlinger et al., 2016; Mesa et al., 2016, 2019) describe what we in this paper call Team-Based Procurement (TBP) approaches. In the first phase, two or more teams are evaluated, leading to selection of a preferred team. In these approaches, only the team is evaluated, looking at factors like qualifications, competence, previous experience, cultural congruence, alignment with the client’s goals and ambitions, and relational and collaboration skills. Prices or product characteristics are not factors.[9] After selection, the preferred team works with the client to develop the product, the corresponding target price, and other commercial conditions. If this succeeds, the IPD agreement is signed. If not, the client must try all over again with another team (Fischer et al., 2017).

The single Target Outturn Cost (sTOC) process is an Australian variant of Team-Based Procurement. In sTOC there is a pre-qualification process before two or three contenders are qualified to undertake a selection workshop in which they present and discuss their proposed team and ideas for design solutions. They may also, in some cases, be required to offer a fee structure, expanding the parameters beyond the evaluation of the team. (Department-of-Treasury-and-Finance, 2006; Ross, 2009; Walker & Lloyd-Walker, 2015; Walker & Lloyd-Walker, 2020).

DUAL TARGET OUTTURN COST PROCESS

The dual (also referred to as multiple) Target Outturn Cost (dTUC) process is a variant of the single process described above (Department-of-Treasury-and-Finance, 2006; Ross, 2009; Walker & Lloyd-Walker, 2015; Walker & Lloyd-Walker, 2020). The difference is that the competitive elements (regarding team, price, and value) have more emphasis in the dual process. The client workshops in parallel with two preferred teams, and both teams calculate a target price. Both team, price, and value are evaluated in the final selection of one of the two competitors. The goal is to select the best-priced solution with the most attractive team skills package (Walker & Lloyd-Walker, 2015).[10]

COMPETITIVE DIALOGUE

As Competitive Dialogue (CD) is presented by Fernandes et al. (2018), the procurement process is divided into two phases, the contract notice phase and the tendering phase. In the contract

[9] The Department of Infrastructure and Regional Development (2015) therefore calls this procurement approach “Non-price selection”.

[10] The Department of Infrastructure and Regional Development (2015) calls this Full Price Selection. If only fees and not total costs are evaluated, they use the term Partial Price Selection. They do however warn against the latter. Mesa et al. (2016) use the terms Best-value total and Best-value fee

notice phase, the client prepares the request. Based on this, the suppliers submit a request to participate in the competition. The client then selects a limited number (approx. 3) of tenderers through a prequalification process. In the tendering phase, the client has individual parallel rounds of negotiations with all tenderers. During the negotiations, product, process, and commercial-related issues are discussed before the client makes an updated and final call for proposals, and the tenderers prepare and submit their final tenders. Finally, the client evaluates the tenders and awards the contract.

Hietajärvi et al. (2017) present a variant of dTUC and CD (without naming it so). In the first phase, the client prepares the tendering document, which includes goals, budget estimates, and evaluation criteria. Based on this, competing consortiums are established and prepare to present a first tender. The client then selects 3-5 consortiums to continue to the next phase, the negotiation phase. In the negotiation phase, the client and each consortium have workshops where they work collectively to develop content for the proposed project. Based on these workshops, the client evaluates each consortium and selects two to continue the process. These two then update their tenders, including price. Finally, based on the updated tenders and workshop experience, the client selects the winning consortium, with whom they sign a contract for the next phase - development.

Also, Jobidon et al. (2021) present a procurement method that seems to be a variant of dTUC and CD. This method is used in Canada.

BEST VALUE PROCUREMENT

Best Value Procurement (BVP) is founded on the understanding of the supplier (the contractor) as an expert and allows the client to be a non-expert (within the profession of the supplier). The idea is early contractor involvement (ECI) in value creation and risk reduction from the client's perspective in combination with an effective procurement process. The process is divided into four phases: preparation, selection, clarification, and execution. In the preparation phase, the client makes a core document describing project objective and scope, the selection criteria and their weighting, and a maximum price (budget ceiling). Pre-qualification is recommended. In the selection phase, each competing supplier prepares a tender consisting of three two-page documents, in total six pages: in the Level of Expertise document, the supplier describes and documents their capability to fulfil the client’s requirements; in the Risk Assessment document they identify the most important risks from a client perspective and a risk mitigation plan, in the Value-Added document the vendor presents recommendations that can increase value for the client. Based on the three documents, price, and interviews with core members of the vendor’s project leadership team, the client selects a preferred vendor. In the clarification phase, the preferred vendor prepares and presents technical documentation, a project schedule, and key performance indicators. Finally, the contract is negotiated and, if the parties agree, signed. In the execution phase, the risk management plan and periodic risk reports are dynamic documents (Narmo et al., 2018).

BVP has been used in the procurement phase for a IPD road construction project in Norway (Johansen et al., 2021). Wondimu et al. (2018) compare CD to BVP, but not in relation to their applicability in IPD project.

METHODS FOR COMPARING ALTERNATIVES

While the procurement methods describe the entire procurement process, the methods for comparing alternatives focus only on the part of the process (how to compare the alternatives). This means that a method for comparing alternatives will be part of a procurement process and that a procurement process might use different methods for comparing alternatives from case to case. Schöttle et al. (2015) describe and compare three methods (for comparing alternatives-in our case, tenders. They compare the three methods through simulation in a constructed case (based on a real turn-key project). The simulation demonstrates that the size of the differences in scores and the tenders' ranking depends upon the method used.

WEIGHTING RATING CALCULATING

Weight Rating Calculating (WRC) is also referred to as Weighted Sum, Scoring System, Ranked Scoring or Utility Analysis. In WRC, the bid price is one of several factors. The weighting of factors and attributes is done directly and indicates the importance of each factor for the client.

BEST VALUE SELECTION

Best Value Selection (BVS) is also referred to as Best Value Scoring Analysis. BVS is based on WPC but differs in the evaluation of the bid price. In BVS, all factors apart from price are calculated as a value/qualification score. The bid price is then divided by the value/qualification score. The smaller this ratio is, the better is the proposal (high value-for-money).

CHOOSING BY ADVANTAGE

In Choosing by Advantage (CBA), the advantages of the alternatives are compared to decide their importance. What is important in CBA is to identify which factors will reveal significant differences between the alternatives, not what factor (in the abstract) will be important in the decision.

DISCUSSION

Through our literature review, we have identified seven unsettled issues, unexplored solutions, and recommendations to team selection in collaborative projects. These are discussed below.

PUBLIC PROCUREMENT

When procuring, public clients are bound by regulations, motivated by considerations of anti-corruption, fair competition, and effective use of public money (value-for-money). They demand the use of objective criteria defined before tendering starts and to be able to document the procurement process. This requires a stable framework and limits the client's ability to adjust during the process. Otherwise, bidders can make claims, complicating the process, forcing the client to pay compensation, or even nullifying the results (Schöttle et al., 2015). The different considerations might pull in different directions, e.g., fairness might interfere with value-creation in the procurement process (Jobidon et al., 2021). Private clients are in a different formal position, with few or no constraints on formal competitive procurement (Lahdenperä, 2012).

It is claimed that a shift to new procurement and project delivery models will require a change in public regulations (Cohen 2010, (Cohen, 2010; Ghassemi & Becerik-Gerber, 2011; Heidemann & Gehbauer, 2010; Rodrigues & Lindhard, 2021), but this is obviously not always the case, and the situation differs between countries: the mood and interpretation of the regulations is gradually changing (Walker & Lloyd-Walker, 2015) and we have in many countries seen new models being promoted and used by public clients also within the framework of existing regulations. In Australia, Alliancing and related procurement processes are well established in public projects. (Department-of-infrastructure-and-regional-development, 2015; Walker & Lloyd-Walker, 2015).

According to Jobidon et al. (2021) dysfunctional regulations and the absence of clear directives and guidelines regarding collaborative models create "a normative fog" (p. 5) that causes uncertainty and complexifies the pathway for public clients as well as tenderers.

Schöttle et al. (2015), discuss the different methods for comparing alternatives that have specific potential challenges when it comes to compliance with public procurement regulations.

PROCUREMENT IN ONE STEP OR THROUGH A SUCCESSIVE TEAM EXPANSION?

Fischer et al. (2017) argue that instead of procuring the entire IPD team in one step, one should start out with a small team and expand it with new participants along the way. This view is supported by Rodrigues and Lindhard (2021). According to the Department-of-infrastructure-and-regional-development (2015) the decision of one or successive [11] steps should be considered from case to case. Both Crespin-Mazet et al. (2015) and Mesa et al. (2019) describe two cases, one where the entire core group was selected at the same time and one case where the parties were selected in two or three steps. Successive selection of new partners could in principle be done using any of the methods described above.

As for the IPD contract, a successive team expansion can be handled in two alternative ways, a sub-agreement approach where the new parties enter a separate agreement linked to the existing agreement, and a joining agreement approach where the new parties join the existing agreement (Fischer et al., 2017).

SHOULD TARGET PRICE BE SET BEFORE, DURING OR AFTER THE PROCUREMENT PROCESS?

Target Value Design (TVD) is a concept related to IPD. In TVD, the target price is set early (before the start of the design process) and used as a constraint to maximise customer value (Ballard, 2011). The alternative to this approach is to set a target price during or after design. In the first case, the target is set solely by the client; in the two latter cases, in dialogue and negotiation between the client and the team of designers and contractors. The procurement methods described above have different approaches to this. In Best Value Procurement (BVP), the target is set by the client as a precondition that the tenderers must accept if they want to participate in the competition. In dual Target Outturn Cost (dTUC) and Competitive Dialogue (CD) the target is set as part of the procurement process, while in Team-Based Procurement (TBC) it is set after the team is selected.

Johansen et al. (2021) discuss early versus late setting of the target price. They argue that if the target is set early, it must be adjusted during or after procurement. This leads them to recommend that the client should set an allowable price early, but that the target price is set in dialogue with the chosen team during or after procurement. References to an Australian debate on a single versus a dual Target Outturn Cost process can be found in Ross (2009).

SHOULD PROCUREMENT BE BASED ON QUALITATIVE OR QUANTITATIVE EVALUATION?

Apart from some possible variants of Competitive Dialogue (CD), all identified procurement methods have a high degree of qualitative evaluation. Such qualitative evaluation cases can be transformed to a quantitative expression through one of the methods for comparing alternatives presented above, or they can be handled purely qualitatively. From the procurement methods identified, the decision to enter Direct Negotiations (DN), will normally be taken based on a purely qualitative judgement. In contrast, dual Target Outturn Cost (dTUC) and Best Value Procurement (BVP) use a quantifying method. Team-Based Procurement (TBC) might use both approaches.

COULD PROCUREMENT BASED ON DESIGN BE AN ALTERNATIVE?

In traditional design competitions, the client evaluates design proposals (mainly qualitatively), and the preferred proposal is selected to be further developed together with the client. In design and price competitions, alliances of designers and contractors present design proposals with a

[11] The Department of Infrastructure and Regional Development (2015) uses the term "progressive".

lump sum price. In this case, the client makes a (qualitative and quantitative) evaluation of the proposals and selects the best value-for-money alternative.

We have in literature found no example of design-based procurement related to IPD. Could this be an alternative in some cases?

THE NEED TO ADJUST THE PROCUREMENT METHOD

In a procurement strategy for an IPD project, the client must answer several questions: What is of importance (value) for us as a client? What is to be evaluated in the procurement process, teams, product proposals, process proposals, prices and/or commercial arrangements? Should the entire team be procured at once, or should we use a successive approach? Should there be competition between teams/companies, or should we negotiate directly with one preferred partner? Should the evaluation be based on qualitative and/or quantitative parameters? How should the parameters be compared and weighted? For example, if we are going to evaluate prices, should this be fees, unit prices and/or aggregated prices for parts of or the entire object? Should aggregated prices be targets or maximums?

The combined answers to these questions create a potential number of procurement methods far beyond the limited number identified in this literature review. According to Department-of-infrastructure-and-regional-development (2015); Lahdenperä (2012); Walker and Lloyd-Walker (2015), the procurement method must therefore be adjusted and specified in each project. This is a situation different from procurement of unit-price or lump-sum contracts in open hard bidding. Here identical strategies and methods might be used from project to project. Especially in public projects, this makes the procurement process more challenging. In addition, it increases the risk of alleged or actual breach of rules and, consequently, potential complaints.

THE NEED FOR INFORMATION AND TRAINING

Selection criteria should be practical and easy to understand in an unambiguous way by both clients and tenders. New procurement methods are unfamiliar to people, more complicated, and harder to grasp than traditional price-only procurement. We must also expect the procurement method and IPD to be new to many participants. Several authors see training of both client and potential teams as important for success in the procurement process (e.g. (Hietajärvi et al., 2017; Narmo et al., 2018; Walker & Lloyd-Walker, 2015).

CONCLUSIONS, LIMITATIONS, AND FURTHER RESEARCH

We have in this paper presented the procurement methods related to IPD that we have identified through a systematic literature review. The goal has been to give an overview, not to go into detail regarding the different methods.

Some of the presented papers are purely descriptive, describing procurement methods used. Others are prescriptive, advising on how procurement of IPD teams should or should not be done. Others, again, are a mix of the two. A few contributions discuss consequences of the different procurement methods for the procurement process (Department of Infrastructure and Regional Development 2015, Walker & Lloyd-Walker 2015). The most important is the effect of the procurement method for the subsequent development and execution phases, and as a result, for project success and outcome. In the introduction, we formulated what could be called the paradox of IPD procurement: it aims at establishing collaboration through means of competition. In our literature search, we found no papers discussing this, neither theoretically nor empirically. This paper contributes to the core conceptual conversation and advancing insight on procurement of collaborative construction deliveries in order to push forth discussions and debates in neglected strands of the construction management and organization field.

IPD is often presented as a game-changer in construction. This is contrasted by its slow uptake. If IPD is a game changer, why is it not changing the game quicker? In IPD procurement, the procurement process is more complex and demanding for the client than in traditional price-focused procurement. At the same time, the client has limited security for what he will actually get when he enters the contract. Can this be part of the reason for the slow uptake of IPD? Based on this literature review, the plan is to address these questions in the next step in our research project on IPD.

There are two main limitations in the type of literature search used: the terms used in the search and the presence of the relevant literature in the databases used. To compensate for this, we have snowballed from identified papers and asked some of the main contributors to the IPD literature for relevant references. The snowballing and direct requests resulted in several relevant papers but didn't change any of the main findings. We see this as an indication of that the search method used has given us a relevant and representative overview of the literature.

SAFETY CULTURE IN CONSTRUCTION INDUSTRY OF NEPAL

Prajwol Neupane[1] and Farook Hamzeh[2]

ABSTRACT

Safety culture is a critical aspect of ensuring safe and productive construction sites. However, many studies in the field of construction that focus on safety culture overlook the unique attributes of construction environments. Current models for safety culture in construction fail to fully encompass the dynamic and diverse nature of construction sites where individuals with differing backgrounds, professions, and levels of experience collaborate to complete projects. These individuals not only come from different cultures and speak different languages, but they also have various psychological, behavioral, and knowledge traits that can affect their safety practices and behaviors. Moreover, different organizations have different settings and perceptions about the safety of their workers and workplace, which can further complicate the development of effective safety cultures in construction. Therefore, there is a clear need for research that focuses on developing more context-specific models for safety culture in construction that can account for these unique attributes and complexities (Hallowell et al., 2016; Hinze and Tracey, 2016; Lingard et al., 2018). The present study presents a framework that incorporates multiple facets of safety culture, including psychological factors, organizational factors, knowledge and awareness, behavioral factors, safe working conditions, safety-oriented climate, resilience, and unsafe behaviors. The proposed framework captures the relationship between these variables and the safety culture of the construction industry in Nepal. The results inferred from the analysis of the survey showed that among the eight variables included in the study (psychological dimension, organizational dimension, knowledge dimension, behavioral dimension, safe workplace, safety climate, resilience, and unsafe behavior), seven of them (excluding unsafe behavior) had a direct positive impact on safety culture in the construction industry of Nepal. In other words, these seven variables were found to be positively associated with the development of a strong safety culture in the construction industry of Nepal. On the other hand, unsafe behavior was found to have a negative impact on safety culture, implying that if workers engage in unsafe behavior, it can undermine the development of a positive safety culture in the workplace.

KEYWORDS

Safety practice, safety culture, construction.

INTRODUCTION

In Nepal, most construction firms adhere to conventional safety practices. However, due to the government's relatively weak occupational health and safety regulations, there is a lack of effective safety management procedures, which leads to numerous accidents every day. Large corporations that use a lot of human labor hire locals from the project site as workers, but they

1 Graduate student, Department of Civil and Environmental Engineering, University of Alberta, Canada, prajwol@ualberta.ca

2 Associate Professor, Department of Civil and Environmental Engineering, University of Alberta, Canada, hamzeh@ualberta.ca

rarely or never provide them with any safety orientation. This highlights the need for a strong safety culture in the construction industry in Nepal. Freshly hired laborers are immediately put to work, where they are unaware of any potential risks related to the building environment. Furthermore, the lowest-qualified bidder frequently receives the contract, and as a result, businesses forego investing in training programs and other measures to improve the industry's safety culture (Adhikari and Pradhananga, 2018; Koirala and Wasti, 2019; Shakya et al., 2018).

The management of workers' health and safety is crucial since it improves any industry's profitability, performance, and production (Ranasinghe et al., 2020). Improving safety performance in construction enterprises requires a thorough grasp of the variables influencing hazard detection and risk perception (Pandit et al., 2019; Ranasinghe et al., 2020). Due to the very high rate of injuries and fatalities that commonly occur in construction fields, the construction industry has a code indicating that it is extremely risky or unsafe (Talmaki and Kamat, 2014; Ghasemi et al., 2015). When compared to the manufacturing-based industry, where the risk of injury is 2.5 times larger, the likelihood of death in the construction sector is 5 times higher (Khosravi et al., 2014). The small unit of fewer than 10 workers working outside the urban workforce border in Nepal is not benefited from OSHA's legislative effort. Koirala (2016) acknowledged that Nepal has not yet ratified the core OSHA principle of the International Labor Organization (ILO). According to Olsen (2009), Nepal has not yet ratified OSHA Convention No. 155 of the ILO. According to trends in occupational injuries related to construction in Nepal, the number of fatal events rose from 5 to 13 between 1995 and 2009. (Joshi et al., 2011; Koirala, 2016; Sanjel et al., 2016). According to reports from Hämäläinen et al. (2006) and Koirala (2016), the rate of fatalities was 10.5 in China, 11.5 in India, and 29.9 per 100,000 workers in Nepal.

There hasn't been much research or previous studies on improving safety performance in the Nepalese construction industry, and what little there is focused primarily on defining external factors that do so, ignoring internal factors and the fundamental relationship between the safety enhancement factors in construction firms (Gautam and Prasain, 2011; Sukamani and Wang, 2020). Construction companies in developing countries face difficulties that are more fundamental, intricate, and severe. These concerns arise in a developing country like Nepal due to the general socio-economic unrest, ongoing resource scarcity, and general inability to find solutions to pressing problems. The lack of effective safety management procedures is a significant problem in the construction industry in developing nations (Koirala, 2016; Sanjel et al., 2016). To focus on accomplishing the goals of improving safety performance, it is crucial to develop the frameworks that the organization should adhere to and manage its resources.

LITERATURE REVIEW

The consequences of inadequate safety measures can have a significant impact on employees, their families, local communities, and the employer (Arboleda and Abraham, 2004). By reducing the frequency of workplace accidents, injuries, incidents, and illnesses, occupational safety can enhance efficiency, competitiveness, production, and profitability (as shown by studies from Chan et al., 2008; Hon et al., 2012, 2014). Accurate documentation of these incidents helps raise awareness and promotes the sharing of important safety information within the organization (Ra and Merisalu, 2010; Hussi, 2005). Effective communication of this information is crucial for managing safety knowledge within the organization (Nuez and Villanueva, 2011). Furthermore, businesses have a greater potential to learn and adopt best practices from other organizations and industry experts in the realm of construction safety (Järvis and Tint, 2008).

Organizational culture is often viewed as a component of safety culture, shaped by attitudes and values specific to health and safety issues (Clarke, 1999). According to Williams et al. (2020), the values, beliefs, rituals, traditions, and practices shared among members of an organization make up the concept of "safety culture" (Kartikawati and Djunaidi, 2018). There have been many efforts to develop a theoretical model of safety culture, with the Layer models (Reason, 1997; Guldenmund, 2000) and Triad models being two of the most widely used (Geller, 1994; Cooper, 2000). The idea behind Layer models is that by understanding the content of organizational culture, it is possible to analyse and improve safety-related elements. However, Layer models are often criticized for lacking objective evaluation tools and failing to account for the dynamic nature of culture (Cooper, 2000; Choudhry et al., 2008). Triad models, on the other hand, focus on the connection between psychological, behavioural, and situational factors in safety management (Cooper, 2000; Geller, 1994). To address these criticisms, Geller (1994) proposed a comprehensive safety culture model that recognizes the dynamic and interrelated nature of individual, environment, and behaviour. Cooper (2000) also developed a reciprocal model of safety culture that consists of three parts: subjective situational characteristics, internal psychological factors (how people feel), and safety-related behaviours (what people do). The model proposed in this research, considers the impact of psychological, organizational, knowledge, and behavioural dimensions, as well as the resilience of the safety culture, the safety climate, and instances of unsafe behaviour.

An organization's atmosphere often includes a variety of individual assessments of the workplace (James & James, 1989). These evaluations include assessments or cognitive appraisals of numerous fundamental workplace elements or traits, such as participation, leadership, communication, and creativity. It is thought that the combination of these assessments can significantly shape the actions and expectations of employees within the organization (Schneider, 1975). The idea that organizations can be seen as having several distinct climates, such as the climate for customer service, the climate for safety, and so forth, stems from the premise that the safety climate is essentially an offshoot of organizational climate. Actions done to improve the overall climate of the organization should also improve the climate for safety to the extent that these general climate aspects shape the climate for safety. Evaluation of these broad climate aspects should, in the end, give designers of interventions a more solid foundation on which to build and more proof that managing safety is not fundamentally different from managing other essential organizational responsibilities.

Typically, acquiring knowledge and skills in the construction industry happens through "on-the-job learning," which is how manual workers improve their knowledge and abilities (Golden and Skibniewski 2009). Learning while working contains both social and individual components (Collin and Valleala 2005). The employee's personal effort in repeating tasks, which is influenced by task features like complexity and mechanization as well as employee professional profiles like talents and prior experience, represents the individual aspect (Srour et al. 2018). The interaction and sharing of knowledge among crew members, which is influenced by the schedule structure, employees' prior experience, crew demographics, and workers' attributes, is comparable to the social part of learning (Kiomjian et al. 2020). Knowledge must be properly defined to comprehend the dynamics of the social side of learning. Knowledge is the skill and know-how a person possesses that enables them to do specialized tasks more effectively (Bock et al. 2005). On construction sites, the informal character of the knowledge-sharing process makes it extremely reliant on the interpersonal interactions between the knowledge transmitter and receiver (Thomas et al. 1998). As a result, the knowledge sharer starts to consider the benefits of the exercise, such as applying knowledge to job performance while managing time and learning from mistakes, or even producing new information by working together to boost team productivity. The outcomes could be quicker payment, employment referrals from other employers, and networking. Nevertheless, it could appear that competition suffers when knowledge is shared. Supervisors must devise strategies to encourage staff members to communicate their tacit knowledge if they want to keep it alive. The process of information sharing among workers is anticipated to be influenced by several social and personal elements, considering the social component of on-the-job training and the pragmatic aspect of tacit and explicit knowledge (Sanboskani et al. 2020).

French and Geller (2012) contend that for a safety infrastructure to be effective, it must actively encourage employee engagement. People modify their attitudes and beliefs to match their behaviors when they decide to change their conduct. Changes in behavior and attitudes are mutually reliant; there is a spiraling, reciprocal interdependence between our outward behaviors and our feelings. This is how minor adjustments in conduct and attitude can finally result in full commitment and involvement from an individual. Therefore, researching the behavioral factor appears to hold promise for enhancing safety performance in an organizational setting. The conduct of employees is the focus of the behavior-based approach to safety. This mechanism can lower injury rates through altering behavior. The behavioral-based approach to safety is solely concentrated on the measurable, observable behaviors that are essential to safety in a specific facility (Burton, 2012). When safety behavior programs are correctly implemented, they result in large improvements in safe performance and significant drops in occupational injuries and illnesses in workplaces with problematic rates of unsafe performance (Cambridge Centre for Behavioral Studies, n.d.). Recognizing employee safety behavior is crucial to raising an organization's overall safety performance. It is possible to evaluate how safe habits might be rewarded by identifying the factors that influence workers' safety behavior.

For the construction sector, safety is essential. Government agencies, business leaders, and university researchers have worked hard to enhance safety performance during the past few decades. For instance, Ontario province passed the Building Trades Protection Legislation in 1911 to govern the safety of tradespeople working in building construction; the Construction Safety Act replaced this act in 1962. (Ontario Ministry of Labor, 2012). A multitude of studies have been conducted to examine the effect of safety culture on safety performance, driven by events such as the Chernobyl Disaster in 1986 (Cooper and Phillips, 2004; Coyle et al., 1995; Dedobbeleer and German, 1989; Glendon and Litherland, 2001; Isla Daz and Daz Cabrera, 1997; McCabe et al., 2008; Neal and Griffin, 2006; Niskanen, 1994; Pidgeon, 1991; Siu et al., 2004). Because of these activities, the proportion of deaths in the construction industry has drastically decreased. However, several nations or regions, like Ontario and the US, have recorded a safety plateau. Over the previous ten years, the fatality rates in the US and Ontario construction industries have been flat. The secret to getting above the plateau is figuring out what influences construction safety performance. One of the elements that may enhance safety performance is the safety atmosphere. People's collective attitudes about workplace safety have been used as a barometer for the existence of abstract safety culture (Zohar, 1980). Regarding the parameters of the safety climate, there is no consensus. In the research studies on the safety climate in the construction industry, attention has been given to the following factors: management commitment, safety rules and procedures, housekeeping and safety equipment, supervisor, and coworkers safety perception (Colley et al., 2013; Dedobbeleer and Béland, 1991; Fung et al., 2005; Mohamed, 2002; Siu et al., 2003). However, other factors that are equally important to safety performance, such as reporting (Fung et al., 2005) and readiness (Hon et al., 2014), are rarely measured. In the meanwhile, the availability of injury data has decreased, making it harder to anticipate safety performance. All of this has forced us to look for a fresh strategy.

The concept of resilience has demonstrated its capacity to enhance safety performance over time. According to Bruyelle et al. (2014), Ross et al. (2014), and Vogus and Sutcliffe (2007), it is regarded as a capacity for an optimistic response and healing capabilities to routine usage as well as maintaining a high level of safety during stress and disturbance. This capacity is essential for human and organizational capabilities and viability (Carmeli et al., 2013). It has been suggested as a fresh strategy for the following generation of safety advancement (Hollnagel, 2015). In high-risk systems with difficulties associated, such as (a) a high degree of interconnection between the system's components; (b) unpredictability and variability, the application of resilience is especially applicable (Costella et al., 2009). A building site requires resilience to create prevention tactics because it is a complex, dynamic, and unstable system (Costella et al., 2009). Managerial commitment, reporting culture, learning culture, anticipation, awareness, and flexibility are the resilience dimensions that are most frequently recognized (Woods and Wreathall, 2003).

Construction sector accidents are complicated occurrences that can involve both the independent and reciprocal impacts of risky activities and conditions. Workers' performance and vision in the workplace might be impacted by dangerous behaviors. However, the driving forces behind the dynamic personalities in the construction business might be more complicated, making it crucial to concentrate on these important driving forces that affect employees' behavior (Jiang et al., 2015). Psychosomatic stress (Siu et al., 2004), safety climate (Fang et al., 2015), danger perception (Bohm et al., 2010), employee engagement, administration commitment, adequate source portion, and collaboration are some of the major elements that have been linked to workers' risky behaviors (Abudayyeh et al., 2005). Early in the 1980s, the safety atmosphere emerged as one of the key subcategories of safety, emphasizing management over actual safety. According to (Zohar et al., 2015 and Cheng et al., 2011), employees' perceptions of safety influence how they behave at work. The relationship between safety policies, procedures, and practices is emphasized by people's perceptions. Other studies have examined key factors that contribute to a safe work environment, such as safety perception, working conditions, safety programs, and management systems, and researchers have tried to identify dimensions of safety climate (Cheng et al., 2011).

METHODOLOGY

A survey was conducted to collect the perceptions of 44 construction practitioners and site personnel regarding the suggested variables. In addition to that, demographic factors like age, experience, profession, and gender were collected and inferences of these factors on other variables were computed and observed. This research is a descriptive study and inferential analysis is done to obtain the results of the research. This research is based on a survey of 44 respondents which is done through a questionnaire. Likert scale questionnaires were used to collect responses from construction practitioners and site personnel who participated in the survey. The Likert scale used a 5-point scale, with 1 indicating "strongly disagree" and 5 indicating "strongly agree" about their perceptions on various constructs developed in the theoretical framework as indicated in figure 1. The data collected was analyzed using SPSS software and MS- Excel. The interpretation is done by descriptive statics, ANOVA, Chi-Square, correlation, and regression tests.

To improve the research's validity and dependability, the researcher indulged himself to facilitate the respondents so that the response rate could be maximized, and probable errors could be minimized. Both the independent and dependent variables were separately tested using Cronbach’s alpha test of reliability to make certain that all designed questions are reliable. A validity construct of variables used in this study was analysed based on different scholarly articles and literature and is presented in table 1.

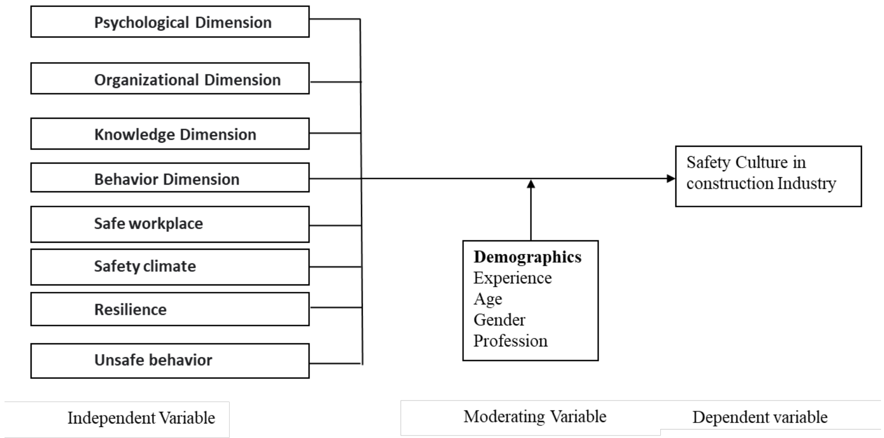

Figure 1: Theoretical Framework

Table 1: Reliability Test

Particular	Cronbach's Alpha if Item Deleted	Remarks
Psychological dimension	0.908	Good
Organizational dimension	0.898	Good
Knowledge dimension	0.901	Good
Behavior dimension	0.898	Good
Safe workplace	0.899	Good
Safety climate	0.902	Good
Resilience	0.904	Good
Unsafe behavior	0.972	Good

The shows the reliability test of individual construct and the overall reliability is found to be 0.91.

RESULT AND DISCUSSION

INDEPENDENT SAMPLE T TEST

An independent sample T test is used to assess the impact of gender groups on the safety culture of the construction sector.

Table 2: Independent sample T Test between Gender Group of Respondent and Safety Culture in Construction Industry

Particular	N	Mean	Std. Deviation	F	Sig. (P value)
Male	33	3.56	0.946	1.817	0.185
Female	11	2.97	0.609	ff	ff

The P value (0.185)>0.05 there is no significant relationship between gender and safety culture in construction industry.

ONE WAY ANNOVA TEST

Since years of experience, age group and profession are used as moderating variables with more than two variables, a one-way ANNOVA test is done to evaluate the influence of these moderating variables on safety culture in construction industry.

Table 3: One Way Annova Test between years of experience of Respondent and Safety Culture in Construction Industry

Particular	N	Mean	Std. Deviation	F	Sig. (P value)
less than 1 year	3	3.8160	0.24966	1.558	0.215

Particular	N	Mean	Std. Deviation	F	Sig. (P value)
1-3 years	14	3.3055	0.68720		
3-5 years	4	4.2344	0.30672		
More than 5 years	23	3.2912	1.06632		
Total	44	3.4173	0.90539		

The P value (0.215)>0.05 there is no significant relationship between experience and safety culture in construction industry.

Table 4: One Way Anova Test between age of Respondent and safety culture in construction industry

Particular	N	Mean	Std. Deviation	F	Sig.
18-30	29	3.4381	0.98945	0.022	0.978
30-45	14	3.3754	0.77454		
Above 45	1	3.3979			
Total	44	3.4173	0.90539		

The P value (0.978)>0.05 there is no significant relationship between age group and safety culture in construction industry.

Table 5: One Way Annova Test between job role and safety culture in construction industry

Particular	N	Mean	Std. Deviation	F	Sig.
Foreman	10	2.683	0.98454	2.556	0.036
Engineer	8	3.8599	0.7439		
Construction Labor	9	3.2032	1.10078		
Accountant/Office Manager	2	3.5240	0.17825		
Plumber/Electrician	4	4.0635	0.18603		
Project Manager	10	3.7517	0.52712		
Environmentalist	1	2.9604			
Total	44	3.4173	0.90539		

The P value (0.036) <0.05 there is significant relationship between job type and safety culture in construction industry.

In general, if the p-value is less than or equal to a predetermined significance level (usually 0.05), then the null hypothesis is rejected in favor of the alternative hypothesis. This means that the observed results are considered statistically significant, indicating that there is evidence to suggest that the relationship between the variables being tested is not due to chance. On the other hand, if the p-value is greater than the significance level, the null hypothesis cannot be rejected, meaning that the observed results are not statistically significant, and there is insufficient evidence to suggest a relationship between the variables.

CORRELATION ANALYSIS

A correlation analysis can only tell whether a strong relationship exists between two variables. But even if a correlation coefficient indicates that a strong relationship exists between two variables, we still do not know the exact shape of the relationship between the two variables. The correlation results were used to answer the research questions or hypotheses.

The table below shows the correlation matrix between dependent variable and independent variables, where, X1 = psychological dimension (Independent variable), X2 = organizational dimension (Independent variable), X3 = knowledge dimension (Independent variable), X4 = behavior dimension (Independent variable), X5 = safe workplace (Independent variable), X6 = safety climate (Independent variable), X7 = resilience (Independent variable), X8 = unsafe behavior (Independent variable), X9 = safety culture in construction industry (Dependent variable).

Table 6: Correlation between Dependent and Independent Variables

	X1	X2	X3	X4	X5	X6	X7	X8	X9
X1	1	859**	.759**	.769**	.731**	.793**	.754**	-0.218	.863**
		0.000	0.000	0.000	0.000	0.000	0.000	0.154	0.000
X2		1	.874**	.892**	.875**	.857**	.862**	-0.173	.957**
			0.000	0.000	0.000	0.000	0.000	0.261	0.000
X3			1	.858**	.933**	.817**	.760**	-0.199	.924**
				0.000	0.000	0.000	0.000	0.195	0.000
X4				1	.932**	.887**	.891**	-0.242	.949**
					0.000	0.000	0.000	0.113	0.000
X5					1	.870**	.804**	-0.251	.938**
						0.000	0.000	0.101	0.000
X6						1	.823**	-0.294	.914**
							0.000	0.053	0.000
X7							1	-0.217	.898**
								0.157	0.000
X8								1	-0.120
									0.439
X9									1

** Correlation is significant at the 0.01 level (2-tailed)

The correlation coefficient of psychological dimension, organizational dimension, knowledge dimension, behavior dimension, safe workplace, safety climate and resilience vs safety culture in construction industry are 0.863, 0.957, 0.924, 0.949, 0.938, 0.914 and 0.898 which means there is positive correlation between these independent variables and safety culture in construction industry. This means that if the industry focuses on improving these variables, it will result in an improvement in the safety culture of the construction sites, which in turn can help reduce the number of accidents and injuries. The corresponding p-value is 0.000, which is less than level of significance (α) = 0.05, signifying that there is significant relationship between these independent variables and safety culture in construction industry.

Whereas the correlation coefficient unsafe behavior and safety culture in construction industry is -0.120 which means there is negative correlation between these unsafe behavior and safety culture in construction industry. This means that if the industry focuses on reducing unsafe behavior, it will result in an improvement in the safety culture of the construction sites, which in turn can help reduce the number of accidents and injuries. The corresponding p-value is 0.439, which is greater than level of significance (α) = 0.05, signifying that there is no significant relationship between unsafe behavior and safety culture in construction industry.

REGRESSION ANALYSIS

Table 7: Regression Analysis of Variables

	Beta	T-value	P-value	VIF
(Constant)	0.618	3.314	0.000	
Psychological Dimension	0.144	4.287	0.000	1.358
Organizational Dimension	0.548	0.691	0.000	1.210
Knowledge Dimension	0.067	2.243	0.000	1.236
Behavior Dimension	0.082	7.071	0.000	1.361
Safe Workplace	0.138	0.963	0.000	1.508
Safety Climate	0.11	1.108	0.000	1.436
Resilience	0.521	9.469	0.000	1.695
Unsafe Behavior	-0.133	-0.147	0.439	1.406
R-square	0.693			
F	109.938			
P	0.000			

The regression coefficient specifies that an increase or decrease in value of 1 unit of independent variable results in beta value increase or decrease in unit of safety culture in construction industry.

For instance, the regression coefficient of unsafe behavior in regression analysis is -0.133 means decrease in value of 1 unit of decrease in unsafe behavior result in 0.133 increase in unit of safety culture in construction industry.

*R*2 value indicates how much of the total variation in the dependent variable is explained by independent variable. Here dependent variable (safety culture in construction industry) is explained by 69.3%. It consists of many other factors as well that influence the dependent variable.

Also, the F value and significance level are 109.938 and 0.000 which states that this regression equation is acceptable.

RESULT AND SUMMARY

Table 8: Summary Result of Hypothesis Testing

Hypothesis	P value	Remarks
Null 1 H_0: There is no significant relationship between psychological dimension and effect on safety culture in construction industry	0.000	Reject
Null 2 H_0: There is no significant relationship between organizational dimension and effect on safety culture in construction industry	0.000	Reject
Null 3 H_0: There is no significant relationship between knowledge dimension and effect on safety culture in construction industry	0.000	Reject
Null 4 H_0: There is no significant relationship between behavior dimension and effect on safety culture in construction industry	0.000	Reject
Null 5 H_0: There is no significant relationship between safe workplace and effect on safety culture in construction industry	0.000	Reject
Null 6 H_0: There is no significant relationship between safety climate and effect on safety culture in construction industry	0.000	Reject
Null 7 H_0: There is no significant relationship between resilience and effect on safety culture in construction industry	0.000	Reject
Null 8 H_0: There is no significant relationship between unsafe behavior and effect on safety culture in construction industry.	0.439	Accept

The study highlights the importance of assessing safety culture in the construction industry using a mixed-method approach that includes both quantitative and qualitative methods. By identifying safety-related problems, interventions can be developed to improve safety culture, which is a predictor of safety behavior and outcomes. However, the questionnaire revealed that various unsafe behaviors were performed by workers on a day-to-day basis, compromising safety and leading to injury or even fatality. These behaviors include ignoring safety equipment, disregarding safety precautions, not paying attention to rules and procedures of workplace safety, skipping daily safety work meetings, and not providing safety suggestions to the supervisor or the team. Unfortunately, workplace safety culture in Nepal is still developing, and many people lack a strong motivation and understanding of why safety is of paramount importance. Employers do not prioritize safety orientation and training, and the government does not have proper OHSA guidelines in place. Moreover, some workers think that wearing safety equipment like hard hats and boots makes them uncomfortable for work and choose not to wear them. Additionally, some individuals lack good judgement and engage in risky activities without realizing the irreparable damage that can be done to workplace safety. It is crucial for these individuals to understand the consequences of their actions, as their behavior can hinder efforts to induce and refine a culture of safety in the workplace.

CONCLUSION AND RECOMMENDATIONS

The study examined a model for a realistic construction safety culture that could help contractors in their efforts to enhance all-around site safety. The results show that the proposed model is sound and that there is a statistically significant relationship between its various components. Various factors like psychological dimension, organizational dimension, knowledge dimension, behavioral dimension, safe workplace, safety climate and resilience show significant relationship with safety culture. Hence, a commendable amount of work should be done in these factors by the organization to further increase safety. Safety is of paramount importance for every age and gender group, but the importance of safety is more to certain profession groups as interpreted by the results. So, people who are directly involved in the construction activities are more vulnerable than those who manage these projects. Therefore, an extra amount of care and precaution must be taken. Unsafe behavior is one of the main factors which directly leads to accidents, hence proper training and research must be done so that workers don’t involve themselves in these activities. Construction is a collective work done by a group, negligence of one person or a group directly impacts the health and safety of other. So, paramount importance must be given to safety which is directly proportional to the culture of industry.

Future research can solve many problems that are related to the study that was given. The suggested model in the current study was validated using a convenience survey (i.e., nonprobability), which was employed to collect data. The most popular technique for assessing safety culture is non-probability surveys (Choudhry et al. 2008; Ojanen et al. 1988). The generalization of nonprobability survey results, however, is debatable (Abowitz and Toole 2010; Al-Bayati et al 2018). Therefore, future research should complement and validate the current findings by combining longitudinal field observations with quantitative and qualitative research (i.e., mixed approach). In fact, the necessity of mixed research methodologies for validating the results of construction research is stressed by Abowitz and Toole (2010) and Al-Bayati et al. (2018). The obstacles faced by the stakeholders in the construction industry in creating, sustaining, and reinforcing a strong safety culture may be revealed by such an attempt. Future work should concentrate on conducting field tests with construction professionals to assess the acceptability, usefulness, and simplicity of the suggested model in comparison to other models already in use by the sector. Future research must also consider the distinctive features of the construction industry. For instance, most construction sites employ numerous contractors and subcontractor organizations, all of which have different perspectives and safety procedures. Future studies could therefore consider the linkages between the safety climates of the contractors and subcontractors in the construction industry.

Even though the research has tried to improve the current safety performance in Nepali construction firms, there are several restrictions that may prevent the research's findings from being simplified or used widely. First off, because the research was carried out using a convenience sample technique just within the Kathmandu valley, results cannot be generalized as representative of the total population of the entire nation. In that sense, data from every province in the nation might be collected by future researchers, leading to more precise results. Second, "Class A" and "Class B" construction firms accounted for most respondents. The analysis of these circumstances may have a different impact on the predictors of "C & D class" Nepali construction enterprises. Finally, this research highlights the need for further exploration of the topic from various perspectives. Potential avenues for future research could include examination of variables such as salary and gender-specific roles as moderators of the relationship between dependent variables. It is also recommended that future studies consider additional factors, such as safety attitudes and safety budgets, to enhance the accuracy of predicting safety culture in the construction industry, even though the current study utilized multiple determinants in its assessment.

SAFETY-I AND SAFETY-II: CONTRIBUTIONS OF UAS SAFETY MONITORING ON CONSTRUCTION SITES

Roseneia Rodrigues Santos de Melo[1] and Dayana Bastos Costa[2]

ABSTRACT

Unmanned Aerial Systems (UASs) have been incorporated into safety management systems to facilitate hazard identification and propose corrective actions on time, meaning practices related to the Safety-I approach. However, its impacts on understanding and dealing with everyday operations in front of adverse conditions, meaning Safety-II practices, are still unknown. Thus, this study investigates the contribution of safety monitoring using UAS to support Safety-I and Safety-II practices in everyday operations. Two case studies in construction projects were conducted, involving the following steps: (a) proposition of UAS monitoring protocol integrated into safety management routines; (b) field tests to monitor safety performance using UASs; (c) data analysis considering Safety-I, Safety-II and Resilience Engineering. As a main result, resilience mechanisms were identified, such as adaptation in the lifeline safety systems, use of photos and videos to improve workers' awareness, and collaborative work between frontline workers. Regarding the Safety-I approach, most of the identified non-conformities were classified as precarious structures on the construction sites, failures in the Personal Protection Equipment (PPE) use, and safety barriers. The perceived limitations emphasized the difficulty in promoting corrective actions due to the lack of flexibility in the constructive processes, availability of resources timely, and absence of slack.

KEYWORDS

Construction sites, safety management, resilience engineering, and digital technologies.

INTRODUCTION

Safety monitoring in construction sites could be considered a complex task due to the many activities that happen simultaneously and the few safety professionals performing them. This complexity becomes even more prominent without adopting digital technologies to monitor working conditions (Guo et al., 2017). In addition, safety professionals faced some issues in inspection routines that imply the difficulty of timely decision-making, such as the high amount of work required for manual data collection and processing, the lack of standardized safety procedures, and poor communication between teams (Cheng and Teizer, 2013; Lin et al., 2014; Rey et al., 2021).

To improve such aspects, previous studies proposed using digital technologies to identify unsafe conditions, streamline data collection and processing and provide real-time information (Lin et al., 2014; Guo et al., 2017; Awolusi et al., 2018). Among the technologies applied to safety monitoring, the Unmanned Aerial Systems (UAS) must be highlighted due to their ability

[1] Postdoctoral Researcher, Department of Structural and Construction Engineering, School of Engineering, Federal University of Bahia, Brazil, roseneia.engcivil@gmail.com orcid.org/0000-0001-9171-7274

to collect high-resolution visual data, monitor large construction sites, and access hard places in less time and at less cost (Melo et al., 2017). Melo et al. (2017) and Martinez et al. (2020) discuss that the use of the UAS facilitates the visualization of hazards and the inspection of safety regulations on construction sites, especially in situations related to the absence of Fall Protection Systems and inefficient use of Personal Protective Equipment (PPE). Based on the irregular situation identified on-field, safety professionals propose immediate or corrective actions to mitigate or eliminate the risk of accidents visualized by UAS (Melo et al., 2017; Rey et al., 2021).

Despite the potential gains related to the use of UAS for safety monitoring, most studies focus on reactive actions (Melo et al., 2017; Martinez et al., 2020; Kim et al., 2020; Rey et al., 2021) since they aim to prevent something negative from happening, Safety-I approach (Hollnagel, 2014). To cope with this matter, Safety-II emerges as a new way to see and understand safety management. Safety-II believes that to improve safety performance is necessary to look at things done correctly in daily operations rather than just looking at errors and unwanted events (Hollnagel, 2014; Wahl et al., 2020; Martins et al., 2022).

According to Martinez et al. (2020), Rey et al. (2021), and Lima e Costa (2023), the UAS could be used for safety planning, construction site monitoring, and risk assessment. However, none of these studies showed the contribution of UAS safety monitoring to improve everyday operations considering Safety-I and Safety-II perspectives. Therefore, this study aims to investigate the contributions of UAS safety monitoring to support Safety-I and Safety-II practices in daily operations on construction sites.

SAFETY-I, SAFETY-II, AND RESILIENCE ENGINEERING

The Safety-I approach promotes a bimodal view of how work is performed. According to this perspective, operation success occurs because the system works as it should, and people work according to procedures. The failures are usually associated with errors, deviations, and system malfunctions (Hollnagel et al., 2015). This approach does not consider complex socio-technical systems' dynamic and non-linear nature (Wahl et al., 2020). Therefore, it is necessary to adopt other strategies to improve safety performance on construction projects.

In this context, Safety-II seeks to understand how people adjust their actions when they face a critical situation to achieve desirable results (Hollnagel et al., 2015; Wahl et al., 2020). According to the Safety-II perspective, positive and negative effects are possible, which makes it necessary to recognize the risks and opportunities of everyday operations (Hollnagel et al., 2015).

According to Hollnagel (2014), Safety-I and Safety-II perspectives might coexist in the same environment, and the balance between them is essential to move toward a resilient performance. Resilience is the intrinsic ability of an organization to adjust its functioning prior to, during, or following changes and disturbances so that it can maintain required operations, even after an unexpected event or in the presence of continuous stress (Hollnagel, 2014).

Resilience emerges from the performance adjustments carried out by people by themselves or by a group, as characterized by Hollnagel (2018). However, the technical, technological, and organizational factors are also essential to support this adjustment (Heggelund and Wiig, 2019).

Some researchers have been seeking to identify the actions and characteristics that influence performance adjustments, characterized as resilience mechanisms or skills (Hollnagel, 2014; Saurin et al., 2014; Heggelund and Wiig, 2019). The resilience mechanism could be interpreted as actions or strategies to deal with the factors that restrain daily work. Wachs et al. (2016) pointed out some examples of "work restrain," such as the limitations of resources or unavailability (labor, equipment, and materials), incomplete project information, high workload, excessive administrative activities, time limitations, and casual incidents. Regarding performance adjustments, Hollnagel (2014) classified them as actions to maintain and create good working conditions; compensate for something missing, such as replacing materials; and propose solutions to avoid future problems, such as updating procedures.

Wehbe et al. (2016) argued that team discussions about safety conditions, team communication, and collaboration support resilience, even as the efforts to propose actions that prevent an error from recurring. Thus, the lack of resolution to correct the non-compliance compromises resilient performance.

As a practical example, Peñaloza et al. (2017) analyzed frontline workers' behaviors in the precast concrete assembly process and noted some resilience mechanisms, such as team discussions about the set of maneuvers required to reduce risk exposure (compensating); the adoption of strategies to deal with rework (creating conditions); and the practice of avoiding activities that bring a high level of uncertainty (avoiding future problems).

During the evaluation of the safety management system, Peñaloza et al. (2020) emphasized that the compliance indicator and safety checklist, the standardized data collection routines, and the involvement of safety and production professionals in safety conditions assessment and planning could be practices managing complexity. Aiming to incorporate Safety-II practices in construction projects, Martins et al. (2022) proposed a framework based on Safety-I and Safety-II concepts. In this framework, Safety-I refers to work as imagined, and it's established in the form of safety procedures. In contrast, Safety-II relates to work as done, and it's assessed by the monitoring of the constructive processes.

Therefore, despite each approach seeing safety in a specific way, Figure 1 shows they are not mutually exclusive but complementary (Hollnagel, 2014; Wahl et al., 2020; Martins et al., 2022). This means that they must be combined to promote a balance between safety practices and procedures, aiming to increase learning with daily work (Wahl et al., 2020; Martins et al., 2022).

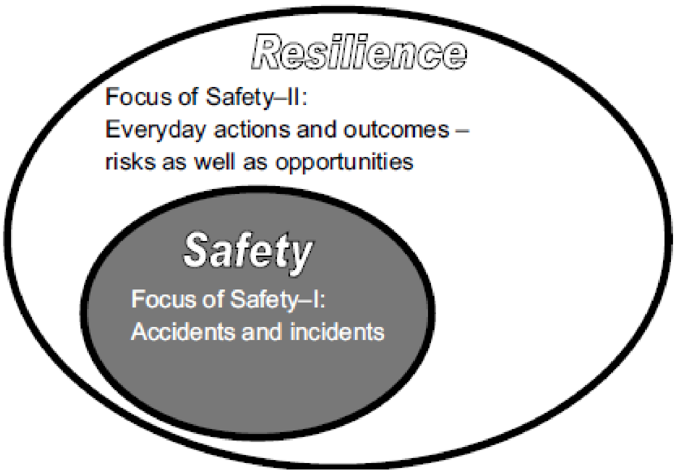

Figure 1: Relationship between Safety–I and Safety–II Source: Hollnagel (2014).

RESEARCH METHOD

This research adopted Case Study as the research strategy, which is a method that emphasizes the real-world context in which phenomena occur (Yin, 2014; Flyvbjerg, 2011). In this study, the phenomenon studied refers to implementing the UAS safety monitoring by adopting Safety-I and Safety-II approaches. The research process was developed according to the following stages: (a) proposition of UAS monitoring protocol integrated into safety management routines; (b) field tests to monitor safety performance using UASs; (c) data analysis considering Safety-I, Safety-II, and Resilience Engineering.

An exploratory case study was developed in Project A, aiming to understand the safety routines through document analysis, interviews, and UAS data collection. Based on this study, a UAS safety monitoring protocol was proposed to be implemented into weekly safety routines to support data collection and analysis (Figure 2). Case studies B and C lasted for 34 weeks and 21 weeks, respectively. During this period, the researcher performed 55 monitoring using UAS technology. Both studies are residential projects for the middle and low-income housing sector. The main construction methods were a continuous flight auger foundation and a cast-in-place concrete wall system. Table 1 describes the primary features of the projects and Flight log data collected in each project.

Table 1: Features of Construction Projects – Case Studies B and C

Case Studies	Project B	Project C
Project features	Land Area: 19,524 m² Total of 380 units Construction time: 16 months Period: Nov/2018 to Oct/2019 34 safety inspections using UAS	Land Area: 16,091m² Total of 300 units Construction time: 14 months Period: Apr/2019 to Oct/2019 21 safety inspections using UAS
Flight Log	Database: 2.210 images Flight time:11 hours and 25 minutes Average flight distance: 1.482 meters	Database: 1.281 images Flight time:6 hours and 19 minutes Average flight distance: 1.340 meters

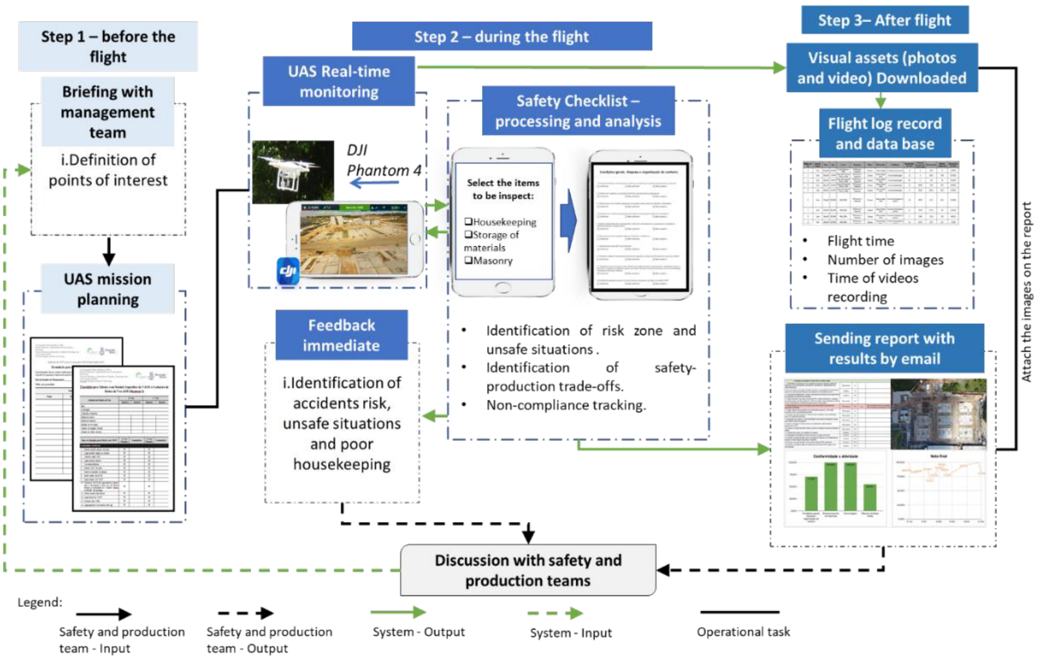

Figure 2: UAS Safety monitoring protocol integrated SMS routines.

During the case studies, the research group automated the safety inspection process, proposing the combination of UAS to monitor safety conditions on-site and a web system to fill out the checklist [OMITTED BY REVIEW]. The UAS safety checklist has 241 items divided into 21 categories (organization and housekeeping, storage of materials, construction site signaling, stairs and ramps, collective protective equipment, and earthwork and foundation). During the monitoring, the pilot controls the drone and gives real-time feedback about the status of each item from the safety checklist for the observer. The observer is responsible to fills out the checklist on the field. In Projects B and C, the safety personnel often participated in the inspections.

The outputs of this phase are the inspection report which contains a safety checklist assessment, the UAS images, and the safety compliance indicator (i.e., the ratio of the sum of compliant items and the sum of items checked). After each inspection, the pilot delivers the report to safety and production teams, including the managers.

The UAS was used to record working conditions, which include non-conformity safety items and informal practices carried out by frontline workers. The inspection report and photos and videos collected using UAS were used in meetings by safety and production professionals to discuss the workplace conditions and production process.

DATA ANALYSIS

Aiming to understand Safety-I practices, it was done a document analysis focusing on operational procedures and a safety checklist, besides the direct observation in safety and production meetings to promote corrective and preventive measures. Two analyses were accomplished based on the UAS safety inspection reports: i) analysis of the safety compliance indicator, identifying the main critical processes and the safety items more recurrent, ii) analysis of non-compliance by constructive process and degree of risk.

From the Safety-II approach, the analysis focused on identifying performance patterns and classifying the system's functional characteristics that contributed to a resilient performance (Wachs et al., 2016; Heggelund and Swiig, 2019). The data collected using UAS were combined with other sources of evidence, such as safety reports, safety meetings, and interviews with safety professionals and civil engineers. A total of nine interviews (a Safety Coordinator, Two Safety Personnel, a Project Manager, a Quality Coordinator, a Production Manager, Two Production Engineers, and a Production Trainee) were conducted to identify the new practices or improvements supported by UAS safety monitoring. The interview data were analyzed using thematic analysis (Braun and Clarke, 2006), allowing for identifying and exploring major themes systematically and flexibly. The thematic analysis considered the following question: *How does the UAS safety monitoring can improve resilience abilities (monitor, respond, anticipate, and learn)?* The codes were extracted by theme and analyzed according to the corresponding mechanisms.

This analysis focuses on two perspectives: i) operational level (i.e., adaptations and actions made by frontline workers to deal with the daily variability); ii) managerial (i.e., decision-making by management teams aiming to improve workplace conditions and avoid non-conformity recurrence). From the operational mechanism, the images and videos collected using UAS were used to recognize adaptation and good practices carried out by frontline workers and production engineers to maintain production workflow. All adaptations were discussed with the safety technician. From the managerial mechanism, the UAS visual assets and the interviews were the primary sources of evidence, and the mechanisms emerged from the thematic analysis.

RESULTS

RESULTS FROM THE SAFETY-I APPROACH

Figures 3 and 4 show the safety performance of Project B and C over time, respectively.

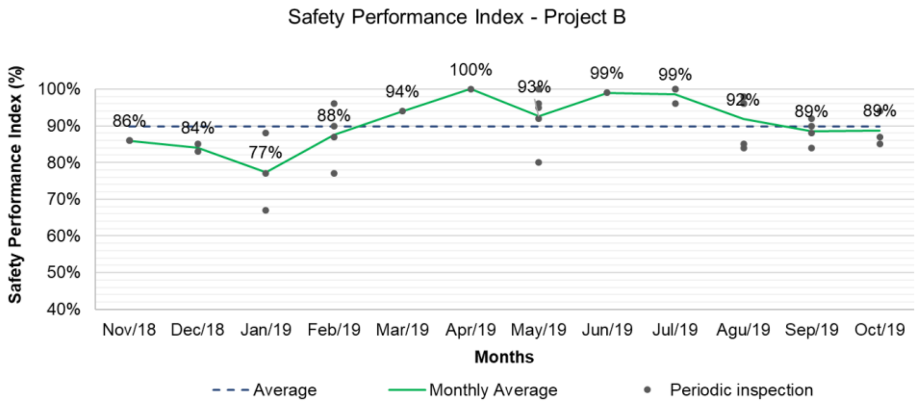

Figure 3: Safety Performance Index of Project B.

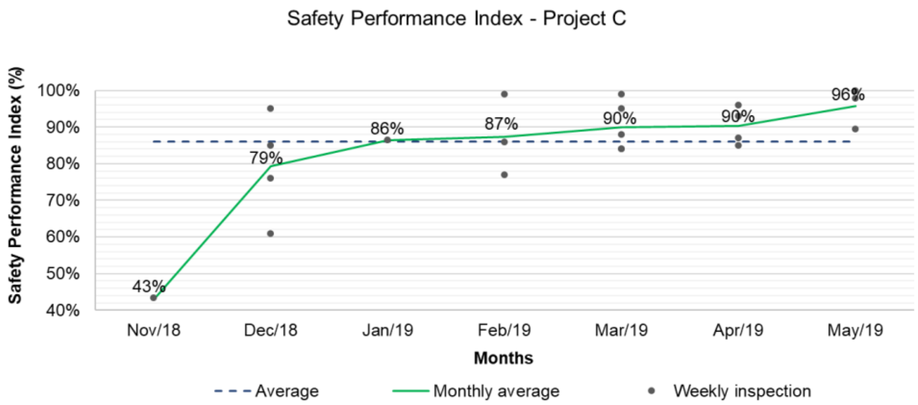

Figure 4: Safety Performance Index of Project C.

In Project B, 1,105 safety items were checked during UAS monitoring, and 102 were classified as non-conformity, corresponding to three notifications per assessment. In Project C, 722 safety items were inspected using UAS, 88 items being non-conformity.

The overall safety performance was 90% in Project B and 86% in Project C. Figure 3 shows that in the first months, the indicator was below the average in both projects, justified due to the lack of safety personnel and the beginning of the site mobilization phase. In Project C (Figure 4), performance improvement is evident over the months, which indicates the team's effort in complying with safety regulations and improving working conditions.

Figure 5 presents the non-conformities by category and by the degree of risk. Regarding Project B, the results indicate that the structural masonry, foundation, cast-in-place concrete wall, and roof had more non-conformities to risk degree 3 (high exposure) than the other processes. Project C demonstrated a similar distribution.

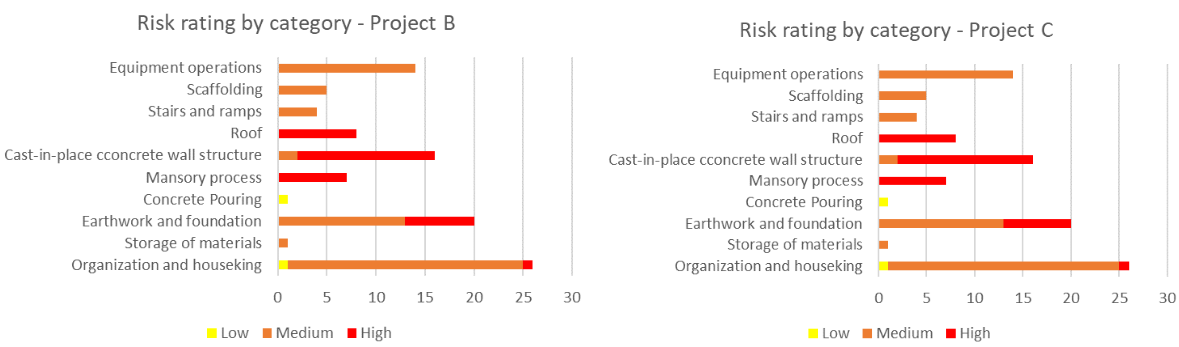

Figure 5: Risk Rating by Category of Projects B and C.

The main non-conformities were: i) waste stored in an inadequate location, ii) lack of signs advertising the risks of the activities, iii) lack of isolation of the cargo handling area, iv) failure in the use of safety belt for working at height, and v) guardrails and safety platforms incomplete or not installed.

In both projects, the number of safety inspections performed increased with the adoption of UAS, contributing to identifying the non-conformities and supporting the corrective measures faster.

RESULTS FROM THE SAFETY-II APPROACH

Table 2 indicates the operational and managerial mechanisms identified in the data analysis. These findings are based on the analysis of visual assets collected using UAS, safety inspection reports, safety and production meetings, and interviews with safety professionals and civil engineers (see the section Data Analysis).

Table 2: Operational and Managerial Mechanisms

Operational Mechanisms	Project	
	B	C
[1] Maintenance of the accesses and internal routes for vehicles and machines to facilitate loading and unloading operations.	✓	✓
[2] Maintenance of the accesses and internal routes for pedestrians, including those not involved in the operations.	✓	✓
[3] Decentralized distribution of materials at the construction site, being them made available at the place of use when necessary.	✓	×
[4] Correct isolation of materials stored in the construction site.	✓	×
[5] Construction of temporary installations (living areas and for storing materials) in regions that do not require repositioning throughout the construction phases.	✓	✓
[6] Marking in the aluminum forms to define the assembly sequence of the parts.	✓	✓
[7] Use wooden structures or metallic guardrails for isolation in excavation areas and work at height areas replacing safety nets.	✓	✓
[8] Adaptation in the lifeline systems connection during guardrail assembly and disassembly.	✓	✓
[9] Use of steel reinforcements as a “barrier” during the guardrail assembly.	✓	✓
[10] Pre-assembly of slab reinforcement and electric installation.	✓	×
[11] Collaborative work between frontline workers during the execution of cast-in-place concrete wall (teams of hydraulics and electric installation, concrete formwork reinforcement, concrete pouring and assembly, and disassembly of collective’s protective equipment).	✓	✓
Managerial Mechanisms		
[12] Use of UAS safety inspection report on daily safety dialogue aiming to discuss the main problems, including housekeeping maintenance.	✓	✓
[13] Use of photos and videos to improve awareness about safety and production routines. Ex. Safety training with technicians about risk perception.	✓	✓
[14] Use of the UAS safety inspection report to promote corrective action on time.	✓	✓
[15] Change in the operational procedures of cast-in-place concrete walls based on photos and videos collected by UAS.	✓	✓
[16] Use of UAS inspection report to evaluate the progress of safety conditions throughout the month and compare it with the safety audit outcome.	✓	✓

The operational mechanisms related to the logistics at the construction site [1-5] appear from the analysis of the conforming items (UAS safety inspection report). It was noted in the UAS safety monitoring and discussed in safety meetings that the safety requirements regarding those mechanisms were always correct. So, they were responsible for maintaining and creating good working conditions. The mechanisms [6-10] were identified during the monitoring using UAS. They were classified as adaptations promoted by frontline workers to compensate for the absence of materials, failures in the lifeline system, and production pressure.

Collaborative work [11] emerge as a mechanism that influences both the creation of good work conditions and compensation for something missing. It was observed in the execution of cast-in-place concrete walls that several teams work together in a restricted space. The results showed that workers helped each other in many moments, for example, during the load of the aluminum forms. In addition, when a team worker was absent, the colleagues did their job to avoid delaying production. Everyone on the team knew to assemble and disassemble the forms of all the rooms.

From the managerial perspective, the safety technicians used the feedback from UAS safety monitoring to discuss with workers the main problems identified, including the ones related to housekeeping [12]. The safety technicians used the feedback from UAS safety monitoring to discuss with workers the main problems identified, especially the ones related to housekeeping [11]. In the same way, the safety coordinator used the feedback provided by UAS monitoring in monthly training carried out with company safety technicians [13]. The use of images and videos about the main problems aims to improve risk assessment and prevent future problems.

The safety inspection report delivered after the UAS flight as well as the immediate feedback (Figure 2) were used to promote corrective action on time [14].

The visual assets were used to promote changes in the execution of the services, especially the sequence of assembly and improvements of collective protection equipment [15]. The feedback provided by UAS monitoring was used to evaluate the progress of the working conditions [16], promoting cycles of learning. The item inspected by UAS monitoring were also verified during the safety audit. Despite being considered a redundancy, this overlap was seen as an opportunity to promote corrective and preventive action in a short time since the UAS monitoring was carried out weekly and the audit only once a month.

DISCUSSION IN LIGHT OF SAFETY-I, SAFETY-II, AND RE

The studies about Safety-I look at errors and non-conformities, blaming the worker for the negative outcomes. While, Safety-II understands that adverse effects are inevitable, and several factors contribute to them due to the complexity and non-linear characteristics of the systems. In this perspective, the worker's participation is indispensable to maintaining operations.

Despite the literature on RE being mature, almost two decades, there is a need to clarify Despite the literature on RE being mature, almost two decades, there is a need to clarify how Digital Technologies (DT) could contribute to a resilient performance. The results show that the UAS safety monitoring supports the identification of nonconformities, supporting decision-making on time. Thus, the UAS monitoring helps understand the types of barriers used and their conditions, allowing the manager to know how much the system operates at the performance limits regarding degraded defenses and barriers.

The visual assets allowed the safety personnel to identify the potential risk of each process individually, especially those regarding work-at-height, the excavation process, and machine operation (such as backhoes, trucks, and cranes). Despite the risk assessment being done before the beginning of the execution, in daily routines, continuous monitoring should be made since new risks could appear from failures in the procedures or the intrinsic complexity of the processes.

Thus, when the information provided by UAS monitoring is only used to promote corrective measures and not to understand what is happening, how the system behaves, and how to avoid the occurrence of new non-conformities, we can say that the Safety-I approach prevails. From the moment that the information contributes to increasing the understanding of how the work is done in practice, it clarifies the adaptations made by frontline workers to compensate for the work limitations, avoiding the occurrence of production disruption for any reason, the system goes towards the Safety-II approach (Provan et al., 2020). Consequently, it becomes more resilient.

According to this understanding of Safety-II and RE, the UAS monitoring furnished visual content to support the discussions between safety and production professionals to promote corrective and preventive actions, encouraging decision-making from different perspectives. For example, interruptions in field activities for correcting unsafe situations, layout changing (storage materials), and use of UAS safety inspection report on daily safety dialogue aiming to discuss the main problems, including housekeeping maintenance.

Safety-II also refers to the learning processes built from previous experiences and knowledge (Hollnagel, 2014). This research found that the UAS monitoring captures the inspector/pilot perspective in the field, which could be mistakes and deviations made, or good practices performed daily. Both case studies used images and videos to disseminate good practice and successful adaptation through training and meeting, especially on the cast-in-place concrete wall process.

While Safety-II practices have been noted, the Safety-I view was predominant. In both case studies, the UAS monitoring has provided helpful information about work conditions. However, the main interest of production engineers and managers was visualizing if the construction site was according to the safety norms. On the other hand, when a non-conformity was identified, it wasn't easy to promote action on time to correct it. This delay or difficulty in acting promptly goes beyond the team's ability to know "when" and "how" to respond. The proposition of corrective measures was influenced by organizational factors, such as the team's technical capacity, availability of resources, the lack of slack in production planning, high productivity targets, and inefficiency in the short term.

CONCLUSIONS

This research aimed to identify the contributions of UAS monitoring integrated into safety management routines for developing resilient mechanisms. The results obtained in Projects B and C show that the UAS monitoring combined with other sources of data and management routines have the potential to contribute to the development and enhancement of resilient mechanisms. Since it improves the system's capacity to monitor the working condition and supports decision-making in a timely manner.

The safety monitoring using UAS made visible both non-conformities and the adaptations performed by frontline workers to deal with work restraint and production pressure. Thus, the visual assets and inspection report proved to be a great source of evidence to be incorporated into the management routines, such as production and safety planning meetings, safety training, risk assessment, the study of critical processes, and layout planning.

From the Safety-I perspective is easy to apply the UAS to identify non-conformity and risk situations in an everyday operation, despite the challenges of using new technology. However, regarding Safety-II further studies need to investigate how to incorporate UAS monitoring into the safety routine to support resilience practices. This is the main defiance since the safety and production professionals need to open their main to look at the adaptations carried out by frontline workers as well as learning with daily practice.

As limitations, the difficulties of accepting new technology from the workers were solved through communication in daily safety dialogues about the use of UAS, the potential risks, and its function. The ongoing work was carried out to raise awareness among engineers and technicians about using images and videos and to use visual assets to improve processes instead of observing people. In addition, the safety professionals argued that the UAS monitoring had low interaction with frontline workers, requiring more routines to integrate them into the monitoring and learning process.

For future research, this paper also indicates the need to investigate using UAS visual assets to support risk assessment and automatic recognition using Machine Learning techniques.

ACKNOWLEDGMENTS

This study was supported by the Ministry of Science, Technology, and Innovation of Brazil through CNPq (Conselho Nacional de Desenvolvimento Científico e Tecnológico) (Grant Number 421262/2018-4) and by the Brazilian construction company MRV Engineering. The authors are also grateful for help provided by the Ministry of Education of Brazil through CAPES (Coordenação de Aperfeiçoamento de Pessoal de Nível Superior) for students' scholarship support.

POTENTIAL APPLICATION OF DEEP LEARNING AND UAS FOR GUARDRAIL SAFETY INSPECTION

Hugo S. Peinado[1], Roseneia R. S. Melo[2], Mírian C. F. Santos[3], and Dayana B. Costa[4]

ABSTRACT

Unmanned Aerial Systems (UAS) can provide valuable information about on-site compliance with safety regulations, especially identifying workers in areas without guardrails or fall arrest systems. Despite the advances in using Machine Learning (ML) and, more specifically, Deep Learning (DL) algorithms for detecting safety systems in construction, the literature indicates a gap regarding automatic guardrail recognition. Therefore, this paper proposes a set of criteria for data collecting and processing using UAS and DL for safety inspections in temporary guardrails while producing cast-in-place concrete wall systems. For this research, an exploratory case study was adopted as the research strategy, developed according to the following steps: (a) database image analysis, (b) field study on constructions, (c) formal meetings, and (d) survey carried out with ML/DL specialists. Results show the main failures in guardrails of cast-in-place concrete wall systems, analyzing which can be inspected using UAS visual assets and ML/DL techniques. Also, it indicates the more adequate construction stages to perform safety inspections on guardrails. These findings may guide future research using UAS and DL algorithms for inspecting guardrail safety systems to further contribute to managers' decision-making.

INTRODUCTION

Fall from height (FFH) is one of the main types of accidents in the construction industry (Fang et al., 2018a; Nadhim et al., 2016; Zermane et al., 2023). To avoid FFH-related accidents, a commonly adopted control measure in the Brazilian context (Brasil, 2020; Peinado, 2019) and international context (Baruffi et al., 2021) are collective fall protection systems, such as guardrails. The guardrail system limits workers' movement, preventing them from reaching the area with FFH risks. Despite this, in the 114 FFH accidents analyzed by Zlatar et al. (2019), missing or inadequate guardrails contributed to 65.8% of the cases, positioning this failed measure as the second leading cause, only after the procedure of work, presented in 81.6% of

the cases. Nadhim et al. (2016) also highlighted that inadequate guardrail systems are among the main factors that cause FFH accidents in construction.

Poor safety is considered waste in the context of Lean Construction (Nahmens & Ikuma, 2009). Waste in production is understood by Ohno (1988) as all activities that add cost but not value. Accidents and injuries are costly in terms of human suffering and affect the level of worker satisfaction and the general well-being of the population. However, they are also financially onerous regarding worker compensation costs, lost time, lost productivity, higher employee turnover, and worker retraining (Nahmens & Ikuma, 2009; Peinado, 2019). During construction activities, monitoring workers and the construction site environment can prevent accidents (Carter & Smith, 2006). Safety monitoring is a critical element of safety management, but this activity is often performed inefficiently. Without adequate technological support, monitoring the entire site becomes an impractical task, given the size and dynamic character of the site (Golparvar-Fard et al., 2009; Guo et al., 2017).

The use of unmanned aerial systems (UAS) (also known as drones) can provide information to improve the safety conditions in construction sites (Costa et al., 2023). The use of UAS to help identify potential risk sites and for safety inspections in building construction has been validated over the last years by the scientific literature, placing it as an essential tool in the context of Construction 4.0 (Rachmawati & Kim, 2022; Costa et al., 2023). Using UAS results in the collection of visual assets allows better visualization of working conditions and, therefore, enhances the improvement of safety inspections at construction sites (Martinez et al., 2020; Melo et al., 2017; Rey et al., 2021).

Considering the large volume of data generated in construction (Baduge et al., 2022) and the limited number of safety professionals on construction site (Kolar et al., 2018), computer vision has been applied to support safety inspections (Akinosho et al., 2020; Pham et al., 2021; Ottoni et al., 2022). According to Baduge et al. (2022), Machine Learning (ML) and Deep Learning (DL) algorithms have been extensively used in the construction industry, addressed to architecture, materials, structures, construction management, progress monitoring, and work safety, among other areas.

The number of publications on work safety in construction applying ML and, more specifically, DL techniques in the computer vision context for detecting safety equipment and systems has increased in recent years (Akinosho et al., 2020; Pham et al., 2021; Ottoni et al., 2022). The papers refer to the automatic detection of personal protective equipment (PPE) (safety belts, hard hats, safety glasses, and vests) and collective protection systems, detection of machines, ergonomics, and positioning of workers, among others (Akinosho et al., 2020; Pham et al., 2021; Ottoni et al., 2022). Kolar et al. (2018) worked on a detection model for guardrail systems. For the training phase of the model, Kolar et al. (2018) used synthetic images resulting from placing the 3D guardrail (developed in Autodesk Revit) in images from the construction environment obtained from Google. The researchers used a dataset with real construction site guardrails images for model validation. Some specifications to be considered in this research: a) Only images from conventional cameras were used for the validation phase, not applying images from UAS cameras, for example; b) only synthetic images were considered for training, assuming that the guardrail will always be visible and without obstructions that compromise its correct visualization, which does not represent the reality of construction sites; c) only one guardrail model was analyzed without further details about the standard supporting its configuration or which construction stages this system is used. Recently, Li et al. (2022) worked on a framework for using UAS and ML to monitor fall hazard prevention systems, such as guardrails. Despite the efforts, the paper focused only on detecting guardrail posts, not considering the entire safety system.

Therefore, this paper proposes a set of criteria for data collecting and processing using UAS and DL for safety inspections in temporary guardrails while producing cast-in-place concrete wall systems. These findings may guide future research regarding using UAS and DL algorithms for inspecting guardrail systems in construction, providing potential problems to be identified, and possible DL techniques for problem automated detection. The primary purpose of pursuing this research field is to support identifying safety systems failures more efficiently and contribute to managers' timely decision-making.

LITERATURA REVIEW

UAS FOR SAFETY APPLICATION

Irizarry and Costa (2016), Costa et al. (2016), and Gheisari and Esmaelli (2019) explored the UAS's potential to inspect safety conditions. The results showed some safety issues, such as inadequate or missing safety guardrails, damaged safety nets, and inadequate scaffoldings. Melo et al. (2017) conducted two case studies at construction sites to assess the UAS applicability to performing a safety inspection, using the visual assets to check the compliance of safety items. The results show that the UAS can provide valuable information about on-site compliance with safety regulations, especially identifying workers in areas without guardrail systems or fall arrest systems. Lima et al. (2021) implemented UAS safety monitoring in a construction site to improve safety planning and control (SPC). The results present that the visual assets collected using UAS could be used to plan preventive and corrective actions, improve the collaboration between the safety and production teams, and increase the transparency of safety conditions.

Through a case study, Martinez et al. (2020) proved that the UAS can support hazard identification and assessment, especially those associated with height conditions, such as missing guardrails and safety nets around unprotected edges, floor openings, and loose or unsecured material at height.

Gheisari and Esmaelli (2018) proposed a workflow using point cloud data generated by UAS to detect the location of the guardrail and openings and then check if they are safety-approved. As a result, they located in a 3D mesh the position of the opening. Mendes et al. (2018) carried out a testbed to evaluate the feasibility of automatic recognition of normative requirements related to guardrails using UAS visual assets. The findings showed that only parametrizable conditions could be inspected through images, lowering the reliability of the algorithm tested (errors close to 20%).

Thus, the literature generally indicates a gap regarding the automatic guardrail recognition integrated with management routines to promote timely decision-making (Mendes et al., 2018; Gheisari & Esmaelli, 2018). According to those authors, the different types of guardrails (color, shape, materials, and geometric properties) are one of the main barriers to automating this process.

DEEP LEARNING FOR SAFETY APPLICATIONS IN CONSTRUCTION

ML algorithms become challenging when working with high-dimension data (Pham et al., 2021). According to the authors, DL algorithms outperformed ML algorithms in safety research once they deal with high-dimensional input data. When equipped with convolutional layers, the DL algorithms become highly efficient in resolving the issue of data sources (e.g., images and videos) (Pham et al., 2021).

Even though the DL has the potential to automate the identification of hazards on construction sites, a fully automatic computer vision-based system still needs to be developed (Fang et al., 2020). Thus, the primary DL technique's challenge is selecting a structure that ensures good performance metrics, such as accuracy and precision (Ottoni et al., 2022), and the fusion of data (e.g., text) with image/video to better understand the nature of the problem (Fang et al., 2020).

Some studies have used DL to monitor safety behavior and identify unsafe conditions on construction sites, especially falling protective equipment (Fang et al., 2018b; Fang et al., 2020; Guo et al., 2020). Kolar et al. (2018) developed a detection model to inspect guardrails by analyzing 2D images captured from construction sites. According to these authors, DL is a promising construction site safety monitoring approach.

However, despite the diverse DL techniques presented in the studies, there is still a gap in testing new solutions to achieve even higher accuracy and fewer false positives for guardrails detection (Kolar et al., 2018).

RESEARCH METHOD

The strategy adopted was an exploratory case study. According to Yin (2018), this strategy aims to identify procedures to apply in future research. The activities performed in this research are illustrated in Figure 1. The following sections describe these steps in more detail.

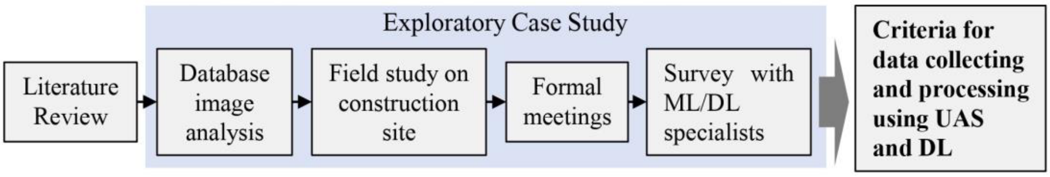

Figure 1: Research Design

CHARACTERIZATION OF THE SAFETY SYSTEMS

In the Brazilian context, guardrail systems are regulated by NR-18 (Brasil, 2020). According to this regulation, the guardrail system can be a solution adopted to prevent workers from falling from height and help avoid the projection of materials in the edge and openings in slabs. If adopted, the system must fulfil measurement, dimension, and load support requirements, among others.

As the formwork system is industrialized, the construction industry has adopted temporary metallic guardrail systems for cast-in-place concrete wall systems. In general, there are two safety systems in this type of construction using guardrails (Figure 2):

The temporary guardrail at the edge of the slab and in the contour of openings in the work area. This system comprises metallic guardrail panels 120 cm minimum high with a toe board supported on the surface (15 cm tall) and guardrail posts fixed on the formwork;

The temporary work platform with guardrails, allowing workers to perform their activities around the story under construction. This system is also fixed on the formwork. The components are work platform consoles, metallic board (floor), metallic guardrail panels with toe board (attending the minimum specifications of the system), and guardrail posts.

Figure 2: Safety Systems with Guardrails in the Construction Site

DATABASE IMAGE ANALYSIS

Ninety images of building construction sites captured using a UAS were selected to identify safety problems in guardrail systems and temporary work platforms. The items specified were considered a problem if they could compromise the correct functioning of these safety systems. These images were obtained from the Research Group database of which the researchers are part. This database has pictures collected using UAS from 9 construction sites. The analysis of the images to create the categories of problems and, subsequently, to identify these problems in each of the photos was carried out by three specialists in Occupational Safety Engineering (OSE) (the first three authors of this paper). The characterization of the OSE is as follows: 1) Civil Engineer, M.Eng., PhD student – 12 years of experience in the construction industry – 3 years of experience in inspections with UAS; 2) Civil Engineer, M.Eng., PhD, Postdoctoral researcher – 8 years – 8 years, respectively; 3) Civil Engineer, M.Eng., PhD student – 6 years – No experience with inspections using UAS, respectively. At least two OSE specialists analyzed each image to ensure that all problems were identified on the images.

FIELD STUDY ON CONSTRUCTION SITE

This stage aimed to identify the production activities of cast-in-place concrete wall structures, including installing and removing safety systems. Two visits were made to the construction site for direct observation of the process and an interview with the engineer responsible for the construction project. The unit case consists of the construction of four buildings in cast-in-place concrete walls of ten floors each, carried out in northeast Brazil. The stages in which the safety systems are installed were identified to determine when UAS flights could contribute to the safety inspection of these systems.

FORMAL MEETINGS AND SURVEY

Formal meetings and a survey were performed to discuss how UAS and ML/DL techniques could work together for safety inspections of guardrails in construction to investigate possible ML/DL techniques to explore these problems and how to standardize the collection of images for better data processing. Five meetings were held, lasting 1 hour and 30 minutes each, with the researchers (OSE) and three ML/DL specialists (ML/DLs). The characterization of the ML/DLs is as follows: 1) Electrical engineer, M.Eng., PhD, Professor, and Researcher – 13 years of experience in the AI area – 3 years of experience specifically in ML/DL-based computer vision; 2) Telecommunications engineer, M.Eng., PhD, Professor, and Researcher – 10 years of experience – 3 years of experience; 3) Electrical engineer, M.Eng., PhD student – 3 years of experience – 2 years of experience.

The survey was carried out with the same three ML/DLs, for each problem type identified in the database image activity. Based on their experience, they were questioned about: 1) The potential for automatically identifying the problems from stage 1 using ML/DL algorithms; 2) What contributes to or limits a problem from being automatically identified by ML/DL algorithms; 3)What ML/DL techniques they suggest for the automated identification of these problems from images collected using UAS; 4) What is the angle of the UAS camera (camera tilt) that they believe to be the most suitable for collecting these images at the construction site (0°, 20°, 30°, 45° or 90° to the horizontal), for further processing by ML/DL algorithms.

To answer the first question, a 5-point Likert scale was used, labeled from 1 to 5, as follows: 1) There is no potential; 2) There is little potential; 3) Not sure; 4) There is a great potential; 5) I am sure ML/DL techniques will identify the problem. The result from question a) was also presented in colors: 1 presented in red, 2 in grey, 3 in yellow, 4 in green, and 5 in blue. The questionnaire was elaborated in Google Forms. Several images were used to represent the problems to be analyzed, and images were collected at construction sites with different angles of the UAS camera.

Based on the previous outputs, the systematization of the results, analyses, and discussions were performed to propose a set of criteria to support safety inspections on construction guardrails using UAS and ML/DL techniques.

RESULTS

TYPES OF PROBLEMS IDENTIFIED AT THE SAFETY SYSTEMS

Based on the analysis of the 90 images from the database by the safety specialists, ten types of safety problems related to temporary guardrails and temporary work platforms with guardrails were identified. The issues and the number of images in which each issue appears are shown in Figure 3.

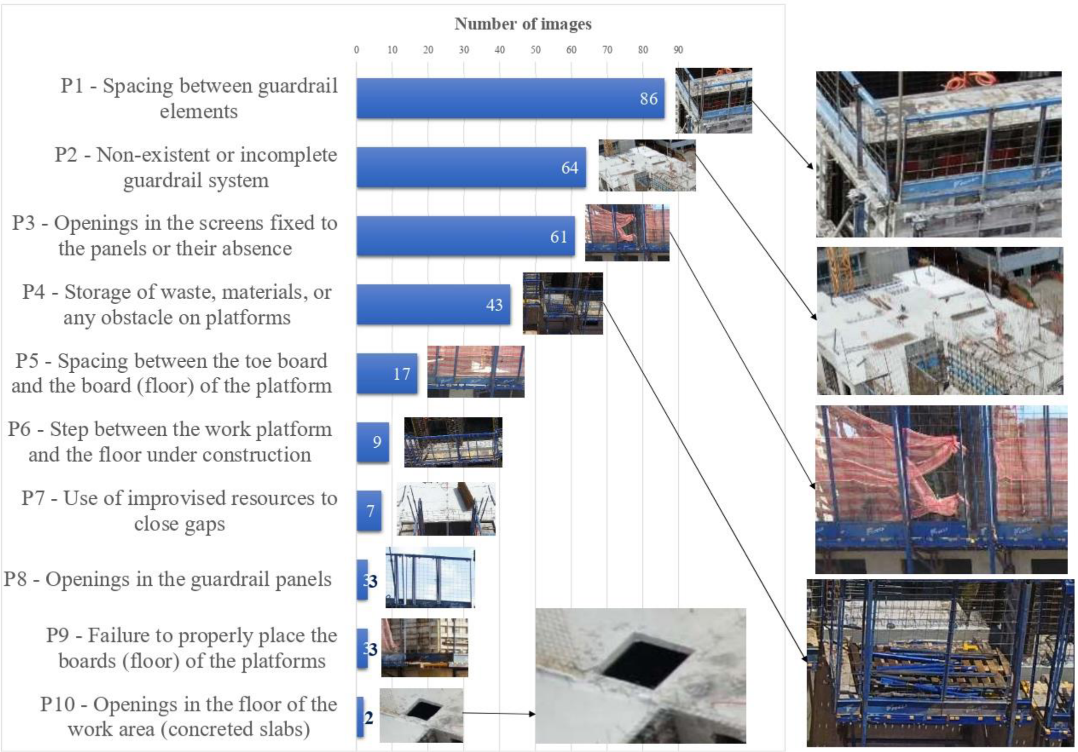

Figure 3: Types of Problems in Temporary Guardrail Systems and Work Platforms

According to Figure 3, problem P1 (spacing between guardrail elements) was identified in 95.5% of the images, while P2 (non-existent or incomplete guardrail system), P3 (openings in the screens fixed to the panels or their absence), and P4 (storage of waste, materials, or any obstacle on platforms) were identified in 71.1%, 67.8%, and 47.8% of the images, respectively. Problems P5 to P10 were identified in less than 20% of the photos.

CONSTRUCTION SEQUENCE TOR THE CAST-IN-PLACE CONCRETE WALL SYSTEM ANALYZED

The sequencing of activities related to the production of the cast-in-place concrete wall system of the unit case is presented in Figure 4. The execution of the structure of each floor occurred in two stages, with side A and side B being built at different times. The company had only a set of formwork (for half of the story). Thus, after concreting the walls on side A and the concrete reached the required design strength (generally around 12 hours), the formwork was removed from side A and positioned on side B. Side B should already have the wall reinforcements, electrical, and plumbing ready to receive the formwork of the walls and continue the activities.

When the forms on side B were removed (after the concrete had hardened), they were taken to the continuity of activities on side A of the upper floor.

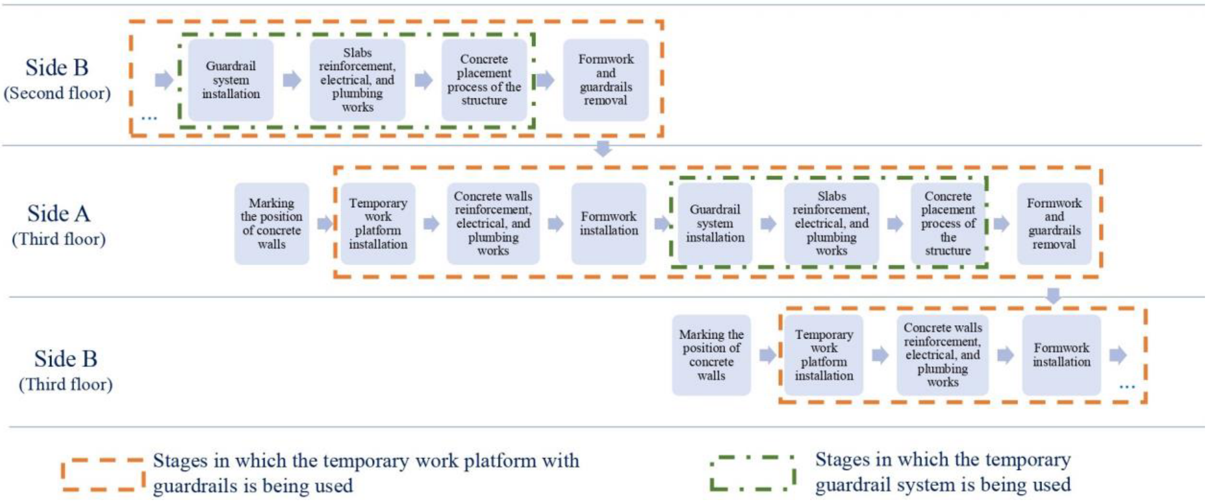

Figure 4: Production Activities of the Structure

Figure 4 shows the activities that integrate the executive sequencing adopted for building each side of the story in the analyzed site. This sequencing was applied from the construction of the second floor to the top floor, in which the installation of the temporary work platform with guardrails became essential. In Figure 4, it is also possible to observe which safety systems were used or were available for use during the execution of each of the activities.

In the process adopted at this construction site, it is observed that only during the activity of marking the position of concrete walls is there no guardrail system or temporary work platforms with guardrails on this side of the construction floor. Lifeline systems were implemented in the construction area for the workers' safety in this activity.

POTENTIAL PROBLEMS TO BE ANALYZED BY ML/DL ALGORITHMS

The ML/DL Specialists' perception of the potential for automated detection by ML/DL algorithms of the ten problems identified in guardrail systems or temporary work platforms with guardrails from images collected with UAS is presented in Table 1.

Table 1: Potential for Automatically Identifying the Problems by ML/DL Algorithms

Problem	ML/DLs 1	ML/DLs 2	ML/DLs 3
P1	4	4	5
P2	4	4	4
P3	4	3	5
P4	2	2	2
P5	2	2	4
P6	2	2	3
P7	3	2	2
P8	2	3	4
P9	2	3	3
P10	4	4	4

ML/DLs = ML/DL Specialists; 1 = There is no potential (red); 2 = There is little potential (grey); 3 = Not sure (yellow); 4 = There is a great potential (green); 5 = I am sure ML/DL techniques will identify the problem (blue).

Based on the evaluation of the ML/DLs, their perceptions converged regarding problems P1, P2, P4, and P10. Furthermore, there was a convergence of two specialists related to problems P3, P5, P6, and P7.

The problems 'Spacing between guardrail elements' (P1), 'Non-existent or incomplete guardrail system' (P2), 'Openings in the screens fixed to the panels or their absence' (P3), and 'Openings in the floor of the work area (concreted slabs)' (P10) were considered with great potential to be detected by ML/DL algorithms from images collected by UAS. According to ML/DLs 2, problems with the image background cleaner (the most explicit image of the problem) contribute to their identification by ML/DL algorithms. ML/DLs 1 and ML/DLs 2 highlighted that the potential for problem detection by ML/DL algorithms increases when these problems are clear and easily identifiable by a person who is not an expert in the field (in this case, in civil construction). ML/DLs 3 also points out that all situations marked with 4 or 5 present images that fit within a pattern. Thus, it is possible to identify the ideal situation and the situation of the problem. Training the ML/DL algorithm with a significant amount of these images will make it more efficient to detect the problems.

The problems 'Storage of waste, materials, or any obstacle on platforms' (P4), 'Spacing between the toe board and the board (floor) of the platform' (P5), 'Step between the work platform and the floor under construction ' (P6) and 'Use of improvised resources to close gaps' (P7) were considered to have little identification potential by ML/DL algorithms. According to ML/DLs 3, for P4, it will be difficult to train the model only to identify materials on the platform. Thereby, materials on the slabs would also be detected, generating numerous false positives. Furthermore, as highlighted by ML/DLs 2, the excess image information harms identifying materials and residues on the work platform. In this case, the specialist pointed out that the work platform's guardrail will negatively interfere with detecting materials on the platform, as it compromises visual identification. Regarding the problem 'Use of improvised resources to close gaps' (P7), ML/DLs 2 highlighted that 'improvised resources' are unspecific and may involve different types of materials to make the inadequate replacement of the guardrail panels. However, for the correct identification of the problem, an image dataset with a recurrence of this problem is necessary for algorithm training.

Referring to ML/DL techniques recommended by specialists, ML/DLs 3 highlighted that there is no simple solution once the variations among algorithms are subtle, mainly for detection purposes. For this specialist, Faster R-CNN has shown better accuracy for practical tests. At the same time, SSD and R-FCN demonstrate a reasonable balance between accuracy and response time (indicated to be used for real-time applications). ML/DLs 1 e ML/DLs 2 also show CNN algorithms. ML/DLs 1 highlights some techniques for classification (VGG16, Inception, Densenet) and detection (Yolo, SSD).

Regarding the angle of the UAS camera to collect images to use in the training and testing of ML algorithms, the three ML/DL specialists converged on the perception that the camera horizontally (0°) or inclined at 20° to horizontally are the most suitable options since it allows easy visualization of problems classified as high potential (4 or 5). Furthermore, two ML/DLs also indicated the 30° angle as a possibility to be explored. Finally, ML/DLs 2 highlighted the use of a vertical angle for the camera (90° to horizontal), as this angle makes it easier to identify the problem 'Openings in the floor of the work area (concreted slabs)' (P10).

DISCUSSION

Based on the constructive sequence presented in Figure 4, using UAS and ML/DL to inspect temporary work platforms with guardrails should be carried out at any time during the execution of cast-in-place concrete wall systems. This flow of activities indicated that at least one side of the building would have this falling protection system installed and used (Figure 5). Regarding temporary guardrail systems, their use appears in specific stages of the work, meaning their inspections will take place at particular stages of the structure's production (Figure 4).

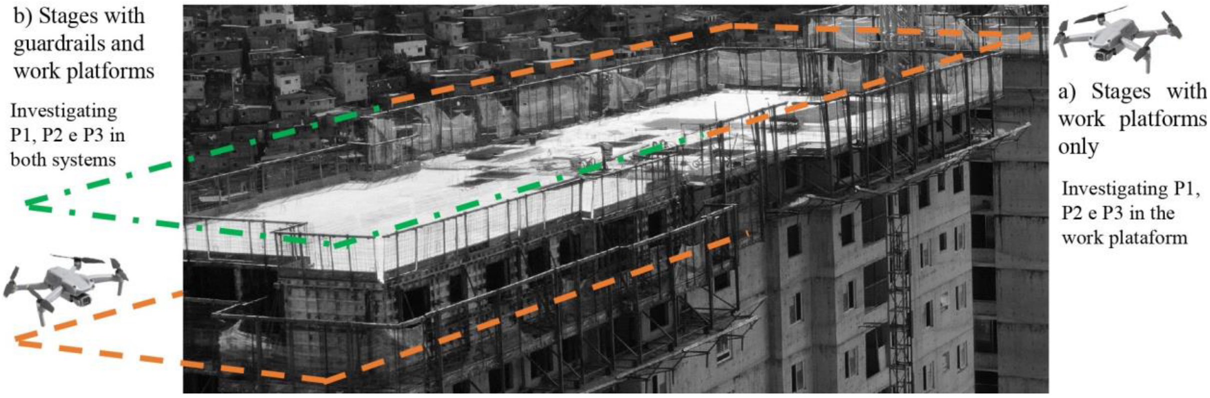

Figure 5: Different Stages for Collecting Data in the Construction Site

This analysis was essential to understand the moments that guardrail inspection should be performed, avoiding unnecessary inspections and consequently reducing non-value-added activities (Womack & Jones, 2003). Thus, the inspection frequency of the safety systems depends on the structure's production rhythm. Therefore, the safety systems should be inspected at a minimum when each story's installation has been concluded.

From the ten problems identified in the falling protection systems used in the cast-in-place concrete wall, problems P1 to P4 appeared more frequently in the images. In contrast, the other problems (P5 to P10) appeared with significantly lower frequency. According to ML/DL specialists' perception of which problems have the most significant potential for automatic detection by ML/DL algorithms, they highlighted: P1 (Spacing between guardrail elements), P2 (Non-existent or incomplete guardrail system), and P3 (Openings in the screens fixed to the panels or their absence). Despite the P10 (Openings in the floor of concreted slabs) being identified by the ML/DL specialists as a problem with great potential to be recognized by ML/DL techniques, it showed low occurrence in the analyzed images. It results in more difficulty using the ML/DL algorithm since there is a need for many images with the referred problem to train it. Thus, this research focused on problems P1 to P3 since they present the most potential to identify using ML/DL and appear more frequently in the images.

Regarding ML/DL techniques, there was a convergence between the recommendations of the ML/DL specialists and the techniques employed and systematized by Pham et al. (2021), Baduge et al. (2022), and, Otonni et al. (2022). Despite the several techniques presented by the ML/DL specialists and in the literature, they mainly focused on using CNN algorithms (a class of DL).

Based on the results and discussion, the set of criteria for data collecting and processing using UAS and DL for safety inspections in temporary guardrails during the production of cast-in-place concrete wall systems is summarized as follows:

The safety inspection with UAS and DL should be performed in some specific stages of the execution of cast-in-place concrete wall systems when the safety systems are already installed;

Ten problems were identified in the safety systems with guardrails. However, only three problems have the potential to be automatically identified by ML/DL algorithms based on the ML/DL specialists' perception and in the occurrence of these problems in the images analyzed, which are: P1 (Spacing between guardrail elements), P2 (Non-existent or incomplete guardrail system), and P3 (Openings in the screens fixed to the panels or their absence);

CNN algorithms (class of DL) should be investigated more for the automated identification of these problems in guardrail systems from images collected using UAS based on the ML/DL specialists' perception and the literature;

UAS cameras should be used horizontally (0°) or inclined at 20° to horizontal for data collecting since it allows easier visualization of guardrail systems' problems for further processing by ML/DL algorithms.

The indicated criteria are important for advancing research involving inspecting guardrail systems using UAS and DL algorithms to further identify these failures with greater efficiency and accuracy. Access to information generated from more agile inspections using UAS and automated detection of problems in guardrail systems (through DL algorithms) may contribute to managers' timely decision-making. This proposition aligns with Principle 8 presented by Liker (2021) regarding technology adoption and adaptation to support people and processes from the organization. In the context of this principle, Liker (2021) highlights that technology has the role of alerting people to problems so they can quickly and creatively respond to them. Based on the experience of Raja Shembekar, Liker (2021) emphasizes that technology provides superior information that enables managers and team leaders to make decisions at a much higher level.

The impacts on visual management are evident once the UAS adds value to the data-collecting process, providing images of the work-in-progress from different perspectives and moving around the construction site more quickly than in conventional situations (Rey et al., 2021; Martinez et al., 2021). In this regard, the UAS combined with ML/DL techniques has the potential to eliminate or reduce the waste of time spent during the inspection, and the safety personnel could be driven to other activities related to workers' involvement and safety culture.

CONCLUSIONS

This research explored the main failures in guardrails of cast-in-place concrete wall systems, analyzing which can be inspected using UAS visual assets and ML/DL techniques. The research has been conducted as an exploratory case study using several sources of evidence, such as questionnaires, database analysis, and direct observation. The results can be generalized to theoretical propositions for similar problems.

The result indicates that four of ten problems (P1 to P4) have the potential to be identified automatically using the ML algorithm. However, this research focus will be on problems P1 to P3 due to the number of images containing the problems. Thus, the discussion defined criteria for data collection using UAS and specified the potential ML/DL techniques used to automatically recognize the guardrails failures during the cast-in-place concrete wall execution. The findings can support the development of a system for automatically detecting safety issues in guardrail systems, which can contribute to managers' decision-making timely related to safety.

Although this research focused on a specific type of guardrail system, this does not mean that ML/DL algorithms could not be applied to other systems. Finally, further studies need to be developed to test ML/DL techniques in this context and propose a method to inspect guardrails using UAS for data collection and an ML/DL algorithm for data processing.

ABSTRACT

Meeting quality expectations is vital to the successful delivery of construction projects. Still, the levels of quality achieved in practice are often unsatisfactory, resulting in rework or acceptance of poor work, and impacting the project cost, schedule, safety, team morale, reputation of the organizations and individuals involved in the project, and overall customer satisfaction. Quality management research has relied on statistical process control, tolerances, and standards development. In the last years, though, attention has been shifting towards theoretical and philosophical foundations of quality, and the role people play in planning to define quality expectations and achieving them. The contribution to knowledge of this paper is to expand on the literature on Behavior-Based Quality (BBQ) by introducing the Behavior-Based Quality System (BBQS) and presenting some of its features. We present theoretical foundations of this system and illustrate some of its features through a case study. The purpose of this paper is twofold, (1) to promote more systemic thinking about the management of quality, and (2) to present features of a system that supports such thinking.

Quality, lean, Behavior-Based Quality (BBQ), Behavior-Based Quality System (BBQS), psychological safety.

INTRODUCTION

Crosby (1979 p. 6) saw quality as a "catalyst that makes the difference between success and failure." The importance of meeting quality expectations is not up for debate; the vast number of research papers and books on the subject are evidence of it. Literature on quality ranges on a spectrum from being technical-oriented to human-oriented. The technical-oriented literature pertains, for example, to tolerances and standards applicable to specific scopes (e.g., Milberg

2006, ASTM 2020). The human-oriented literature pertains, for example, to management practices (e.g., Crosby 1979, Deming 1986, Juran and Gryna 1988), methods and tools to minimize mistakes due to human error (e.g., Shingo 1986, Godfrey et al. 2005, Tommelein 2019), and the culture and behaviors of those involved in the quality process (Flynn 2001, Thomas et al. 2002, Howell et al. 2004, Pounds et al. 2015, Oakland and Marosszeky 2017, Spencley et al. 2018, Gomez et al. 2019, 2020).

Researchers and industry practitioners proposed Behavior-Based Quality (BBQ) as an approach to quality that highlights the human factor (e.g., to err is human, beliefs) of all people involved in the quality delivery process, from those planning the process to those executing it and assessing whether quality expectations are met. Yet, publications to date describe BBQ's intent but do not expand on how to apply it. The system described in this paper, Behavior-Based Quality System (BBQS), embraces BBQ; specifically, this paper provides a systemic overview of the BBQS and expands on BBQS's features using illustrations from a case study.

LITERATURE REVIEW

QUALITY IN CONSTRUCTION

Crosby (1979) proposed one of the most well-known definitions for quality, "conformance to requirements." He said that requirements need to be "clearly stated so that they cannot be misunderstood." In construction, ensuring that requirements are clearly stated is challenging and time-consuming because of the multiple stakeholders involved in the design and construction of a project. Many associations have developed standards, codes, and regulations that provide valuable information for designing and building construction projects (e.g., Arditi and Gunaydin 1997, ASCE 2012). However, quality issues persist, resulting in rework that can amount to as much as 12% of the total project costs (Love et al. 1999) and delay a schedule by as much as 9.8% from the original target (Dougherty et al. 2012). Despite the need to improve the delivery of quality, Koskela et al. (2019) described a decline in the quality movement due to apparent weakness in the theoretical and philosophical foundations of the subject. With this paper, we aim to contribute further to those foundations of quality.

FROM BEHAVIOR-BASED QUALITY (BBQ) TO A BEHAVIOR-BASED QUALITY SYSTEM (BBQS)

Extensive research has been conducted on Behavior-Based Safety (BBS) in construction (Geller 2001, 2005, Li et al. 2015). A search on the topic of "behavior-based safety" in the Web of Science database and Google Scholar shows 366 and 7,080 articles to date, respectively. BBS foundations suggest that safety on a project can be improved by fostering behaviors needed for safety, such as wearing protective gear or using an equipment guard (Geller 2001). BBQ is built on similar foundations, focusing on behaviors to improve the delivery of quality by fostering alignment and minimizing quality issues once work is built (Spencley et al. 2018).

Spigener (2001) described BBQ as an approach to quality that consists of engaging personnel in quality and fostering the "right behaviors" while moving away from disciplinary actions as tools for improvement. This resonates with Deming's (1986) principle of eliminating fear from the workplace to deliver quality. Researchers explored BBQ and its connection to Lean, especially to respect for people and reliable promises (Gomez et al. 2019, 2020). When managing quality, for instance, Gryna et al. (2005 p. 127) suggested to "treat all people with dignity", which reflects the Lean principle of respect for people. Similarly, understanding, aligning, and meeting certain quality expectations requires making and keeping commitments, which reflects reliable promising (Winograd and Flores 1986, Macomber and Howell 2003).

Over the past two decades, several studies have highlighted the importance of fostering psychological safety in the work environment due to its impact on team performance and learning (Edmondson 1999, Carmeli 2007, Huang and Jiang 2012). In construction projects, performance is measured in terms of cost, schedule, quality, etc. Researchers explored the connection between Lean and psychological safety (Howell et al. 2017, Gomez et al. 2020) and proposed psychological safety as a foundational principle for BBQ (Gomez et al. 2020). Psychological safety for BBQ is viewed from a team perspective (Edmondson 1999, Edmondson and Lei 2014). In construction, a team member is everyone involved in the project delivery, from the client, to the architects who design the project, to the contractors building it. Within a construction project team, psychological safety allows the project team members to (1) talk about mistakes when these occurred instead of trying to hide them, and plan to avoid their reoccurrence, (2) ask questions to clarify expectations before building, and (3) share their concerns when requests are not feasible or achievable within the project constraints, etc.

Crosby (1979) highlighted the need to design systems to manage quality that prevent defects. Gordon et al. (2021) proposed that a more systematic view of BBQ could deliver better project outcomes. However, what such a system might look like hasn't been defined yet. Inspired by Ballard and Tommelein's (2021) work in articulating a benchmark to meet and improve upon, the first author is currently working on research to describe a BBQS and its features. An extensive literature review on quality cannot be presented here due to page length limitations; please refer to Gomez' (2023 forthcoming) dissertation. The following section presents a framing of the features that one might desire to have in a system for managing quality.

WHAT DOES THE SYSTEM LOOK LIKE?

We propose BBQS features while thinking of those doing the job; aiming to facilitate BBQ adoption. The features of the system we propose include:

1. Functions of the system: the job needed in the service of delivering quality
2. Presuppositions to be aware of: assumptions people bring when managing quality
3. Principles and behaviors that are the foundations of the system: the rules of action and the behaviors desired for quality
4. Processes involved: the steps and people involved in delivering quality
5. Methods and tools: methods and tools that facilitate the processes to deliver quality

Table 1 describes the behaviors desired of people using the system to manage quality in their everyday work. In the text that follows we illustrate how these were observed, and what processes, methods, and tools the team used to deliver quality. The remaining features are expanded on in Gomez (2023).

FINDINGS FROM PRACTICE

METHODOLOGY

We used a descriptive case study approach (Yin 1993) to explore some of the system's features and how these may have influenced the quality outcomes. We documented this case after the project was built. The General Contractor (GC) who built it considers it one of their best-in-class projects. This case is a Design-Build (DB) Tenant Improvement project with lab areas, a vivarium, and office spaces. Due to the collaborative nature of DB projects, the GC and trades such as mechanical, electrical, and plumbing, were onboarded during design. In addition, most of the GC' staff had worked together for 1-3 years on another project, prior to this one.

The first author surveyed 22 team members asking questions with responses scored on a 7-point Likert scale. In addition, she interviewed 10 of the same team members, from the architect to the drywall- and taping foremen, and asked them to describe and illustrate the following:

1) What actions did project team members take that relate to BBQ? (2) Did the team use any BBQ processes? Which ones? (3) What methods and tools fit the quality delivery process?

Table 1: Behaviors Desired for Quality in the BBQS

Behavior	Focuses on
Being respectful	Treating others with dignity and courtesy and helping them develop their capabilities (Fuligni et al. 2005, Lalljee et al. 2007)
Active caring	Looking out for the people doing the work and the quality of the work (Roberts and Geller 1995, Randall 2013, Spencley et al. 2018, Gomez et al. 2019)
Making reliable promises	Making and keeping commitments (Winograd and Flores 1986, Stoljar 1988, Macomber and Howell 2003)
Speaking up	Sharing ideas and expressing freely any question, concern, suggestion, etc., relevant to the work in discussion (Premeaux 2001, Hilverda et al. 2018)
Being diligent	Being careful, probing, not just accepting information or resources given, as is, without checking (Bernard et al. 1996, King et al. 2012, Powell 2017)
Active listening	Trying to hear not only the words that are said but the message being communicated (Bodie 2011, King et al. 2012)
Active learning	Applying the Plan-Do-Check-Act (PDCA) cycle of continuous improvement (Edmondson 1999, Kostopoulos et al. 2013)

The examples illustrated in this paper focus on drywall installation and are part of a larger study in progress. However, our hunch is that many of the features described are likely applicable to other scopes of work as well. We explore the team's psychological safety as a preamble to analyzing the features of the system in a context.

TEAM PSYCHOLOGICAL SAFETY

The GC's leadership described this team as a high-performing team. In this case, we hypothesized that the team members would show high psychological safety due to the relationship described in the literature between psychological safety, learning, and team performance. Indeed, all participants interviewed reported feeling psychologically safe to speak up and share their mistakes so that the whole team benefited from it and learned together.

"I believe we make it safe for everybody to discuss." – Drywall Project Manager (PM)

"We can rely on one another. We admit our mistakes and shortcomings." – Architect

"I'm not shy reporting any mistakes that I make, and no one here is... Everyone can speak up here." – GC Assistant Superintendent

Early in the project, the project team hosted a series of team building workshops provided by an external consultant. All the staff members who were onboarded at that time were invited to participate in these workshops. The consultant assessed each member's personality and used their responses to help them get to know each other better.

"From the profiles that [the consultant] generated, he was able to say, 'you are this kind of person, you'll say hi to everyone, and you'll do this or that.' It really helped us all to understand people better at those early stages in the project." – Architect

Although these workshops were held only at the beginning of the project, the team continued organizing activities such as happy hours and team lunch-and-learn sessions to continue strengthening the relationships between them, especially with those who joined the project later.

Through the survey, we also explored whether there was any difference between how psychologically safe craft and staff team members felt. Table 2 shows that craft scored lower; therefore, an opportunity exists to foster psychological safety more at the craft level. The drywall company belongs to the GC, so craft workers may tend to have longer job tenure, and any improvements would benefit the team in the short- and long term.

Table 2: Team Psychological Safety for Craft and Staff (1=low, 7=high psychological safety)

Psychological Safety in Relation to	Craft Perception	Staff Perception
Team leader/supervisor	5.418	6.720
Peers/other members of your team	5.947	6.500

We speculate that the staff-craft gap in psychological safety may have a connection with (1) staff members receiving more people skills training and opportunities to connect at a more personal level, (2) experiences where craftworkers were mistreated, yelled at, sent to do most tedious work in retaliation of a mistake they made, (3) craftworkers being paid hourly may feel that their jobs are more instable and avoid taking interpersonal risks for self-protection, etc.

TEAM BEHAVIORS DESIRED FOR QUALITY

We present evidence of the BBQS behaviors as described by the project team members:

Being Respectful

Participants reported being treated with respect and receiving opportunities to keep developing their capabilities. The Lean principle of respect for people is reflected in the team's effort to learn to appreciate diversity and be aware of other team members' perspectives while helping them continue expanding their technical knowledge.

"All the ideas were always heard, whether you were an engineer or a manager, everyone was heard equally, and I'd say that as a great sign of respect… [when using the layout robot, the GC asked users:] Did you feel it was useful? Was it confusing to you? What else do you think we should layout with this?... there was definitely a lot of feedback after each area [was completed], and we kept iterating the [layout] process to make it better and more useful." – Virtual Design and Construction (VDC) Engineer

Active Caring

Participants described many actions the team took showing active caring, e.g., by preventing or minimizing trade damage to the extent possible, and engaging team members in quality conversations. The team hosted conversations about so-called Distinguishing Features of Work (DFOW) for various scopes of work; drywall was not one of them, but still, they planned the scope well, heavily relying on the experience of the drywall division.

> *"This is the first job where I found it easy to find the information we needed... The GC superintendent helped us a lot in that aspect; all walls had QR codes with all relevant information [we needed to build]." – Drywall Foreman*

> *"It was refreshing having a young, energetic team that was out there to do a great job." – Architect*

MAKING RELIABLE PROMISES

Participants reported doing well in making and keeping promises, e.g., agreeing to apply level 5 finish to a drywall wall, considering the resources available of manpower and time required to complete the work as per the acceptance criteria.

> *"We are good about saying when something is not achievable. They [other team members] might not agree with this, but there it is." – Drywall PM*

> *"On this project, requests were talked about in our group; sometimes [the GC] would say this area has to be done tonight, then we would talk about it, [and make a*

counterproposal], and we would agree to finish half of it that day and the rest the following day." – Drywall Superintendent

Speaking Up

Participants reported being confident when expressing their thoughts, concerns, questions, etc. We noticed, however, an overreliance on others to speak up. As shown in Table 1, craft felt less psychologically safe than staff members; being deliberate in designing means for craft members to communicate with minimal or no barriers could help them speak up.

"I like to ask; I prefer to ask or be asked rather than having to do the thing again." – Drywall Foreman

"Most people have felt empowered to say, 'I think I've got an issue here; can I just talk to you about it?', even if it's just as simple as: 'am I being crazy?', can you just take a look at this real quick one?" – Architect

Being Diligent

Participants described in detail the process they followed in planning and building for quality. For instance, typically checking the information to ensure it is complete, accurate, etc. In the field, similarly, checking expiration dates, materials, etc. Diligence requires being constant. Even when things are going well, it is important to keep checking and not become complacent.

"I dedicate myself to doing QC and making sure we don't miss things." – Drywall Foreman

"We did two weekly office hours… we sat down and went through any open questions; like there is a window here and you can get daylight on this wall, so we're going to see any imperfection [due to light conditions on the wall so this wall better have a level 5 finish]." – Architect

Active Listening

Participants reported they tend to pay full attention to the speaker, trying to understand what this person says, and what not.

"Our team does a really good job, we've got experienced people, but they don't let their ego or pride get in the way, and they are willing to listen." – Drywall PM

"If you have an idea to share, everyone listens and pays attention. If you have a problem, you'll get an ear to listen to you." – GC Assistant Superintendent

Active Learning

Participants described strategies they took to learn, from experimenting with the layout robot to documenting quality issues on PlanGrid. The team could use, however, a strategy to analyze root causes, such as 5 whys or cause mapping, to avoid having the issue reoccur.

"Everyone was very open to trying new processes, or innovate, and make something better… For the robot, we had a lot of iterations on what was good, what was not useful, and what was actually not good at all and confusing to people." – VDC Engineer

"When we find a mistake on a floor, we try to avoid it on the upper floors… Still, we've had repeating mistakes that occurred. It wasn't a lot but some stuff that slipped our minds… During the daily rush that we have in the field, it's impossible to follow [remember] all the lessons learned." – GC Assistant Superintendent

PROCESSES

The quality process, from design to production, requires multiple steps and involves many people. We limit our description of this section to subprocesses that the team thought really helped them manage quality beyond their typical practice.

User Flythrough Sessions

These sessions were an extension of what is typically done in BIM coordination. In these sessions, the focus was on including the end-users in the model review. End-users had the opportunity to virtually see what the requirements in the project drawings and specifications look like when built. This project had four different user groups (1) environmental health and safety, focused on constructability and safety, (2) biology lab users, focused on lab usability, including, for example, applicable requirements for their lab equipment, (3) vivarium lab users, also focused on lab usability, and (4) general facility management, focused on accessibility and maintenance. All these groups participated in the flythrough sessions and provided feedback.

Distinguishing Features of Work (DFOW)

The GC introduced the DFOW process to the client, architects, and trade partners early in the project. Even though no specific DFOWs conversations were scheduled for drywall work, the project team had conversations about various aspects of that scope during construction:

> *"[we talked about] what's coming up that they need our input on; for example, we're going to be building this feature wall next week; what do you want to see? When do you want to come and take a look at it? What kind of things are you concerned about here? Are there any details or junctions that drywall needs to pay attention to?" – Architect*

Trade Damage Control

Trade damage is a tough topic of conversation between subcontractors. Typically, the amount of damage is assessed and allocated to subcontractors, based on the number of people they had on the project, when the GC is closing out contracts. In this case, the team defined a process (Figure 1) that allowed them to distribute damage costs monthly. Doing this periodically allowed them to accurately assess whose responsibility it was and provided cost clarity for trades since they were getting monthly updates regarding their portion of the costs.

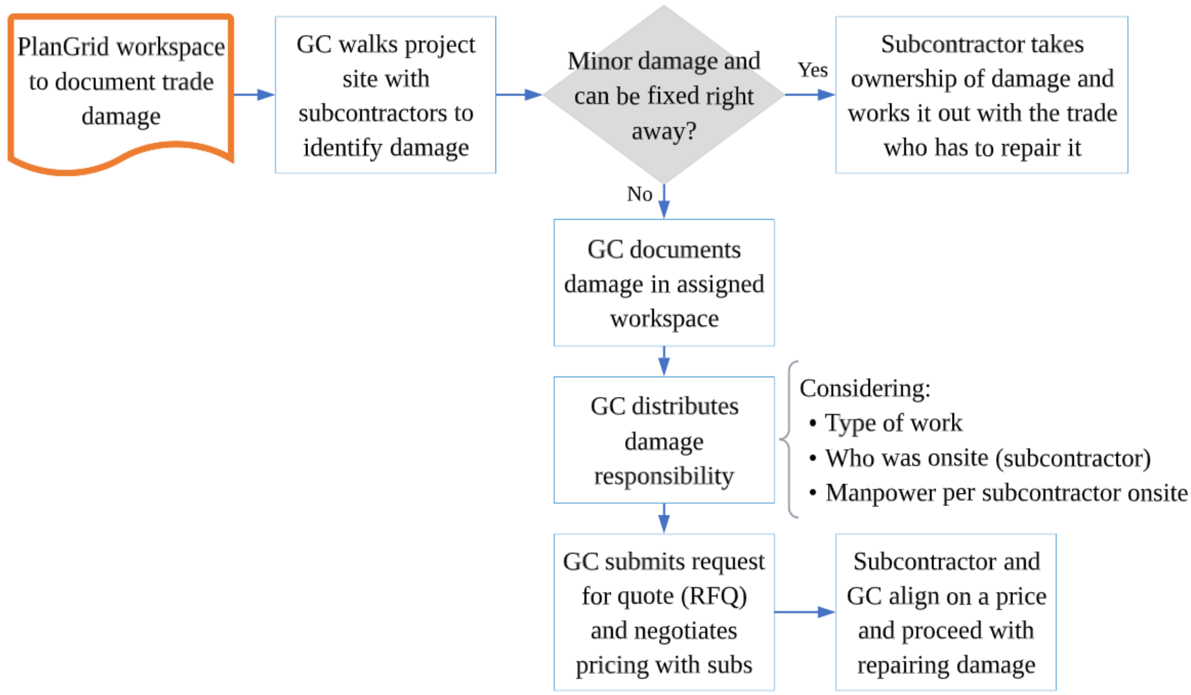

Figure 1: Quality Control: Trade Damage Management Process

The process established by the team resulted in a better distribution of damage costs:

> *"We have the biggest crew on the jobs, so we have the most manpower. In past projects, trade damage costs would be divided based on how many men you had on the job, so we would have the highest trade damage cost. Here [the GC] didn't do that. The GC took the daily reports to figure out who was in the area [assigning the damage to the ones who caused it]." – Drywall PM*

Architect Site Walks for Quality Control

The architect participated in scheduled walks to provide feedback on the acceptance of work throughout construction.

> *"We did regular walks once or twice a week with GC superintendents and produced weekly architectural field observation reports. Those walks and the field observation reports were used for corrective action with the trade partners" – Architect*

Methods and Tools

This section describes the project-specific methods and tools used to support the delivery of quality.

Automating Walls Layout

The GC used a robot they designed themselves to print layout information on the floors (from a CAD file), using lines, symbols, and different colors and inks as needed. This robot was first used on a large scale on this project. The robot laid out things that contractors needed with greater detail and faster than the manual layout.

> *"We had four lines for each wall [Figure 2]. So, if a pipe has to go exactly in the center of a wall, you'll have laid out one layer of sheetrock or two layers of sheetrock [to see verify pipes don't clash with the drywall board]." – VDC Engineer*

Figure 2: Wall Layout Painted on Floor Slab by Robot

Lean methods and tools involved in the adoption of this automated process include, for example, (1) mistakeproofing by using one specific ink color on the floor per contractor, so they do not get confused with the lines of other contractors, (2) visual management by printing the lines of each drywall board to be installed, so things that are to be embedded on the wall such as pipes do not clash with where the wall is to be installed, and (3) PDCA and collaborative design of operations by gathering feedback from the users (craft and foremen) to improve the use of the robot to better suit the needs of the field.

Facilitating Information in the Field through Dynamic QR Codes

The superintendent, who struggled on previous projects having to search more than a dozen drawings to inspect the work on one wall, developed an initiative that the GC carried to other projects after the success of this case. This initiative consisted of developing PDF packages with all relevant information to build and inspect a wall, and post these packages using dynamic QR codes in the field. Anyone on the project with a smartphone or iPad could use the QR code and access the information package. Each package included, for example, the architectural plan, electrical, mechanical, and piping plans, lighting plan, snapshots of the 3D model, and elevation views. Dynamic QR codes allowed the team to modify the content in each package without replacing the physical QR code posted onsite.

> *"The superintendent used it [QR code] a lot because every time she walked; she could say 'hey you can't close this wall because something is missing here.' Once you close the wall, there is a lot of rework. Compared to her previous jobs, where she had to open the wall for changes, here we had very few cases where we had to open something for a change." – VDC Engineer*

Before closing walls, the GC's assistant superintendent walked the site to inspect the work and took pictures of where the pipes were located (Figure 3). When a wall is closed up, and some other contractor or the owner needs to install something and screw something into the wall, they know exactly where the pipe is located and can avoid damaging the pipe by drilling into it.

Lean methods and tools for such information available include, for example, (1) visual devices comprising QR codes on each wall with all the information pertaining to that specific wall (and not the entire floor), (2) standardization by developing a format with the expected content in each PDF package so that the development of the packages could be done by a third party instead of an assigned superintendent or project engineer.

Visually Communicating Expectations and Outcomes

The team adopted visual management to communicate the expectations of delivered work and whether the work conformed with the acceptance criteria defined. For instance, when preparing for city inspections in the framing stage, the drywall contractor spray-painted the fasteners on the framing bottom track (Figure 4). When the city inspector walked the site, he quickly verified that fasteners were installed, conforming with the agreed acceptance criteria. The inspector appreciated the drywall team doing this because it helped them to conduct inspections faster.

> *"The [city] inspector asked me to paint all the [fasteners on the bottom track] so that he didn't have to spend time looking where they are; he just wanted to walk and quickly see where they were installed." – Drywall Foreman*

Figure 3: Photo Included in PDF Package Showing Pipe Location with Respect to Corner

Figure 4: Fasteners Ready and Spray-Painted Green for Inspection

DISCUSSION

The system we introduced in this paper, the BBQS, is one way to approach BBQ from a systems perspective. While building the BBQS, we identified a set of features to facilitate BBQ understanding and adoption. Because every project team is unique, practitioners may apply some of the BBQS features more than others and to a different extent. For instance, in our case study of a project that successfully delivered quality expectations, we analyzed how the behaviors feature was observed by the participants involved and what opportunities for improvement can be explored further. In terms of active learning, although the interviewees reported doing well in learning from issues and experimentation, the learning process itself could have been improved. Participants acknowledged that some defects were repeated because it had 'slipped my mind' to develop countermeasures. The team could have documented the lessons learned more systematically and reviewed those lessons before moving to the next work area.

The BBQS features we presented are intertwined. For instance, the processes developed by the team supported the behaviors they displayed and vice versa. For example, when using the QR codes, the team enabled every trade to do their quality control and encouraged them to raise any issues while checking their work. Also, trade damage discussions fostered discipline in documenting damage, and created a fair and transparent environment that contributed to team collaboration and an increase in active caring for the work of others, ergo minimizing damage. The BBQS features of a quality system based on Lean foundations are meant to be further refined and augmented.

CONCLUSIONS

Few publications have addressed the role of the human factor from a behavioral perspective of those participants involved in defining quality expectations and meeting them. Some emphasized the need to develop a more behavior-based approach to managing quality, proposing BBQ for construction projects. Acknowledging that behaviors matter for the delivery of quality expectations, this paper answered the question: How do we take the main idea of BBQ and make it actionable so that project teams can implement it? This paper contributes to the literature by proposing a more systemic thinking about BBQ and presenting the features of a system, the BBQS, that supports such thinking.

ACKNOWLEDGMENTS

Development of the ideas presented in this paper was supported in part by gifts made to the Project Production Systems Laboratory (P2SL). ASSESSING QUALITY PERFORMANCE OUTCOMES & THE RELATIONSHIP WITH RFI AND PCI PROCESSES: A GENERAL CONTRACTOR CASE STUDY

Elizabeth Gordon[1], Keila Rawlinson[2], Neha Dabhade[3], Dean Reed[4], and Charlie Dunn[5]

ABSTRACT

This paper is the third in the series, taking a cross-discipline view of project performance to investigate and understand the potential correlation between system inputs and outputs. In the 2021 paper "The Impact of Implementing a System Approach to Quality: A General Contractor Case Study," the authors compared project performance outcomes and team cultural assessments for 11 projects that had implemented a Systems Approach to Quality (SAQ), the Intervention group, against a similar set of projects that had implemented a compliance-based approach to quality, the Control group. This paper continues to investigate the project performance outputs for these two groups and specifically looks at the Request for Information (RFI) and Potential Change Item (PCI) workflows. This case study considers if RFI and PCI metrics can be used to determine if better quality design contributed to better performance outcomes. Then it considers how RFI and PCI processes relate to SAQ implementation. The authors' findings suggest that applying SAQ resulted in project teams documenting RFIs sooner in the project lifecycle and experiencing faster closure rates compared to the Control group.

KEYWORDS

Systems Approach to Quality (SAQ), Request for Information (RFI), Potential Change Item (PCI), Change Order (CO), design quality, performance outcomes

INTRODUCTION

THE REWORK PROBLEM & DESIGN QUALITY

Rework is a known problem in the Construction Industry. This General Contractor (GC), with a current US $5.9B revenue, headquartered in California and working throughout the US, Europe, and Singapore, experienced unpredictable results when delivering their final product. Sometimes the GC delivered work to meet customer expectations; sometimes, the GC achieved zero defects at substantial completion; and other times, the GC spent a lot of time and money

to close out open issues. Even when the GC met plan and specification requirements, sometimes the owner would say, “That was not what I was expecting. Tear it out and re-do it.” (Spencley et al., 2018).

Receiving accurate information promptly to plan and build the work has long been discussed as essential to preventing rework and growth of project costs (Hughes and Zack 2012). Design quality and preventing design errors and omissions are vital as they directly influence the overall performance of construction projects (Alarcon and Mardones 1998). A study performed on nine industrial projects found that design deviations averaged 78% of the total count of deviations. These were further sub-categorized, and “design changes for improvement (DCI) caused, on the average, the greatest number of deviations, 13.3%, followed by design changes in process (DCP), 10.9%, and design changes initiated by the owner (DCO), 9.9%, while 13.2% of the total number of deviations were classified as design changes of unknown origin (DCU)” (Buratie et al., 1992). Furthermore, design changes averaged 79% of the total costs for all changes and 9.5% of the entire project costs (Buratie et al., 1992).

Hughes and Zack (2013) attribute this lack of information to a shift away from a master builder that designed, planned, and executed the work. While project designs have become more technically complex, designs and building duration times have become condensed, leading to missing information on the design documents (Dougherty et al., 2012). Thus, the Request for Information (RFI) process became a tool for the construction industry to ask designers clarifying questions about the intent of the design and receive the information necessary to build what was expected. If impacts are associated with the RFI response provided, the general contractor submits the proposed scope, costs, and schedule impacts in the Change Order (CO) process (Dougherty et al., 2012).

Measuring the outputs of the RFI and CO processes has become standard metrics to evaluate how a project is performing. First, RFIs have been used to measure design quality (Tilley et al., 1997), a leading indicator of how projects will perform. In the ASCE study “Defining the Success Status of Construction Projects Based on Quantitative Performance Metrics Thresholds,” RFIs and Change Orders quantities were used to differentiate between successful and non-successful projects (Aboseif et al., 2022). Similarly, this GC uses the volume of RFIs a project experiences to signify if projects have unanticipated changes and potentially could not meet the existing contractual requirements. If the count of RFIs for a project increases above the weekly average the project has been experiencing, this is considered a warning that the design quality does not reflect the information the GC needs to build. However, one challenge with this approach is that these comparisons were all made without distinguishing between successful and unsuccessful projects (Aboseif et al., 2022).

THE RESEARCH QUESTION

In previous research, the authors identified that projects implementing a Systems Approach to Quality (SAQ) achieved better performance metrics across quality, safety, cost, change management, schedule, and collaborative culture, versus a similar set of projects that implemented an industry standard, compliance-based approach to quality, the Control group, (Gordon et al. 2021a). Through this current research, the authors continued to investigate the project workflows for these two groups and looked at the Request for Information (RFI) and Potential Change Item (PCI) workflows, which is a required and leading step to issuing a formal Change Order (CO) for this GC. The authors endeavoured to understand the following:

- Can the RFI and PCI process metrics collected by this GC support assessing if design quality contributed to the Intervention group achieving better project performance outcomes and more collaborative cultures?

- Are there discernible differences in outputs for standard communication workflows, the Request for Information (RFI) process, and the Potential Change Issue (PCI) process through the project lifecycles?
- Can the outputs of these standard communication workflows be leading indicators of project performance and cultural outcomes of projects?

The hypothesis: SAQ projects which created systems to build from knowledge and information, understand and align objective expectations for deliverables, including design packages, would have fewer RFIs and less towards the end of the project as many details were worked out ahead of time. Also, the categorization of the change would help identify those associated with design quality. When the change occurred would be an indicator of how SAQ influenced information flow. The authors also planned to review how the groups documented schedule information in the PCIs to understand how implementing SAQ influenced teams' internal planning and communication. The authors sought to determine if project RFI workflows would provide evidence about project design quality.

This study is important as it assesses standard process outcomes between projects that implemented SAQ and experienced better performance outcomes versus a Control group. The findings of this study can help leaders create project performance process thresholds and identify when projects "are in trouble" and need help, such as a different strategy or support.

THEORETICAL FRAMEWORK

SYSTEMS APPROACH TO QUALITY (SAQ)

Bertelsen described construction projects not as linear and ordered but as complex and dynamic systems (Bertelsen 2003a; Bertelsen 2003b). Like Bertelsen, this GC recognized projects are complex and dynamic and desired reliable, consistent, and predictable outcomes for quality on their projects (Spencley et al., 2108). To solve the rework problem this GC faced, they developed a Systems Approach to Quality (SAQ) (Gordon et al., 2021a). Foundational to SAQ are the principles: identifying Points of Release (PoR), when work is released to the next phase, building from knowledge and information, understanding expectations, and Distinguishing Features of Work (DFOW) from each stakeholder's perspective, aligning expectations to measurable acceptance criteria for the work, tracking and visualizing leading indicators, and performing causal analysis when evaluated work does not meet the expectations of the deliverable (Gordon et al. 2021a). These principles are applied to the project strategy and across the projects' many workstreams of safety, quality, cost, planning, and change management to deliver the expected deliverable at each PoR.

PREVIOUS RESEARCH

This paper is the third in a series to assess projects that implemented SAQ, the Intervention group, versus a similar set of projects that implemented an industry standard, compliance-based approach to quality, the Control group. The first paper measured project performance outcomes between the two groups for cost, schedule, change management, safety, quality, and cultural outcomes using Quinn's Competing Values Framework (CVF) and found that those that implemented SAQ had better performance outcomes more aligned with company objectives (Gordon et al. 2021a). In follow-up research, Gordon et al., 2022 reviewed contract date relative to project duration and studied staffing and resourcing profiles between the project groups to understand if different inputs contributed to better performance outcomes (Gordon et al. 2022).

Through this previous research, the following was reported:

- "Cost: The median value of cost growth for the Intervention group was 5% and 9% for the Control group. The median value of fee gain for the Intervention group was 4% and -35% for the Control group.
- Schedule: The median value of schedule growth at mobilization for the Intervention group was 11% and 18% for the Control growth.
- Change Management: The median value of contract changes was 5% for the Intervention group and 13% for the Control group.
- Safety: The median value of incidents per $100M for the Intervention group is 1.5 and 1.9 for the Control group.
- Quality: The median value of claims as a percentage of contract cost for the Intervention group was 0.14% and 0.87% for the Control group.
- Project cultures: Using Quinn's Competing Values Framework (CVF), the Intervention group reported more collaborative cultures" (Gordon et al., 2021a).
- Signing the contract, the Guaranteed Maximum Price (GMP) as a percent of project duration: The median value for the Intervention group was .09% and 19% for the Control group" (Gordon et al., 2022).
- The median value for time coded to VDC resources was approximately 3x more for the Intervention projects (Gordon et al., 2022).
- The Intervention projects also outsourced more project management work (Gordon et al., 2022).

LITERATURE REVIEW

The RFI and CO processes are standard processes in the construction industry and have been used to assess drawing quality and communication of construction projects. Tilley et al., 1997 concluded that evaluating the RFI workflow with the drawing register can indicate design and documentation quality and status of project performance and analyzing the number of RFIs relative to contract value and project schedule, and response times can be used to assess the severity of the issues (Tilley et al., 1997). Similarly, a 2021 Construction Industry Institute study stated: "'RFI/$M' is a shorthand metric for project communication and design quality. In general, more RFIs are a 'bad sign.'" Furthermore, several studies review project RFI metrics for the projects investigated (Tilley et al., 1997; Hughes et al., 2013; Construction Industry Institute, 2021). The Navigant Construct Forum studied a data set of 1,362 projects from all over the globe between 2001 and 2012. They documented the following:

- There were 1,083,807 RFIs submitted on these projects, averaging 796 RFIs per project.
- Average number of RFIs per million dollar is 9.9 for all projects.
- First response was calculated at 6.4 days and a median response time of 9.7 days (Dougherty et al., 2012).

Aboseif et al., 2022 published criteria for success metrics for communication by using quantitative performance data from 96 projects:

- RFI per $million less than or equal to 8.6
- RFI processing time less than or equal to 7 calendar days
- Fewer than .39 change orders per $million

Although the RFI process has waste and inefficiencies (Tilley et al., 1997, Alarcon and Mardones, 1998; Uusitalo et al., 2020), the RFI process is a standard communication process.

In the literature review, the authors realized there is a gap in investigating what the RFI and PCI flow looks like through the project lifecycle.

RESEARCH METHODOLOGY

METHOD

To investigate their questions, the authors used the same project data set from the 2021 and 2022 case studies (Gordon et al., 2021a; Gordon et al., 2022). Eleven projects that implemented SAQ and were within 90% of completion by January 2022 were chosen as part of the Intervention group. For each SAQ project, a project of similar contract size, geographical location, and core market, when available, that did not implement SAQ was chosen for the Control group. The authors again applied the design thinking and systems thinking concepts and tools from the Center for Innovation in the Design & Construction Industry's (CIDCI) online innovation lab (CIDCI 2022) (Gordon et al., 2022). The process involved six steps.

First, the authors further explored the problem statement using the "web of abstraction" tool to frame and re-frame the question. Next, the authors spoke with experts in operations, data analytics, project controls, and scheduling. The discussions revealed that the organization had dashboards to understand the number of RFIs project teams were experiencing each week compared to the project's current average. Additionally, one operations expert analyzed RFI-to-PCI ratios to help project teams forecast the amount of PCI work based on RFIs produced. Through the enterprise Operations Data model tool, the authors could observe the counts of RFIs, and PCIs related to data points, like the reason for and the type of assembly associated with the RFI and PCI. The scheduling subject matter expert identified, including the proposed time of work in the PCIs and whether the work can be done concurrently or will extend the critical path, is crucial information needed to forecast more reliable plans.

The third step involved reviewing the collected data and identifying the information needed to investigate the questions. During the study period, RFI and PCI information was collected in a centralized project management software platform. When project teams seek clarification or an interpretation of the contract drawings, an RFI is initiated in the software when the subject, created date, from, and to fields are entered. When additional details such as discipline, agency review required, questions, suggestions, potential schedule and cost, and relevant attachments are added, the RFI is submitted via the company's project management software to the appropriate project stakeholder and enters pending status. If the stakeholder's response requires additional time and money above the contracted baseline work, a Potential Change Item (PCI) with scope, cost, and schedule impacts is submitted via the project management system for owner approval. Once the required fields of Type of PCI (Owner, Category Transfer, or Original Budget Change), Description, Status, and Date Initiated are entered, the PCI is created. When the owner approves the PCI, a formal Owner Change Order (OCO) is submitted.

Next, the authors mapped the available information to the questions and brainstormed how to visualize and compare the groups' data. The authors planned to visualize and analyze the type of RFI categorization through the project lifecycle. However, since RFI categorization was an optional field, this data was not available for many of the projects. Similarly, the amount of time projected for the work was an optional PCI field, and this information was not always available. Thus, the authors focused on looking at the counts of RFIs and the value and count of PCI data through the project lifecycle to determine design quality. The authors developed visuals of the data and then analyzed it.

DATA COLLECTION

From the company's enterprise project management software platform for both the RFI and PCI workflows, the following data was exported for each RFI and PCI: date created, date information is requested, date submitted to project stakeholder, date response submitted, and date closed.

The RFI and PCI data were compiled and reviewed for each project by two different project duration views. The first view compiled the RFI and PCI data for 1) the time before signing the GMP and 2) after signing the GMP. In the previous study, the authors found a significant difference between when the Intervention and Control groups signed the GMP, .09% and 19% of project duration between mobilization and substantial completion, respectively (Gordon et al., 2022). Thus, the authors investigated if there were differences in the RFI and PCI patterns for these durations. Secondly, the authors normalized the information by standard project milestones: actual mobilization date and substantial completion (Gordon et al., 2022). The authors looked at the time before mobilization and called this period the pre-game quarter. Then for each project, the authors compiled standard durations for the project lifecycle by taking the time between the actual mobilization date and substantial completion date and dividing that into four equal durations that included: mobilization date to 25%, 25% to 50%, 50% to 75%, and 75% to substantial completion. Data for each project was reviewed in these five quarters and aggregated into each group, to compare group trends.

For RFIs and PCIs, the following metrics were calculated for each project and then for each group, Intervention, and Control by the two durations: 1) Total count, 2) percent of the total count, 3) average closure rate, 4) RFI/PCI per million 5) RFI per 1000 hours of staffing.

Table 2: Performance Metrics and Units of Measurements

Metric	Formula
RFIs/PCIs per $million	$\frac{Total\ Count\ of\ RFIs/PCIs * 1{,}000{,}0000}{Contract\ Value}$
RFIs per 1,000 hours of GC Hours	$\frac{Total\ Count\ of\ RFIs * 1{,}000}{GC\ Hours}$

DATA FINDINGS

The following RFI and PCI performance metrics were calculated: 1) RFIs per million were 5.2 and 6.4, respectively, for the Intervention and Control groups; 2) RFIS per 1,000 hours of GC hours were calculated as 9.4 for the Intervention group and 11.8 for the Control; 3) PCIs per million were 4.1 and 5.6, respectively for the Intervention and Control groups.

Figure 1 compares the total GC hours for the Intervention group versus the Control group for each quarter of the project. The y-axis represents the count of staff hours reported in the GC's weekly billing submissions, and the x-axis represents the entire project lifecycle in the five quarters. The x-axis is standard for all the following graphs.

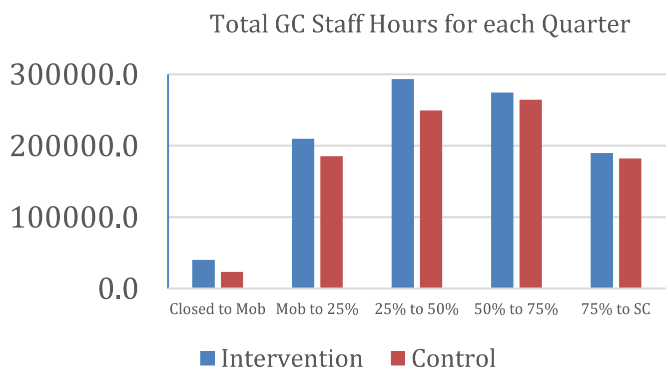

Figure 1: Count of total GC hours

Figure 1 shows that overall, the Intervention group reported 12% more staff hours than the Control group. In the pre-game quarter, before being on-site, the Intervention group had nearly double the staff hours as the Control. Box and whisker charts also revealed that the Intervention group had more variability in the count of hours staffed for their group of projects.

The graphs in Figure 2 show two views of the total RFI counts for the Intervention and Control groups. The left chart summarizes the count of RFIs for each duration in the project lifecycle, and the right graph plots the median values of the counts as a percentage of total counts for each duration.

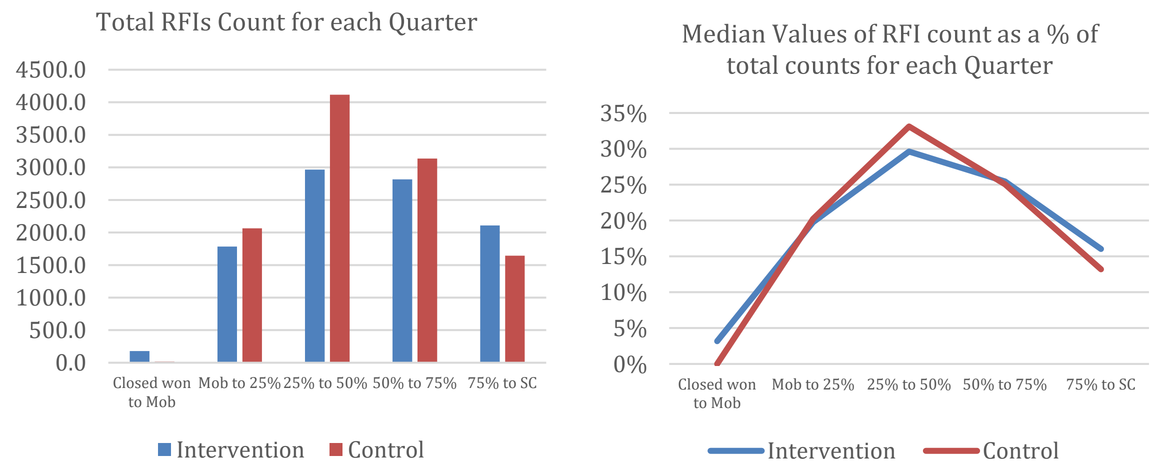

Figure 2: Total RFI counts and median value RFI count as a percentage of total counts.

Overall, the Control group submitted 10% more RFIs than the Intervention group. One significant difference is that the Intervention group reported 9.5x more RFIs than the Control projects before mobilization. In the three quarters after mobilization, the Control group had more RFIs. In the last quarter, the Intervention group submitted 25% more RFIs. For the graph on the right, the median values are similar for the percentage of total counts. The box and whisker analysis demonstrates that both groups had similar ranges and much variability for the four quarters after mobilization.

Figure 3 provides comparable PCI visualizations. The left graph summarizes the count of approved PCIs, and the right chart summarizes the median value of approved PCIs as a percentage of total approved counts for each of the five time periods.

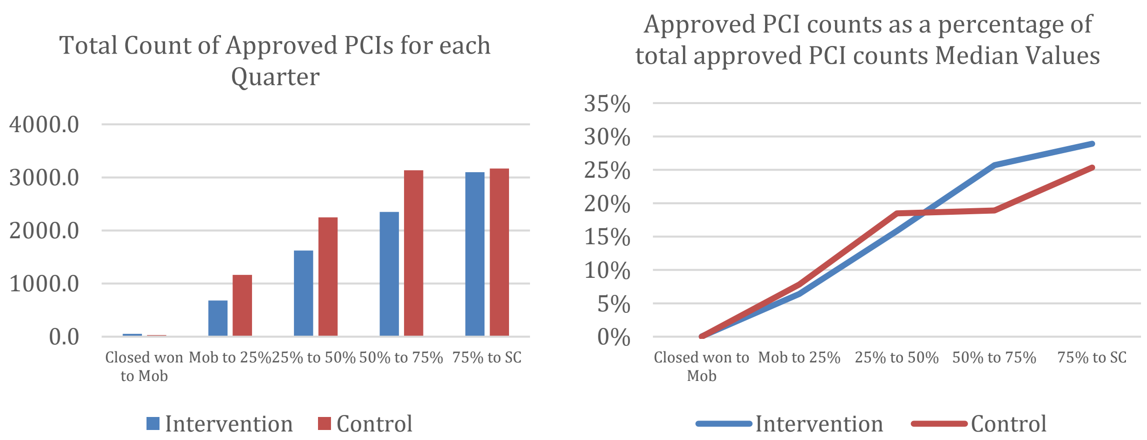

Figure 3: Count of approved PCIs and the median value of approved PCIs as a percentage of total approved PCI counts.

The left graph of Figure 3 shows that the Control group had more approved PCIs throughout the project lifecycle. This is expected as the previous research documented 8% more change than the Intervention group as a percentage of the overall contract value. The graph on the right shows that the Intervention group had more variability and a range of PCIs approved in the last two time periods of the project.

The RFI closure rate was calculated by subtracting the RFI date created from the date closed. Then, the average closure rate was found for each project in each duration, and the median value for each group, Intervention vs. the Control, was plotted as shown in Figure 4. The y-axis represents days in time, and the x-axis represents the normalized periods.

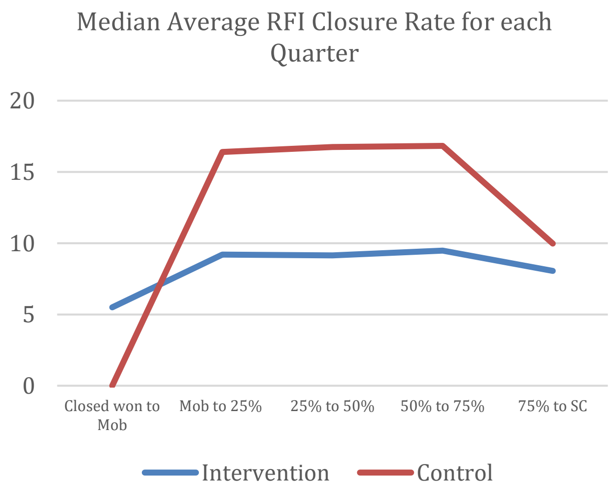

Figure 4: Median values for the average RFIs closure rate for the Intervention Group vs. Control group for the normalized periods.

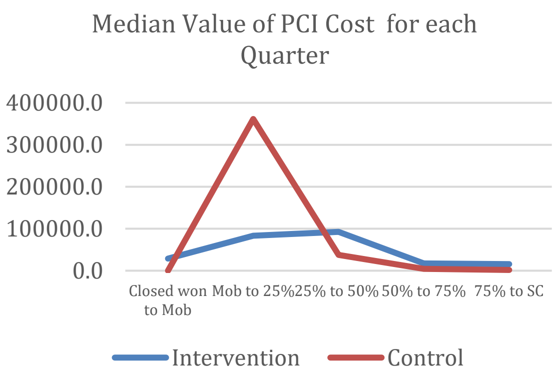
From mobilization to 75% of the project duration after mobilization, the Control group's median average closure rate is 16 days. This is twice the Intervention group's median value, which was an 8-day closure rate during this period.

Figure 5, the left graph, shows the median PCI cost for each group during each of the five quarters. Previous research showed that the Control group experienced more change as a percentage of the total cost. For the Control group, the median value for PCI cost spikes after mobilization, and the box and whisker charts reveal that the second quarter experiences the most variability. For the Intervention group, the box and whisker charts show that the pre-game quarter, the quarter before mobilization, experiences the most variability in PCI costs. Figure 5, the right graph, shows the average PCI closure rate for each quarter. While the Intervention group's median value for closure rate steadily increases until the quarter before substantial completion, the median value for closure rate for the Control group is highest in 25% to 50% of the project after the GMP was signed.



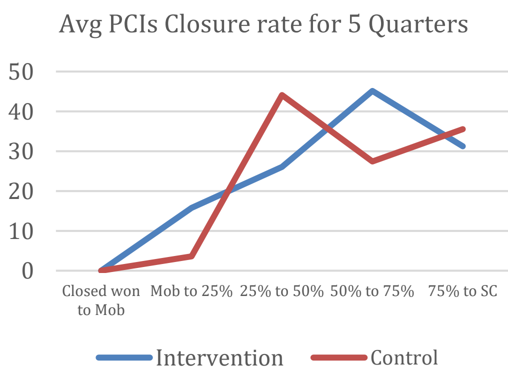


Figure 5: Plot of median values of the PCI cost for five quarters.

LIMITATIONS OF THE DATA

Data limitations include 1) that this is only a case study of 22 projects; 2) the projects were either classified as having implemented SAQ based on conversations with the project team and their presentations at the organization's Monday Quality Calls forum (Gordon et al., 2021a) or not implemented; 3) Total counts of RFIs were based on RFIs with a created date and not a submitted date. The authors found a small percentage of RFIs that were created but not submitted; 4) When the contract required the project team to use a different project management software system, fields were used that coincided with the data collected in the GC's enterprise system; 5) The analysis does not distinguish between project delivery system; 6) The RFI and PCI analysis does not differentiate between the type of change requested – whether it was a clarification, error or omissions, an improvement, or change directive; 7) Category transfers were included as PCI counts.

DISCUSSION

MEANING

The Intervention group, which consisted of projects that implemented SAQ, submitted more RFIs before mobilization. This suggests that implementing SAQ and formal documentation of early and essential design decisions could contribute to signing the contract sooner, which allows the GC to focus on the execution of the work and better performance outcomes. Both groups had roughly the same median values of RFIs created before and after GMP, approximately 20% and 80%, respectively. However, the Intervention group's median value for signing the GMP was within 1% of mobilization, 18% sooner than the Control group. This suggests that the RFI and PCI work needed by mobilization for a project to have reliable outcomes can be determined and used to measure how projects are trending. The Intervention group, with twice as much stuff as the Control, also asked more questions earlier in the project lifecycle, suggesting implementing SAQ and staffing, and not design quality was a key to contributing to better performance outcomes.

The median value for the closure rate of RFIs for the Intervention group after mobilization for three quarters, while the project was in construction was 8 days. The Control group's median value for this same time was 16 days. The Intervention group received information in the project earlier and faster than the Control. This experience could contribute to the Intervention group's results on Quinn's CVF, where they ranked higher on collaboration than the Control group Control that more collaboration would lead to even more success (Gordon et al., 2021a).

Also, the timeframe when projects experienced Potential Change Items (PCIs) differed. The Intervention group experienced a lot more variability in the pre-game quarter before mobilization, while the Control group experienced more variability in the quarter following mobilization. This suggests that the Intervention group, applying the principles of SAQ, was better able to adapt and communicate and resolve changes with stakeholders earlier in the project and agree to the GMP sooner. Also, the large PCI numbers the Control group forecasted after mobilization could have contributed to the delays in signing the GMP.

The data also showed that the Control group had created 54% more total PCIs. The Control created nearly 3x as many PCIs as the Intervention group in quarter three, 50%-75% between mobilization and substantial completion. However, only a third of those created PCIs turned to approved status. The elimination or rejection of created PCIs could account for the Control group's lower average closure rate compared to the Intervention group during this period. This also demonstrates the additional workload the Control group was experiencing with fewer staff.

IMPLICATIONS

This study demonstrates how normalizing views of cross-discipline information in relation to project lifecycle can provide more insight into leading indicators or early system outputs that could alert the GC's organization to how a project's performance is trending and when intervention is needed. The work is also important as it demonstrates how GCs can leverage their enterprise data to intermediate benchmark project deliverable outputs that produce known outcomes.

CONCLUSION

KNOWLEDGE GAINED BY PARTICIPANTS, AND VALUE FOR PRACTITIONERS

The authors learned from this case study that RFIs documented before mobilization can be a leading indicator of project performance success and collaborative cultures. The GMP will also likely be signed earlier in the project lifecycle. Additionally, more PCIs in the pre-game quarter is another leading indicator of project success and suggests that the organization look at PCI value in relation to the mobilization date to understand how projects are trending. The RFI closure rate significantly differed between the groups suggesting this is a critical lagging indicator demonstrating that a project is experiencing issues.

When the authors compared their case study findings for RFIs per million and closure rates against reported industry metrics, they found some differences. Hughes et al., 2013 research indicated that 9.9 RFIs per million is typical for projects, and Absoeif et al., 2022 stated that 8.6 RFIs per million was a successful project threshold. In this case study, both Intervention and Control groups had median values below that criteria, 5.2 and 6.4, respectively. This finding highlighted for the authors the importance of performing these studies and broadening them with their organization's data to understand representative benchmarks.

Finally, normalizing views of the organizational data to standard project milestones and taking a cross-disciplinary view of the data is essential for a more holistic understanding of what projects are experiencing. From this work, the following are early indicators for a successful project: the percent of total estimated staffing hours spent in planning before mobilization, the number of RFIs based on estimated project value that should be submitted before mobilization, and the planned duration for GMP approval needs to be by mobilization.

FURTHER RESEARCH

While it is generally accepted that lower RFI counts equate to better quality design (Construction Industry Institute, 2021), this would suggest the Intervention group had more complete, clear, and concise information to build from. However, more investigation is needed to answer this question. In implementing SAQ, the teams' focus on understanding and aligning expectations for processes of engagement, communication, and for information needed to build could have contributed to fewer RFIs as well. This project group also documented 3x more VDC resources, likely facilitating increased communication and understanding. A social network analysis of the project groups could also be performed to analyze if there are patterns for how stakeholder knowledge intersects with the social network to create a better-quality design. Additionally, the type of change requested in the RFI should be analyzed to categorize the reasons for the change and assess design quality. The authors would also like to investigate the types of PCI changes each project group is experiencing and how proposed schedule information is documented to understand if any internal communication and planning patterns exist that could inform project performance trends.

For further research, the authors also aspire to explore the interactions and workflows for understanding and aligning stakeholder wants, needs, and project expectations and how the workflows and processes differ between the groups. The authors want to investigate how these project system outputs are visible in the organization's enterprise system data. This knowledge can be used to determine additional leading indicators of project performance trends.

Furthermore, the authors suggest broadening this study and previous papers from 2021 and 2022 to apply multivariable statistics to create statistical thresholds for project performance outcomes, cultural outcomes, staffing and resourcing profiles, and standard process outputs. For benchmarking, the authors would like to explore these views based on project type, customer accounts, design partners, project delivery system, and other project characteristics that would inform the GC's execution strategy.

OCCUPATIONAL STRESS IN CONSTRUCTION: FOSTERING AN IGLC RESEARCH AGENDA

Saad Sarhan[1], Stephen Pretlove[2], Alan Mossman[3], and Mohammed Z.E.B Elshafie[4]

ABSTRACT

Globally mental health is a serious concern, particularly in construction. According to the Health and Safety Executive (HSE, 2021), stress, anxiety, and depression are the second biggest cause of work-related ill health in the UK construction industry. Occupational stress and mental health issues should, therefore, be treated with the same level of significance as physical health and safety risks in construction. To the authors’ knowledge, there are very few, if any, published empirical IGLC papers that have explicitly focused on this concern. This study was conducted using case-study interviews and a focus group with industry experts, to explore and promote the concept of ‘occupational stress’ in construction. The study provides novel contributions to knowledge, which include: identifying seven main sources of stress (i.e. stressor) in UK construction projects, revealing ‘workflow interruptions’ as a prevalent and severe source of stress in construction, shedding some empirical light on the inadequacies of the critical path method, and generating new questions and proposals to pave the way towards a future IGLC research agenda for tackling occupational stress and mental health issues in construction.

KEYWORDS

Lean construction, stress, mental health, flow, waste

INTRODUCTION

Occupational stress is increasingly becoming an issue of major concern all over the world. In the UK, for instance, it is estimated that stress-related illness costs the British industry £5 billion each year, with the Health and Safety Executive (HSE) calculating that stress, depression or anxiety account for 44% of all work-related ill health cases, and more than half of all sick days in an average year. The COVID-19 pandemic, the Russia-Ukraine war and the resulting global economic recession have further compounded these issues, by creating additional unprecedented social and economic pressures on the mental health and well-being of many people, particularly those working in construction.

In the US, the 2021 National Veteran Suicide Prevention Annual Report shows the [military] veteran suicide rate was 31.6 per 100,000 veterans in 2019. The adjusted suicide rate for the same year for all US adults is 16.8 per 100,000. The data shows the construction industry suicide rate is 53.2 per 100,000. Does that mean it is *"easier on a person’s mental state to be*

asked to prepare for and propagate war than to work in construction?" (Winningham 2022). It doesn't have to be this way.

Stress in itself is not an illness, but it can make people ill. HSE (2021) defines work-related stress as "*the adverse reaction people have to excessive pressure or other types of demand placed on them*". Stress affects employees, their families and colleagues, by making their physical and psychological condition worse. This in turn affects employers who have to deal with increased sickness absence, lost productivity, human error leading to re-work, increased accidents, replacement of staff and poor performance within their organisations. Figure 1 illustrates how the level of stress can impact on the individual's performance at work.

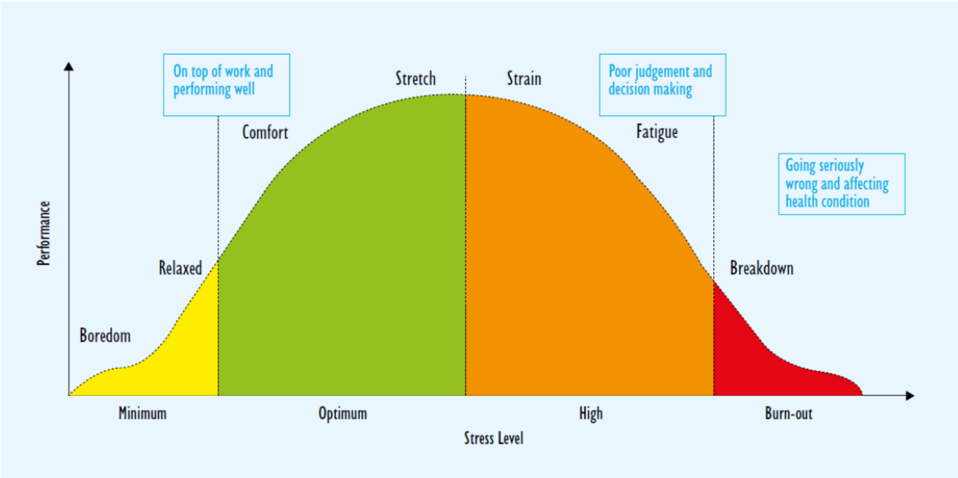

Figure 1: The Influence of Stress on the Individual's Work Performance
[Chart produced by Mates in Mind; cited in CIOB (2020)]

Despite the relatively low levels of 'reported' work-related stress in the construction sector, when compared to other industries, there is anecdotal evidence that occupational stress and mental health are increasingly becoming critical issues of concern within the sector (CIOB, 2006; HSE, 2007; CIOB, 2020). Several empirical studies have identified work-related stress as one of the root causes of unsafe behaviours in construction (for example, see Seo et al., 2015; Leung et al., 2016; Wu et al., 2018). Other major social problems such as high absenteeism, presenteeism, alcoholism, drug abuse and suicide have also become increasingly reported as consequent to occupational stress in construction. The CIOB's (2020) report described mental ill-health as a silent *crisis* within the construction industry, with males three times more likely to commit suicide than those in other sectors.

Why are People in Construction Particularly at risk?

People working in construction are particularly vulnerable to suffering from mental health issues (Oswald et al., 2019). There are various systemic and inherited problems in construction (Sarhan *et al*., 2017), such as its risk-averse and blaming culture, cut-throat price competition, the traditional macho culture, long and fragmented supply chains, late payments, slim profit margins, tight deadlines and challenging working conditions, skills shortage and job insecurities, all of which contribute towards increasing stress and anxiety in construction.

Most of the workforce in construction are self-employed, and thus getting regular and reliable work can be very challenging for them. This job insecurity can contribute significantly to their poor mental health. In addition, these casual or self-employed workers may not have or be aware of any mechanism for reporting their work-related stress and mental health issues. Furthermore, the majority of workers in construction are employed by small and medium enterprises (SMEs), and it can be difficult for smaller companies, due to their limited budget and resource constraints, to put the right arrangements in place for supporting the mental health and wellbeing of their employees.

RESEARCH GAP AND OBJECTIVES

Many research studies have focused on investigating physical health problems and safety performance in construction. However, much less research has studied mental health issues affecting construction practitioners (Oswald et al., 2019). In addition, efforts in both academic and practitioner communities in construction focus mainly on managing occupational stress, as opposed to preventing or reducing its occurrence. Many studies on stress in construction have set out to identify its causes and effects at individual, task and organisational levels. Very few, if any studies, have sought to investigate the sources of stress (i.e. stressors) at a project or supply-chain level.

Lean Construction (LC) has shown to be effective in managing H&S risks in construction through integrating safety into production planning and control processes (Saurin et al., 2002; Sacks et al., 2005). Various LC tools and techniques have been used to improve safety performance in construction, including the use of the Last Planner® System, 5Ss program, BIM, visual management, and off-site construction. The idea is that an early focus on physical safety performance will also help in improving productivity, process transparency and minimising time and cost wastes resulting from accidents on construction projects. Guided by the two core lean principles of respect for people and continuous improvement, a limited but increasing number of IGLC studies have been used to promote the importance of considering psychological safety in construction.

Interestingly, there are only six conference papers within the IGLC repository (from 1996-2022) that explicitly focused on this critical topic of mental health in construction (see Table 1). This study, therefore, hopes to contribute to this topic by presenting the findings of a focus-group with UK industry experts. The ultimate aims of this study are to:

- Identify the main sources of occupational stress in UK construction projects,
- Propose strategies for preventing or reducing stress in construction projects
- Promote an IGLC research agenda for addressing mental health issues in construction

RESEARCH METHOD

This study forms part of a larger research study that was funded by a UK charitable trust to develop supply-chain management (SCM) strategies for improving stress management and productivity in construction. The study adopted a qualitative multi-methods research approach, comprising a qualitative systematic literature review, case study, and a focus group. Empirical data were collected from a UK case-study through site observations and iterative semi-structured interviews. The case-study was selected because it was a live project which allowed the first author of this study to conduct multiple visits, observations and iterative conversations with the site team. It was also delivered by one of the most recognised main contractors in the UK, which was an essential criterion, to allow the study to capture examples of best practices in relation to H&S and SCM. The authors also had direct access to the client's project management team. The main features of the case-study project are as follows:

- Higher Education building in the UK
- Design and Build project procurement method using two-stage tendering
- Contract value ~£30 Million, duration was 2 years
- NEC 4 contract, BIM, and prefabrication techniques were used.

In total, 19 in-depth interviews were conducted as part of the case-study with a sample of construction workers at different levels (e.g. forepersons, supervisors, site workers, project managers, site managers) and representing the various parties of the project supply-chain (client, main contractor, and subcontractors). The data collected from the case study interviews and site observations were analysed using NVivo software, following Strauss and Corbin's (1998) formal procedures for data coding and analysis. A focus group was then used to evaluate the findings of the case-study (i.e. the themes and conclusions that emerged from the qualitative data analysis phase). This paper focusses on the findings of the focus-group.

FOCUS GROUP: METHODS AND TOOLS USED

This focus group was conducted to evaluate the findings of the case-study, collect feedback from wider industry stakeholders, and assess the extent to which its findings could be generalised. Focus group participants were selected to ensure that all participants had broad and significant experience in the construction industry (see Table 2).

Table 2: Focus Group Sample

No.	Job title of participants of the focus group	Years of Experience
P1	Consultant and Fellow Member of the Institute of Civil Engineers (FICE)	30+
P2	National Civil Engineering Director at the Civil Engineering Contractors Association	30+
P3	Professor of Sustainable Construction	30+
P4	Professor of Lean Project Management	30+
P5	Operational Change Manager at a Leading Consultancy Company	20-30
P6	Engineering Manager at a British County Council	20-30
P7	Business Development Manager at a Subcontractor	20-30
P8	Business Development Manager at a Charitable Trust	10-20
P9	Growth Development Manager at a Leading UK Charity Organisation	10-20
P10	Group Director of H&S at a Main Contractor	10-20
P11	Production and Performance Manager at a Global Consulting, Engineering and Construction Management Company	10-20
P12	Health & Safety Programme Manager at a Leading Global Construction Company	10-20

The focus group was conducted online and lasted for an hour and a half. Two of the authors of this study started by delivering a 20-minute presentation to summarise the findings of the case-study. They then introduced an interactive survey using a web-based response system named Poll Everywhere. This application allows the participants to anonymously answer questions. The results are, however, displayed and updated live for all to see. The whole session was video recorded (following the agreement of all the participants) to capture feedback, interactions, and comments during the discussion of the results.

RESEARCH FINDINGS AND ANALYSIS

The following sections summarise the main findings of the study.

THE MAIN SOURCES OF STRESS IN CONSTRUCTION PROJECTS

Based on the findings of the case study (listed in Figure 2 below), the focus group participants were asked to select the stressors that they believe are ‘prevalent’ in construction projects. ‘Work demands’ (i.e. work load, and unrealistic project budgets and demands) and ‘workflow interruptions’ were considered the most prevalent stressors by most of the participants, as shown in Figure 2.

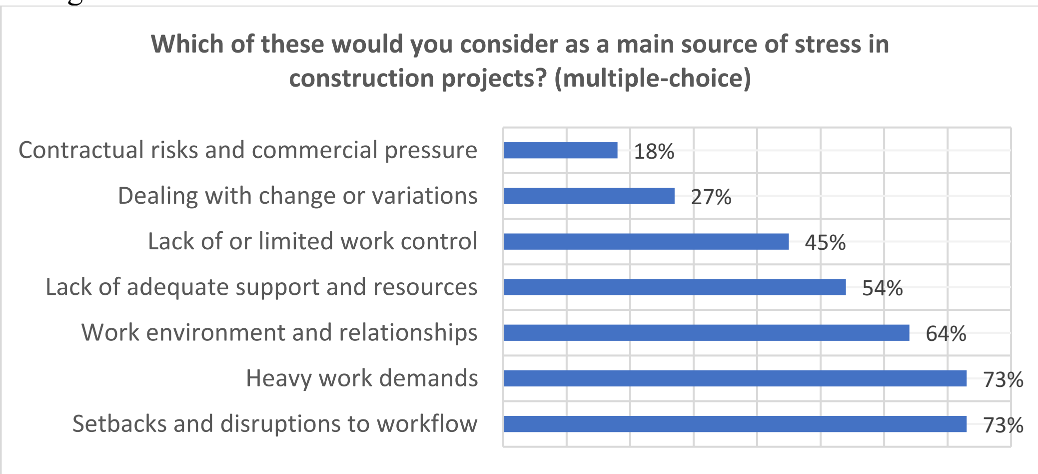

Figure 2: The Main Sources of Occupational Stress in Construction Projects

Following this, the participants were asked to assess the main causes of workflow interruptions as identified from the case-study. The participants were also provided with the opportunity to suggest any other factors and to provide any additional comments to support their answers.

MAIN CAUSES OF WORK-FLOW INTERRUPTIONS IN CONSTRUCTION PROJECTS

Two factors were agreed upon by more than half of the participants of the focus group as main causes of workflow interruptions in construction projects (see Figure 3). Some other suggestions and interesting comments were provided by the participants, as follows:

- *“It reflects the **culture** in construction not a particular site”.*
- *“Lack of building **the right team culture** to support the **collaboration** required”*
- *“Over promising on **unclear expectations**. Pressure then cascades to the team”*
- *“The **complexity** of the construction supply chain”*
- *“The **uncertainty** created by weather and conditions that we didn't know about”.*

As shown in Figure 3, the findings suggest that the work-related stresses that construction workers may experience in construction projects mainly stem from the pre-construction stage. In particular, it appears that both the construction programme and design could have a significant impact on the performance, mental health and wellbeing of the people working on site. Thus, the following questions (see Figures 4-6) were introduced to identify and gain a better understanding of the limitations and potential sources of stress embedded in the way we traditionally design, plan and procure construction projects.

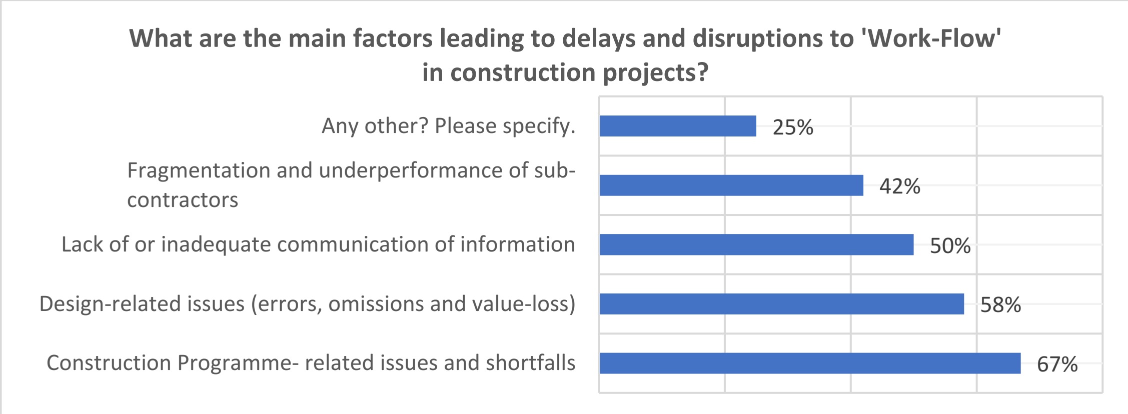

Figure 3: Main Factors Leading to Delays and Disruptions to Workflow in Construction Projects

Construction Programme-related Shortfalls

The participants criticised traditional planning techniques used in construction, based on the critical path method (CPM). The main concern raised is that CPM leads to the development of static programmes that do not account for the high level of uncertainty that characterise many construction projects (Figure 4). CPM is used to manage work in projects by pushing trade crews to deliver work based on schedules prepared weeks, or even months, before the project even starts (Koskela et al., 2014; Mossman and Sarhan, 2021); this leads to unnecessary stresses and frustrations for people working on site. As stressed by one of the participants "in competitive bidding situations, the programme is often tightened by corporate management staff in order to win the project - even though the bidding teams may not be the ones eventually delivering the project". In addition, CPM does not take into consideration the coordination between the trades that is required to allow work to flow.

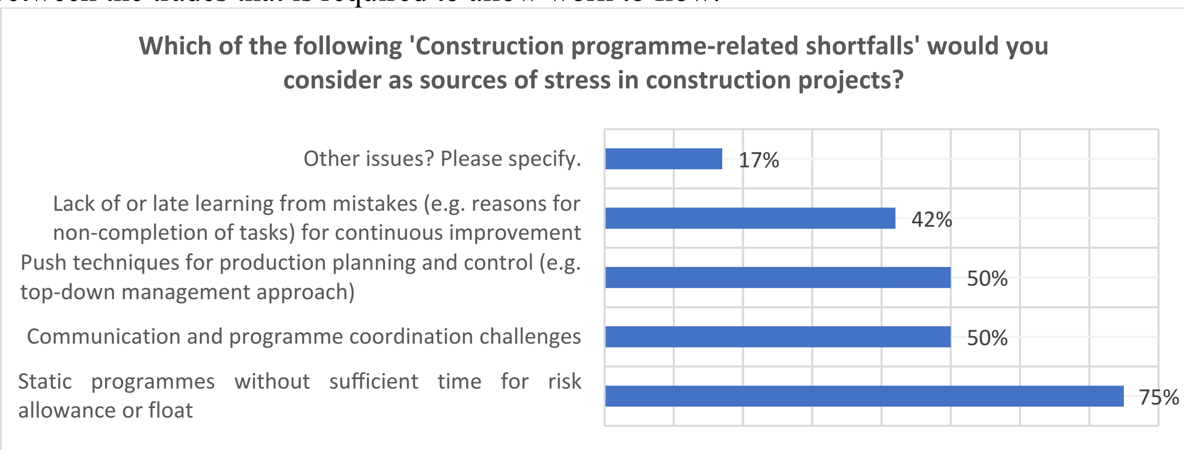

Figure 4: Construction-Programme Shortfalls as Sources Of Stress in Construction Projects

Design related Issues

Design changes were considered as a major source of stress and frustration in construction projects (Figure 5). Interestingly, design changes have been reported in many studies as a common problem in construction, due to its influence on project performance (see for example, Cox et al., 1999; Gharaibeh et al., 2021). However, there are hardly any studies that have considered their impact on the mental health and well-being of project participants.

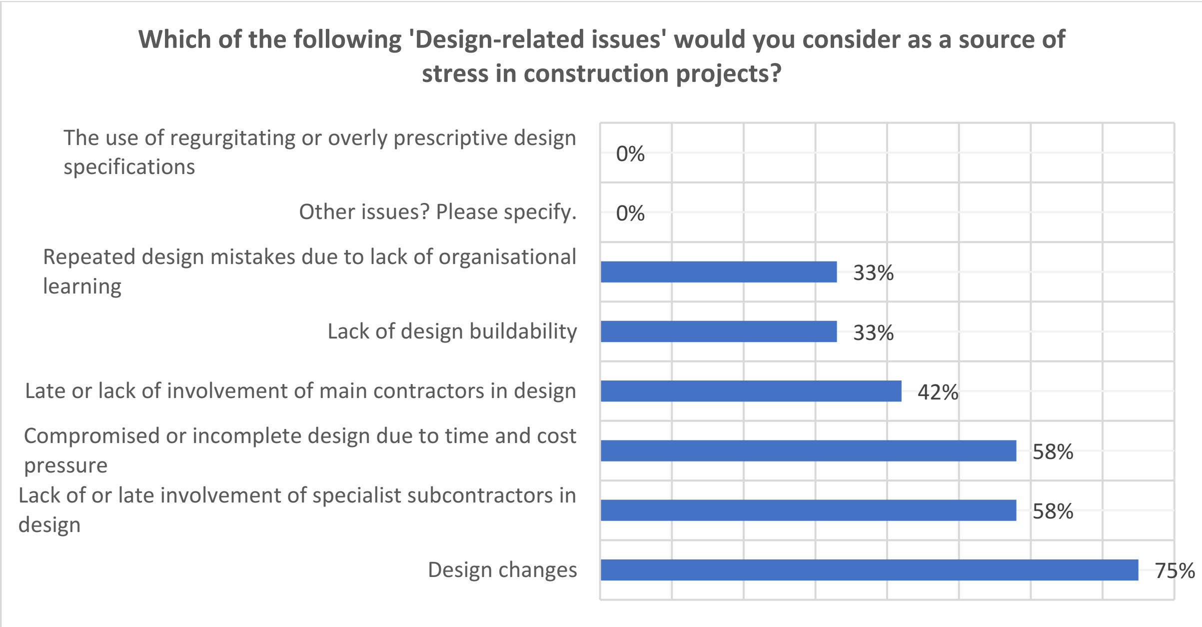

Figure 5: Inefficiencies in Design as a Source of Stress in Construction Projects

Design changes in construction usually occur due to: (1) changes in client requirements and value engineering purposes (2) design errors and omissions. From a lean perspective, there should not be a major concern with client changes during the project, as creating customer-value is part of the job. It is the responsibility of the delivery team to explain the change to the workers once they have ensured that the client understands the cost and time implications of the change and agrees them. However, as one participant reported, stress in construction projects usually occurs due to *"unrealistic changes made by the client organisations without fully understanding the impact that the change will have on the delivery team"*. Obviously, changes due to design errors or emissions lead to rework – that is waste. However, these design-related changes may not always be frustrating for everyone, as it could be argued that more work to do can be beneficial for the contractors and tradesmen involved, if they are compensated and feel valued.

Two other important design related issues were selected by the majority of the respondents as potential sources of stress. One is concerned with the need for engaging specialist subcontractors in design. This was also described by a participant as follows: "*main contractors have a very skeleton staff - the bulk of the work is done by specialists and these people can be missed out of the loop - especially M&E*".

The other issue relates to the contractual and commercial pressures that seem to influence the quality of design (for example, late or low payments). Interestingly, it was suggested in the focus group that "*designers need to be made more aware of occupational health issues within construction and not leave the contractors to sort it out*". Thus, it seems that design can play a major role in preventing or reducing stress in construction.

Both of these reasons point to the value of procuring construction with IPD or Alliance relational contracts that bring the whole delivery team together at the earliest stages of a project.

Contractual and Commercial Pressures

Most of the participants agreed that 'single-stage competitive tendering based on cheapest price and shortest programme' is a prevalent yet stressful practice (see Figure 6). Other factors were highlighted including 'contractual and commercial pressures; this has been described by a participant as follows:

> *"Commercial assumptions in the bidding phase can be over optimistic. I believe there has also been a trend for clients to push risk further downstream into consultants and contractors without necessarily allowing the budget to deal with those risks adequately in advance".*

There was also an emphasis from the participants on the importance of 'early involvement' of key members of the supply chain to support collaborative costing and design (Zimina et al., 2014; Namadi et al., 2017). For example, it was stated that "*the whole team of client, contractor, designer and the supply chain need to be engaged as early as possible - even at concept stage - so that there is full understanding of what is to be delivered and for how much!"*

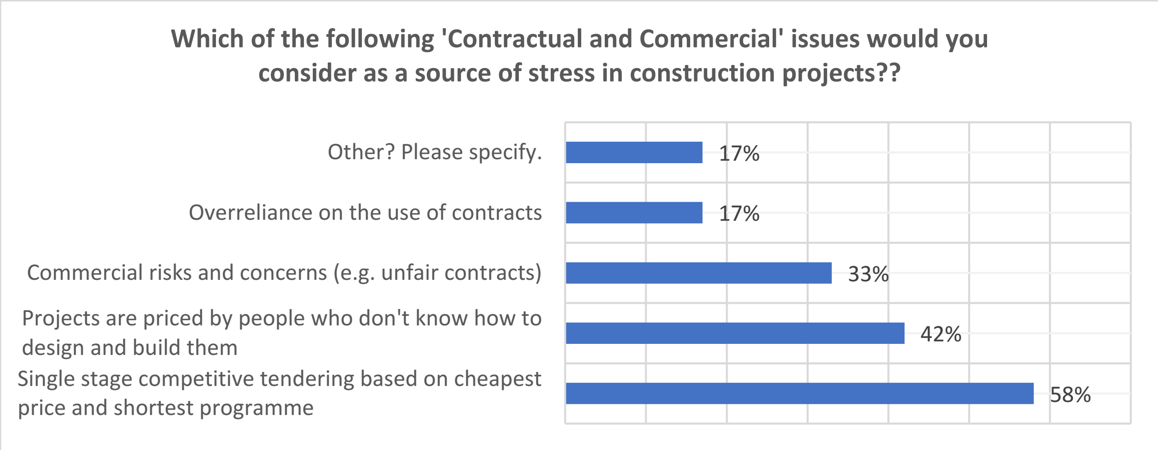

Figure 6: Contractual and Commercial Issues Influencing Stress in Construction Projects

This section has discussed the main sources of stress in construction projects revealed by this study, and it focused particularly on workflow interruptions and their causes. The next section looks at the findings in relation to stress prevention and reduction.

Strategies For Preventing or Minimising Stress in Construction

Common organisational practices for managing occupational stress used in construction tend to be 'reactive' rather than 'proactive'. Reactive practices include, for example, the use of fair and inclusive HR policies, offering counselling services, employee assistance programmes, and mental health awareness, training and first aiding — knee pads if you like. There are very few, if any studies, that have focussed on identifying or investigating strategies used at a project level. The following question, therefore, included a list of 'preventive measures' at a 'project supply-chain level' as identified in this study.

As can be seen in Figure 7, 'inclusive and collaborative planning' was the most recommended strategy for stress reduction in construction projects. This is an interesting finding, especially since the majority of the focus group have never heard of or used the Last Planner® System (LPS) for production planning and management – also known in the UK as 'collaborative planning'. This, therefore, suggests that the lean construction community can play a major role in promoting and improving mental health in construction through using and testing relevant LC theories and practices, such as the LPS, 5S, Target Value Design (TVD), and visual management techniques.

The effects of the implementation of the LPS on projects in Denmark (Thomassen 2003) appear to confirm the idea that predictable flow creates much less stress on projects. In the Danish projects that used LPS, sickness absence fell by 65%. It is generally accepted that sickness absence is associated with work stress.

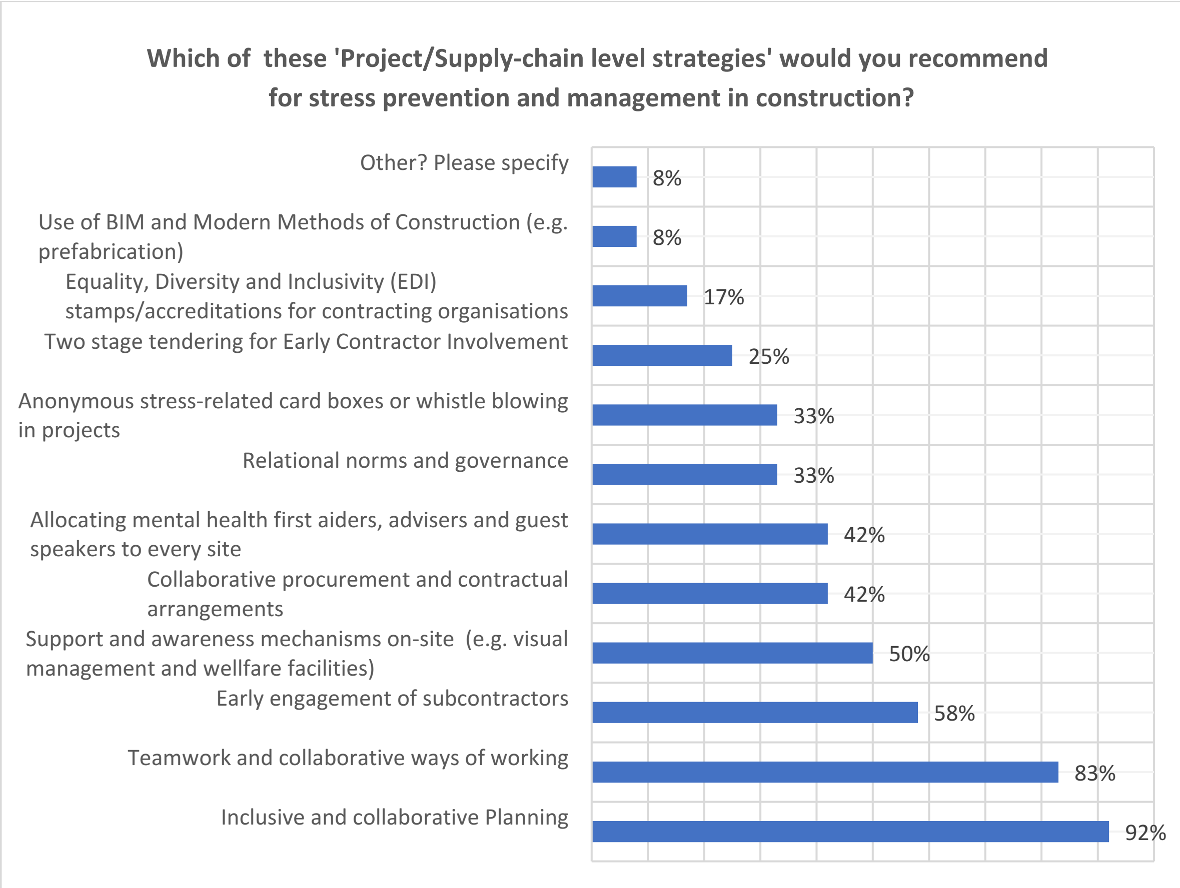

Figure 7: SCM Strategies for Reducing Occupational Stress in Construction Projects

TOWARDS A RESEARCH AGENDA

The empirical findings of this study have indicated that ‘workflow interruptions’ are a common and severe stressor in construction that can seriously affect the construction employee’s job performance and well-being. This raises the following fundamental question (RQ):

> **RQ:** ‘How can work-related stress and mental health considerations be incorporated into production planning and control processes in construction?’

This question is introduced to encourage further empirical research and foster an IGLC research agenda for addressing mental health issues in construction. One suggestion is to incorporate the HSE’s Management Standards (see HSE, 2019) into the Look Ahead Planning phase of the LPS when tasks in the Look Ahead period are *made ready* (i.e., constraint free) for the construction crew to deliver them when they want to (Mossman and Sarhan, 2021).

The UK’s HSE Management Standards are designed as a guideline for effective stress management. They address six key areas of *work design* that, if not properly managed, can lead to poor health and wellbeing, lower productivity and increased sickness absence (HSE, 2019). The Look Ahead window is when *work* is Made Ready. We also need a process for making *workers* ready. The six item HSE “checklist” is: (1) Demand – *e.g. can you cope with the demands of your job?*; (2) Control – *do you have a say in how your work is planned?*; (3) Support – *do you feel supported in your work?;* (4) Role – *are you clear about your role and responsibilities on the project?;* (5) Relationships – *can you have an open and honest conversation with people at any level in any organisation on the project?;* (6) Change – *is change well managed on the project?*. (For more detail on the checklist see HSE 2019)

The findings of this study, augmented by further empirical studies on the links between the concepts of *workflow* and *work-related stress* in construction, have potential to influence policy by incorporating ‘flow’ into the HSE’s Management standards for stress prevention and management.

It has been previously argued that the IGLC community should rethink the prevailing conceptualisation of ‘waste', so that it can account for both ‘environmental wastes’ (e.g. carbon emissions and energy consumptions) and ‘social wastes’ (e.g. unhealthy and unsafe practices) rather than focussing merely on process and physical wastes (Arroyo and Gonzalez, 2016; Sarhan et al., 2018). This study echoes and contributes to these arguments, by suggesting that the sources of stress (i.e. stressors) in construction projects be classified as ‘social wastes’. The stressors identified here could also be classified as sources of process waste in construction.

CONCLUSION

This study was conducted to explore the concept of ‘occupational stress’ in construction and has led to novel contributions to knowledge. ***First***, the study identified seven main sources of stress in UK construction projects (Figure 2). ***Second***, the findings of this study revealed that ‘workflow interruptions’ are the most significant source of stress in the construction project studied. It is, therefore, suggested that strategies for stress-reduction in construction should focus on finding innovative ways for enhancing workflow in construction. ***Third,*** it is suggested that policymakers should consider the potential for incorporating ‘flow’ into the HSE’s Management Standards. This study also identified two main causes of workflow interruptions in UK construction projects: (1) Construction Programme-related shortfalls; and (2) Design-related issues. Accordingly, the importance of engaging specialist sub-contractors in both design and construction programme development has been highlighted. ***Fourth***, it is suggested in this study that ‘stress’ and ‘risks’ are closely related in construction, as both tend to be pushed and transferred down the supply-chain. In particular, ‘single stage competitive tendering based on cheapest price and shortest programme’ has been identified in this study as a deeply rooted source of stress and value-loss in construction projects. ***Fifth***, ‘inclusive and collaborative planning’ is identified by the participants of this study as the most recommended strategy for stress prevention and/or reduction in construction projects. Accordingly, this study suggested incorporating the HSE’s Management Standards into the Look Ahead Planning phase of the LPS. ***Finally***, the study formulated new research questions and ideas, to contribute towards fostering an IGLC research agenda for tackling mental health issues in construction.

OPPORTUNITIES FOR FURTHER RESEARCH

This study focused on a single project. There are opportunities to do similar research on other projects in the UK and elsewhere in the world. There are also opportunities to use radically different research methods to see if they come up with similar or different results. It is suggested that further studies could also focus on investigating the sources and impacts of occupational stress on the productivity of different levels of workers within the construction project context.

Future studies are encouraged to investigate how lean design (e.g. TVD) and contractual arrangements (e.g. relational contracts) influence the mental health conditions of the project teams and workers involved. Furthermore, there is also scope for investigating the roles that emerging technologies and visual management techniques could play in supporting both ‘workflow’ and ‘stress reduction’ in construction projects.

ACKNOWLEDGEMENTS

This research has been enabled by a research grant from B&CE’s Charitable Trust. Any conclusions and opinions expressed in this paper reflect the personal views of the researchers, based on the information gathered.

INVENTORY AND PILING WASTE: A COMPUTER VISION APPROACH

Inshu Chauhan[1], Eelon Lappalainen[2], Ana Reinbold[3], Ilari Palsola[4], and Olli Seppänen[5]

ABSTRACT

Construction sites contain a lot of waste, and eliminating it enables productivity gains and health and safety improvements. Computer vision is a promising technology that is being used in various construction applications. Construction sites with limited human resources could benefit from automated computer vision-based waste analysis. This paper presents preliminary findings related to the algorithm-based waste detection of piling works and explores potential applications from a visual management perspective. An experimental approach was used in the study, and images from a construction site in Finland were used to train the algorithm. The main findings revealed that the amount of waste shown by the images was substantial and that ground-level and drone images could be combined to create a comprehensive view of pile waste inventories. This paper also presents potential applications of image-based pattern recognition for infrastructure sites where the use of drone and ground-level images is standard practice. Several problems emerged when using transfer learning to train the algorithm, the most significant of which were variations in the scenery of images used for training and the limited number of images. The solutions to these problems lie in collecting more data and experimenting with other deep learning-based methods which will be explored in future.

KEYWORDS

Lean construction, waste, visual management, computer vision, piling.

INTRODUCTION

WASTE IN CONSTRUCTION

Since the beginning of the 1990s, the construction industry has been inspired by the manufacturing industry's lean management school of thought and used its tenets as guidance when solving long-term construction problems related to unreliable planning, uncertain production flow and productivity, constant delays, and budget overruns (Koskela, 1992; Koskela et al., 2002). One of the principles of lean management is identifying and eliminating production-related waste, which interrupts production flow and increases operating costs (Ohno, 1988; Shingo, 1985).

Ohno (1988) identified seven types of waste: overproduction, transportation, stock on hand, idle time, processing, movement, and the production of defective products. The identification of waste in construction industry activities has become a fruitful research field, relating the waste in construction sites, the complexity of construction activities, and production flow interruptions (Koskela, 2004; Koskela et al., 2013; Macomber & Howell, 2004).

Since identifying waste in dynamic environments, such as construction sites, is time consuming and challenging (Lee et al., 1999; Achell et al., 2013), the construction industry once again looked to the manufacturing industry for a supportive tool and identified Gemba walks as an ideal option. The Gemba walks concept was implemented by Ohno (1988) in the car manufacturing industry and described by Womack (2011) as a management practice used to grasp the current situation before acting. Gemba walks can be connected to the visual management (VM) concept of being able to collect the information available at a site with a glance (Galsworth, 1997). The people involved in Gemba walks must know how to correctly identify waste during construction site walkthroughs. Time, training, and team commitment are required to develop this skill (Kerem et al., 2013).

VM was mainly developed to meet the practical needs of the manufacturing industry related to information-based problem solving through the use of simple visual aids and tools (Tezel et al., 2016). In addition to the simple tools of VM, new technologies, such as CV, have been proposed for use in safety management, progress monitoring, productivity monitoring, and quality control (Paneru & Jeelani, 2021; Tezel & Aziz, 2017). CV can support the identification of waste connected to overproduction and inventories. State-of-the-art CV algorithms can detect objects with the help of feature extraction. The use of CV algorithms to identify and reduce construction waste is a promising area of research (Wang et al., 2020). By using CV algorithms to identify objects, construction waste can be significantly decreased.

COMPUTER VISION

CV is the science of recognizing objects of interest with minimal human intervention. CV supports the automation of tasks that require visual assessment. This makes CV an important technology for the automatic detection of critical tasks in construction. One of the growing needs of utilizing CV is rapidly, accurately, and comprehensively understanding a dynamic construction site (Martinez et al., 2019). This visual assessment can have many applications, including construction progress monitoring, construction site safety management, construction waste management, and quality control of building elements.

According to an elaborate review by Martinez et al. (2019), CV has mostly been used to enhance construction site safety by tracking equipment, materials, personnel, and other resources. Next prominent utilization of CV is in productivity analysis by activity monitoring and scan-to-BIM (Building Information Modelling) to obtain an as-built situation from a construction site (Golparvar-Fard et al., 2012; Masood et al., 2020). In addition, CV methods have been developed for inspection and condition monitoring of infrastructure (Bay et al., 20008). No significant research on the combination of CV and construction waste management was conducted before 2019 (Martinez et al., 2019). However, a few research papers after 2019 have focused on construction waste management using CV as discussed in the next paragraph.

Much of the waste-related literature explores the detection of concrete, bricks, plastics, foam, stone, timber, and other types of construction waste (Davis et al., 2021; Na et al., 2022; Seunguk et al., 2022; Song et al., 2022; Zhou et al., 2022). The main objective of previous research was recognizing waste in building construction works through the use of CV and deep learning models. Wang et al. (2019) developed a construction waste recycling robot with the help of CV. The robot used R-CNN (Recurrent Convolutional Neural Network)-based object detection to find scattered nails and screws in real time so that those objects could be collected and recycled. Also, Wang et al. (2020) used SLAM (Simultaneous Localization & Mapping) and instance segmentation to recognize residual pipes and cables. The methodology involved guiding a robot in on-site waste sorting and recycling. Most of the aforementioned works focused on small projects, such as building site construction waste, which includes common building materials. Research on the use of CV in large infrastructure sites and piles is limited.

The present study focused on inventory-related waste accumulated during piling work at an industrial construction site. Furthermore, it explored how CV can be applied for more efficient waste identification and better visualization of the waste problem of providing visual identification of the waste as a VM tool.

DATA COLLECTION AND SETUP

The data was collected from a 70-hectare industrial construction site in Finland. Pile waste inventories (PWI) were observed within a 22,000-square meter area, which included one building. During the observation period, the construction site was mainly in the piling work phase, although work phases in which foundations, concrete frames, and underground pipelines and power cables were built parallel with the piling works.

The data was collected over a 27-week period from March 2021 to September 2021, and the images included spring, summer, autumn, and snowy periods. Each week, ground-level photographs were taken by the site supervisor, and drone images were taken by the measuring team. The approximate distance between the ground-level photographer and the piles varied from a few meters to hundreds of meters. Regarding drone photography, the vertical distance between the camera and the ground varied from 55 meters to about 145 meters. Of the 563 drone images obtained, 21 were included in this study. In addition, 212 ground-level images and 29 combined orthographic images (i.e., a combination of several drone images of the entire site area) were included in the analysis.

The first step in any CV- and artificial intelligence (AI)-related problem is the creation of an annotated dataset that has all classes. For this purpose, the researchers saved the images to a cloud service and then annotated them using a freeware labeling software program called makesense.io. Four categories were used as classes: 0) concrete pile cut-off inventory, 1) steel pile cut-off inventory, 2) concrete pile inventory, and 3) steel pile inventory. The first two consisted of cutting waste or broken piles left after the piling work was completed, while the other two comprised intact piles that had not yet been driven and were in temporary locations on the construction site or next to the pile-driving rigs. Although there was a considerable number of images covering the site area, at the end of the labelling task, only 110 images were used. These were the images that contained one or more of the four categories of classes.

The CV setup was based on transfer learning, which involves initially training a neural network on a small dataset instead of one with thousands of images (Pan et al., 2009). The weights from the pre-trained neural network were improved by using features from ground-level and drone images containing PWIs. YOLO v7 which is a deep learning algorithm was chosen for object detection because of its accuracy and speed (Wang et al., 2022). The YOLO algorithm is originally trained on a set of common objects including a car, a hat, an umbrella, dogs, a door. To detect objects from the construction site, the algorithm parameters were changed based on the features of images with piles. 110 images with a total of 535 labels, including all four classes, were used to change the parameters of the trained YOLO v7 model with the resolution of the images as 4608 × 3456. Processing such a large image for a neural network requires a very high memory and processing power. To avoid CPU and GPU limitations, the algorithm was set up using Google Collaboratory services.

ANALYSIS

During the manual labeling process, 535 PWIs were identified in the images. Specifically, 233 were identified from images taken at ground level, and 302 were identified from drone images. In the ground-level images, 64.4% of the PWIs were concrete PWIs, and 35.6% were steel PWIs. Of the designed and driven piles, 84.6% were concrete piles, and 15.4% were steel piles; the number of steel PWIs was proportionally higher than expected based on the number of designed piles. In the drone images, 63.6% of the PWIs were concrete piles, and 36.4% were steel piles. Furthermore, 54.5% and 37.4% of the PWIs detected in the ground-level and drone images, respectively, were cut-off PWIs. Moreover, temporary pile inventories for piling work purposes (located near piling rigs) comprised 45.5% of the observations in the ground-level images and 62.6% in the drone images. Table 1 shows the observed PWIs.

Table 1: Observed pile waste inventories.

Waste class	Observations from ground-level images	Observations from drone images
0. Concrete pile cut-off inventory	95 (40.8%)	102 (33.8%)
1. Steel pile cut-off inventory	32 (13.7%)	11 (3.6%)
2. Concrete pile inventory	55 (23.6%)	90 (29.8%)
3. Steel pile inventory	51 (21.9%)	99 (32.8%)
Total	233 (100%)	302 (100%)

Figure 1 illustrates examples of classified PWI observations. The top two images are typical pile cut-off inventories after pile driving, while the other examples are typical work-in-progress inventories near pile rigs. Outside of the research location, there was a larger buffer storage area for piles; that area, the size of the buffer inventory, and buffer fluctuations were not explored at this stage of the study.

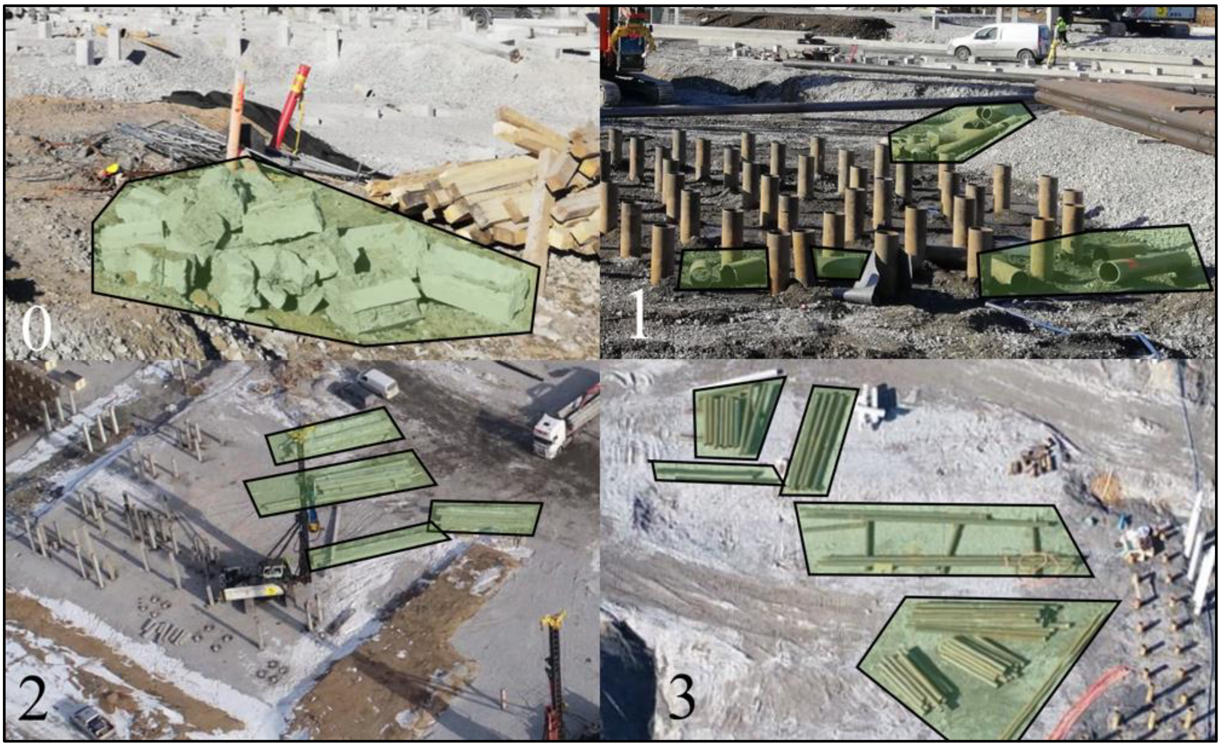

Figure 1: Four Examples of Observed Pile Waste Inventories

The green boundaries shown in Figure 1 correspond to the labeling used to teach the algorithm to identify PWIs. The numbering corresponds to the waste classes in Table 1. Figure 2 shows the observations obtained from the ground-level images of waste inventories over time.

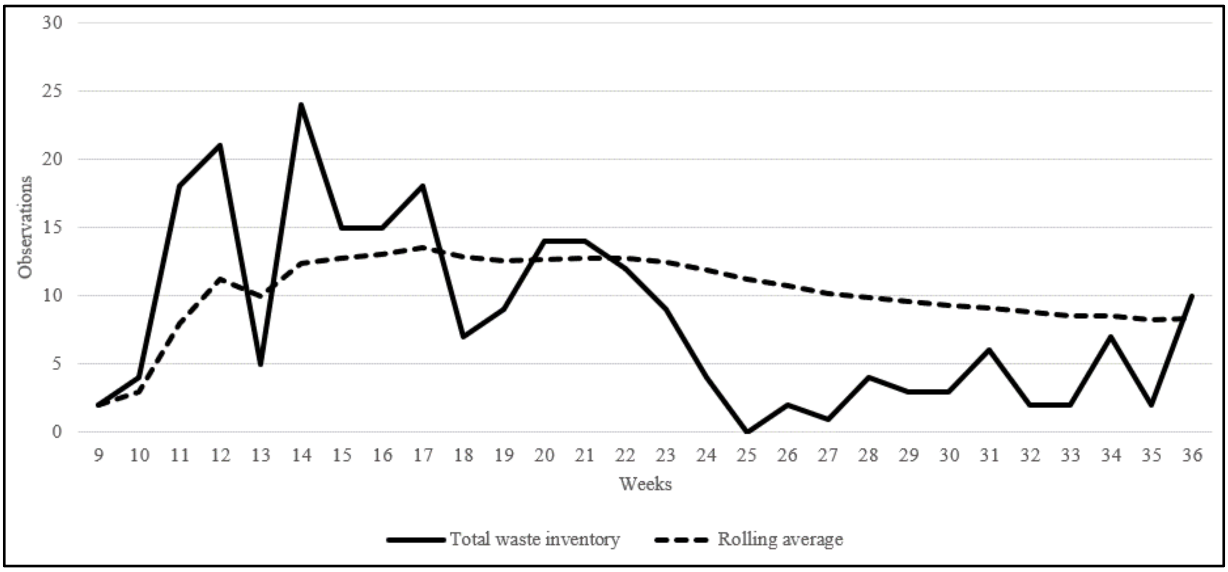

Figure 2: Observed Waste Inventories Over Time: Ground-Level Images

The number of PWI observations in the ground-level images increased after the piling work started and reached an average of 13.9 observations per week between Weeks 11 and 23. Once the summer holiday period started, the number of PWI observations dropped to average of 3 observations per week between Weeks 24 and 35, increasing only at the end of the observation period in Week 36. The average number of observations over the entire period was 8.3 per week. Figure 3 shows the corresponding PWI observations from the drone images.

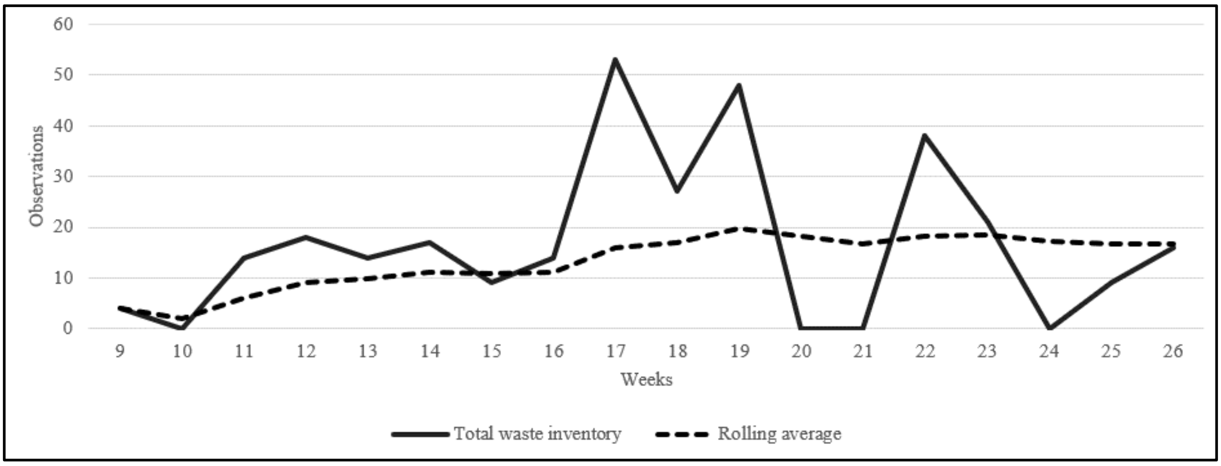

Figure 3: Observed Waste Inventories Over Time: Drone Images

The PWI observations from the drone images differed from those from ground-level images. Between Weeks 11 and 23, the average number of observations was 21 per week. In other words, about twice as much pile waste was observed in the drone images as in the ground-level images. During the summer holiday period, only 2 weeks were observed; there were 9 observations in Week 25 and 16 in Week 26. In Weeks 17–19, there was a clear peak in PWI observations, with an average of 42.6 observations per week during that period. The average number of observations over the entire period was 16.8 per week. Therefore, about twice as many PWI observations were made from the drone images as from the ground-level images.

Figure 4 shows the number of piles driven in pieces and the number of PWI observations. The amount of PWI observations was largely in line with the progress of the piling work.

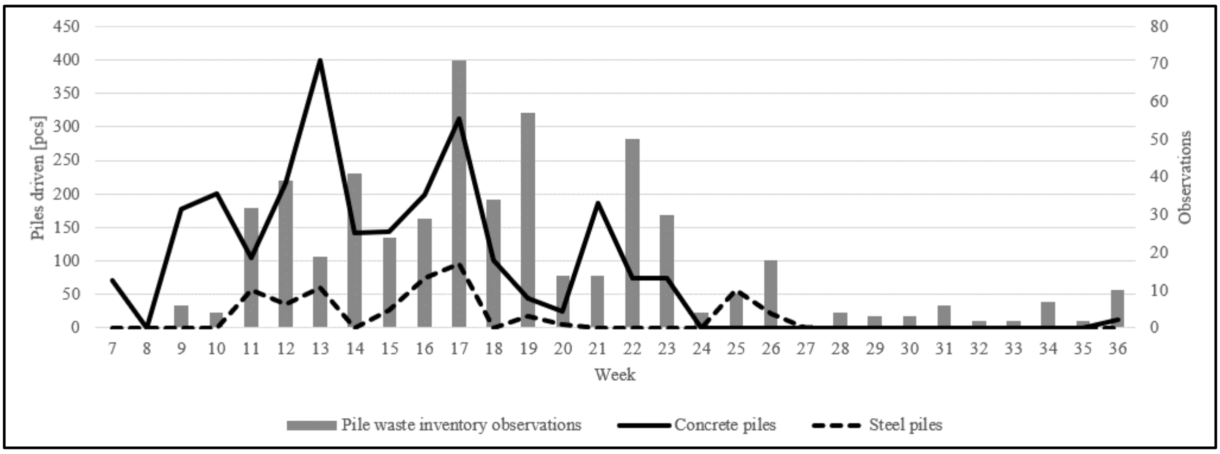

Figure 4: Piling Progress and Pile Waste Inventory Observations

To summarize the waste observation results, the amount of cut-off waste was significant—37,5% to 54,5%, depending on the observation method (a photo taken by a human from the ground level vs. a photo taken by a drone). Twice as many waste piles were detected in the aerial images taken by drones as in the ground-level images taken by supervisors. Regarding the observation area (22,000 m2), the average number of PWI observations was 0.001 per square meter, with a maximum of 0.003 observations per square meter (drone images). Since cut-off waste is smaller in size as compared to full pile, the high altitude of the drone photography may have contributed to the less frequent cut-off waste observations compared to the ground-level photography. Meanwhile, since twice as many PWI observations were made from the drone images, it can be assumed that the high-resolution drone images also included all of the PWI observations made from the ground level. These likely duplicates were not investigated in or removed from the present study because the primary purpose of the images and the waste observations was to train the algorithm; obtaining a large number of images and observations, despite possible duplications, supported the learning of the algorithm.

OBSERVED CHALLENGES IN THE SETUP AND COMPUTER VISION

In the first experiment, full-resolution images were taken to train the neural network. The first experiment was conducted for 50 epochs. This means that the algorithm read the images at least 50 times to derive features from them When the images were read in a batch size of eight, Google Colab crashed; however, the image reading process worked for a batch size of four. A recall and mean average precision (mAP) of less than 10% was achieved in the first trial. For the algorithm to detect any relevant information from a new image, a recall and mAP of at least 50% is desired.

For the second experiment, the image size was reduced to 920 × 720, the batch size was 8, and the number of epochs was increased to 100. Although recall in the 93rd epoch increased to 43.5%, the model was unable to detect the PWI while testing on a new image. This result can be attributed to various considerations. One possible reason could be that most images had multiple labels, a large image size, and objects that seemed smaller as compared to other objects in the high resolution imagery; therefore, the algorithm was unable to properly learn the features of these images. Another reason could be that the dataset was too small; for object detection, neural networks are generally trained on about 1,000 images. When we reduced the size of the images, some information was lost from the pixels. Another important challenge was that the site was very dynamic, and the images had variable backgrounds because they were taken during various seasons. For CV, it is desirable to use a training image with some kind of similarity within the features and background of the images, so that the algorithm can better detect the features of objects of interest.

DISCUSSION AND CONCLUSIONS

Waste identification and elimination are the main principles of lean construction (Koskela, 1992). As such, it is essential to visualize waste and identify it properly. VM can provide real-time visualization and support improvements during the construction phase. Given the increasing prevalence of digitalization and efforts to employ it at construction sites (Martinez et al., 2019), technologies can also be incorporated into DVM (Digital Visual Management) devices, providing updated information and real-time understating of the construction site reality leading to decentralized decision-making (Koskela et al., 2018; Reinbold et al., 2020). The present study builds on the contributions of Tezel and Aziz (2017), Li and Liu (2019), and others who have combined VM and drone technology in an infrastructure construction context.

The study data (i.e., the area images) was collected manually by site supervisor during site visits, and differences in the images inhibited the use of CV for data analysis. Manual data collection poses obstacles because it is time consuming and costly; nonetheless, it remains the main form of data collection in construction sites (Kerem et al., 2013). The shift to digitalized means of data collection in construction sites will enable not only the collection of data in a shorter timeframe and with lower costs but also the provision of data that is better suited to the use of CV and other AI technologies in the future.

Since cut-off waste is smaller in size, the high altitude of the drone photography may have contributed to the less frequent cut-off waste observations compared to the ground-level photography. The large number of PWIs observed in the drone images compared to the ground-level images may indicate that supervisors choose a tidier viewpoint because such images are typically used in reports sent to clients. In this respect, drone photography may be a less unbiased way of collecting PWI information from an infrastructure site (Flyvbjerg, 2021). Meanwhile, since twice as many PWI observations were made from the drone images, it can be assumed that the high-resolution drone images also included all the waste observations made from the ground level. These likely duplicates were not investigated in or removed from the present study because the primary purpose of the images and waste observations was to train the algorithm; obtaining a large number of images and observations, despite possible duplications, supported the learning of the algorithm.

The trained model was unable to detect piles in images; however, there was positive foresight as recall went from 10% to 43.5% in the second trial. Reliable pile detection results could be achieved in the future by increasing the training data and employing mid-range image resolution. In addition, dynamic site conditions and background variability may be achieved by obtaining more images per season from different perspectives. Our future work will include training the algorithm with a larger annotated dataset and exploring different algorithms that can handle remarkably high-resolution drone images.

The present study contributes to the development of approaches for determining how CV could be used for achieving lean construction. CV has become a tool for understanding the actual situation in many applications, such as self-driving cars, and construction progress monitoring. The technology can be utilized to improve lean construction practices. For example, CV can be used to streamline the process of observing any construction material inventory or waste which is a subjective process in the construction industry in the current scenario. CV can also be used to generate new types of data for the visual management of construction sites. Furthermore, by comparing both types of datasets (i.e., ground- and drone-based images), we were able to identify challenges in each. For drone images, the coverage is wide; however, the objects appear smaller. For ground-level images, objects are more identifiable in images with a tidy appearance. This work can also be used to determine the most useful dataset for monitoring construction inventories and waste on large infrastructure sites.

One of the lean principles is based on 'maximising value while minimising waste' (Ohno, 1988, p.175). Minimizing waste is essential to enable professionals to deliver increasingly higher value. It is usually difficult to estimate the amount of waste without conducting an inventory. The present study can be used as an example of how waste and excess or misplaced inventory can be identified using CV. This study also demonstrates that it is possible to develop a CV-based tool for inventory management on construction sites alongside existing manual inventory and waste identification methods.

SUSTAINABILITY AS TARGET VALUE – A PARAMETRIC APPROACH

Sebastiano Lombardo[1], Arve Hindenes[2], Sigmund Aslesen[3], and Sigmund Reff[4]

ABSTRACT

Our time is characterized by climate changes that impose sustainability in every industrial activity, an additional objective to our design and construction processes. The classic Lean Construction approach needs to be further developed to take sufficient care of the sustainability issue. The design of modern buildings is a work process that can be set up and run with tools that secure a more sustainable final product. This study proposes to extend the classic range of objectives pursued by the Lean construction approach, as to include sustainability in the design process, in a systematic and structured way. The case of a building project is analyzed. In the early design stages, advanced structural design tools are used to explore various alternative designs of the bearing structure. The structural design tools are combined with tools used to calculate embodied carbon in the construction. The levels of embodied carbon following each of the many possible, alternative, structural solutions are estimated. These insights are provided to the owner in a very early stage of the design process. Through these design practices owners and investors can add sustainability targets to the classical project targets (cost, quality, time), and include sustainability as a part of the fulfillment of the client's functional needs.

KEYWORDS

Lean construction, Target Value Delivery (TVD), sustainability.

INTRODUCTION

Lean production thinking applied to construction management has evolved since 1940. Today it represents an approach to facilitate and secure value creation for the client as well as the actors involved in a construction project (Abdelhamid et al. 2008). Although the concept of value may be defined in various ways (Lombardo et al. 2017), in construction projects value is often understood as the fulfillment of the client's functional needs, and of the financial objectives of all involved actors (Drevland and Klakegg 2017). This understanding of value entails the set-up of project objectives like low production costs, optimized production flow, waste reduction, alignment of design and production, and pull production planning (Kalsaas, 2020). These objectives remain within the technical realms of engineering and construction and are widely acknowledged as fundamental to achieving high levels of efficiency and quality in the AEC industry. The relatively recent introduction of practices like integrated concurrent engineering, virtual design and construction (Fischer et al. 2017), and last planner system (Ballard et al. 2000), capitalizes on this understating of value and this kind of objectives.

In our times, climate changes impose the objective of sustainability on all of us, in every industrial activity, as a new objective to our design and construction processes. Although sustainability is an easy objective to embrace, work practices and tools are yet to be fully developed to secure a sustainable production process and a sustainable final product. This paper questions how sustainability can be an explicit goal of a construction project. And how can the design process support sustainability goals? This research witnesses the search for methods, tools, and practices aimed at introducing elements of sustainability in the construction design process.

LITERATURE REVIEW AND THEORETICAL APPROACH

LEAN APPROACH AND ITS LIMITATIONS

Waste reduction, workflow optimization, design and construction alignment, pull production planning are some of the concepts bound to secure a Lean construction process. A well-implemented Lean construction approach will help designers, and contractors, to focus on cost, quality, and performance objectives. The arguments in favor of including sustainability goals in the definition of project performance are well established in the literature both in terms of principles to be used to guide the design and construction (Bourdeau et al. 1998; Huovila & Koskela, 1998), and on work processes to be adopted at various design stages (Yates and Castro-Lacouture, 2018). Yet good intentions are often curbed by the boundary conditions provided by the project schedule and budget. Consider a large building that shall be designed and built. The number of possible alternative (architectural, structural, energy) solutions that can be studied is in fact quite limited. The designers may not have enough time and resources to analyze enough alternatives to find optimal solutions. Other restrictions may come directly from the very set of project goals adopted by the owner of the project. If sustainability, in any of its facets, is not included among the project goals, it is improbable that the final product be checked in that respect.

Therefore, the normal design approach based on optimizing cost, quality, and time does not necessarily end up in an optimal solution when it comes to sustainability. Two main questions arise:

How can sustainability be an explicit and ineludible goal of a construction project? And how can the design process of modern buildings be set up to support sustainability goals, such as “the reduction of greenhouse gas emissions”?

These are the research questions of this study, through which we propose an approach to extend the classic range of objectives pursued by the Lean construction approach, as to include sustainability, in a systematic and structured way. A clear definition of sustainability is needed.

SUSTAINABILITY DEFINED

The concept of sustainability is a complex one, and its definition may vary depending on the context in which it is used and may include social, ecological, cultural, and environmental facets. The 17 sustainable development goals of the United Nations (UN) provide a good framework to find a definition suitable to the purposes of this study. Under goal 13 – Climate Change - in particular, several nations explicit their commitment to reducing their greenhouse gas emissions (the EU committed to a 30% reduction, Norway to 55%) (NRK, 2022). The AEC industry may produce an impressive effort to contribute to this reduction. This view can be adapted to focus on the reduction of greenhouse emissions as the AEC industry’s main contribution to the cause of a more sustainable global development.

A THEORETICAL APPROACH TO SUSTAINABLE DESIGN

For a broader review of decision-making methods and how these may affect sustainability goal-setting in construction projects see Penadés-Plà et al. (2016). The approach this study proposes is based on putting sustainability as an explicit objective for the design to be developed, and on giving it the same importance as classic goals like "cost", "time" and quality". This approach largely resonates with the concept of Target Value Design (TVD) which is used to set up project objectives. TVD requires that a fixed goal is set for any given value to be achieved through the design process. Normally a target *cost* is considered relevant and important, along with a target *quality level* and a target for the final *delivery deadline*. The design work is then organized and managed to achieve those targets, following a specific set of rules to check misalignments thought the work process (Zimina et al., 2012). We build this study on previous research connecting sustainability and lean construction (Johnsen and Drevland, 2016) and propose here to set up a sustainability target in addition.

Provided that sustainability is a broad concept, and given the definition this study has chosen, the target to be used to guarantee that sustainability is considered among the project goals can be related to an effort to minimize the greenhouse gas emissions from the building construction project. This target must be quantified, approved by the owners, and implemented in each project phase, from early planning, through the design process and to construction and operations.

The method used to set up this target, and the work process applied in the project is presented in the following sections, limitedly to the early planning and design phases.

METHODOLOGY

This research is executed as an explorative in-depth study of one case. A general contractor company that normally adopts lean construction approaches and has clear ambitions within sustainability; the opportunity to witness a phase where project goals are about to be set; good access to informants and to the corporate database; made this case well suited to our research purposes. Data were collected over six months through non-participant field observations with the design team during the design work; semi-structured in-depth interviews of four key contributors; recording of project plans and project deliverables. To focus our study, our data collection was limited to the design phase of the HQ construction project and focuses on sustainability in the design process rather than on the product.

THE CASE STUDY

Veidekke is a large general contractor in Norway. The company is planning to build its Head Quarters in the Capital city and wants to use this project as an opportunity to contribute to the national effort to cut greenhouse gas emissions. The office building is about 20000 m^2, over five floors, including the cellar. Although the general geometry is defined by the architect, the solutions for the bearing structure, including foundations, are not defined from the start. This study focuses on the assessment of various solutions for the bearing structure, and how this part of the project has been designed to contribute to achieving the sustainability target.

The following alternatives can be considered for the bearing structure:

1. Traditional bearing system in hollow cores slabs (HC) and steel.
2. Traditional bearing system in bubble-deck slabs and steel.
3. Modular building with solid wood decks. Support in the form of glulam beams and columns (hybrid solution)
4. Cast-in-situ concrete solution with post-tensioned slabs.

For each alternative, a large number of variations can in theory be considered, depending on the geometry variables of the construction elements (e.g., walls, beams, slabs), the positions of the elevator shafts, and the solution chosen for the façade, just to mention the most obvious ones. There is therefore a large number of possible solutions to be assessed and, besides the tools that make such an assessment possible, it is necessary to know which criteria the final decision shall be based on.

FINDINGS

TARGET VALUES DESIGN AND CHOOSING BY ADVANTAGES

Target Value Design (TVD) is the approach Veidekke chooses to establish the criteria to be used in the choice of the preferred solution for the bearing structure. In this case, a target *cost* is set, together with a target for the schedule and project completion date before the design starts. A set of target values are set up to assure the qualities of the final product (e.g. room program, functions, materials, etc.). High *flexibility* in the use of the surfaces (floors, walls) during the lifespan of the building is another important target, along with maximal usage of Veidekke's *own resources* (workforce, production technologies). Finally, and most interestingly, a target value is also set up for the maximum allowable volume of greenhouse gas emissions. The building shall be realized with *50% lower emissions* than a comparable building being built in the same period, in the same region, with the most common solutions for design and construction methods. In addition, the new HQ building shall qualify both as Breeam Excellent and as Green Building according to the EU taxonomy (Rademaekers, 2014). Putting these targets influences all the design decisions and forces the designers to adjust their thinking and their choices to achieve these targets.

In the following section the set-up of the design process is described, to explain the approach, the work process, and the tools there were adopted.

THE DESIGN WORK PROCESS

Having received from the owner and the contractor the set of target values, which included a reduction by 50% of the emission of CO2 compared to similar projects in the region, the design team went on preparing the structural analysis that should deliver solutions within the given targets. The design process can be summarized in the following main steps:

Step 1. Architect provides the main geometry of the building (Revit model, LOD200).

Step 2. The main geometry of the building was given by the architects, the second step was to decide on the technology to be used to realize the bearing structure. The first two structural solutions to be analyzed, were the two main variants with steel frames and prefabricated slabs: (alt. 1 post-tension slab and alt.2 use of bubble deck).

Step 3. Given the main geometry and one alternative of the bearing structure, the designers and the contractor identified the geometrical elements, or variables, of the bearing structure that should/could be modified (position and dimensions) in order to explore many variants of the given solution.

The following variables were considered:

- Location and dimensions of piles
- Position and dimensions on columns
- Location and dimensions on load-bearing walls
- Location and typology of slabs
- Floor heights
- Location of bathroom cabinets
- Location and size of lift, stair and technical shafts
- Placement of tension cables, if any, in the plane and in the cross section

Step 4. The list of variables to be considered flexible was used to set up a parametric model (in Grasshopper software) of the bearing structure. This model allows the simultaneous variation of a given number of the above-mentioned variables, and the creation of as many sub-alternatives of the given structure.

Step 5. Besides the geometrical model (e.g., Revit, LOD200) components (materials, loads) to be used for the structural calculations are *also* included in the parametric model. A full-fledged Finite Element Model (FEM) in SAP 2000 (a structural calculation tool) is contained in Grasshopper and interconnected with the Revit model. In this way, any change in the geometry entails new figures in the finite element analysis. For any given geometry a complete FEM analysis is delivered, and a preliminary structural analysis verification is automatically performed.

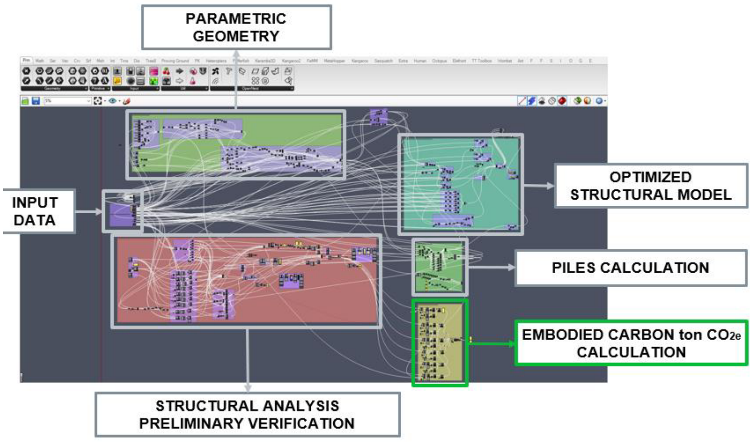

Figure 1: Parametric Model (Grasshopper) including Geometry, FEM and CO2 calculations

Step 6. Software, for the estimation of the emission of CO2 equivalents (in this case OneClick LCA) is plugged into the parametric model. Given a geometric and a structural solution (including the chosen materials) for any given alternative bearing structure an estimate of the greenhouse gas emission is delivered, provided that the Environmental Product Declaration of the elements used in the structure is available.
Step 7. An optimization plug-in for Grasshopper (in this case Opossum), including two of the best-performing, single-objective optimization algorithms is launched and, after some necessary iterations, a solution is optimized to minimize the volume of CO2 emissions.

The process from Step 2 to Step 7 is iterative, as shown in Figure 2.

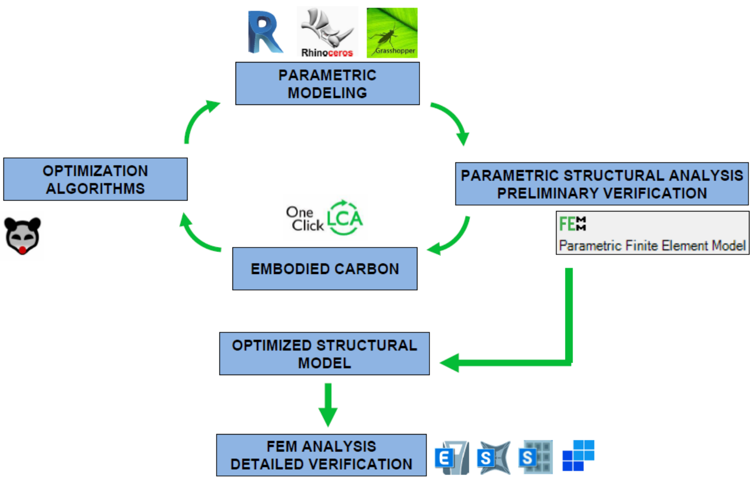

Figure 2: Optimization cycles - parametric approach

Step 8. A final detailed FEM analysis is performed to verify the given structure, and the results are provided along with the relative CO2 emission estimates.
Step 9. Based on the four assessment criteria (construction cost, room flexibility, use of own resources and CO2 emissions cut) a choosing-by-advantage approach (Suhr, 1999) is taken to perform the final assessment (see table 1). Hence, sustainability is included as a determinant factor in the final choice of the most advantageous alternative solution for the bearing structure.

Table 1: Choosing By Advantages table

	Post tensioned.	**pts**	**Bubble decks**	**pts**	**Hollow cores**	**pts**	**Wooden structure**	**pts**
Cost	2nd most expensive	4	2nd most expensive	4	Least expensive	6	Most expensive	1
Additional cost	*5%*		*5%*		***0%***		*15%*	
Flexibility	most flexible	6	2nd most flexible	4	2nd most flexible	4	Least flexible	1
Loss in flexibility	***0%***		*-10%*		*-10%*		*-40%*	
Own Resources	Max usage of Own Resources	6	High rate of Own Resources	4	No use of Own Resources	1	Low rate of Own Resources	2
Own res. used	***100%***		*90%*		*0%*		*50%*	
CO2 emissions	31%	4	29%	2	33%	5	34%	6
Variation CO2e	*-3%*		*-5%*		*-1%*		***0%***	
SUM pts		*20*		*14*		*16*		*10*
Advantages in	*2 criteria*		*none*		*1 criterium*		*1 criterium*	

In the table: Points are given from 1 to 6 (best); Relative advantage is given in relation to the best alternative for any given criterium (e.g., CO2e from Wooden structure is best, and post-tensioned structure is 3% higher emissions than that). The criterium "CO2 emissions" provides a percentage reduction in embodied carbon from the reference building.

From the choosing-by-advantages approach, the two most advantageous solutions appear to be the one based on hollow cores and steel, and the one based on bubble decks and steel.

The parametric analysis of a large number of these two bearing structure alternatives resulted in several estimates of the tons of CO2 equivalent produced by each solution. The values of the most optimal solutions for each alternative are reported in the following.

The first solution: Bearing Structure with post-tensioned slabs offered a CO2 equiv. the emission level of CO2e = 1525 ton (Embodied Carbon for lifecycle from cradle to site, stages A1 A3 and A4) see Fig. 3

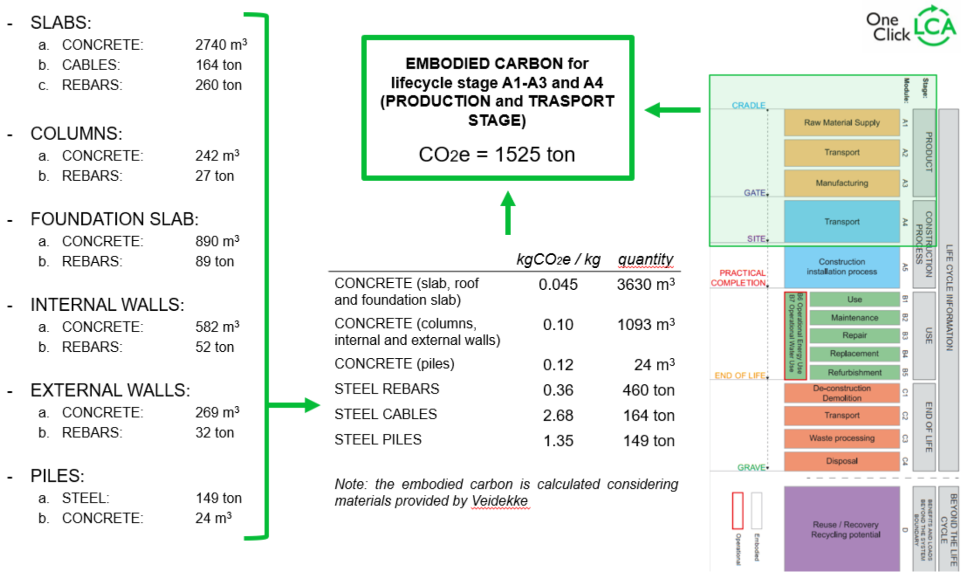

Figure 3: Alternative 1 - Post-Tensioned Slab – Embodied Carbon

The second solution: Bearing Structure with bubble deck slabs offered a CO2 equiv. the emission level of CO2e = 1056 ton (Embodied Carbon for lifecycle from cradle to site, stages A1 A3 and A4) see Fig. 4

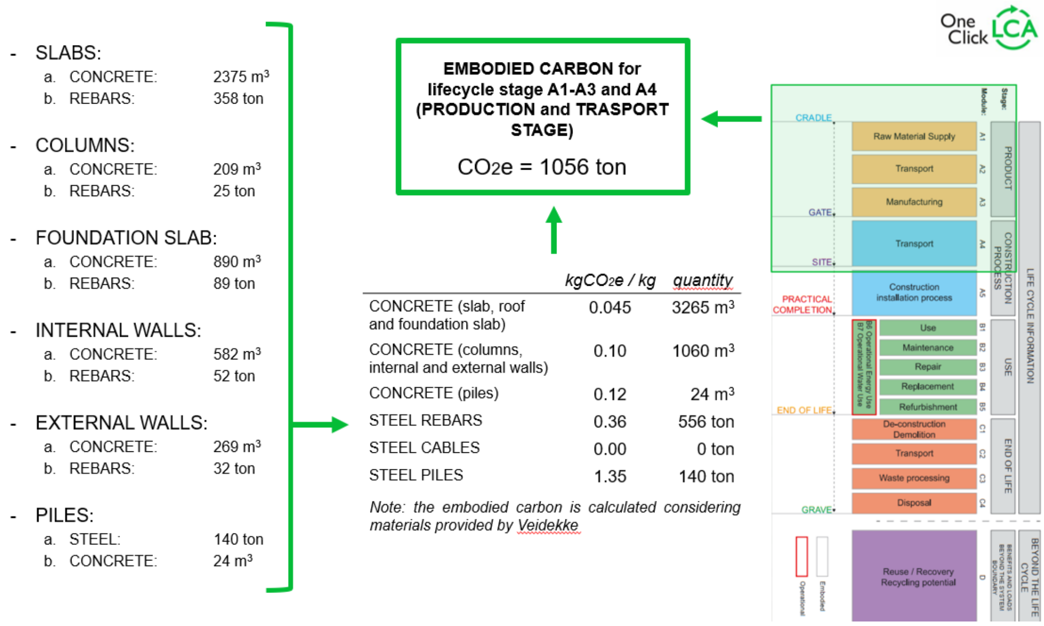

Figure 4: Alternative 2 – Bubble Decks – Embodied Carbon

The cases studied show that one solution, with bubble decks, has a significantly lower greenhouse emission level.

DISCUSSION

The findings show that the approach used in this project provides a powerful tool to elicit insights from the structural engineers in a phase that traditionally is the exclusive realm of project developers and architects.

During the planning phase sustainability target values are set up along with the classic project management cost, time, and quality targets. Already in the very early project phases, a parametric design approach can be used to determine which parts of the bearing structure can be considered as flexible and which parts shall remain fixed, as determined by the architects. The parametric model implements the variable parameters and runs the FEM analyses of the alternatives to yield optimized solutions that match the target values given at the outset. The parametric model is then used to run analyses of a large number of alternative structural solutions. Already at this early stage of the project development, parametric modeling is used to get insights into CO2 emissions levels. For each solution, quantity estimates of the greenhouse gas emission are provided for each alternative solution of the bearing structure. There is no theoretical limitation to the number of variants that can be studied.

Although the technology of parametric modeling enables these analyses at a very early stage in the design process, the core of the methodology rests within the set-up of the Target Values that steer the optimization process. Sustainability is therefore a choice made *a priori*, i.e. at the outset of the decision-making process. It is the owner of the sustainability goal, who takes the responsibility to set the sustainability targets. The investors may own the sustainability goal, as well as the general contractors. The latter will have to implement the targets in the construction process. In the case studied the structural engineer included embodied carbon calculations in their structural analyses. The designers, such as architects, engineers, and sustainability consultants need to contribute to the sustainability targets, by applying the right competencies to the design process. Although innovative and in line with the generic call to help in fighting climate change, the choice of giving sustainability such an important place in the design process does not appear as a simply idealistic one. The project uses choosing by advantages methodology to assure that while sustainability is taken systematically into account in a rigorous decision-making process, the other assessment criteria are given equal attention. The final choice includes sustainability considerations and reflects a larger spectre of assessment criteria.

CONCLUSIONS

The Veidekke HQ pro

ject shows that Target Value Design opens the door to including sustainability in the design process from the first phases of the project life cycle. This is in line with the principle of Lean construction, and yet this approach requires innovative technologies and rigorous decision-making methodology when sustainability is included among the goals of the project.

Advanced parametric modeling of the bearing structure makes it possible to analyze a large number of alternative structural solutions, in early design stages, and at a pace that makes it valuable to invest in such insight, for both investors and architects.

Getting this kind of insight requires therefore both the technical capability of running parametric structural models integrated with greenhouse emissions software, and the political willingness to break with traditional planning practices and let structural engineers "intrude" in the early project phases. The added value of this modeling approach is given by the high number of alternative solutions that can be studied at a very early stage of the design process. Provided that the project sets up a target value for the CO2 emissions, the design optimization process can be modeled accordingly.

The adoption of choosing by advantages decision-making system makes it possible to balance sustainability goals with other more classic objectives.

A systematic application of this method, structured and implemented as described, could change the design practices in the AEC industry and merge the fundamental principles of Lean construction with the ineludible needs for the sustainable development of our cities and infrastructure.

The limitations of this study are mainly related to the structural analyses of only two kinds of structures. Other limitations are those implicit in the kind of software that was used to calculate the structures and the CO2 emissions (e.g. precision of the optimization algorithms; the precision of the embodied carbon data of the materials and components adopted in the construction).

The results of this study could therefore spur further research efforts. The proposed approach could be repeated to study different kinds of bearing structures (e.g. including materials such as CLT or aluminum). The software used to calculate CO2 emissions could be further developed so as to include estimates of the impact on the project phases that were not included in this study.

DEFINING CO_2 EMISSIONS OF A CONSTRUCTION PROJECT ON THE BASIS OF PROGRAMMATIC INFORMATION

Ari Pennanen[1], Saku Metsärinne[2], and Pyry Haahtela[3]

ABSTRACT

The environmental impact that a product has over its subsequent life is largely determined by decisions taken during the delivery process, i.e. defining needs for the product, choice of geometry, and choice of materials (Ashby W.R). Ashby's description is universal, covering all kinds of products. But if we make an interpretation to construction, environmental impact is due to

- programming process (needs for the product),
- massing during preliminary design (choice of geometry), and
- choice of materials during detailed design.

At the moment, CO_2 emissions are mostly defined from the use of materials during detailed design and construction, and from life cycle consumptions based on detailed design. In the detailed design stage, quantities of materials can be measured. And, as the mass of the building, internal conditions (e.g. internal climate) and external conditions (e.g. climate) are known, life cycle emissions can be modeled (or actually, calculated).

The problem is that this kind of approach does not involve a project definition or early massing during preliminary design to challenge designers to consider CO_2 emissions as they steer early design forward.

However, the most important decisions in relation to environmental impact are done during programming and massing in the preliminary design stage. If we set a question whether we need an auditorium or not, the decision made affects vastly more than latter decisions of the materials of the supposed auditorium. The need for an auditorium is not a design problem, rather it is a functional (i.e. programming) problem. And onwards, massing during preliminary design dictates the quantities of the materials measured later (more or less efficient massing, corridors, compact or scattered, more or fewer floors, etc). Longer distances between customer functions affect the quantities of staircases, external wall, air exchange ducts, cabling and site processes during construction in site (Pennanen, Ballard, Haahtela).

The authors argue herein that life cycle analysis (LCA) calculations should be used to help customers set goals, i.e., LCA should be used to steer design. Similarly, LCA should steer contractors and designers in detailed design. If CO_2 emissions are defined only from material quantities of detailed design, analysis is then rather declarative than helping to steer the design, as the calculation happens after the last responsible moment for programming and material selection.

This paper presents a theory and applications to involve the client and early design to proactive steering of CO_2 emissions during programming and early design; allowing all parties

INTRODUCTION

The question: "Do we need an auditorium?" cannot be solved by design. Showing a sketch with and without an auditorium does not provide more information to the actual question. Indeed, the answer to the question of whether or not an auditorium is needed is based on a customer's or users' functional needs. By contrast, the decision that a client or users need an auditorium, or they do not, has a large impact on CO_2 emissions during construction and over the auditorium's life cycle. In fact, the decision of WHAT to build is much more significant than a decision of HOW to build it (i.e., what is the frame structure of the auditorium, what kind of finishing, or what kind of air conditioning). Given the impact of the programming decision, i.e., the decision of WHAT to build, it is critical that designers, contractors, and clients understand steering.

And further, massing during preliminary design (i.e. three dimensional geometry defining how functions are located in the building) dictates internal distances, perimeters, projections etc. floor by floor, and thus dictates most of the quantities measured in detailed design (Pennanen, Ballard, Haahtela 2011), (Pennanen 2004).

Understanding this phenomenon, steering in programming and all design phases should be understood.

THEORIES OF STEERING

Theories of steering generally (not only for construction) are introduced under themes of managing complex systems. When construction is considered, complexity arises from different points of views of strategic leaders, operative managers, users, investors, and neighbors among others. And, if we ask for a sketch design from a hundred architects, we will likely get a hundred different solutions.

Theories of managing in conditions of complexity are associated, for instance, with "holism", "feedback", "cybernetics", "cellular automata" and "adaptive systems". Most of the modes of complexity management, especially when social systems are considered, are based on feedback and iteration loops, and assume closed loop production systems. Feedback and iteration loops consists', for example, of owners' wishes, measurement of consequences of said wish (money, time…), withdrawal from original wish, new proposals etc. In contrast to open loop systems, the output produced in closed loop systems is used to adjust or steer the system to its targets. That is done by measuring and comparing actual output to intended. (Simon 1996).

Construction project management requires purpose that are set in the very early phase before design starts. Goals can normally be derived from a customer's strategy. Goals can be addressed to

- functionality
- CO_2,e emissions
- costs
- time
- toxic emissions
- etc.

As the goals are multiple, the models needed to support decision-making should model, rather than one specific item, the entirety of the project itself. For steering, a digital twin of a building that spans over its lifecycle is needed. (Haahtela 1980).

CLOSED LOOP ITERATION

As construction is considered, iteration cannot, of course, be based on constructing buildings, demolishing them, and making better ones.

Steering and closed loop control requires modelling. BIM modelling is not appropriate for modelling customer needs, as those customer needs are its input information.

The environmental impact that a product has over its subsequent life is largely determined by decisions taken during the construction process, i.e. defining needs for the product, choice of geometry and choice of materials (Ashby 2013). Calculating costs in both emissions and currency is very similar. You multiply quantities of resources used by the unit cost, in currency or emissions, of using a single resource. Steering projects to goals for reduced carbon and other emissions should and can be added to the scope of project management.

BACKGROUND: STEERING FOR CONSTRUCTION APPLICATIONS

The Underlying theory of steering a construction project (Target Costing of a Construction Project) has been developed in Finland by professor Yrjänä Haahtela in 1980’s (Haahtela 1980). Steering is based on a target that is defined before a solution to fulfill the target (in any stage), and then verifying if the solution fulfills the target. If not, a new solution should be created. The target should not be defined by solutions to fulfill the target. E.g. target for proper design (spaces, timetable, building cost, maintenance cost) should not be defined by means of designing, but rather by means of programming.

Steering is possible if for a set of needs (a problem) there are multiple solutions to fulfill the needs. To a simple problem, such as $ax^2 + bx + c = 0$, steering is not needed, as there are two, one or no right answers (among real numbers). You must just learn how to find it. But if you ask a hundred architects for a solution to a single set of customer needs, you will get a hundred different solutions. And that will be repeated with engineers and even with planning the site operations. And before that with programming. The steering concept is aware that there is a big variety in design solutions for a single programming (as well as in programming solutions for a single customer functionality) (Haahtela 1980). It has been studied that there is a weak correlation between costs and architectural soft quality (Niukkanen 1980) among varying possibilities. It means that it is possible to set a steering range of costs of building to be narrower than the range of all possible architectural solutions without losing architectural soft value. And it can be done before design. By means of the concept, design can be steered in targets defined before the design has been started.

The steering concept was set in the early 1980’s and has been developed until now. Original application was based on spaces needed in programming (Haahtela 1980), and it was expanded to the actual customer functions in the early 2000’s (Pennanen 2004).

Steering a construction project in accordance with complexity management concepts is very simple in concept, though quite difficult in practice.

The steering process is based on:

- Defining the goal (functional, financial, CO2…)
- Rapid measurement of the proposed solution to provide the goal
- Analyses of whether the proposal meets the goal
- Rapid feedback to the actors creating the proposals
- Actions to minimize the difference between the goal and the proposal

- New measurement

Although the steering steps are simple, the steering problem arises from the difficulty to create useful information for management in a complex environment. Suh (2005) defines that a design system has a total amount of information that can be split into two groups, useful and superfluous information. Useful information relates solely to the satisfaction of functional requirement, whereas superfluous information does not affect the relation between the goal and design solution. To succeed, the main focus should be on useful information and superfluous information should be minimized (Suh 2005). If a doctor is asked when programming a hospital, whether he/she requires spatial support for surgery and whether he/she likes brick as a material in external wall, the former information is useful in programming and the latter is superfluous, because only the spatial support impacts the ability of the design to achieve the goal of providing a safe environment for patient care. As the customer and producer change throughout a construction project, so too does the language of usable information (owner or user for project management, owner or user for design, project management to design, project management to contractors, design to contractors). Thus, useful information must be studied through participants and project stages. The goal for the customer likely will not be the number of column footings and attributes of each footing, though these parameters will be useful information for the foundation subcontractor to meet their goal.

In a steering process, proper information is needed quickly and continually to provide management with goals, measurements and rapid feedback. In many cases, modelling is needed to create information (Haahtela 1980), (Pennanen 2004).

INFORMATION USED IN PROGRAMMING FOR STEERING CONSTRUCTION PROJECTS

Ideally, steering in project definition results in the following:

- All customers and stakeholders have expressed their business scope, needs and wishes.
- Business scope has been transferred to language that both the customer and the designer can understand, e.g., activities, spaces, performance.
- Customer knows the costs at completion and is willing and able to pay for the determined benefit and functionality.
- Customer knows the CO2,e emissions the project will create
- Customer is willing to launch the design process.

INFORMATION USED IN DESIGN

To understand how designing results in cost and CO_2 emissions, it is worthwhile analysing how designs that were initially very complex conceptual designs end in simple detailed manufacturing solutions. Design can be divided into two orthogonal perspectives (Pennanen et al. 2011):

- shape of the building and connections of the functions (concept design)
- building components (detailed design)

The design starts with solving the interdependencies (the connections) between the customer's activities and massing the building in its urban environment. There are numerous possible conceptual solutions for a customer's specification (and for the target cost), and the cost variability is vast. When we deal with concept design, the components, like cooling beams, suspended ceiling or details of external wall are normally not specified. Concept design can be understood as designing for the customer.

When the customer accepts the concept design, designers start to concentrate on determining the building components and materials that can be found in the market and sizing them (detailed design). It lasts until the construction is finished. Detailed design can be understood as designing for production and for the contractors.

Concept design determines the quantities of building components (in a single-floor building there is more roofing than in two-floor building, but fewer stairs). On the other hand, detailed design determines the unit costs of those components. The building cost and CO_2 emissions are a product of these perspectives: quantity times unit cost/CO_2 release.

INFORMATION USED IN LCA CALCULATION

The environmental impact that a product has over its subsequent life is largely determined by decisions taken during the delivery process, i.e. defining needs for the product, choice of geometry and choice of materials (Ashby 2013). Thus, Life Cycle Analysis calculation must cover helping the customer to set goals (project definition), steering designers (design) and steering contractors (construction).

If, during project definition, only valuable functions are determined to be built, the size of the building, and also its environmental impact, will be reasonable. Raising the utilization of the spaces by co-using them for many functions leads to smaller total floor area being constructed, which in turn leads to less emissions. Programming might be the most powerful tool to cut CO_2 emissions. In environmental thinking, less really is more.

During design and construction, the CO_2 emissions are due to production of building materials, transportation of the materials and site energy consumption. During the use of the building, emissions are due to energy use during occupation (heating, cooling, air exchange, energy of the user equipment, use of water…), replacing building materials (e.g. replacing heating unit after 15 years) and possible fuels to produce energy for consumption (oil, sun, water, biomaterials). How the building is demolished after use also affects CO_2 emissions. Recycling of the building materials lowers the lifecycle emissions that are caused by producing building materials (Ashby 2013).

LCA calculation requires steering, as target cost and CO_2 emissions values in Target Value Design. The problem is how to define a building level target and component level targets for steering and fast feedback. Otherwise, project teams will calculate what has happened, not what should happen.

In component level simulation the building level targets are assigned to the building components before start of design. Building components can be, for instance, external wall, cooling system, lighting system or nurse call system, material and work. Cost of the building product is easy to find for project management, but how to define the environmental impact of the building materials? There are statistics for most common materials. But more important, an Environmental Product Declaration (EPD) is a standardized way of quantifying the environmental impact of a product (verified in accordance with the ISO 14025). More and more of the producers of building material also inform about e.g. the CO_2 emissions released when producing the product. The project manager gets the cost and CO_2 emissions from the same source.

Innovations and development with modelling systems is needed to enable better steering of sustainability in construction. There already exist models that can support effective space planning and design in relation to business activities.

SIMULATION OF DESIGN AND CONSTRUCTION

Within Haahtela Group in Finland, the problem of various kinds of information concerning just the same building is solved by simulation of programming, design and construction (Haahtela 1980), (Pennanen et. al 2001).

Simulation is based on a fact, that clients, designers and contractor do their decisions in predictive ways, based on function.

The material /equipment use of an operation theatre is big. There is a plant room for circulation fans, ducts and HEPA filters. A 1000 lux lighting and tiling on the walls. Can all these materials and equipment be derived from the requirements of the function: limited particles in air (e.g. ISO5), hygienic surfaces? If so, they can be simulated from the function without designing. If we need a 1000 lux lighting, given assumptions on the lumen values of a luminaire fulfilling the functional requirements, quantities of luminaires can be simulated.

The basis to simulating massing arises from the spaces and function. For example, the need of natural light in rooms, the ability to access certain spaces from street level, and the possibility to locate a function in a basement. The city plan and its external requirements provide the framework for the massing.

The Simulation model uses programmatic information as initial information and results all building elements and components needed for desired functionality. It simulates decision making of real world architects, engineers and contractors. The simulated building can be considered as one possible solution among many others.

RESULTS OF SIMULATION AND COSTS

The literature on cost estimating is in general agreement that the level of accuracy of estimates increases with the specification (and eventually production) of the asset. The earlier the estimate in the life of the project, the lower its accuracy. Consequently, assessments of conceptual estimate accuracy are quite low. An extreme example: "…at this stage [prior to design], almost nothing is likely to be known about the building except its general size, and therefore it is pointless to go into detail about the cost before any designing has been done." (Ferry, et al., 1999). As a result of an incomplete specification of the asset to be constructed, the industry has historically accepted high levels of variance between the estimated and the actual total installed cost. Customarily, during pre-design, the industry has accepted a standard of +/-30 % of variance from estimates, after adjustment for changes in scope.

The previously described wide variance is based on projects that do not have proactive steering process with simulation of project delivery. With projects where proactive simulation has been used during programming and early design, the standard deviation of budgets before the design has been started compared to completed costs is less than 5 %. Thus, it has been shown that the simulation model and steering are powerful tools (Ballard, Pennanen 2013).

POSSIBILITIES TO STEER CO2 EMISSIONS, AS WELL AS COST, BEFORE DETAILED DESIGN

If programming and design simulation can successfully steer the costs of a construction project, it is possible to steer CO_2 emission, too. So that the customers decisions are in the front line, then designers, and finally procurement and construction in site.

In Finland, such simulation is in use, but, at the moment, researchers are lacking results, population of completed construction projects with simulation of CO_2 from early programming and design.

Researchers have made a study, calculating the correlation of costs and CO_2 emissions due to preliminary designs. The project was a day care center in Töölö district, Helsinki. The population was four preliminary design solutions. They were the best architectural solutions resulting from the competition. There were no bad ones, only good ones. One of them was built later.

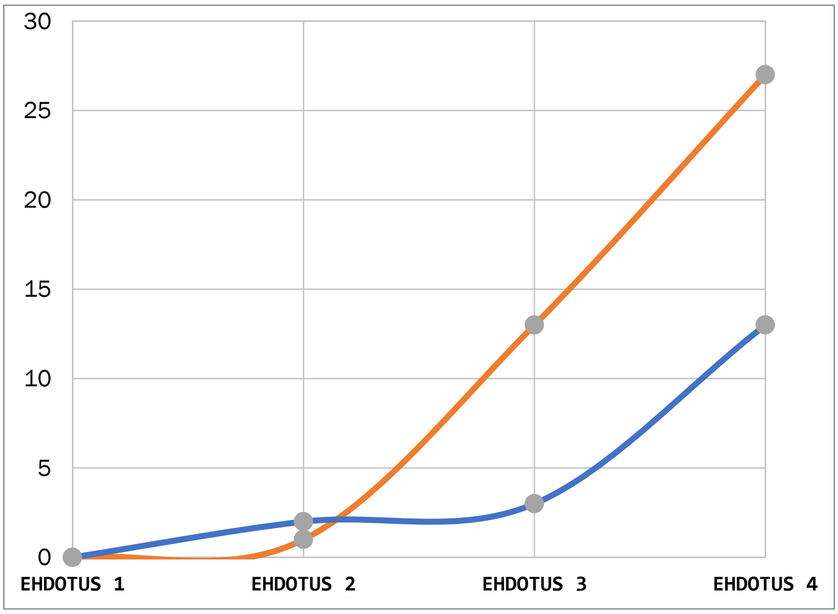

Figure 1: Four Architectural Proposals for a Single Programming of a Day Care Center. Blue curve: Cost variance of the proposals (%). Red curve: Variance of CO_2 emissions of construction (%) (Harvala A. 2022).

Ehdotus (Proposal) 1…4 are alternative design proposals for the same programming. Lower curve describes construction costs (0…13 %) and upper the CO_2 emissions of construction (0…27 %) (Harvala A. 2022).

The first conclusion (based on very low population) is that variety among proposals is high in relation to costs and CO_2 emissions (that was supposed basing previous research). Variety of soft architectural quality in this population is low, as the best four proposals are considered. The phenomenon is a subject of steering, from programming to the use of the building! As the correlation between costs and CO_2 emissions is strong, the researchers suppose that the proven methods to steer costs can be applied to CO_2 emissions.

In conclusion, simulating and steering projects from their earliest stages allows stakeholders to consider and actually change the environmental impact of the construction before the realization of the emissions. While costs in building projects have been considered this way for longer, they mainly impact only the stakeholders themselves. The emissions, however, impact the entire planet. It would thus seem prudent to utilize simulation and steering in project management, for both costs and especially CO_2 emissions.

FUTURE RESEARCH

Simulating CO_2 emissions from programmatic data has just begun. The investors get information of CO_2 emissions before design, based on their decisions. And later based on the designs as well.

Researchers need more evidence from on-going projects. It seems that it can be provided.

On the other hand, life cycle emissions are not included in this research. The simulation model, as used for predicting function and massing, is also capable to steer life cycle emissions. That is the issue of another paper.

ON-SITE WASTE MANAGEMENT: A USE CASE OF LEAN CONSTRUCTION AND ARTIFICIAL INTELLIGENCE SYNERGY

Fabrice Berroir[1], Pierre Guernaccini[2], and Jean-Sébastien Sottet[3]

ABSTRACT

The construction industry generates more waste than any other industry. Waste management is getting more and more attention as the policies and mentalities evolve to face the challenges ahead: climate change, materials shortage, circular economy. Most of the waste management activities consist in waste sorting and is carried out downstream of the construction execution, resulting in lower material recovery performance. This paper proposes a method to segregate waste (separate waste based on how it is created) to enhance the reuse, recovery, and recycling of construction waste. Therefore, it investigates the applicability of Lean Construction methods and Artificial Intelligence (AI) tools and their potential synergy. Directly applying classical waste management AI tools (as used in recycling centers) was tested based on real case data. It required an excessive need for data and training. Alternatively, a Lean Construction framework based on a combination of the 5S method, and the Takt Time Planning method was proposed. It enables the streamlining of flows in order to mitigate the impact of on-site constraints on AI training. We instrumented this Lean Construction approach with an AI tool that checks the quality of the construction waste segregation process by detecting mixed materials in dumpsters.

KEYWORDS

Lean Construction, process, sustainability, Artificial Intelligence, waste segregation.

INTRODUCTION

Inspired by the Toyota Production System, Lean Construction aims at a systematic reduction of wastes within the production processes related to construction. To be applicable and relevant for the construction sector, the original list of seven wastes from Ohno was supplemented based on the Transformation Flow and Value theory of production (Bølviken, 2014). In addition to the original time losses, Lean Construction also put emphasis on material losses and value losses. Material losses, consisting of Excess Inventory and Scrap waste (Ramaswamy, 2009) have indeed been highlighted as a major problem for the construction industry (Formoso, 2002).

Reducing material wastes in construction is also a major concern outside of the Lean Construction Literature because the tremendous amount of CDW (Construction and Demolition Waste) has a tremendous environmental impact worldwide. For example, in France, CDW represents 70% of the total waste (Ademe, 2021) and 30% of total waste produced worldwide

(Papargyropoulou et al., 2011). On average, more than 35% of CDW will and up in landfills annually (Menegaki and Damigos, 2018).

As an answer, Construction waste management processes aim at identifying, reducing, reusing, and recycling materials generated during construction to minimize their negative impact on the environment and turnover (Olabode, 2019; Esin and Cosgun, 2007). However, there is a lack of data about the handling costs of waste to drive companies towards more significant effort and investments, and notably to justify the investment on dedicated technologies. Moreover, positive incentives, such as labels and good brand image, as well as negatives, such as taxes or penalties, are not compelling enough to support diversion of CDW, and a more efficient regulatory framework and public incentives are needed (Purchase et al., 2021).

Most practices and research in the C&D Waste Management research and practice are based on a "3Rs" principle, which refers to reduce, reuse, and recycle and establishes a classification of the actions related to Waste Management arranged according to their impact to the environment (Peng, 1997; Kazerooni, 2012). Further possible "Rs" have been proposed, but an overarching principle remains to prevent as much disposal as possible: waste that cannot be reused or recycled, will most likely end up being burnt or landfilled (Nagapan, 2012). All material waste that cannot be reduced should be kept reusable or recyclable, which requires separating the various types of materials. Considering the climate emergency, recent regulations put a growing emphasis on these principles while becoming more compulsory. For instance, the revised waste management law in Luxembourg compels construction companies to sort 7 types of materials during the execution phase: wood, inert materials, metal, glass, cardboard, plastic, plaster, and hazardous wastes (Ministère de l'environnement, 2022).

For a construction company, such new regulation implies extra cost for sorting scraps in the mixed waste dumpster or being able to handle separate flows for material wastes. In both cases, the added costs or activities fit within the Lean taxonomy of waste (Bølviken, 2014) and should thus be considered from a Lean Construction perspective.

Therefore, Lean Construction might answer some of the barriers to on-site sorting strategies highlighted by Bao et al. (2019). However, the Bao study also points out a lack of technological solutions. In other sectors, such municipal waste management, sorting is performed by technologies based on Artificial Intelligence (Lu and Chen 2022). The use of such technologies in construction is a topic of growing interest, as it relates to their applicability for material waste management in construction.

More recently, the interplay between Lean Construction and AI have been studied from a theoretical perspective by (Cisterna et al., 2022). The authors highlight the potential for synergies between LC and AI: material waste management might be one of these.

This article will investigate the applicability and synergies of Lean Construction and AI for the purpose of reducing disposal on construction sites.

BACKGROUND

Assisting waste management through AI is uncommon in the construction industry, even as the use of intelligent computer-vision seems very promising for object sorting tasks. Early ideas date back to 2000 (Mattone et al., 2000). Most of the waste management solutions appear downstream of the execution phase, with recycling robots (Lukka, et al., 2014) and especially in recycling centres. A lot of facilities are equipped with conveyors and robotic arms to sort waste though in some cases the sorting is operated by humans. A challenge for waste sorting derives from the fact that many wastes are already mixed, and some are difficult or impossible to separate (for example, coating with plastic and metal); this type of waste will most likely end up being burnt or serve as landfilling.

A different approach lies in the segregation, where waste is separated into dedicated containers as it is created at the workstation; this eliminates the need for later sorting activities. This approach is common in sectors like municipal waste or household waste (Lu et al., 2022) where AI-based waste segregation is performed in closed dumpsters with image recognition algorithms and automated segregation. This reduces human intervention and error by leveraging a tool able to complete segregation. However, use of such tools is made possible by the relative homogeneity and small size of the waste; moreover, these tools can usually manage only 3 types of waste (paper, plastic, metal) and are not suited for bulky and dense material. Thus, the direct applicability of such technologies is very limited in the construction sector.

Recent work (Lu et al., 2022) demonstrated the identification of precise waste elements (i.e., known as semantic segmentation) to help with the segregation and precise identification of mixed wastes. This technique may be suitable in a construction site's context though the specific training of the AI model should be adapted for a construction site's needs and operational contexts. Indeed, semantic segmentation is quite a complex AI model that requires a lot of training and that may be less robust in construction because of the variety of situations on site.

Moreover, if that kind of approach seems efficient from a technical perspective in a specific evaluation case, the role of the humans involved is not sufficiently considered, which may be particularly inadequate to construction as highlighted by Noueihed and Hamzeh (2022). Therefore, a practical waste management process, encompassing the whole waste management is needed to ensure its applicability in construction.

Regarding Lean Construction approaches, the 5S method has already demonstrated its capacity to reduce material wastes and losses of control on material flows by maintaining clean and tidy workspaces (Berroir et al., 2015), and seems thus, applicable for waste segregation. However, authors also showed that 5S should not be applied dogmatically and in isolation but combined with flow identification and management methods to streamline flows, facilitate change management, and make improvements last from project to project. Hence, a waste segregation process based on several Lean Construction tools should be proposed.

This article assumes that waste segregation should be preferred to downstream sorting. The current AI methods listed above are not encompassed in any Lean process, and thus, they may be difficult to apply in the context of CDW segregation on site. This paper will focus on enabling CDW segregation based on intertwined Lean Construction and AI.

METHODOLOGY

To investigate the applicability of AI for waste management in the specific context of construction sites, we propose to follow a Design Science Approach (DSA). The grounding of our proposition is based on the aforementioned background work on AI and Lean Construction and their related limitations. The DSA proposed artifact is a Lean Construction process encompassing an AI tool for waste segregation and it will be compared to an approach based on AI only (similar to what is applied in other sectors). The solutions will be evaluated according to the amount of data needed as well as the feasibility of the training, maintenance, and update of the AI model. Accordingly, the research was split in 2 cases:

Case n°1: AI tool without Lean

This case is based on current practices of AI implementation and training in other sectors. Research protocol consisted of:

1. Data collection from 2 construction sites in Luxembourg
2. Training of the algorithm
3. Evaluation of the amount of data and training time for an implementation on site.

Case n°2: AI tool integrated in a Lean Construction process

Considering that AI alone is not a "silver-bullet" solution to solve on-site waste segregation, this case investigates what Lean process could be applied and how it can integrate with the development and implementation of an AI solution for onsite waste segregation. The authors sought to address two questions:

How can LC enable the integration of technology in the segregation process? (Q1)

How to train and maintain an efficient AI model for on-site waste segregation? (Q2)

Subsequently, the research was conducted as follows:

1. Proposition of Lean Construction process for waste segregation on site with computer vision (using planning data from the second pilot site cited in case 1)
2. Development of a computer-vision AI model (visual waste recognition).
3. Test of first round training in controlled conditions
4. Evaluation of the amount of data and training time for an implementation on site.

A third case, "Lean process without AI," is not considered here because literature already established that such a solution would be applicable. This case needs to be studied in future research from a performance and efficacy perspective.

RESULTS

CASE N°1- AI TOOL WITHOUT LEAN

The first case was performed through the data collection of waste on two construction sites in Luxembourg. Cameras were installed near waste collection zones, above dumpsters and enabled to take one (1) photo every minute, collecting more than 25000 pictures overall. From an AI perspective, the training environment was uncontrolled (dust in the air or on the material , water, snow, overlapping materials).

These dumpsters were supposed to collect only one type of waste. However, a lot of wastes were mixed (plastic with wood, metal with plastic, plastic bags with various waste inside). Training an algorithm to identify various type of waste in such a context resulted in a time-consuming labelling phase. Half of the data was totally unsuitable for exploitation because scrap was too mixed or hidden inside plastic bags (see fig.1). In the other half of the photos, materials were altered (e.g., wood was contaminated with paint or oil) as well as overlapping materials created errors in the AI training, as did variable conditions (lighting modification, rain, snow).

Figure 1: Example of dumpster pictures used to train the model

As a result, the training time was over 200 hours, and the recognition rate was below 60%. Accordingly, implementing such an AI tool on a construction site would require training and updating the model several times during the project, as the material flows evolve. Hence this method is not robust nor suitable for replication.

CASE N°2 AI TOOL INTEGRATED IN A LEAN CONSTRUCTION PROCESS

How can LC enable the integration of AI in the segregation process? (Q1)

Dealing with messy and overcrowded workspaces is the goal of the 5S method (e.g., Berroir et al., 2015). Aligned with 5S, segregation requires to identify materials flows exiting the workspace and to be able to keep them separate as much as possible. A limitation reported during the data collection on site was the use of many plastic bags and the mixes of scraps. It was reported from the pilot projects that most of these materials were already mixed at the workspace. Small piles of materials left at the workspace rapidly tended to become mixed chunks of wastes. Separating such waste from AI automatically is nearly impossible, and the resulting waste are costly as they end up in disposal. Moreover, companies on site usually rejected the responsibility to clean up for each other, meaning that un-segregated piles of waste were challenging to process, as no one contractor had responsibility for clean-up and segregation. Hence, applying a 5S method would contribute to waste segregation as reported by Leino (2014). Main expected benefits are reported in table 1.

Table 1: Expected contribution of 5S to waste segregation on site

1st S, Sort	Systematic elimination of unused material before they get mixed
2nd S, Set in order	One place for each material
3rd S, Shine	Visual workspace: systematic cleaning, any leftover pile is visible as an anomaly
4th S Standardize	Adapted equipment (bins and container) and rules at company level
5th S, Sustain	Rigorous application of standards and inspections

Accordingly, the implementation of 5S appears highly beneficial for waste segregation, but as shown by Berroir et al. (2015), its implementation and maintenance over time greatly benefits from other Lean Construction methods. Methods that enable balancing and identifying the flows of material would enable identifying and adequately sizing the equipment required to collect and carry the waste. Such an approach was proposed by Heinonen and Seppänen (2016), learning from examples from cruise ship cabin refurbishment, they suggested improving takt time application in construction by explicitly considering logistics and garbage collection at the planning level. In practice, they proposed to implement garbage collection points but practical implementation in construction and location of the collection point was left for future study. Consequently, based on the case of the second pilot projects involved in this research, we considered several setups for such collection points.

A single "one-fits-all" setup of waste collection point would need to be suitable for segregating all types of waste generated from every task performed in the work zone. Enabling this type of collection point would require a lot of equipment since one collection point would be needed at every floor where there is some work and since the collection point should be composed of all the different containers. This option might often not be applicable for space reason, it might strongly increase costs. The opposite approach would be to define individual containers for each team with the appropriate equipment for their various waste streams. This approach might also require excessive amount of equipment since many waste streams are common to several trade and could be mutualized. Additionally, it would require workers to move all the equipment with them, which should be avoided from a Lean Construction perspective as it appears as a new time loss for the workers and is particularly not suitable in cases where they may have work in progress on several zones at the same time. Moreover, the collection of the waste by a logistic operator would require additional capacity. Lastly, this setup does not really take advantage from balancing and identifying flows of material in the way that Heinonen and Seppänen (2016) documented and would in practice look very similar to a case where everyone is managing its own wastes. Consequently, the proposed solution for this case n° 2, is to take advantage of a "takt timed" planning to find a balance between these 2 setups and to define collection point based on takt phases as for example in figure 2.

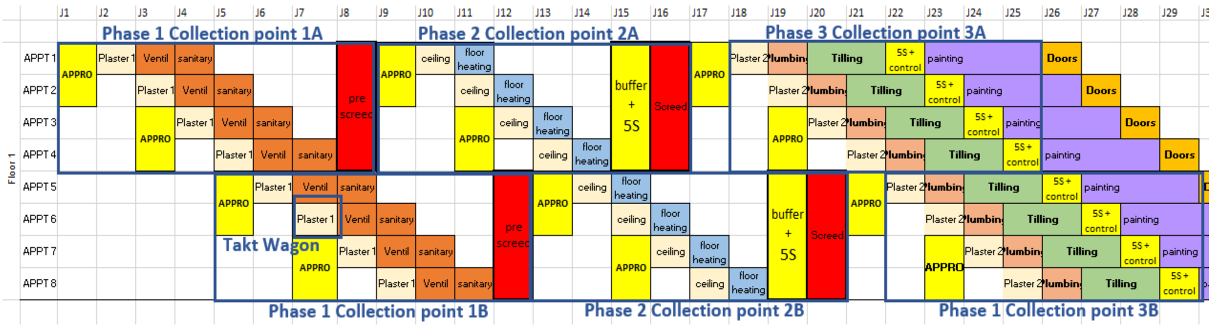

Figure 2: Example of takt timed planning extract with visualisation of the collection points

More precision on the tasks can be found on table 2, but the details of this planning is of little importance since this example only aims at illustrating the idea of defining and sizing Collection Points based on takt phases. Typical level of details of a takt times planning enables explicit consideration of deliveries and cleaning (highlighted in yellow in fig. 2). This example presents a group of tasks in different takt zones circled in blue and referred to as "phases". Implementing waste collection points at a "phase level" would result in 3 different setups of collection points, each one following a group of trades.

In this scenario, a phase encompasses half the apartments of a floor, meaning that each collection point would have 2 instances (e.g., Phase 1 "A" and "B") intended for the same flows. Thus, workers would always have access to the right container at the floor where they are supposed to work. This level of detail allows to anticipate the kind of waste managed at each collection point as illustrated in table 2. This list is not exhaustive but intended to show that material waste flows can be identified individually at the level of each collection point based during planning. Furthermore, the application of the takt time method would result in more stable amount of waste generated, thus allowing construction managers to select waste containers with the required shape and capacity.

Table 2: Identification of potential waste types at each Collection Point

Collection point	Tasks	Type of waste
CP1	Plaster (1st layer) Ventilation Sanitary Pre-screed	Plaster, Aluminium (rail), packaging plastic, pallets, Gravel, wood, tubes, cardboard
CP2	Ceiling Floor heating screed	Plaster, Aluminium (rail), plastic packaging, polystyrene, plastic tubes, pallets, Cardboard
CP3	Plaster (2nd layer) Plumbing Tilling	Tilling, Plaster, Aluminium (rail) Pallet, cardboard,
Out of CP (collected directly by subcontractor for each task)	Painting Doors Electrical	Paint can, plastic packaging, electric wire, gravel,

To ensure waste collection at each task/takt wagon level, teams should be equipped with small individual containers (e.g., big bags or rolling dumpsters) as presented in step 1 of figure 3. Material can be then brought to the collection point where containers can be equipped with cameras and a visual recognition tool trained for the relevant containers and types of wastes, as represented in figure. 3.

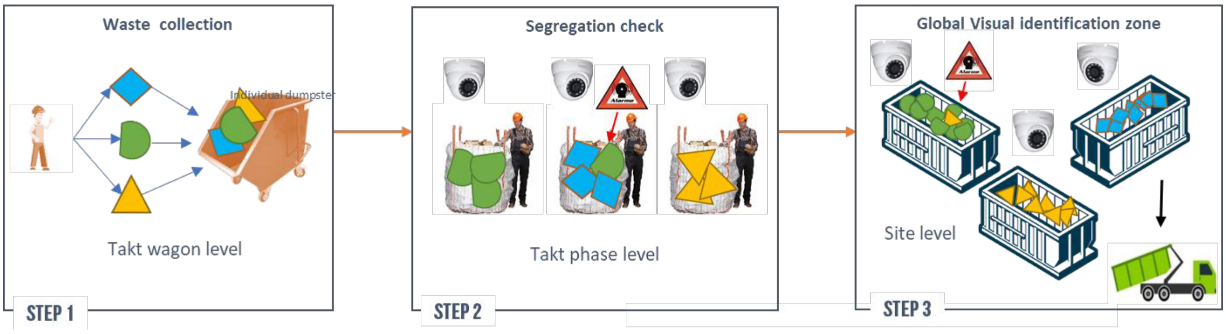

Figure 3: AI supported waste segregation process

Compared to what was performed in case 1, the waste collection points operate at an intermediary level in the management of waste flows; the control device prevents mixing of wastes, supporting "clean containers" (one type of material per container) onsite. A last control, Step 3 of Figure 3, is based on larger dumpster observation by camera. This uses a similar AI approach with different training data as the large dumpster situation is different from the small "local" dumpster situation. The large dumpster can also be a last quality control point for downstream waste recovery (even if it goes beyond our approach) to prevent costly mixed waste from leaving the jobsite. Contrary to classical "waste recovery" activities performed downstream of the execution phase, the LC framework proposed allows project teams to streamline material flows, perform waste segregation on site, and reduce the impacts of environmental constraints that hindered the applicability of visual recognition on the construction sites.

How to train and maintain an efficient AI model for on-site waste segregation? (Q2)

The key to the success of this solution is the visual recognition system that can detect and characterize each material despite the constraints of an uncontrolled environment (the construction site): dust (in the air or on the material), water, snow, or contaminated materials (painting or oil covering a part of the material). Another key constraint will be the overlapping of materials when the dumpsters will be emptied into larger dumpsters or big bags. In many cases, the materials can be partially or fully hidden from the camera.

The solution is based upon in-situ data (photos) that rely on the trained AI models introduced in the previous section. This AI, notably its training and maintenance, comes with a cost that downstream waste recovery will not face. However, it directly puts the responsibility to the person producing the waste whilst facilitating their success is the sorting of their waste (by directly providing adapted containers and explicit zones). A simple set-up was selected for the waste recognition and segregation AI model. To do so, a camera was set on top of a big bag/dumpster deployed on site. This camera helps to capture waste drop activities as soon as they occur. Indeed, the wastes are supposed to be dropped in the correct container (big-bag or dumpster). As shown in Figure 4, the technical process is articulated as follows: 1) the camera detects an activity. This step is required to avoid having a continuous execution of the waste recognition model; indeed, the model should only run when waste needs to be detected in order to reduce the energy demand from the AI system that is likely running off of batteries. 2) In a second step, the model is executed on an embedded device (e.g., a Jetson Nano card). It tries to detect the waste being dropped and whether or not this material is correct for the container (e.g., putting only wood in the wood dumpster). 3) In a third step, the algorithm warns the personnel about the correctness of waste segregation or alerts if a mix is detected, and it creates a log that keep a trace of the current detection. This trace can be used later to know if there is still mixed waste in the container, to know where it is, or to identify false positive cases that can be used for future training of the AI model.

A simpler AI approach than the one described in (Lu and al., 2022) was selected, since it's important to have: 1) a human in the loop, and 2) more robustness for recognition and thus less training. As a result, the training relies on multiple simple classification models. Each of them identifies the presence of a single material in the image captured by the camera. If more materials are recognized, then a mix is detected.

An important step of any deep-learning model is the training, mostly based on the extension of a pre-existing recognition model. Indeed, most of the recent approaches extend (i.e., use transfer learning) an already trained model based on daily-life objects (e.g., boats, cars, bananas, ducks, etc.). Basing the training on pre-trained algorithms drastically reduces the number of required photos.

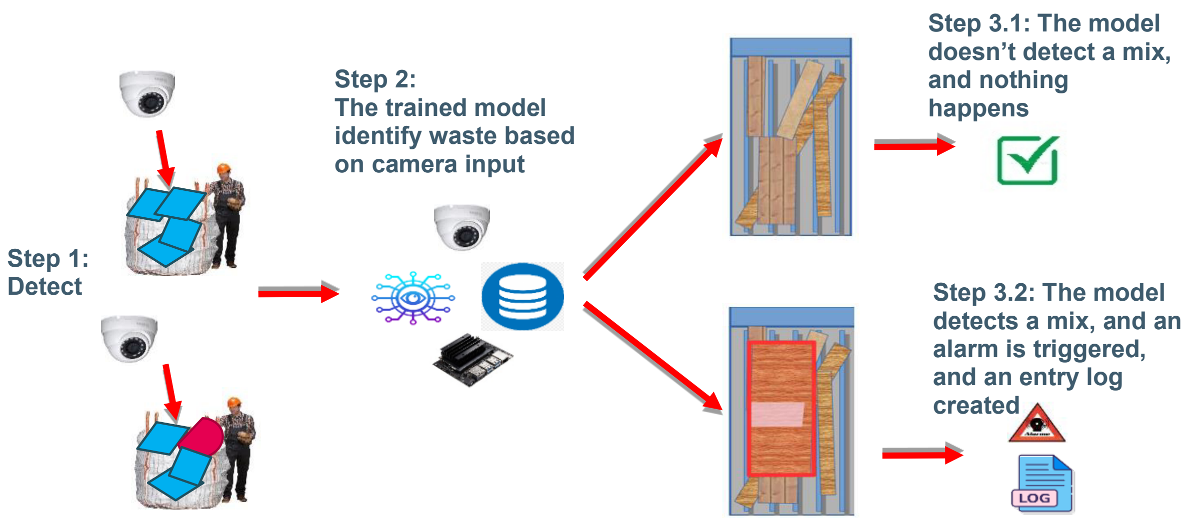

Figure 4: The waste identification technical process

Moreover, following the same principle, the training of the models has been started in a controlled environment (laboratory training; see Figure 5), with 4 basic materials: wood, metal, plaster, and bricks. It consists of around 550 images of the basic material and 550 images of the basic materials mixed with others. The concept of the first round of training was to have an already sturdy model before deploying it on-site but also diminish the quantity of data needed to train the algorithm. Certainly, training the algorithm directly with on-site data would require at least 10 times as many photos, as discussed in other studies (Lu and al., 2022), and it is very likely to face a lot of peculiar cases, thus disturbing the learning phase. Starting the training in a controlled environment allowed good recognition results (above 90%) of the 4 basic materials with fewer data.

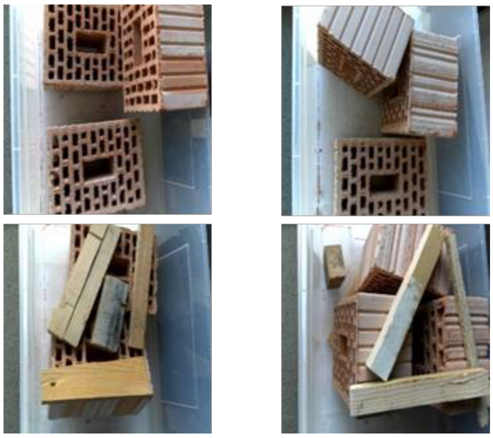

Figure 5: Lab training sample: two upper photos brick not mixed; the two lower brick mixed

Once the results are confirmed in the laboratory, a second round of training will start on-site, with constraints (lightning modifications, dust, rain, overlapping materials, contaminated materials) to strengthen the algorithm and have a fully functional tool. This training phase will be longer since it is expected to have more mistake occurrences due to the on-site constraints weakening the algorithm's performance.

Since such AI model cannot be 100% effective, we will have to introduce 2 "bypass" buttons. The idea of those buttons is to make the system robust according to the site or construction company specifically without blocking or keeping mistakes in the automated part of the segregation process. As illustrated in Figure 6, the two buttons will help with the identification of the false positive and the false negative solution (i.e., mixed, or not mixed wastes). These bypass buttons, called "force push," will be used in case the models make a mistake. For example, the model detects a mix but there is no mix, the "Force NO MIX" button will be pressed to notify that the model made a mistake, and, hence, will learn from the mistake.

In the other case, a mix is not detected by the model, the "Force MIX" button will be pressed to notify an error, and the model will hence learn from that mistake.

If a mistake is recuring, the training will be extended through the identified wrong situation to make the system more robust. More experiments will be needed to implement a correct pace of training when there is sufficient data to make another training.

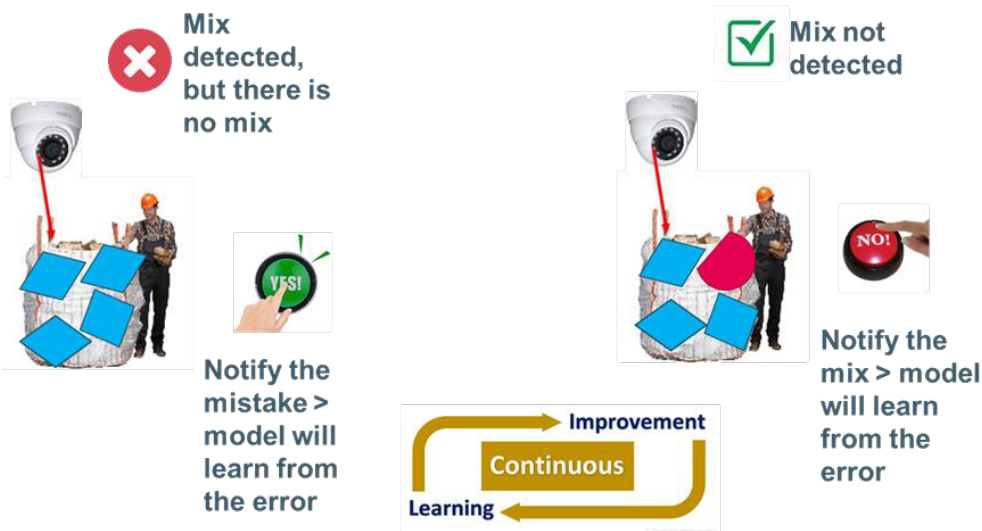

Figure 6: Notification buttons on site of false-positive and false-negative with continuous learning

As a summary, a set of simple trained models is operating, and it detects the presence or absence of each individual material on a camera. It is based on in-lab training that is enhanced with on-site image training. The results of those models are then crossed together to state if there is a mix or not. It is also vital to allow for tracking and reporting incorrect classification to enable the model to learn from the site or construction company. The idea is to be able to learn from errors to ensure a more robust detection.

DISCUSSION

The Lean Construction framework proposed in this article might be applied without the AI control tool, but with a human supervision. Further research could thus compare the Lean Construction + AI framework proposed here to a Lean Construction without AI solution according to their respective performances in real case conditions. Showing the benefits of the AI integrated solution would prove the synergy between Lean and AI for the use case of waste management on construction sites.

The explicit identification of deliveries and garbage collection in the Takt Time Planning, as illustrated in this paper, can contribute to further reductions of environmental and economic impacts of the construction sector based on the application of Lean Construction techniques. Hence, it would contribute to merging upstream (logistics) and downstream material flows (garbage collection) similarly to what is presented by Heinonen and Seppänen (2016) in the context of ship cabin refurbishment. The implementation of garbage collection would allow a third-party logistics operator performing Just-In-Time deliveries to easily collect the scraps and return them with their current (standard) vehicle, achieving an integrated reverse logistics chain and reducing the impact of transport. Further development of the AI tool may also integrate quantity estimation and forecasting to better identify when collection points should be taken off, and in what priority. This may also contribute to collecting more data about the waste generated on construction sites to provide policy makers with quantitative data from construction sites that supports defining and implementing new environmental policies.

CONCLUSION

This paper introduced an instrumented AI based process dedicated to waste segregation on construction sites. To do so, a first experiment was conducted to train an AI model without a Lean approach; it resulted in a time-consuming training and showed insufficient performance. Indeed, this first experimentation forced us to face all the on-site constraints at once, resulting in: (1) a time-consuming labelling phase for AI training (requiring a lot of data) and (2) a more complex AI approach (semantic segmentation).

The complexity of the problem can be lowered by identifying and streamlining material flows using Takt Time planning and 5S, offering a proper framework for the waste segmentation process that mitigates the on-site constraints. A simpler or more reliable AI model can thus be used, with shorter training time and less required input data.

However, the AI tool presented here is not fully functional since it has not been trained nor tested yet on a construction site, so it has yet to confront the "noise" of the environment (lightning modifications, dust, rain, overlapping materials, contaminated materials). This second round of AI training will be the core of the future work to be carried out on the tool as well as its integration on various construction site typologies.

ROLE OF WORK FLOW IN REDUCING LIFE CYCLE ENERGY CONSUMPTION IN CONSTRUCTION

Musab Jamal Maraqa[1], Rafael Sacks[2], and Sabrina Spatari[3]

ABSTRACT

Lean construction aims to improve the construction industry by focusing on flow and value and eliminating waste. Reducing waste can also meet environmental goals by reducing greenhouse gas emissions (GHGs) and improving environmental performance. Many green building rating systems have emerged over the last three decades as instruments to incentivize the production of buildings that minimize the impact on the environment and human health. However, those approaches are oriented toward the end product only, leaving builders without guidelines on effective processes to reduce operational waste. This research reviews and evaluates opportunities to mitigate GHGs and improve environmental performance through lean construction. It measures the effects of lean principles on reducing GHGs by improving the flow. Case study research was used to measure the quantity of diesel used for heating two construction projects in a cold climate; one is a traditionally managed project and the other is managed using Virtual Design and Construction (VDC) and the Last Planner System (LPS). Results show that the floor cycle time reduced from 189 days to 115 days in the lean-VDC project, a reduction of 64%. Also, the total embodied GHGs reduced from 1,037-tons CO_2e to 629-tons CO_2e, a reduction of 408-tons CO_2e.

KEYWORDS

Lean construction, life cycle assessment (LCA), energy consumption, flow, transformation-flow-value

INTRODUCTION

The construction industry is responsible for a significant amount of energy consumption and greenhouse gas emissions (GHGs) (IEA, 2019). Construction waste in Israel represents major source of waste. It contains different construction materials like steel, blocks, tiles, plastic materials, gravel, and soil (Katz and Baum, 2011). In 2016, the amount of construction waste rose to 7.5 million tons, (Tal, 2016).

Lean construction aims to eliminate different types of wastes by focusing on flow and value. Waste in construction, understood from the lean point of view, comprises not only physical waste but any exhaustion of resources that does not satisfied value to the customer (Womack and Jones, 2003). Bølviken et al., (2014) studied the wastes in construction from the Transformation-Flow-Value theory (TFV) point of view. They proposed a definition of waste

as the use of more inputs than needed and unwanted output. This definition can cover aspects inside production, including exhausting more than is needed and to producing unwanted things. They classified the transformation waste as physical material waste, non-efficient use of material, and non-optimal use of machinery, energy, or workers. For the flow waste, they mentioned waste in the workflow and the product flow. Workflow waste includes the unnecessary movement of people, waiting and inefficient work, while product flow waste includes, materials not being processed, and unnecessary transportation of material. Finally, for the value waste, they classified them in two waste categories: main product and by-product. The main product waste is lack of quality and intended use. By-product waste consists harmful emissions or injuries and work-related sickness.

Green building rating systems aim to provide healthy facilities, designed and built in a resource-efficient manner (Kibert, 2007). According to Robichaud and Anantamula (2011), there are several pillars of green buildings: the reduction of environmental impact, the increase of health conditions of facility users, the economic returns to investors, and the total life cycle impacts on the project phases. There are different green building rating systems that are well known. These rating systems aim to take a holistic perspective on a building's full life cycle. Yet, there are gaps in how these rating systems capture all processes within the cradle-to-grave context of buildings.

Many researchers studied the effects of lean construction on reducing construction waste and improving environmental performance. Saggin et al. (2015) examined the relationship between lean and LEED in a case study. They calculated the amount of physical waste reduced in a LEED-certified project managed using a lean management approach. They calculated the total volume of waste and normalized it by square meter. Results show that the waste was reduced from 13.53 cm/m^2 in the traditional management project to 10.93 cm/m^2 in the lean project, a reduction of 20%. Koranda et al. (2012) studied the integrity of lean construction and sustainability in six different construction projects in the Midwestern United States. They used qualitative methods, interviewing project managers to identify the waste sources for sustainability and lean. They concluded that sustainability practices result in reducing physical waste generated during construction which lean also aims to eliminate. However, they identified several differences between the two concepts. Lean construction aims to eliminate the different types of physical, process, and operational wastes, while green building rating systems like LEED and BREAM focus on reducing physical waste.

Maraqa et al. (2022) studied the effect of lean construction in minimizing physical and operational waste. The researchers studied three construction projects with different management approaches. One was managed traditionally, the others were managed using VDC and the Last Planner System. The researchers analysed the partition wall activity since it represents one of the main finishing activities during the construction phase. They found that the embodied GHGs in the lean-VDC project per meter square of partition area were 12 kg CO2e/m^2 compared to 58.4 kg CO2e/m^2 in the traditionally managed project. The reduction of GHGs in the lean-VDC project demonstrates the potential of lean practices in improving environmental performance. A further study examined the effect of lean and VDC practices in improving the process and reducing associated operations waste (Maraqa et al. 2021). The researchers monitored block worker activities and divided them into value-adding and non-value-adding activities. The results showed that lean and VDC implementations raised the value–adding activities to 68.4%, compared to 35.8% in a traditional project.

Other studies measured the effect of lean implementations on improving process and operation flow in construction. Maraqa et al. (2021) studied the role of implementing BIM and lean to improve the flow in eighteen construction projects with different combinations of management approaches. Based on a 10-point scale, their results showed that lean and BIM implementations improved the workflow to 8.12, compared with 4.91 in projects that implemented traditional management. However, this study measured the impact of lean and BIM in improving the workflow from a management perspective without considering the environmental impacts.

Green building rating systems have been criticised because they do not address the environmental problems across the life cycle of a building, and for their transformational checklist approach, which lacks a methodological basis for efficient implementation of green practices during the construction phase. Carneiro et al. (2012) claimed that green building rating systems like LEED does not allow the flexibility valued by lean construction, and it recommends the implementation of environmental interventions without concern time and cost minimization. They argue that while LEED and lean construction practices contribute to the pillars of sustainability, since both focus on the waste elimination concept, the two methods differ in their application. Other researchers claimed that there are some contradictions between green building rating systems and lean construction practices. In some cases, implementing lean construction practices such as the just-in-time delivery concept can consume more energy sources and emit GHGs (Green, 1999).

The objective of this research is to evaluate the potential for improving the construction workflow and reducing the project cycle time in cold climate areas. The research analyses two hypothetical projects with different management approaches: traditional and lean management. Also, three scenarios - Original, Process (location flow) optimization, and Operations (crew flow) optimization - were modelled to evaluate the amount of energy consumed in each, which helps the project manager make better decisions in managing the sub-contractors to guarantee the achievement of general optimization rather than local optimization. These decisions can have an adverse impact on the amount of GHGs emissions resulting from the project during the construction phase. The researchers selected the cold climate areas since the projects in these areas need to be heated during the wintertime which is not required in temperate or hot climate areas.

FRAMEWORK TO MEASURE ENVIRONMENTAL EFFECTS IN THREE DIMENSIONS: TRANSFORMATION, FLOW AND VALUE

Most researchers focus on green building rating systems from a transformational perspective. They focus on the embodied GHGs in the products (construction materials) and the transportation of the product from the source to the project. However, they neglect the processes and their associated operations effects, so they miss the impact of the wastes related to flow and value. Lean thinking guides the process of construction in a complementary way. It deals with construction as a production system that has three dimensions: transformation, flow, and value. Within those dimensions there is an opportunity to improve environmental performance. We developed a framework to measure the environmental effects of construction projects from these three dimensions (transformation, flow, and value) (Figure 1). The framework integrates the transformation, the flow, and the value for all the processes executed in the project and it considers the environmental impacts resulting from not achieving the value within the required time frame. The framework highlights the missing elements in the current state of the green building rating systems. Those missing elements relate to flow and value. Missing flow aspects are waiting, inspection, rework, construction method, and weather conditions. Missing value aspects include value delay (not achieving the value within the required time frame due to project schedule overrun), not achieving the value at all, and overdesign of parts (e.g. excessive slab thickness, steel reinforcement) and of building systems (HVAC, elevators, etc.).

We compare the effects of the flow dimension in two construction projects with contrasting management methods executed in cold climates. One of them is assumed to be managed traditionally, and the second to be managed using lean and VDC management approaches. The aim is to test the impact of location cycle time on the environment by consuming different types of fuels for heating during the winter. The two cases highlight the importance of reducing the waiting time between the different construction processes during the construction phase to improve the environmental performance of the construction process in cold climate areas.

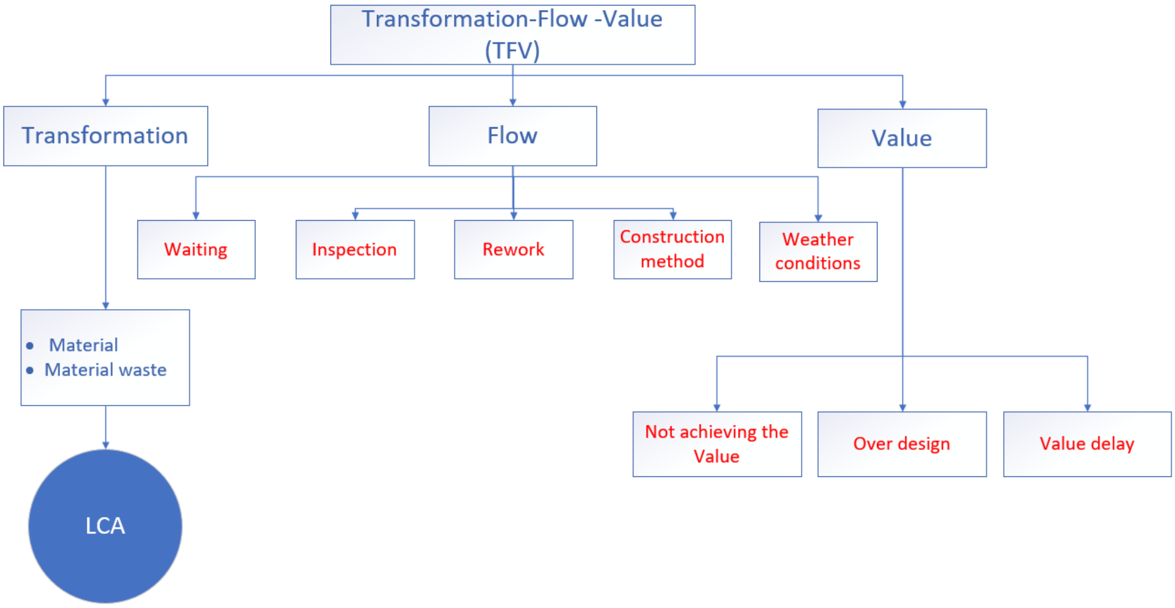

Figure 1: Framework to measure the environmental impacts based on the TFV theory. The boxes with red text represent missing elements in current assessment methods.

METHODS AND DATA

A case study research method was used to study the flow effects on the project's energy consumption. Detailed data, which include start and finish dates for each floor for two high-rise residential construction projects, were collected from the control department of a construction company in a temperate climate region but simulated in a cold climate region by calculating diesel consumed by heaters for heating the project. The two identical projects selected represent two different construction management approaches. The first project was a traditional project without any BIM or lean implementations, while the second project was managed using VDC, 5S and the last planner system (LPS).

The start and finish dates for each floor were used to draw the flow line charts for the two projects using Excel. Two hypothetical cases were evaluated: location optimization to remove the location waiting and crew optimization to remove the crew waiting. The cycle time is defined as the total time from the start of processing of a product until completion. This allows assessment of the marginal impact of implementing VDC, 5S, and LPS in reducing the cycle time. The diesel consumption for heating the construction projects was calculated based on the cycle time for the three scenarios in the hypothetical cases.

LCA following ISO (14040/ 44, 2006) was used to quantify the GHGs results from heating the construction project. Life cycle assessment (LCA) is a framework for evaluating the environmental impacts of products and materials (ISO, 2006). Many researchers used this framework to assess the environmental impacts of products within the economy, including building materials and construction projects (Junnila et al. 2006; Miller et al. 2019; Tian and Spatari 2022). The embodied GHGs were calculated for heating the construction projects in the different flow scenarios to test the flow effects from an environmental perspective.

CASE STUDY DESCRIPTION

The first author has worked in cold climate areas, and observed the amount of diesel consumed by heaters to heat the construction project. During the winter, temperatures declined to around 30 ºC below zero, which means all construction activities, equipment, and cranes must be stopped unless the construction site is heated to create safe working conditions, which required increasing the ambient indoor temperature to 5 ~ 10 ºC above zero. Heating is required before, during, and after casting concrete (to enable the chemical reactions) as well as for the different finishing activities and mechanical, electrical, and plumbing (MEP) system installations (to prevent cracking or breakage of fittings and pipes). These activities consume tremendous amounts of energy to guarantee appropriate work conditions, and the losses are very high because the heating is required for open spaces which are not enclosed or insulated, or enclosed with temporary materials.

The fuel used by heaters is diesel, which has a very high carbon footprint. The cradle to grave GHGs, which include extraction, processing, transport and distribution, and combustion, in one liter of diesel fuel is 3.31 kg CO_2e (One Click LCA, 2023). Each diesel heater consumed 18 liter/hour, and there were tens of heaters around the construction site. Some of these heaters worked 24 hours before and after casting the concrete. Hence, the space cycle time has a strong effect on the environment in cold climate areas, which is neglected within the green building rating systems, and the potential importance of optimizing construction workflow to improve environmental performance during the construction phase.

Detailed data for the start and finish dates for each activity in each location were collected from the control department of a construction company for two identical residential projects completed by the same construction company in a temperate climate zone. The data were used to build line of balance charts for the projects and calculate the space cycle times and the space waiting times.

The first project is a residential construction project consisting of 23 floors with six typical apartments on each floor with an area of 600 m^2. The activities studied are the structural system and six finishing activities: the partitions, electrical, plumbing, HVAC, plaster, and flooring. Virtual design and construction (VDC) using Revit and lean construction principles like LPS and 5S were applied in the project. VDC produced highly detailed models for the partitions, electrical, plumbing, HVAC, plaster, and flooring systems, which accounted for all interactions between these systems and optimized their arrangement. During preparation of the VDC model, the VDC manager shared the ideas with the different crews, who in turn removed the clashes between trades' systems, to plan and optimize the activities sequence. VDC played an important role in reducing the scope and frequency of changes that result from a lack of coordination between different design disciplines. Also, the VDC model helped the construction manager, and engineers in supplying the right quantities to the right location at the right time. Also, in this project, the company applied LPS including look-ahead planning and weekly work planning meetings to improve the workflow and reduce location and crew waiting.

The second project is a residential construction project, which consists of 23 floors with six apartments on each floor with an area of 600 m^2. The activities studied are the same as the first project. This project was built and managed traditionally without any lean or VDC implementations. This project was built and managed by the same company in a period before they started their BIM and lean journey. So, this project was used as a benchmark to test the marginal impact for implementing the lean and VDC practices in reducing the space cycle time and waiting time.

We assumed that diesel heaters were used for heating the construction project in each case to guarantee the appropriate temperature inside the construction project. The heating was assumed to be used mainly for the structural systems, the mechanical and electrical works, and the finishing works. While this paper presents a case study in cold climate areas, the work acknowledges that in temperate and hot climate areas, construction companies do not heat construction projects.

FINDINGS AND RESULTS

The as-performed data from the two construction projects were used to compute the floor cycle times and the associated diesel consumption for heating in cold climate areas. Two additional hypothetical scenarios were considered using simulation:

a) Process optimization, in which tasks from the original schedule were considered to be performed as soon as possible, resulting in continuous work in the locations and minimum cycle-time.
b) Operations optimization, in which the crews were assumed to have continuous work.

Table 1 lists the cycle time for each floor for the two projects with their hypothetical scenarios. The results reveal considerable differences in the cycle time between the traditional project and the lean-VDC project. The average actual cycle time was reduced from 189 days in the traditional to 115 days in the lean-VDC project, a reduction of 64%. Figures 2 and 3 present the flow line charts for the lean-VDC project and the traditional project for the three scenarios (original, location optimization, and crew optimization).

Regarding the hypothetical scenarios, the difference in the cycle time between the original state and the location optimization state for the lean-VDC project is 6 days with a percentage of 6%. However, in the traditional project, the difference is 88 days with a percentage of 87%. These results demonstrate that the location waiting in the lean-VDC project is significantly lower than that of the traditional project. This reduction is mainly due to implementing the Last Planner System (look ahead planning and the weekly work planning), which considered reducing the waiting for both the location and the crew and this shows that the general contractor succeeds to manage the subcontractors to achieve global optimization rather than local optimization.

In the lean-VDC project, the difference in the cycle time between the actual and the crew optimization is 101 days with a percentage of 88% (Figure 4). This means that if the general contractor leaves the subcontractors to manage themselves, the project duration will be extended dramatically. However, applying LPS from the phase planning to the weekly planning meeting results in balancing the work packages between the different subcontractors. In the traditional project, the difference in the cycle time between the actual and the crew optimization is 143 days, with a percentage of 75%. This implies that the subcontractors in this case managed the project from their perspective to achieve local optimization.

From a fuel consumption point of view, the amount of diesel consumed for heating the spaces was measured for the traditional and lean-VDC projects (Table 2). The amounts of diesel were calculated for each floor along its cycle time and then normalized per meter square of the finished building. The average amount of diesel consumed for heating one floor in the traditional project is 13,624 litres, whereas the lean-VDC is 8,264 litres, a reduction of 65%. In the traditional project, the average amount of diesel required for heating a floor in the ideal state (location optimization) is 7,294 litres. The difference between the actual state and the ideal state is 6,330 litres, or 87%.

In the lean-VDC project, the average amount of diesel required for heating a floor in the ideal state is 7,829 litres, and in the actual state is 8,264 litres. The difference is 435 litres, or 6%. This shows that the actual state in the lean-VDC project is not too far from the ideal state. The total GHGs in the Lean-VDC project is 629-ton CO_2e, while in the traditional project it is 1,037 tons CO_{2e}. The difference between the traditional and the Lean-VDC project is 408 tons CO_{2e}, a reduction of 65%.

CONCLUSIONS

The two hypothetical construction projects analysed herein show that lean principles like VDC and LPS play an important role in reducing the project duration and the location cycle times, which is a crucial issue in cold climate areas. The average original project cycle time was reduced from 189 days in the traditionally managed to 115 days in the lean-VDC managed project, a reduction of 64%. Also, the difference between the average cycle time in the original scenario and the location optimization is six days which means that the general contractor succeeds to manage the subcontractors to achieve global optimization rather than local optimization. However, in the traditionally managed project, the difference in the average cycle time between the original scenario and the location optimization scenarios was 88 days, which means that the sub-contractors achieved local optimization rather than global optimization, resulting in extending the project cycle time.

From an environmental point of view, the amount of diesel consumed in the lean-VDC managed project is 8,264 litres, while in the traditional managed project it is 13,624 litres, a variance of 5,359 litres (65%). The amount of energy used for heating the construction project, which has a significant impact on the environment, could be reduced due to implementation of lean and VDC management approaches.

We conclude that lean practices like LPS and VDC play an important role in improving the workflow and reducing the project cycle time by achieving global optimization rather than local optimization. This contributes to dual benefits for the sub-contractors and the general contractors (win-win relation). Also, the results show the importance of reducing the project cycle time in cold climate areas. The total GHGs reduced from 1,037 tons CO_{2e} to 629 tons CO_{2e}, a reduction of 65%.

These results underscore the importance of reducing the project cycle time from an environmental perspective in cold climate areas. However, this is not the case in temperate or hot climate areas since there is no need to heat the project. Other environmental factors should be investigated in these areas, such as workers' transportation from and to the construction project, or the camp energy consumption in cases where workers live at the construction site.

This research focuses on the effect of heating construction projects during the construction phase. It focuses on cold climate areas since it is needed in these areas, and there is no need for heating in temperate and hot areas. Other issues like workers traveling from and to the construction site, energy sources used for operating equipment, and machines like cranes, elevators, etc, should be considered in the different climate areas. Although these issues are not quantified in this paper, the researchers suspect that they will have considerable impacts on the environment and will be shared between cold, temperate, and hot climate areas. Considering all these emissions will amplify the results. Further research should include these emission sources to visualize the process effect from an environmental perspective.

RESEARCH LIMITATIONS

This paper explored the effect of heating construction projects in cold climate areas by using hypothetical case studies from temperate climate areas and assessing them in cold climate areas. Recently, the researchers have begun collecting data from a project in a country classified as a cold climate area, and in the future, more representative results from the cold climate areas will be published.

LEAN CO-ACTING WITH CIRCULARITY? AN INVESTIGATION IN PRODUCT-SERVICE SYSTEMS IN RENTAL HOUSING

David Parker[1], Tuuli. E. Jylhä[2], Gerard A. van Bortel[3], and Daan F. J. Schraven[4]

ABSTRACT

Circularity is positioned as an alternative model to achieve sustainable prosperity. Lean construction highlights not only building delivery with less but also contributing to sustainable development. However, lean is criticized for reducing waste only within organizational boundaries while neglecting the impact of waste beyond the boundaries. On the contrary, circularity originates to reduce waste in the system and is currently seeking approaches to implement waste reduction in circular production. To speed up the transition to sustainable resource consumption, the co-act between lean and circular construction seems evident. This research studies resource consumption in product-service systems (PSSs), which are acknowledged to reduce resource consumption. This research first assesses the ability of PSSs to slow and close the loops. After this, the research discusses the complementarities of circularity and lean to co-act toward the same goal. The multiple case studies demonstrate that PSSs have the potential to slow and close the loops. However, PSSs are not inherently circular, but each PSS needs to be designed to be circular system-by-system. Furthermore, the theoretical discussion encourages lean to co-act with circularity. The PSSs provide a system view to lean: to reduce current and future waste and to avoid value losses in multiple life cycles.

KEYWORDS

Circularity, servitization, product-service system, building components.

INTRODUCTION

In recent years, circularity has been introduced as means to sustainability in many scholars, including the built environment and construction studies (e.g., Benachi et al. 2021, Munaro et al., 2020; Ghaffar et al., 2020). For example, Chen et al. (2022) stated that circularity in construction could be "a new model to retain the value of resources and to prevent the use of virgin materials and waste outputs, not only by recycling and reusing of materials but also primary by reducing the need for resources". Furthermore, circularity in general is proposed to be the transformative model for sustainable prosperity (Azevedo et al., 2017; Lacy et al., 2020). Similarly, lean construction literature highlights not only building delivery with fewer resources but lean delivering sustainable prosperity (Huovila & Koskela, 1998; Novak, 2012a; Novak 2012b). At the same time, product-service systems (PSSs) are recognized as an alternative

model to reduce resource consumption while ensuring economic growth (Lacy et al., 2014). In PSSs, commonly known as Product-as-a-Service (PaaS), the customer pays for access to the product and its functionality, which in traditional models are acquired through ownership. When the PSS provider stays the owner of the product, the PSSs provider is incentivized to extend the lifespan and usage of the product and its materials, and to reduce costs (Halme et al., 2004). However, it remains unclear to what extent PSSs are circular (Fernandes et al., 2020; Van der Laan & Aurisicchio, 2020).

PSSs are not widely studied in lean construction literature although servitization in general has started to receive more attention in the construction sector due to the paradigm shift "from delivering a product to satisfy the user needs" (Liu et al. 2021). Servitization in the construction sector is mainly implemented either in the operation phase (such as in maintenance, energy management, or in security), or in production servitization, where "construction activities are conceptualized as construction services" (such as material supply services or computing services) (Liu et al., 2021). To summarize, servitization adds value to the existing products, while PSSs utilize services to contribute to dematerialization.

Although waste reduction is one of the key concepts in lean, lean is criticized for focusing on "the immediate usage of the resource within a specific process" (Nadeem et al., 2019) and missing the system level, i.e., the environmental and economic impact beyond the organizational boundaries (Schmitt et al., 2021). Circularity does take the system perspective when optimizing resource usage from one life cycle to another while (Nadeem et al., 2019). On the other hand, current circularity research is seeking approaches to reduce resource consumption on the process level. Schmitt et al. (2021) stated that lean could "increase the efficiency of all circular flows, thus greasing the wheels of circular economy". For example, Kurdve and Bellgram (2021) studied how lean can operationalize circularity on the shopfloor level. The general complementarities between circularity and lean encourage further investigation of the co-act between circularity and lean construction.

To summarize, both lean and circularity have a common interest to reduce resource consumption. PSSs are argued to reduce resource consumption, but it remains unclear to what extent PSSs are circular. This leads to a twofold aim. First, to assess the ability of PSSs to slow and close the loops according to the circularity principles and second, to discuss the complementarities of circularity and lean to co-act towards the same goal in PSSs. A multiple case study approach was selected to analyze the ability of PSSs to slow and close loops in Dutch rental housing. The Netherlands is experiencing an urgent housing crisis. It is estimated that 900,000 homes need to be built before 2030 to arrange for homes for the increasing population and address the current housing shortage (Ministerie van Binnenlandse Zaken en Koninkrijksrelatie, 2019). At the same time, the Netherlands has set an ambitious goal to improve the energy efficiency of the current housing stock and to develop a circular economy by 2050, and to reduce the consumption of raw materials by 50% by 2030 (Government of the Netherlands, 2016). This also applies to the Dutch housing sector. The ambition to expand and improve the housing stock in the Netherlands can lead to a huge increase in resource consumption but also pose an opportunity for innovation, such as PSSs, and incorporating circular economic principles in residential buildings.

The remaining paper is structured into four parts. First, PPSs are presented including the four models: input-, availability-, usage- and performance-based models. After this, the method section presents the multiple case study method and the selected PSSs. The results outline the ability of PSS to slow and close the loops according to the circularity principles case-by-case and across cases. Finally, the discussion focuses on interpreting the results and theorizing complementarities between lean construction and circularity in PSSs.

PRODUCT-SERVICE SYSTEMS

Historically, the target of the companies has been to sell their products to their customers. In the 1980's and 1990's, many companies searched for solutions to create and capture more value in the competitive market. Within this search, some companies decided to start selling products and services together to better serve their customers. This was discussed as 'servitization of businesses' (Vandermerwe & Rada, 1988) and it is currently gaining increased attention in the race towards circularity due to its ability to reduce resource consumption.

In the traditional economic models, producers are typically motivated to reduce cost via mass production: by providing standard quality without the incentive of providing products with long lifespans (Mont, 2002). Another typical quality in mass-production is that the maintenance responsibility of the product is transferred to the buyer at the moment of the purchase. This all leads to resource-intensive production and consumption. From PSSs perspective, the circular incentives aim to reduce resource consumption through two approaches. In the first approach, the customer owns the product, and the producer offers maintenance and a take-back program for the customer. This approach does not guarantee that the product will be returned to the producer (Van Ostaeyen et al., 2013). In the second approach, the ownership of the product remains for the producer and the customer has access to use the service. This type of ownerless consumption ensures that the product is returned to the producer (Van Ostaeyen et al., 2013). When the producer sees the returned product as an asset and the material is recycled in the next production line, the "take-make-dispose" logic is broken without risking economic growth.

There are four principles to evaluate the circularity ability of PSSs as established by Bocken et al. (2016). The first two principles represent the product's capability to slow and close loops. Product slowing the loops refers to prolonging the use period of the product (Bocken et al., 2016). In the PSSs context, this typically refers to the product's capability to receive preventive maintenance. Product closing the loops refers to reusing the materials through recycling (Bocken et al., 2016). The authors (2016) list three design strategies to close the loops: design for a technological cycle, design for a biological cycle, and design for dis- and reassembly. These strategies enable easy use of the product components or material in the next loop. The last two principles refer to the ability of business models to slow and close loops. When a business model is slowing the loop, it enables a long product life span and reuse of products (Bocken, et al. 2016). For example, the business model allows that the product is used to its maximum, or that the residual value of the product, as Bocken et al. 2016 call it, is (fully) exploited in the same or in another PSS. Finally, the circular business model closes loops, when being able to capture *"the value from what is considered in a linear business approach, as by-products"* (Bocken et al., 2016). In PSSs, this means that the product or its components, and material are recycled.

Four types of PSS systems can be distinguished (Van Ostaeyen et al., 2013): input-, availability-, usage- and performance-based models each characterized by different fee structures and levels of servitization (Figure 1). The servitization level is the lowest in input-based and the highest in performance-based models. Next, these four PSS models are briefly introduced in a housing context.

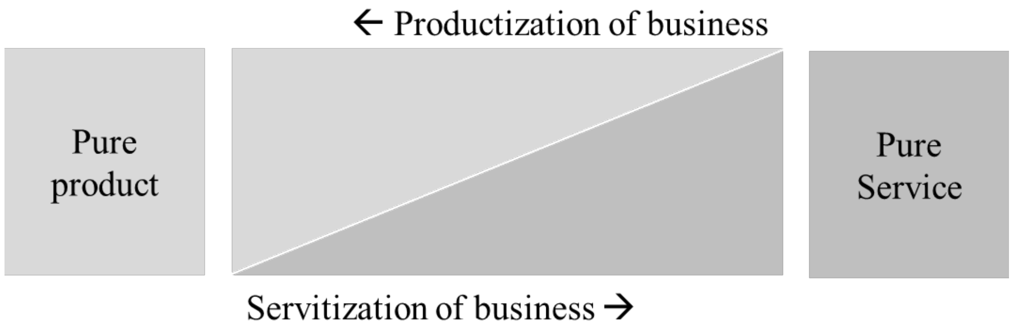

Figure 1: Servitization and Productization (in Parker (2021), based on Vandermerwe & Rada (1988), Tukker (2004) and Leoni (2015).

INPUT-BASED MODEL

In the input-based model, the housing provider owns the product and pays service fees to the PSS provider for the services that are needed to operate the product. The services may comprise, for example, product maintenance, supply of consumables, product's pay-back program, and consultancy services for the user to ensure that the product is used efficiently and effectively (Tukker, 2004). A typical example from the housing sector is a heating boiler that the housing provider purchases, including an agreement for maintenance and inspection and a take-back program at the end of the product's lifespan.

AVAILABILITY-BASED MODEL

In the availability-based model, the PSS provider owns the product, and the housing provider leases it. The fixed recurring fee paid by the housing provider includes the product's availability regardless of how much it is used. In addition, the fee needs to cover the maintenance and repairs that keep the product in operation (Tukker, 2004). Furthermore, for the duration of the model, the availability is only pertained to the one that pays, meaning that the product or is usage is not shared. A typical example in the housing sector is a kitchen that is owned and maintained by the PSS provider and leased by the housing provider.

USAGE-BASED MODEL

In the usage-based model, the PSS provider owns the product, and the housing provider leases it. Compared to the previous model, the major variation is that the housing provider pays for the usage of the product, not for the product's availability (Van Ostaeyen et al., 2013). A typical example in the housing sector is the lease of an elevator: the housing provider pays a lease based on the annual distance traveled by the elevator and the PSS provider retains the ownership and keeps the product in operation.

PERFORMANCE-BASED MODEL

In this model, the housing provider pays a leasing fee to the PSS provider only when a desired performance is attained. In this model, the PSS provider, as the owner of the product, adjusts and maintains the product to attain the required performance level (Tukker, 2004). A typical example of this type of model is companies that do not only provide heating and cooling equipment, but instead provide a defined indoor climate (temperature, humidity, and indoor air quality) (Tukker, 2004). Performance-based housing products were not yet identified within the housing market; thus, this model was excluded from the empirical research.

RESEARCH METHODS

MULTIPLE CASE STUDY APPROACH

PSSs in buildings could target products or services at multiple building layers. A distinction for building layers was discussed by Brand (1994): structure, skin, services, space plan, stuff, and site. Different building layers have different duration of service lives and offer different functions that a building user could enjoy and pay for. For example, renting furniture in an empty home would target the building layer 'stuff', but could be changed based on users' taste in style. On the other hand, the choice of stone or wood for structural and insulation, could not be changed by every new tenant of a buildings' whims. Therefore, the implications for choosing a workable PSS may vary with targeting these different building layers.

To analyze a variety of products from multiple building layers and a variety of PSS models (including input, availability, and usage models), our research follows a multiple-case study approach. Multiple case study design allows replication (Yin, 2013). In this research, this means that the circularity of PSSs is studied among variety of products and business models to make analytical conclusions about the capability of these systems to slow and close the loops. This replication ensures that similar types of findings are found if they exist. Table 1 summarizes the case study selection criteria.

Table 1: Case study selection.

		Cases						
		A	B	C	D	E	F	G
Represents a variety of PSS models:	Input	x						
	Availability		x	x	x			
	Usage					x	x	x
Possible to include both perspectives: housing provider and PSS provider		x	x	x	x	x		

Seven cases were selected to cover the three PSS models: input-, availability- and usage-based models, based on a variety of building layers and PSS types. The size and market position of the housing provider and PSS provider vary per case. In five cases (cases A-E), two interviews were done per case: an interview with the representative from the housing provider and from the PSS provider. In the two cases (cases F-G), the representative from the housing provider was unavailable and the interviews were limited to the representative from the PSS provider. All 12 interviews were conducted in spring 2021 and they were recorded and transcribed for the analysis.

INTRODUCTION TO THE CASES

In this section, all the cases are briefly introduced. In case A, a PSS of two existing elevators in a residential building of 78 apartments is studied. The housing provider owns the elevators and has a 5-year service contract with an extension option with the PSS provider. The housing portfolio of the housing provider includes 10.000+ rental homes, and the housing provider has used PSS before in their portfolio.

In case B, PSS kitchens are studied in a project where an office building was transformed into housing. 15 of the PSS kitchens are based on a lease-to-own service contract with a pay-back program. The housing provider has paid an installation fee to the PSS provider and is also responsible for the recurring service payments. One kitchen is owned by the PSS provider (as a pilot) and the housing provider pays a service fee for it. The housing provider is a small, young organization in the social housing sector managing a 5-year-old, small portfolio of rental homes at the time the case study was conducted. This was their first PSS purchase. The PSS provider is also a beginner in the field and at that moment has installed 10 PSS kitchens.

Case C is also a transformation case from office to housing. In this transformation project, an availability-based model is used for 130 windows. The windows are owned by the PSS provider and the housing provider only pays the recurring service payments – no installation fees or down payments are part of the deal. At the time, the housing provider had a portfolio of 10+ housing buildings and had operated for 12 years. This was their first PSS project. The PSS provider had a long business experience (30+ years), but this was also their first PSS contact.

In case D, the study object is the PSS of a battery storage system in a 50-apartment housing building. The PSS provider owns the battery storage system. The housing provider has paid an installation fee and is responsible for the recurring service payments (no down payments were included). The housing provider has a large portfolio of social rental homes (16.000+), and the PSS provider has sold more than 100 PSS batteries.

Case E is another elevator case study but with a different PSS model: 14 elevators are installed in a new construction project including a total of 485 homes, of which 200 are rental homes owned by the housing provider. In this case, the PSS provider is the owner of the elevators, and the housing provider only pays recurring service payments based on the usage of the elevators – there are no down payments or installation fees for the housing provider. The PSS provider has sold the product (i.e., elevator) for more than 65 years and since 2017 with the PSS model. Their PSS portfolio includes 200+ elevators.

Case F includes the PSS of a heat pump in a housing building including 27 homes. The PSS provider owns the heat pump, and the housing provider only pays recurring service payments based on usage – there are no down payments or installation fees for the housing provider. The housing provider is an association that owns and rents the residential units for long term. At the moment the case study was conducted, the PSS provider has sold this product for 2+ years and installed 3 PSS heat pumps.

In case G, solar panels are installed on the existing residential buildings. The PSS provider owns the solar panels, and the housing provider only pays recurring service payments based on the usage – there were no down payments or installation fees for the housing provider. The housing provider is a long-term owner in social housing and the PSS provider has at that moment sold their PSS panels for 9+ years.

RESULTS

The results are first presented case by case including table 2, which summarizes each case. After this, the results of the cross-case analysis are discussed.

SINGLE CASE STUDY ANALYSIS

In case A, the analysis identifies that circularity is supported through preventive maintenance of the elevator. The input model encourages preventive maintenance, and this maintenance extended the lifespan of the elevator. The interviewee from the housing provider stated: "*They* [=the PSS provider] *have the diagnostics, and they can support us in making the right decisions. And they can also know the equipment that we're replacing and parts we're adding to make the useful life longer*." In other words, the product can receive preventive maintenance and the PSS model offers that maintenance. This slows down the resource loops.

In case B, the analysis finds many circular aspects. The kitchen design itself allows easy repair and maintenance that is also provided through the availability-based PSS model. This means, for example, that the fronts are changed after 5 years if the kitchen is used intensively. In other words, the product and the availability model slow down the resource loops. In addition, the disassembly design of the kitchen and the PSS model allowed the product to be looped into another destination by extending the product value. The PSS provider in case B stated: "*For* *the appliances, indeed, it's all about companies, eventually taking back their product and using it in the highest value possible at the stage. That's either directly using it again, refurbishment, remanufacturing, and you go down the R-ladder in the end, recycle. And that is something that we put in the contract.*" This indicates that the product and the PSS model contribute to slowing and closing the loops.

In case C, the analysis also identifies many of the circular aspects. First, the PSS provider was responsible for keeping the quality of windows as high as possible. The representative of the PSS provider said: "*We have a long-term performance contract with them to keep the quality as high as possible so that we can enlarge the lifespan of the materials*." This means that the product itself and the related service slow down the loops. In addition, both the housing provider and the PSS provider highlighted that the product and/or materials are looped again after the disassembly. For example, the representative of the housing provider stated that "*You push the manufacturer to think about their product, how is this going to be disassembled, how it is going to be brought back in the loop again*" and the representative from the PSS provider stated that *"...100% must be recycled and reused. [...] We set up the new brand, in the DNA is already embedded that we just reuse it till the end*.". This means minimized extraction of natural resources: the business model and the product are closing the loops through looping the products and/or materials and through a principle that only looped products and/or materials are allowed to be used.

In case D, it was not found that the product itself (i.e., the battery) is contributing to slowing or closing the loops, but that the business model is. The availability-based PSS allowed that the PSS provider exploits the residual value of the batteries: the remaining lifespan of the replaced batteries was utilized in smaller systems, where they were still suitable for use. This utilization extended the lifespan of these batteries, i.e., slows down the loops.

In case E, the analysis identifies many circular aspects to slow down and close the loops. As in case A, in this case the lifespan of the elevator is extended through advanced maintenance. In other words, the PSS extends the lifespan of the elevator (slowing the loop). The business models are also aiming to slow down the loops by utilizing the residual value of the materials, including the creation of reverse logistics. The estimation was that "*if these materials are not available anymore, they will become more expensive*", as the representative of the PSS provider in case D stated it. In addition, the product itself and the usage-based PSS, in which the PSS provider is the owner of the elevator, contribute to closing the material loops. It was stated by the representative of the PSS provider that approximately 90% of the elevator parts are recycled and the remaining 10%, that is electronic parts, are not. This contributes to closing the loops.

In case F, the analysis does not identify any circular aspect of the product or the related business model. The business model does provide preventive maintenance, but this maintenance is not expected to extend the lifespan of the heat pump. The material of the heat pump is also not reused or recycled. The PSS provider stated: *"It is very difficult to take out the materials. We've asked now, the heating suppliers, to make a system which can be [a] modular system where you can take out some blocks in 15 years and put in back another, which they do, of course, but they don't do it with the vision of how to reuse [it]."*

In case G, the analysis finds only one aspect that supports circularity: preventive maintenance expands the lifespan of solar panels. The solar panels are designed for preventive maintenance but not for disassembly. This means that the residual value is not utilized and circular input is not generated. The representative from the PSS provider stated: "*Either the solar panels are very good, and everything is normal, so we keep on doing it [...]. Or we reinvest exactly after 20 years, put new panels on, and everything is continued [...]*.".

Table 1: Summary of the case studies.

	Cases						
	A	B	C	D	E	F	G
Product: slowing loop	x	x	x		x		x
Product: closing loops		x	x		x		
Business model: slowing loops	x	x	x	x	x		x
Business model: closing loops		x	x		x		

CROSS-CASE STUDY ANALYSIS

In slowing down the loops, preventive maintenance seems to play a key role in the PSS cases. The business model provides preventive maintenance and extends the lifespan of the product. In addition, due to the circular product design, the product can receive predictive maintenance. Together these aspects slow down the loops. This was found in five cases out of the seven (in cases A, B, C, E, and G). Case D did not follow this logic in slowing down the loops. In case D, the loop was slowed down through the business model that kept the ownership of the product with the PSS provider, who could, after replacement, use the remaining lifespan of the product in another system with another client. This means that the lifespan of the product is used to its maximum, i.e., the business model (not the product) slows the loop.

In closing the loops, the disassembly or deconstruction ability of the product was instrumental in the easy use of the product and its materials in the next loop. In addition, the business model was designed to catch the product from one loop and to deliver it to another through recycling (cases B, C, and E). Contrary to expectations that the usage-based model closes the loops effectively, as proposed for example by Ostaeyen (2013), cases F and G did not contribute to closing the loops: the product, nor the usage-based PSS, were designed for reusing the product or its materials.

To conclude, PSSs have a high potential to be circular when the product and the service in the system are designed for circularity. However, not all PSS are inherently circular meaning that the use of PSSs does not automatically lead to circularity.

DISCUSSION

Within the highlighted role of circularity in sustainable development, PSSs are commonly accepted business models to reduce resource consumption. Based on the existing literature, it was expected that the utilized circularity principles are increased when moving in the PSS axis of input-availability-usage. However, this was not the case in this research, where the 7 PSS cases were conducted and analyzed. The results imply that the PSSs are not inherently circular, but each PSS needs to be designed to be circular system-by-system. Similar results can be found in the literature (e.g., Blüher et al., 2020; Tukker and Tischnener, 2006). The results do not imply that PSSs should not be used to contribute to achieving circularity but that the PSSs need careful design at all the stages of design.

This paper claims that PSSs provide an example for circularity and lean construction to co-act towards the same goals – to reduce resource consumption and to deliver sustainable prosperity. Benachio et al. (2021) studied "the interactions between lean construction principles and circular economy (CE) practices". We see these interactions as natural interfaces for circularity and lean construction to co-act and supplement each other. In their paper, Benachio et al. (2021) recognize the CE practice that is studied in this paper: ownerless consumption, where the manufacturer stays the owner of the material. Benachio et al. (2021) refer specifically to the moment after the end-of-life of the first building meaning that the manufacturer takes responsibility for and makes an opportunity at the first looping moment. In PSSs, the system can take on this responsibility, when, as the cases A-E and G illustrate, the product and/or the business model are designed for that. For example, in case C the manufacturer carried on the responsibility of the first loop of the windows as was also done in case D with the battery although the product itself did not support circularity.

After studying circularity in PSSs, the discussion is moved to postulate key complementarities between circularity and lean in PSSs. In general, lean and circularly deal with two key concepts – value and waste – but have major differences in embracing these concepts. Complementarities can be explained via these concepts.

In lean, value is defined by the customer (e.g., Womack and Jones, 1996; Ballard et al., 2001; Salvatierra-Garrido et al., 2008) and the flow is made at the pull of the customer (e.g., Womack et al., 1990; Howell and Ballard, 1998). In circular terms, material is seen as a source of value, and the value of resources is used to the maximum in the life cycle of the material (Nadeem et al., 2019; Bocken et al., 2016; Schmitt et al., 2021). Nadeem et al. (2019) interpret this as a limitation and argue that this kind of “highest utility of resources all the time” accelerates the resource depletion. In closed loops, the circular philosophy highlights upcycling meaning that in recycling and reusing the value of the material should be retained or improved (Bocken et al., 2016). To conclude, the concept of value in circularity does not include the customer’s perspective and the concept of value in lean does not include the maximum use of the material value.

In PSSs, the two value concepts complement each other. According to Romero and Rossi (2017), PSSs deliver value-in-use. From a lean perspective, the PSS extends the concept of value from one life cycle to another, for example by utilizing the residual value of the product in another system (such as in cases D and E). In terms of lean, the use of the residual value would avoid future value losses. From a circularity perspective, PSSs ensure that only the needed resources are consumed. PSS makes sure that the resource is consumed at the time it is needed (i.e., at the pull).

Similarly, waste is seen differently. In lean, waste refers to the use of more than needed and unwanted output (Bølviken et al., 2014). Furthermore, the non-value-adding activities are removed through continuous improvement (in Japanese kaizen) (Imai, 1997). Waste in circularity has another meaning. In a closed-loop system, waste from one life cycle is used as a resource (i.e., source of value) in another life cycle. Wasted resources are transformed into new forms of value, as outlined in Bocken et al. (2016). By slowing the loops, the prolonged use postpones the end of the resource’s life. When products and parts are designed for dis- and reassembly, they are easily looped in other cycles (Bocken et al., 2016).

In PSSs, the waste concepts complement each other. The concept of waste from lean can improve the operational efficiency of PSSs. Romeno and Rossi (2017) have studied circular lean PSSs and they claim that lean can eliminate “waste in the manufacturing activities and services operations that affect the PSS efficiency”. Unfortunately, circular systems do not widely acknowledge that resources are wasted in the circular processes themselves. Korhonen et al. (2018) stated that “all CE-type initiatives, projects and activities generate environmental impacts and consume resources”. In the PSS cases, the production of circular elevators, windows, or kitchens consumes resources, as does the preventive maintenance of these products. Lean focuses on throughput optimization on the shopfloor (Schmitt et al., 2021). Therefore, the concept of waste lean can complement circularity by operationalizing waste reduction on the shop floor and increasing the operational efficiency of the circular production system itself (Schmitt et al., 2021).

The circularity of PSSs complements the concept of waste in lean. PSSs provide a system approach to lean, not only to reduce resource consumption in the current process but from one life cycle to another. This means that future waste is reduced, when the product is designed for dis- and reassembly and thus easily reused, recycled, or remanufactured. To be circular, lean needs to build its reserve production practices.

CONCLUSIONS

Within the highlighted role of circularity in sustainable development, PSSs are commonly accepted business models to reduce resource consumption. In lean construction, PSSs as such are not highlighted. Therefore, this paper first assessed the ability of PSSs to slow and close the loops; and after this, discussed the complementarities of circularity and lean to co-act towards the same goal. A multiple case study approach was followed.

The case studies imply that PSSs are not inherently circular, but each PSS needs to be designed to be circular system-by-system. This does not imply that PSSs should not be used to contribute to achieving circularity, but that PSSs need careful design at all the stages of design. Furthermore, the theoretical discussion encourages lean to co-act with circularity in PSSs. PSSs provide a system view to lean: not only to reduce resource consumption and deliver value in the current processes but also from one life cycle to another. This would mean that future waste is reduced and that the value losses are avoided when the value of resources is fully exploited. For circularity, lean offers an approach to reduce resource consumption in the circular processes themselves by operationalizing waste reduction on the shop floor. Furthermore, the integration of the customer's perspective into the concept of value ensures that circular products are used at the pull of the customer. It is advisable to investigate these complementarities not only systematically further within a PSS but also between PSSs.

The paper has its limitations. First, the research on PSS types in the building context is quite novel empirically, rendering only a handful of cases that can be easily studied. The case selection is limited to the input-, availability- and usage-based PSS models since no performance-based models were available for this study. Secondly, this research is limited to qualitative assessment of resource consumption based on interviews. In future studies, quantitative data are needed to assess the effectiveness of PSSs in reducing resource consumption. Thirdly, as many organizations are still new to the PSS workings, the results may themselves have an impact on how practitioners are still learning and working with these business models. Fourthly, the notion that the design of the model has an influence on its ability to achieve circularity, implies that more design choices need to be explicit for this relation to be studied more targeted. Lastly, the lean analysis was not part of the original data analysis in the cases. This limited the lean discussion on the theoretical level urging to continue studying the topic with real cases in the future.

Recommendations resulting from the study include a few notable directions. First, as more applications in practices are piloted and upscaled, research studies like these need to keep pace with the collective learning, if we are to generalize the true nature of PSS on circularity. Second, more emphasis in future studies needs to be performed on the specific design choices for PSS applications, the object, and the level of achieved or intended circularity. Lastly, due to circularity and lean acting alone towards the same goal, it would be interesting to further explore the co-acting possibilities between lean and circularity in the construction sector. Alone the journey towards delivering sustainable prosperity might be faster, together we might go further.

ACKNOWLEDGMENTS

This paper is based on a graduation thesis entitled 'To lease, or not to lease? A critical evaluation of Product-Service-System building components in rental housing' by David Parker. The graduation was part of the Management in the Built Environment at Delft University of Technology and was conducted during autumn 2020 - spring 2021.

CHOOSING BY ADVANTAGES (CBA) TO SELECT THE BEST LOCATION FOR A SOLAR PHOTOVOLTAIC PLANT IN THE PRE-FEASIBILITY STAGE

Kevin Aza[1], Andrews A. Erazo-Rondinel[2], Lao J. Li-Albrizzio[3], Mauricio A. Melgar[4], and Anthony F. Paucar-Espinoza[5]

ABSTRACT

The energy transition from fossil fuels to pollution-free and sustainable energy has been a common goal for all countries worldwide. In line with this transition, the Peruvian industry and many others worldwide seek to develop new renewable energy projects. Solar photovoltaic energy is the preferred option due to the significant potential in its territory. This research aims to show the application of the CBA methodology in selecting the best location for a solar Photovoltaic (PV) plant to develop a pre-feasibility study whose area of interest are the Peruvian Andes. The analysis was based on identifying the advantages of each factor considered in evaluating the best sites for the location of a solar PV plant. The results showed that the CBA methodology is very important when performing pre-feasibility studies for solar PV plants, where costs do not make substantial differences between alternatives. This research will be a valuable tool for the community of professionals in developing renewable energy when performing pre-feasibility studies in which there needs to be more information on the area of interest. The aim is to define the location with the best solar photovoltaic potential.

Choosing By Advantages, Solar PV Plant, ubication, Lean Construction, Sustainability, decision-making.

INTRODUCTION

Energy consumption by the world's population has increased exponentially in recent years, so the search for new energy sources, preferably renewable and non-polluting, has become necessary. Solar energy has been approaching as a solid response to the problem and has gained ground in the main first-world countries, spreading over the years to developing countries (García de Fonseca et al., 2019). However, constructing facilities for energy generation using

solar panels, which capture sunlight and convert it into energy, has required rigor and demand for the correct energy supply to society. Determining the best construction location for the solar plant is one of the critical points when seeking to generate energy (Aly, 2017) since it influences the technology of solar panels, the amount of energy produced, ease of construction, and economic costs, among others.

That is why different researchers have applied mathematical methods to select the location of a solar plant. Wang et al. (2018) proposed using a Multi-criteria Decision-making model (MDCM) that combined three methodologies, including Data Envelopment Analysis (DEA), Fuzzy Analytical Hierarchy Process (FAHP), and Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS). On the other hand, Sánchez-Lozano (2013) proposed combining the Geographic Information System (GIS) and MDCM methods such as AHP and TOPSIS. The aforementioned mathematical methodologies are the ones that are mainly used in research on the selection of the location of solar plants.

Although these applied mathematical methods help us decide, they do not adapt to different cases or extract the project context (Martínez et al., 2016). One method adapted to the projects and the context is Choosing By Advantages (CBA), a decision-making system developed by Suhr (1999), whose importance lies in the advantage of the factors rather than the factors themselves. CBA has applications in different topics, including those related to sustainability.

Goh et al. (2022) apply CBA for the selection of the location of a solar plant in Southern California, USA, during the feasibility stage. This application of CBA is focused on a reality that has different characteristics, first at the level of development phases (the information available at a feasibility stage is very different from that of a pre-feasibility stage), and then at the country level, considering the deficiencies in Peruvian regulations regarding the promotion of renewable energies. (Gamio et al., 2017). The study of the quantification and tabulation of meteorological data from stations between 1975 and 1990 (Tamayo, 2011) determined that compared to other countries, Peru has solar energy availability in almost all of its territory, being large and uniform throughout the year (SENAHMI, 2003).

Therefore, the following research aims to implement CBA for the selection of the location of a solar plant in Peru in the pre-feasibility stage. To this end, a literature review on the decision-making methods in solar plants is carried out, followed by the implementation of CBA. Then the results are discussed to evaluate whether the factors change by geographical location and project development stage.

BACKGROUND

In this section, the authors will initially discuss Choosing by Advantages (CBA) due to its relevance to understanding the difficulties in determining a construction site for a photovoltaic solar plant.

DECISION MAKING IN SOLAR PLANTS

The appropriate location of a solar PV plant is the most critical decision in project design and subsequent construction (He-Yau & You-Jyun, 2017). Thus, some authors have developed different decision-making methods to solve this problem. One example is El-Azab & Amin (2015), who proposed an algorithm to optimize the selection of locations to build a solar plant in North Africa and the Middle East and applied it to a case study in Egypt. The algorithm defined the average global solar radiation for each day, calculated the transmission losses, and calculated the average energy generated in a year. Finally, the net transmitted energy of all alternatives was compared to choose the option that generates the most energy in a year.

Thongpun et al. (2017) used the DEA method to select the location of a solar plant in Thailand based on the efficiencies of plant sites in 77 provinces in Thailand. Factors affecting the efficiency of solar panel systems, energy output power, and solar plant area selection were considered: resource availability, economic impact, environmental concern, social concern, and accessibility. Once the study was completed, efficiency percentages were obtained for a linear and non-linear DEA model.

Rezaei et al. (2017) investigated seven regions in the Iranian province of Fars to assess the best location for constructing a wind-solar hybrid power plant. Wind and solar potential were considered the most critical factors. This information was obtained using the Weibull distribution function and the Angstrom-Prescott equation in the Meteorological Organisation of Iran database from 2006 to 2015. The method consisted of using fuzzy TOPSIS for data analysis and ranking, then MCDM methods (AHP, DEA) were used to verify the results obtained.

Lee, Kang, and Liou (2017) propose a multi-criteria decision-making model to choose the best construction site for a photovoltaic solar plant in Taiwan. The model consists of using interpretive structural modeling (ISM) to determine the interrelationship between criteria and sub-criteria, then using fuzzy analytic network process (FANP) to obtain the weights of the sub-criteria, and finally, multi-criteria optimization and compromise solution (VIKOR in Serbian) to rank the photovoltaic solar plant locations. After the application, it was obtained that the most important criteria were costs and physical environment. At the same time, the most critical sub-criteria were land utilization, land cost, repair and maintenance cost, and soil quality.

Rediske et al. (2020) proposed a model for the location of photovoltaic power plants in the central region of Rio Grande do Sul - Brazil. The model consists first of an area analysis with the gvSIG software, using the AHP method to give weight to each factor, and finally using TOPSIS for the order of alternatives. An area of 1823.35 km2 was studied, determining that 19.91% was excellent for the location of a solar plant. They considered the most critical factors of the environmental type, location, climate, geomorphological, Substation Distance, and Solar Irradiation.

CHOOSING BY ADVANTAGES & SUSTAINABILITY

CBA is a multi-criteria decision-making system based on the importance of "advantages" between alternatives (Suhr, 1999), which includes principles and definitions, where models, methods, tools, and techniques are also concentrated. The CBA system includes methods for virtually all decisions, from the very simple to the very complex. Among all these methods, Arroyo (2015) indicates that the most used is the Tabular CBA Method. In the construction industry, there are many applications where this method can be used; mainly, it has been applied in different sustainable decisions, showing many benefits, for example:

Arroyo et al. (2013) applied this method to improve decision-making in selecting ceiling tiles, showing benefits such as identifying relevant sustainability factors, providing documentation for rational decision-making, and identifying relevant advantages to make transparent, transparent, and conflict-free exchanges between options. Also, Arroyo et al. (2015), in a commercial interior design project, chose a sustainability alternative for roof tile materials; the study contributed to knowledge by integrating stakeholder perspectives considering sustainability factors, identifying sustainability factors according to context, and how to discriminate IofAs, among others.

Arroyo et al. (2016) compared CBA and Weighting Rating and Calculating (WRC) in groups of professionals to make decisions involving sustainability factors in architecture, engineering, and the construction industry.

Torres-Machi et al. (2019) evaluated the sustainability of pavement management decisions. AHP and CBA are used in a case study comparing pavement maintenance technologies using cold-in-place recycling and traditional solutions based on mill and overlay.

Perez and Arroyo (2019) used CBA and Design Structure Matrix (DSM) to redesign the waste collection program. CBA was used for three complex decisions and supplemented with

DSM to decrease negative iterations by finding the proper order of decisions. By applying CBA, sustainability solutions are achieved, and by applying DSM, it was possible to solve the problem of being able to consider decisions.

Milion et al. (2021) used CBA to classify the impact of defects in residential buildings and improve sustainable managerial decisions where risk can affect the quality of projects from the customer's perspective.

Finally, Goh et al. (2022) apply CBA for the selection of the location of a solar plant in Southern California, USA, during the feasibility stage. Through an exhaustive literature review, Goh et al. (2022) identified the different factors in their decision-making. The factors that obtained a higher score for decision-making are in the following order: solar irradiation potential, policies, and payback period.

RESEARCH METHODOLOGY

CASE STUDY

The case study is selected due to the importance of solar PV energy in the energy development strategy (Goh et al., 2022). The case study consists of a project for a Potential Study (typical of a pre-feasibility stage) for the conception and development of a solar PV plant in the Andean region of Peru. Therefore, the two most relevant aspects for the project owner were: the location of the asset (close to important cities in the Andean region of Peru) and the capacity and energy yield of the solar PV plant. However, due to the experience and knowledge of the professionals involved in the project (technical staff), additional criteria were established for developing an asset of this type. Therefore, the area of interest had to be studied for different location options.

Thus, four alternatives with appropriate characteristics and conditions for a solar PV project are proposed, from which the best one has to be chosen. For this reason, it is necessary to consider a methodology that enables one to decide based mainly on value, which will be discussed in more detail in the following sections.

CHOOSING BY ADVANTAGES

For the CBA application to determine an optimal construction site for a photovoltaic solar plant, the decision involved the participation of an electrical specialist, a geographic information specialist, a hydrological specialist, a geotechnical specialist, and a renewable energy specialist. Due to the fundamental role of the participation of the professionals involved in the project in defining the context of the decision (Martinez et al., 2016), the CBA Tabular Method allows for capturing the perspectives of decision-makers with different opinions. The steps involved in applying the CBA Tabular Method are detailed in the seven steps indicated in Figure 1:

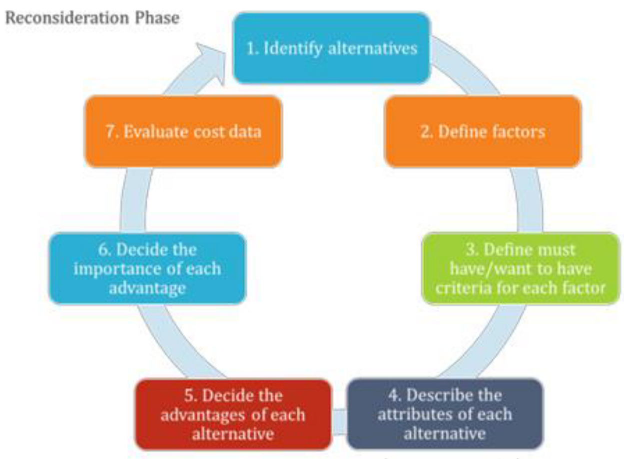

Figure 1: CBA Tabular Method steps (Arroyo, 2022)

The application of the steps of the CBA Tabular Method in the case study will be explained below:

Step 01: Identify the alternatives

A preliminary analysis is made in an area near major cities in the Andean region of Peru. Next, a suitable construction site is sought for the location of a photovoltaic solar plant. In this step, the project team identified four zones as alternatives (Table 1).

Table 1: Alternatives of Case Study

Alternatives	Description of the alternative
Alternative 1	Location A in the central Peruvian Andes, of approximately 888 hectares.
Alternative 2	Location B in the central Peruvian Andes, of approximately 1375 hectares.
Alternative 3	Location C in the central Peruvian Andes, of approximately 694 hectares..
Alternative 4	Location D in the central Peruvian Andes, of approximately 975 hectares.

Step 02: Define the factors

The project team needs to identify factors that support discerning the best alternative among those listed. Following the review of relevant literature and consulting with industry experts, six essential factors for site selection are suggested as follows in Table 2:

Table 2: Factors of Case Study

Factor	Unit of measurement	Description of the factor
The slope of the land	The measure of slope [%]	It is essential to know the slope of the land when the owner wants to build a solar PV plant on the site because the lower the slope, the shading effect will be. The slope also affects how it will be built (whether it will require additional work) or whether the land is appropriate for construction.
Distance to the connection point	The measure of distance in Kilometer [km]	The distance to the connection point (electrical substation or transmission line) where the energy will be directed must be considered when designing the solar PV plant. The longer the distance, the higher the transmission losses.
Availability of area for future expansions	The measure of surface area in Hectare [Ha]	The project owner has expressed his long-term interest in further developing photovoltaic generation in the country. Thus, this project would be a first step in its strategy and seek to expand the solar PV plant in the coming years.
Condition of access routes	-	The condition of the main access roads to the alternatives is important to make the most efficient choice. Poor road conditions can cause problems during the construction of the solar PV plant.
Power generation	Amount of energy generated (kWh) per installed capacity (kWp) (Specific	Solar power generation is a crucial factor, as this influences the capacity and energy yield of the future solar PV plant.

	energy production) [kWh/kWp]	
Presence of protected ecosystems	-	The presence of protected or endangered flora or fauna within or near the solar PV plant in a country as biodiverse as Peru implies elaborating a detailed environmental management plan, a series of inconveniences with land use permits, or even the impossibility of using the site for a photovoltaic generation.

Step 03: Define the criteria for each factor

The criteria to select the best alternative among the four available are based on the degree of impact on the project's viability. These have been based mainly on the Preliminary Selection Criteria, the analysis criteria of the field visit, and the estimated generation in the Preliminary Evaluation of Photovoltaic Energy Production (shown in Table 3).

Step 04: Describe the attributes of each alternative

The information collected from the four alternatives is used to obtain the attributes according to the factors and their criteria mentioned in the previous steps. The least preferred attribute is underlined and will serve as a point of comparison to describe the advantages (shown in Table 3).

Step 05: Decide the advantages of each alternative

Criteria are applied to identify advantages. In this case, the team first identified the least preferred attribute, highlighted it, and then used it as a basis for the comparison with the other attributes in each factor. Then, differences are defined as the advantages of the alternatives. The most significant advantage for each factor is shown in red and italics in Table 3.

Step 06: Decide the importance of each advantage

This part of the process is collaborative, and decisions are reached through discussion within the project team and the technical staff. A factor listed the most preferred advantages, and they are given an order of priority to define which are the most relevant when choosing an alternative.

Subsequently, a ranking is generated with weighting where the IoA (Importance of Advantage) is defined as the supreme advantage (a most important advantage when the decision is made) with a value of 100. Then, the IoAs of the other most preferred advantages is defined, always having as reference the value of the supreme advantage. Finally, with the IoAs for the most preferred advantages already defined, the IoAs for the other advantages were calculated proportionally (shown in Table 3).

Table 3: Evaluation using CBA Tabular Method

Factor (Criterion)		Alternative 1		Alternative 2		Alternative 3		Alternative 4	
Land Slope	Att.:	**3% - 5%**		**5%-10%**		**5%-10%**		**3%-5%**	
(The less, the better it is)	Adv.:	It has less slope	Imp 40		Imp		Imp	It has less slope	Imp 40
Distance to connection point	Att.:	35 Km		**11 Km**		29 Km		**47 Km**	
(The closer, the better it is)	Adv.:	12 Km closer	Imp 20	36 Km closer	Imp 60	18 Km closer	Imp 30		Imp
Area availability	Att.:	888 Ha		**1375 Ha**		**694 Ha**		975 Ha	
(The more available, the better)	Adv.:	194 additional Ha	Imp 3	661 additional Ha	Imp 10		Imp	281 additional Ha	Imp 4
Condition of access roads	Att.:	Medium		**Bad**		Medium		**Good**	
(The better condition, the better it is)	Adv.:	Better condition	Imp 20		Imp	Better condition	Imp 20	Much better condition	Imp 30
Energy generation	Att.:	**2121.7 kWh/kWp**		2174.9 kWh/kWp		2252.1 kWh/kWp		**2313.7 kWh/kWp**	
(The more it generates, the better it is)	Adv.:		Imp	53.2 kWh/kWp more	Imp 28	130.4 kWh/kWp more	Imp 54	192 kWh/kWp more	Imp 100
Presence of protected ecosystems	Att.:	**Not found**		**Yes**		**Not found**		**Not found**	
(The less presence, the better it is)	Adv.:	Less presence	Imp 50		Imp	Less presence	Imp 50	Less presence	Imp 50
Total IoA		133		98		154		224	

Step 07: Evaluate cost data

In this step, the project team did not evaluate costs because this research is related to the pre-feasibility stage of a project to construct a photovoltaic solar plant. At this project stage, costs do not generate differences between alternatives, so selecting the best alternative was based only on value.

DISCUSSION

In order to select the 4 study alternatives, an exhaustive search had to be carried out in the area of interest so that, based on the established factors and criteria, four sites with attractive attributes could be determined for further study.

Thus, the application of the CBA Tabular Method for the selection of the best alternative for the location of the solar PV plant has proved to be convenient, as it has taken into account factors typical of a pre-feasibility study that can lead the way for the large-scale development of solar PV projects and, why not, also of renewable energy projects in general in Peru.

In this way, it was possible to define the advantages of each factor considered, which is classified by the technical staff who adopted the methodology with great enthusiasm. In Peru, value is only sometimes prioritized in engineering and construction projects. Therefore, some benefits gained were training staff in CBA and identifying the value of each alternative in an engineering project. Meanwhile, barriers to implementing the CBA method were the initial unwillingness of top management to leave conventional methods behind and the time for staff training in CBA.

During this discussion, it was determined that energy generation was a preponderant factor in the project's conception. It will be the source of income that will make the project viable throughout its useful life and is closely linked to the other factors. The other factors were also considered relevant in the analysis, but taking into account that, for example, there are projects by the Peruvian State for the improvement and expansion of the National Interconnected Electricity System and the National Road Network; these will eventually have a lower preponderance than energy generation.

Compared to Goh et al. (2022), who conducted similar research where they applied CBA for the location of solar panels in Southern California in San Bernardino and Riverside counties, the research has shared certain factors.On the one hand, while in the present investigation, the factor of "power generation" has been taken into account, Goh et al. (2022) considered the "solar irradiation potential" factor, both alluding to the fact that it is important to consider the amount of energy that would be produced due to the position of the solar plant that would allow it to capture the most significant amount of sunlight.

Another couple of factors that are also similar between the present investigation and the investigation in California are, respectively, "Condition of access routes" and "Distance to roads/substations." Both factors refer to the fact that it would be more appropriate to select a place with easy access to reduce as much as possible the costs of transporting materials or equipment and to facilitate the construction of the plant. Regardless of the context of the work, the factors mentioned above will likely be considered when deciding the location of the solar plant due to its high impact on value generation. However, other factors may or may not become part of the analysis, depending on the context of the decision that comes to be considered when applying the CBA (Martinez et al., 2016).

Goh et al. (2022) mentioned that sixteen factors were obtained to apply the CBA, which were obtained due to the assistance of experts and important institutions worldwide. For that reason, special consideration was not taken to the context of the place. On the other hand, the present investigation considered only six factors that are focused on the context of the project. For this reason, there is a big difference between the factors used in both investigations. For example, we have the factor "availability of area for future expansions," which is essential in selecting this research because the project owner has shown great interest in expanding the photovoltaic solar plant. Another example would be the factor "presence of protected ecosystems," which has a high preponderance in the study area due to the high biodiversity in the flora and fauna of Peru. Likewise, the main factor was power generation, which has also been considered by similar investigations that applied other MCDM methods, such as Rediske et al. (2020), Rezaei et al. (2017), Sánchez-Lozano (2013), among others.The factors that are most often repeated in this type of research are "solar irradiation," "distance to roads," and "distance to substations." In addition, in some studies, the "slope" and "distance to power lines" are considered, as in the present investigation, and others, the "agrological capacity" is considered instead.

However, the main difference between Goh et al. (2022) and the present paper is the information required for the analysis. While Goh et al. (2022) propose an analysis with 16 criteria, in which data from a feasibility study are framed, where the technical characteristics of the location are known, in this paper, we intend to establish the analysis based on identifying the potential of different locations within an area of interest, considering that the information that may be at hand (such as geology, connection conditions, among others) is minimal or non-existent. Basic design criteria will be considered for this selection.

CONCLUSIONS

The application of the CBA Tabular Method enabled selection of the best location for a solar PV plant in the pre-feasibility stage, considering the Andean region of Peru as the area of interest. As part of this analysis, it was determined that Alternative 4 is the best located for the rest, standing out mainly for its energy generation and its low slope. Other factors in its favor are the good condition of its accesses and the absence of protected ecosystems within or near the alternative. As factors in which it does not have an absolute advantage over the rest, we can mention a smaller area available for expansion (compared to Alternative 2) and the distance to the connection point. These factors should be re-evaluated later (during feasibility) to determine whether they can improve their contribution to the value of the project.

This study aims to contribute to developing renewable energy projects at a preliminary stage (pre-feasibility), mainly in Peru, which has one of the world's most considerable solar PV potentials (Gamio, 2017). It also seeks to promote the use and study of the CBA decision-making system in various industry and engineering sectors, applying it in this case to a project closely linked to sustainability, climate change, and energy transition.

The results obtained indicate that the application of the CBA Tabular Method helps to select the best alternative for the location of a solar PV plant based on the value it provides, considering that in the development of pre-feasibility studies, the costs are referential and do not mark essential differences between the alternatives.

Likewise, the authors suggest implementing other lean principles in solar plants: process management in the evaluation of photovoltaic solar assets (value stream mapping), implementation of the last planner system in the construction of photovoltaic solar plants, application of lean project delivery system in the development of photovoltaic solar projects and others. Specifically, as the next steps for extending this research, further research on selecting equipment (technology) in solar photovoltaic plants and applying Choosing By Advantages decision-making system should be performed.

ACKNOWLEDGMENTS

The authors would like to thank the technical staff who were part of the decision-making process and all the team who were part of the project.

ANALYSING FILM PLASTIC WASTE IN RESIDENTIAL CONSTRUCTION PROJECT

Krishna Chauhan[1], Antti Peltokorpi[2], and Olli Seppänen[3]

ABSTRACT

Sustainability and lean construction are closely interrelated topics to consider. However, sustainability issues in construction projects are rarely discussed in International Group for Lean Construction (IGLC) community. The major aim of this research is to analyze the film plastic waste in residential construction project. For the analysis, three cases were selected, where the amount and quality of film plastic waste were investigated from the beginning of project to the end. According to the results, 1009–1710 kg of film plastic waste was separately collected (about 0.5–1.0% of total waste). In addition, the generated pattern of film plastics was approx. 0.34 kg/m2 and each apartment generated approx. 26.20 kg. The most film plastic is generated in the interior phase of the work stage, which includes tasks such as partition work, furniture installation and home appliance installation. Furthermore, based on the results of this research, we have developed a preliminary web modelling tool: kalvomuovi.fi, which could be adopted for estimating the amount of film plastic waste in a residential construction project. Future research could further develop the web model tool for other type of construction projects, such as, schools, hospitals, and shopping centers. Also, future research is necessary to develop better recycling technology of film plastic waste.

Green construction, film plastic waste, modeling platform- kalvomuovi.fi, lean construction

INTRODUCTION

Green construction and plastic use are currently an issue of major concern that has sought significant attention of media, policymakers, environmental activists, as well as academic practitioners (Mikkonen et al., 2020; Häkkinen et al., 2019; Ramboll, 2020; Yle, 2021). The main concern with the dramatic increase in the use of plastic has been its significant and adverse effect on human health, as well its potential contribution to climate change and environmental degradation and toxicity.

According to Material Economic (2018), the plastic use is increasing by 10 million metric tonnes per year, and it is estimated to reach 800 million metric tonnes per year by 2050. The plastic industry is intricately linked to the global economy. It is considered the seventh most value-adding industry in Europe, which consists of about 60000 companies and provides about 1.5 million jobs with a value of about 350 billion euros (Häkkinen et al., 2019). Muoviteollisuus (2021) estimates that in Finland the plastic industry consists of almost 600 companies and employs over 10,000 people. It is estimated that, on average, Finnish residents produce about 15 kilos of plastic waste per year (Yle, 2020). In response to this problem, Kosonen and Varis

3 Associate Professor, Department of Civil Engineering, Aalto University, Finland, Olli.Seppänen@aalto.fi

(2019) presented a plastic roadmap for Finland, which suggests several actions for reducing, reusing, recycling, and replacing plastic.

Due to various advantageous properties of plastic, such as lightweight, flexibility and dielectric properties, it has been used in different applications. Häkkinen et al., (2019) mentioned that about 45 % of plastic is used for packaging, 19% is used for construction, 12 % in consumer products, 7% in transportation, 4 % electronics and 12 % is used for other applications. They further indicated that a very small portion (about 10%) of plastic is recycled while the rest is discarded which ultimately end up in landfill.

The use of plastic in building and construction improves the physical health of a building by ensuring good thermal moisture and gas insulation performance (Schiavoni et al., 2016). In construction, plastic is used in building products and materials, for instance, flooring, windows, insulation products, and kitchen. Plastic is present in construction products, as a building material, and film plastic is also used for packaging construction materials.

In fact, it has been argued that film plastic is used significantly in construction activities, for instance, for construction product packaging, site workers' food packaging, and also during different work stages (Ramboll, 2020). A few studies have analysed the plastic packaging waste in construction (E.g. Pericot et al, 2014; Pericot and Merino, 2011; Selke and Culter, 2016). They mention that primarily plastic packaging waste were the films. However, their results include the sheets and rigid forms of packaging plastics (e.g. crates). Also, the research on packaging plastic waste excludes the films produced on site, for instance, films used in site protection and site works and activities. Film plastic normally ends up in the landfill due to difficulties in the recycling centres. For all those reasons, research on film plastic waste is explicitly necessary. To the best of our knowledge, till date there has been no research on the use of film plastic in construction. Specifically, this research aims at answering the following research questions:

- How to collect film plastic waste from a construction site?
- How much film plastic waste is created in construction projects (mostly residential)?

THEORETICAL BACKGROUND

PLASTIC IN CONSTRUCTION

According to Plastic Europe (2020) about 4000 million metric tonnes of plastic was produced from 1950 to 2019. This amount mainly includes, polypropylene (PP), polyvinylchloride (PVC), polyethylene (PE) polyethylene terephthalate (PET), polyurethane (PU), polystyrene (PS), and polyester (PES) (Häkkinen et al., 2019; Napier, 2016). Table 1 presents the plastic type composition, physical properties, and possible application in construction.

Table 1: Plastic types and possible application in construction (Awoyera and Adesina, 2020

Plastic types	Physical properties	Application in construction
HDPE	Rigid	Table, chairs, plastic lumber
LDPE	Flexible	Bricks and blocks
PP	Hard and flexible	Aggregates in asphalt mixture
PS	Hard and brittle	Insulation material
PET	Hard and flexible	Fibres in cementitious composites
PC	Hard and rigid	Aggregates in cementitious composites

Even though various types of plastics are used in the construction sector; PVC, Polyethylene-high density (PE-HD), Polyethene low density (PE-LD), PP and EPS (Expanded Polysterene) are mostly common. Table 2 presents the types of plastic generated in the building and construction sector in the EU in 2018 (Plastic Europe, 2019).

Table 2: Building and construction plastic waste generation in the EU in 2018 (in kt)

Plastic types	Total waste generation	Recovery	Disposal/landfill
PE-LD	90	70	20
PE-HD	225	164	61
PP	130	95	35
PS	30	21	9
EPS	140	95	45
PVC	910	683	228
Other	235	172	63
Total	1760	1300	461

Plastic quantity used in construction depends on building types, products, and work stages. For instance, Monahan and Powell (2011) estimated the use of plastic to be 7.4 kg/m2 in a model-house study. Ruuska and Häkkinen (2015) presented 12-21 kg/m2 in a block of flats. Furthermore, Jeffrey (2011) argued that approximately 1% of total construction demolition to be of plastic. Similarly, Häkkinen et al., (2019) evaluated the quantity and types of plastic in concrete and wooden residential buildings and day care centres. Their findings showed plastic quantity to range from 6 to 28 kg per gross m2.

FILM PLASTIC IN CONSTRUCTION

The demand for film plastic is increasing worldwide. For instance, in 2015, the film plastic demand rose in Asia by 40% and in Western Europe and North America the demand was equally significant (18%) (Stastista, 2015). The increasing demand for film plastic is associated with its diverse applications. Essentially, such applications can be divided into two groups: packaging and non-packaging. In packaging, film plastic is used to protect the product itself, which is called primary packaging, and also film plastic is for safe transportation of the product as a secondary packaging (Hellström and Sagir, 2007; Horodytska et al., 2018). Non-packaging use includes, for example, films from construction, agriculture, trash bags, etc. In general, all plastic could be formed into film plastic, however, based on the polymer application, films from the PE-HD, PE-LD ja PE-LLD (polyethylene linear low-density) is mainly used in construction (Headley Pratt Consulting, 1996; Polymerdatabase, 2021).

Some studies have analyzed the packaging waste in construction. They generally include cardboard, woods, and plastic (Pericot et al., 2014; Pericot and Merino, 2011; Selke and Culter, 2016). Perico and Merino (2011) presented the the packaging waste generated in three construction site cases: 1) 100 social housing projects, 2) 118 dwellings and 3) 112 housing construction projects (table 3).

Table 3: Packaging waste in construction projects in Spain

	Cardboard		Muovi		Wood	
Cases	Weight (kg)	Volume (m3)	Weight (kg)	Volume (m3)	Weight (kg)	Volume (m3)

I (100 blocks)	2887,36	67,31	1691,71	34,73	74832,85	958,58
II(118 blocks)	4039,33	88,25	2320,35	46,25	104457,24	1225,47
III (112 blocks)	4823,45	71,15	2236,54	42,59	99823,66	1167,94
Total= 330 (blocks)	11750,1	226,71	6248,6	123,57	279113,75	3351,99

In our research, the primary focus is on analyzing the presence of film plastic in construction projects. So, while analysing previous literature on packaging waste, our emphasis is on packaging plastic.

Based on the calculation presented by Pericot and Merino (2011) the average plastic packaging waste per middle sized building (~8 floor) is about 19 kg (table 3). They further mentioned that majority of plastic packaging waste was film and sheet plastic, which were used to wrap the pallets. And, one-way slab products were the highest producer of packaging waste in construction projects.

Pericot and Merino (2011) further suggest waste management strategies for reducing plastic packaging waste in construction. They include, for example, segregation at origin by waste specific container at site, wrapping the product until it is going to be used and immediately store packaging waste once the product has been opened. According to them, this would help to maintain the product in better conditions as well as prevent it from potential packaging damages. In addition, the compactors could be used to reduce the plastic volume, and waste management training could be provided to construction staff.

Pericot et al., (2014) further studied the packaging waste of midsized ten housing blocks constructed with the Mediterranean conventional procedure. This includes, for example, deep foundations with concrete piles, one-way slabs, flat roofs, brick facades insulated with polyurethane foam and so on. Table 4 presents the average packaging waste quantities presented in their study.

Table 4: Packaging waste in different construction stages

	Cardboard		**Plastic**		**Wood**	
Construction stages	**Weight (kg/m2)**	**Volume (l/m2)**	**Weight (kg/m2)**	**Volume (l/m2)**	**Weight (kg/m2)**	**Volume (l/m2)**
Site remediation	0	0	0	0	0,01	0,01
Foundations	0,01	0,01	0	0	0	0
Structures	0,01	0,02	0,12	0,19	0,33	0,3
Envelopes	0,02	0,03	0,06	0,1	0,6	2,21
Partitions	0,01	0,02	0,12	0,19	0,64	0,59
Building services	0,88	1,18	0,01	0,02	0,13	0,12
Thermal and moisture protection			0,07	0,12		
Roofs	0,02	0,03	0,04	0,07	0,05	0,05
Finishes	0,25	0,34	0,1	0,17	0,15	0,13
Signaling equipment	0,05	0,07				
Exteriors and swimming pool	0,01	0,01	0	0	0,02	0,02
Total	1,26	1,71	0,52	0,86	1,93	3,43

According to Pericot et al., (2014) study plastic packaging waste mainly produced in the partitions (~28%), structures (~20%) and finishes works (~20%). In line with the previous research (e.g. Pericot and Merino,2011; Jang et al., 2020) they also mention that the high portion of plastic packaging waste generated from the palletizing and primarily they include film and plastic sheet.

Even though the research works mentioned above have evaluated the packaging waste in construction, their primary focus was not on the film plastic waste in construction. They mention that the majority of packaging waste was films and plastic sheets. Hanny (2002) explains that a significant portion of the packaging plastic waste included the rigid forms, especially in secondary packaging, e.g. crates and shipping pallets. Selke and Culture (2016) distinguished different packaging plastics as: Plastics with thickness of 0.003 in or less are considered film, and materials with thickness of 0.010 in or greater are considered sheet. Furthermore, studies on packaging plastic that evaluate films produced in the site such as film used for site protection, poly bags and site workers' food packaging, are missing.

FILM PLASTIC COLLECTION METHOD

Different countries have different strategies for waste collection. For instance, in the United States, two types of collection methods are used: 1. single- stream: all the waste (e.g. paper, glass, plastics and metal) are collected in the same bin, and 2. dual-stream: the waste is collected separately, such as, plastic, paper, glass and metal (Cimpan et al., 2015). Even though the dual stream process collects plastic separately, film plastic is rarely separated (Horodytska et al., 2018).

In the EU, some of the member states have adopted film plastic waste collection strategies. However, even in such countries, film plastic is still collected in the mixed plastic bin. Table 5 presents EU countries that have adopted the film plastic collection strategies.

Table 5: Film plastic collection schemes in European countries (Cimpan et al., 2015; Seyring et al., 2015; Horodytska et al., 2018)

Film collection schemes	EU countries
Co-mingled flexible and rigid plastic collection	Austria, Netherlands
Collected with mixed plastics	Germany, Slovenia, Hungary, Sweden, Spain, Portugal
Some collection with mixed plastics	France
Rigid and film plastics are collected separately	Italy
Plastic (PE) films collected separately	United Kingdom
Collected with mixed recyclables	Ireland

To evaluate the packaging plastic waste from construction site, Pericot and Merino (2011) used a tool called "SMARTAudit" where waste was quantified and categorized by source, type, number, cause, and cost. In this process, well-trained observers evaluated the volume of waste from the mixed waste container at construction site. However, they recommend placing separate plastic waste containers on construction sites for proper waste management.

Overall, the collection of film plastic waste from a construction site is not an easy task. The site needs to be equipped with different collection bins, which is not always viable. Collection may face several challenges such as busy environment of the site, lack of space, attitude of people towards waste sorting, etc. (Ministry of Environment, 2020). Even though the collection of film plastic seems to be time-consuming and extra work, it has been argued that construction projects would still benefit from avoided waste collection fees (Ramboll, 2020).

METHOD

Case study is appropriate research for in-depth investigation and multi-faceted understanding of a complex topic (Yin, 2018). Multiple sources of evidence are used in this research approach. Thus, this research is conducted based on the multiple case study approach.

For analysis, three building construction projects were selected for the in-depth investigation. They are presented in table 6. All the cases have implemented some techniques of lean. For example, all projects have adopted prefabricated products. They have adopted waste (material and process) minimization techniques, e.g., Choosing-by-advantages (CBA) in design and construction phase. The cases were selected to ensure that the amount of film plastic could be collected from the beginning of the project to the end.

Table 6: Case information and amount of film plastics

	Case 1	**Case 2**	**Case 3**
Gross area (m2)	3863 m2	5617 m2	3460 m2
Number of apartments	54	76	38
Number of floors	7	9	8
Collected film plastic waste	1596 kg (0,96 % of all waste)	1710 kg (0,53 % of all waste)	1005 kg
Film plastic waste / m2	0,41 kg /m2	0,30 kg /m2	0,29 kg /m2
Film plastic waste/ apartment	29,6 kg	22,5 kg	26,4 kg

For collecting the data, we agreed with our case projects that they would collect film plastic separately. For this, all site workers were instructed to collect the film plastic separately. To ensure that the film plastic measurement was accurate, a separate film plastic container with instructions was placed on every floor. Film plastic waste was collected in the dedicated container and measured.

According to Poon et al (2001) building construction workers are often reluctant to conduct on-site waste sorting which is considered to be time consuming and labor intensive. To address this issue, our case projects also instructed their cleaners to place film plastic waste into the right container. In addition, the project researchers also visited the site often to analyze the amount of film plastic in other containers and at the same time observed the quality of film plastic in different work stages. The amount of film plastic was obtained from the waste collector. The amount was further corrected with the amount thrown into the wrong container, even though it was almost negligible.

RESULTS AND ANALYSIS

RESULTS FROM TASK LEVEL ANALYSIS

Firstly, the amount of the films waste produced in each activity listed on the schedule was analyzed separately for our cases. The activities that required several products to be installed naturally generated bigger portion of the film's plastic. Table 7 presents the major task-level activities that generates the greatest amount of film plastic.

Table 7: task-level activities that generates the highest amount of film plastic

SN	Task -level activities	Case 1 (kg)	Case 2 (kg)	Case 3 (kg)
1	Furniture installation	187,42	112,64	65,14
2	Ceilings of apartments	121,51	93,87	43,43
3	Partition work	93,31	93,87	52,73
4	Wooden windows and balcony doors	92,22	156,45	67,21
5	Laminate	88,91	93,87	20,68
6	Wall tiling	84,57	112,64	68,24
7	Roof	75,01	35,20	38,77
8	Leveling works	67,52	112,64	43,43
9	Final cleaning	65,25	156,45	51,70
10	Bathroom installations	59,27	56,32	55,83
11	Aco wall installation	55,74	117,34	15,51
12	other	605,00	568,20	485,75
	Total	**1596,00**	**1710,00**	**1009,19**

After analyzing the amount of film plastic waste in each activities of our cases, we then organized tasks in the following five construction stages, which allow the comparison of the results obtained in every project:

1. Foundation: Foundation wall, Foundation pillars, beams
2. Frame and roof: Frame of building, roof work
3. Interior work: Partitions, furniture installation, home appliance installation
4. MEP installation: Mechanical, electrical and plumbing work
5. Finishes and closures: Operational tests, official inspections

TOTAL AMOUNT OF FILM PLASTIC WASTE

In all cases, the portion of the film plastic waste was about 0.5-1% of total waste. The total amount of film plastic ranged from 1005 kg to 1710 kg. According to the U.S. Environmental Protection Agency (2016)'s volume-to-weight conversion, 1 kg of film plastic will occupy 0.05 m^3 of container space if the films are stored without heavy compression. This conversion is used to evaluate the volume of film plastic in our cases. Table 8 presents the number of films produced in each site per works stages and their volume:

Table 8: Total amount of film plastic in each case

SN	Tasks	Case 1 (kg)	Case 1 (m3)	Case 2 (kg)	Case 2 (m3)	Case 3 (kg)	Case 3 (m3)
1	Foundations	45,39	2,27	31,29	1,56	27,92	1,40
2	Frame and roof	156,11	7,81	132,98	6,65	183,01	9,15
3	Interior work	819,20	40,96	934,01	46,70	548,51	27,43
4	MEP installation	573,05	28,65	596,08	29,80	244,39	12,22
5	Finishes and closures	2,26	0,11	15,65	0,78	5,17	0,26
	Total	**1596,00**	**79,80**	**1710,00**	**85,50**	**1009,00**	**50,45**

As table 8 demonstrates, film plastic was mostly produced in the interior Workstage. It's mainly due to the activities such as partition work, furniture installation and home appliances installation—where most of the product required installation and their packaging plastic constituted the high amount. On the other hand, a minimal amount of film plastic waste was generated in finishes and closures. This is apparently because this stage involved mostly administrative tasks where no product installation is required.

Following the trend that interior activities produce most of the film waste, we have considered that the total area of the building and the number of apartments is the major factors for film plastic waste production. It is also visible in table 12 that case 1 produces the greatest amount of film waste, mainly due to the higher gross area and number of apartments. The total amount of film plastic generated in respect to gross area is presented in table 9.

Table 9: Total amount of film plastic per 100m2

NRO	Tasks	Case 1 (Kg/100m2)	Case 2 (kg/100m2)	Case 3 (kg/100m2)	Average (KG/100m2)
1	Foundations	1,17	0,56	0,81	0,85
2	Frame and roof	4,04	2,37	5,29	3,90
3	Interior work	21,21	16,63	15,85	17,90
4	MEP installation	14,83	10,61	7,06	10,84
5	Finishes and closures	0,06	0,28	0,15	0,16
	Total	**41,32**	**30,44**	**29,16**	**33,64**

While comparing the three case results, case 1 has produced the higher amount of film plastic waste. However, case 2 has the higher gross area and number of apartments. Citing the discussion with case 2 project personnel, some amount of film plastic was thrown into the other containers by mistake by the site workers. And, from our site visit observation and discussion with the project personnel, film plastic was collected as accurately as possible in case 1. Table 10 further presents the films plastic waste per apartment. Analyzing the result of the three cases, each apartment of residential building will produce about 26.20 kg of film plastic waste.

Table 10: Amount of film plastic waste per apartment

SN	Tasks	case 1 (Kg)	Case 2 (KG)	Case 3 (kg)	Average (KG)
1	Foundations	0,84	0,41	0,73	0,66
2	Frame and roof	2,89	1,75	4,82	3,15
3	Interior work	15,17	12,29	14,43	13,96
4	MEP installation	10,61	7,84	6,43	8,30
5	Finishes and closures	0,04	0,21	0,14	0,13
	Total	**29,56**	**22,50**	**26,55**	**26,20**

DISCUSSION

In this research we have analyzed the amount of film plastic waste generated in construction sites. To the best of our knowledge, this is the first research conducted that evaluates film plastic waste from construction site. Some previous studies have analysed the plastic waste, such as, Pericot et al., 2014; Pericot ja Merino., 2011; Häkkinen et al., 2014. However, their study included all type of plastic waste produced in construction sites (e.g., plastic pallets). Our research was solely focused on film plastic waste.

In our case projects, film plastic waste was collected separately onsite. According to Poon et al. (2001), building construction workers are hesitant to carry out on-site waste sorting that is considered to be time and labor demanding. A similar experience was shared in Percot et al.'s (2014) study indicating onsite segregation was around 1.80%. However, in our cases, the sorting rate was about 75% -- this is also mentioned in the project report (Lyytikäinen et al., 2020). It is mainly because in our case projects, film plastic containers were placed in multiple places, e.g., in every floor, yard and a larger film plastic waste container alongside other waste containers. Posters with instructions on waste sorting were stuck on the containers. Furthermore, cleaners were also instructed to correct the waste into the right container if necessary. For those reasons, segregation rate was higher in our cases.

Quantification of plastic waste for each activity is challenging. Pericot et al., (2014) emphasized that the suitable method would be to isolate the different waste categories generated in every activity. However, in practice, it is difficult to follow this procedure without disturbing the construction activities in multi-story residential buildings (Katz and Baum, 2011). To resolve this problem, we have adopted a task-intensity based approach. In this approach, we first analyzed the site activities and scaled them according to the amount of film plastic waste they could generate, in this research we refer that metric as intensity of the task. The intensity marking is discussed and validated with site personnel as well as in project meetings. Thereafter, all our case schedule's task were marked with intensity and evaluated accordingly.

After analyzing film waste amount for each activity, we created a database for film plastic waste produced in each activity of construction site. Based on the database, we developed a model, and it could be used to evaluate the amount of film plastic in future project for residential construction. This could ultimately help for better site waste management plan. Especially, it will help to figure out the size of the container to be placed as well as it will make easier for waste handling company for the frequency needed to pick up film waste which ultimately contribute to cut greenhouse gas emission somehow by avoiding unnecessary truck movement to the site.

Recently, plastic waste as threat to the environment is heavily discussed in academia, industrial professionals and the media. Many scholars discuss that the construction is one of biggest generators of plastic waste. However, there is no statistics available how much approximately amount of film plastic could be produced onsite and it would be necessarily making the waste management plan for the construction site. In this case, our database and model developed based on it, could contribute to develop the standard database, for instance, it could be used by statics Finland, Environmental Protection Agency, etc.

Overall, the findings from this study, specially kalvomuovi.fi platform, is an important initial step for removing plastic waste form construction site. As our platform would help to analyse the film plastic waste at the planning phase, which would help improve the site waste management plan. This would ultimately help to for implementation of Lean and green approach to the construction site.

CONCLUSION

To evaluate the amount of film plastic in construction site, we have evaluated three residential construction projects. To facilitate the most accurate possible measurement of film plastic waste, we have adopted the output method- so that we can measure the waste entering into the site as well as generated within the site. Based on our analysis, film plastic were collected from 1005-1710 kg (about 0,5-1,0 % of all waste) in our cases. The higher amount of plastic films were generated during interior Workstage. This includes the site activities requiring installation of more products e.g., furniture installation, partitions (More detail task level analysis, refer table 11).

Furthermore, while summarizing the analysis of our three cases projects, it showed that 33,64 kg film plastic waste was produced in every 100 m^2 and 26,20 kg was produced per apartment. Based on these results, we have developed a modelling tool that is able to evaluate the amount of film plastic in every work stage for the future projects.

During the site visit, the quality of the film plastic was also evaluated. Quality analyses were mainly based on: a) cleanliness and b) color / brightness. In our analysed cases, portion of the dirty film plastic was very low almost negligible, some cases have collected dirty film plastic in a same container as it used to collected film plastic whereas some have collected in discarded collect in the same container. In any case, the recycling company will clean the films before they process them. Similarly, it is also observed that the portion of non-color film was almost negligible. Thus, the authors did not apply strict rules about color while collecting film plastic.

At the end, based on case study results, the authors developed a platform called kalvomuovi.fi: that can be used to estimate the amount of film plastic waste in residential construction projects.

In this research, the authors analyzed only three cases and based on that, developed a model. For generalization, results from three cases may not be sufficient as the data sample could be considered thin. The model thus requires further testing to validate it for different cases. Also, all of the cases analyzed in this research were residential buildings, so the model presented will only be applicable for residential buildings. Further research is necessary to measure waste from other types of buildings (e.g., hospitals and schools.).

GREEN IS GOOD: FIRST RUN STUDY OF A SUSTAINABLE BUILDING STRUCTURE

Sigmund Aslesen[1], Arve Hindenes[2], Sigmund Reff[3], Espen Stordal[4], and Sebastiano Lombardo[5]

ABSTRACT

The study made an account for in this paper is based on the hypothesis that introducing a climate-friendly building material to construction production may fundamentally impact project performance. In the paper, evidence is given for a prolonged, costlier process of erecting the building structure if an extremely low-carbon concrete combined with a 100 percent recycled aggregate is applied. Findings suggest various measures to be taken, to accelerate the hardening of the concrete. Otherwise, a positive environmental effect may easily diminish the overall project performance. The paper is based on a First Run Study (FRS) including a full-scale mock-up of a part of the building structure, including ground floor, wall, columns, and slab. As part of the study, data was collected about the temperature, firmness, and relative moisture of the concrete, and the effects of different actions applied to accelerate the hardening process. The impact of this study is an estimated risk reduction of 1,5 percent in the context of the project it was intended to support. The paper concludes that this type of experimentation should happen prior to actual performance to prevent construction projects from falling short of time and finances caused by unexpected results.

Lean and Green, First Run Study.

INTRODUCTION

In the first run study presented in this paper, an extremely low-carbon concrete combined with a 100 percent recycled aggregate is applied in a physical mock-up on site. The research carried out investigates whether – and under what conditions – it is feasible to use this substance in the building structure of a five-floor high, 11 000 square metres office building. The completed structure will be the first of its kind using this type of concrete to the full. To deliver the project is Veidekke, one of the largest general contractors in Norway. As part of its climate strategy, the company will reduce greenhouse gas emissions by 50 percent by 2030. An overview of emission sources from all building and civil engineering-related activities in the company shows that the use of concrete stands for as much as 31 percent of the total 269 000 tons of CO^2 emissions. Veidekke is also on the client side of the project, in companionship with OBOS, Norway's largest housing developer. Together, they have decided that the new-building project should at least contribute to a 50 percent reduction in greenhouse gas emissions. This makes it a primary concern to initiate changes that really make a difference in sustainable development.

To prevent global warming beyond 1,5 °C above pre-industrial levels, the Intergovernmental Panel on Climate Change (IPCC) has concluded that greenhouse gas emissions must decline by 43 percent by 2030 and to net zero by 2050 (UN DESA 2022). Then being green, for lack of a better word, is good. Green here alludes to a mindset based on ensuring that activities, be they individual, corporate, or otherwise, reflect an overall concern for safeguarding the planet Earth and its natural resources. The construction industry generates about 38 percent of annual total greenhouse gas emissions globally (United Nations Environment Programme 2022). Size matters in this respect, the construction sector being one of the largest in the world economy, with about $10 trillion spent on construction-related goods and services every year (McKinsey Global Institute 2017). Furthermore, the cement and concrete industry is responsible for about 8 percent of global carbon dioxide emissions, more than double those from flying or shipping (Niranjan 2022). This means that, in the efforts to make a difference, the industry's attention needs to be drawn specifically to the emissions produced elsewhere and brought into construction production in form of building materials. The results presented in this paper can thus be of great value to an industry with a huge potential to turn the heating process on the planet down.

FIRST RUN STUDIES

First Run Studies were introduced by Ballard and Howell (1994) as a method to improve downstream performance, by changing how we do the work. The method is linked to craft operations and described as a process where the operation is examined in detail, where ideas and suggestions are requested from all parties, and experiments are performed to explore alternative ways of doing the work. The study ends with the definition of a performance standard, which in turn is challenged to meet or beat the best done thus far (Ballard and Howell 1994). A First Run Study reminds of the Plan-Do-Check-Act (PDCA) cycle, which was popularized by W Edwards Deming (Aguayo 1991). The cycle, also known as the Deming cycle, describes a simple method to test information before making a major decision. When running an experiment, the first step includes planning (or designing) the experiment, the next performing the experiment, and thereafter, checking the results by all the information gathered through the test, before acting upon the decisions based on those results (Aguayo 1991).

In the manufacturing industry, the concept of pilot production has evolved under somewhat the same line of reasoning as the PDCA cycle. Pilot production is typically applied to verify a new product and its production system. Almgren (2000), using the experiences of the Volvo Car Corporation, describes pilot production and manufacturing start-up as two processes that greatly affect development costs, time to market, and product quality. Pilot production refers to pilot runs carried out in a production system intended for commercial use. During pilot production, pilot vehicles are built and assessed from a product and production system perspective. Pilot production aims to identify and prevent disturbances affecting the final verification before the start of volume production (Almgren 2000). Manufacturing start-up is typically divided into two sequential phases, low-volume and high-volume production, where low-volume production is done to fine-tune the factors affecting performance before high-volume production (Almgren 2000).

In the IGLC conference proceedings, First Run Studies are scarcely represented. An interesting contribution to the topic is done by Tsao et al. (2000), which – even though it does not include a real first run – exemplifies the potential use of the method to prepare the installation of metal door frames at a prison project. In prisons, the door frame installation differs from the usual due to added security measures. The paper underlines that to improve the process of installing frames, different perspectives need to be considered. The authors conclude that this rarely happens, as all parties are seldom brought to the table to consider work structuring together early enough (Tsao et al. 2000). In the authors' view, thinking about system-wide solutions is also hampered by a contracting mentality. Instead of questioning a bad design, a worker complains and works around it, because their contracts are already signed, and work must proceed (Tsao et al. 2000). A few years later, altogether three real First Run Studies are presented to the IGLC by Saffaro et al. (2006), to investigate the role of it as an experimentation technique. The authors conclude from these studies that production constraints typically interrupt a proper application of the cycle observation-reflection-action, thus leading them to question the capacity to deal with prototyping issues in a dynamic environment (Saffaro et al. 2006).

Construction production, it seems, is not very suitable for experimentation. Koskela (2000) has a somewhat alternative perspective, seeing the actual building as a prototype where the production stage is used to eliminate errors generated in the design or production planning processes. Does this mean every construction project is a first-run exercise? To the point it is, Saffaro et al. (2006) suggest that virtual models must be used to eliminate design uncertainties and errors, thereby removing product-related problems that do not allow the prototyping exercise to focus on work methods and standards. At the same time, production in construction is always locally bound and dependent on physical factors such as soil and weather conditions (Vrijhoef and Koskela 2005). While virtual models, most certainly, are helpful to reduce design uncertainties and errors, they cannot replace the transformation of the design into physical reality which must still rely on the use of physical mock-ups (Pietroforte et al. 2012).

METHOD

The First Run Study was carried out, using a combination of laboratory testing and a physical mock-up. In addition, a digital model was developed to visualize all the planned actions to be taken on different parts of the physical mock-up. The laboratory testing was carried out to test different combinations of concrete, specifically focusing on the effects of using a recycled versus a normal aggregate. The physical mock-up was erected in situ, at the exact same site as the later office building is being built. The mock-up was done in the winter to test how the extremely low-carbon concrete responded to low-temperature exposure.

1. The digital model was used:
    a. To make a visual representation of the physical mock-up
    b. To identify which actions should apply to various parts of the physical mock-up
    c. To do quantity calculations and take-offs from the model, as part of planning the structural work
2. Laboratory testing was necessary:
    a. To test the elasticity, firmness, and relative moisture of the concrete combined with the use of the recycled aggregate
3. Use of the physical mock-up allowed:
    a. To collect reliable data about the concrete and structure
    b. To include air temperature in the evaluation
    c. To measure the effect of different actions, on the hardening process

For the testing performed in the laboratory, different tools were applied. To test the elasticity of the concrete, fresh concrete was poured into small, cubic-formed containers which in turn were exposed to vibration. To test the concrete's firmness, the cubes were later exposed to pressure using a manometer to measure the megapascal. To measure the relative moisture in the concrete, a moisture meter was applied.

A physical mock-up was erected, about 100 m² in size, and including 27 m³ of concrete. The building structure was cast in place, using post-tensioned reinforced slabs. Every cast was monitored, using concrete sensors to measure the temperature, strength, and maturity of the concrete. Several actions were applied to accelerate the hardening process, amongst others including heating pipes containing glycol, hot air fans, infrared ovens, insulation plates, surface accelerators, polyethylene foam, and heating cables.

RESULTS

THE RECYCLED AGGREGATE

The laboratory tests were done partly to find out more about the quality of the recycled aggregate, partly to investigate the effects of using it in fresh concrete, and partly to study how the concrete appears when using 100 percent recycled aggregate.

The quality of the recycled aggregate was controlled using several measures, amongst others to check the density and variation in the size of grains, their ability to absorb water, and their chemical composition. This is because the quality in turn will determine how the concrete appears. The control checks uncovered that the recycled aggregate had much the same quality as virgin aggregates.

To test the workability of the fresh concrete, a slump was poured into a funnel-shaped form which was pulled up to measure how much the substance floated (Figure 1). Thereafter, E-module testing was done on concrete cylinders (Figure 2), including the use of equipment to measure (and regulate) the elasticity of the concrete.

Figure 1: Controlling the workability of the fresh concrete

Figure 2: E-module testing

THE PHYSICAL MOCK-UP

The physical mock-up was erected in Oslo, Norway, in February-March 2021. The middle temperature in the area is then -2 °C. The timing was decided because the weather was an important parameter to include in the tests. To control for variations, the outdoor temperature was logged on a regular basis. The structural work, including the ground floor, supporting walls, columns, and slab, was a replica of a part of the office building later to be built. After all the tests were completed, the mock-up was demolished.

The ground floor

The ground floor was divided into four fields, to which different actions were applied to be able to control their effects (Figure 3). Field 1 included the use of a surface accelerator and covering up by using polyethylene foam directly after the cast. The cast was done directly on the gravel. Field 2 included the use of insulation underneath the cast, membrane curing, and covering up when the cast was ready to walk on. Field 3 included the use of heating pipes, membrane curing, and covering up when the cast was ready to walk on. The cast was done directly on the gravel. Field 4 included the use of insulation underneath the cast, heating pipes, membrane curing, and covering up when the cast was ready to walk on.

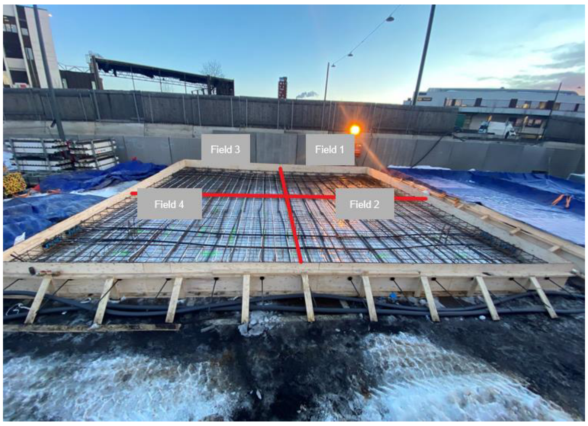

Figure 3: The ground floor, including the four fields

Findings related to the ground floor (Figure 4) show that the temperature in the fresh concrete drops heavily, especially in field 1 which include only limited actions and where the cast is done directly on the gravel. This has to do with the extremely low-carbon concrete, which develops no heat of its own. Thus, if the cast goes on in the winter, actions will be necessary to avoid a drastic temperature drop. Of all the actions applied, the most effective combination seems to be the one used in field 4 with insulation underneath the cast, heating pipes, membrane curing, and covering up when the cast is ready to walk on. The temperature development in the concrete affects the hardening process. As a result of the extremely low-carbon concrete being a “dead” substance, the hardening process is delayed and occurs only after 20 hours or more. When measured in megapascals, it takes about 24 hours for the ground floor in fields 2 and 4 to have reached an acceptable level of strength (5 megapascals). From the findings, one may conclude that especially heating pipes and insulation appear to boost the hardening process.

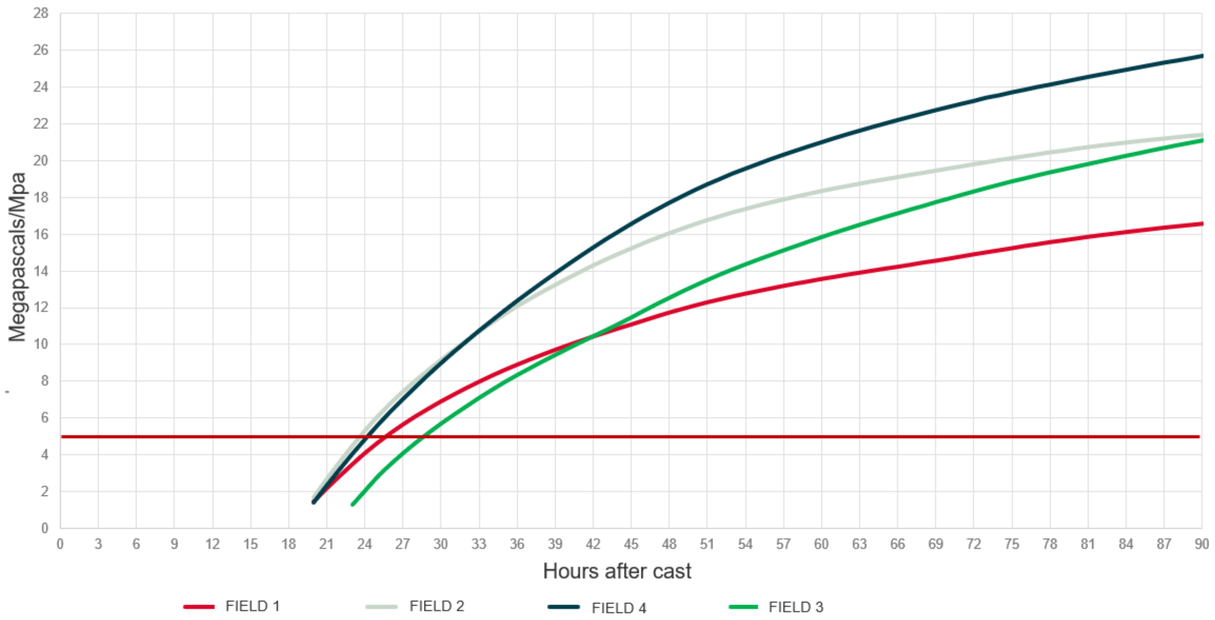

Figure 4: Hardening process of the ground floor

The columns

Altogether four columns were included in the mock-up. Different measures were applied to each of them (Figure 5). Column 1 was insulated by a double layer of polyethylene foam, while column 2 had only one layer of insulation. Column 3 had heating cables included in the concrete, in addition to one layer of insulation. Column 4 had heating cables on the outside, underneath one layer of insulation.

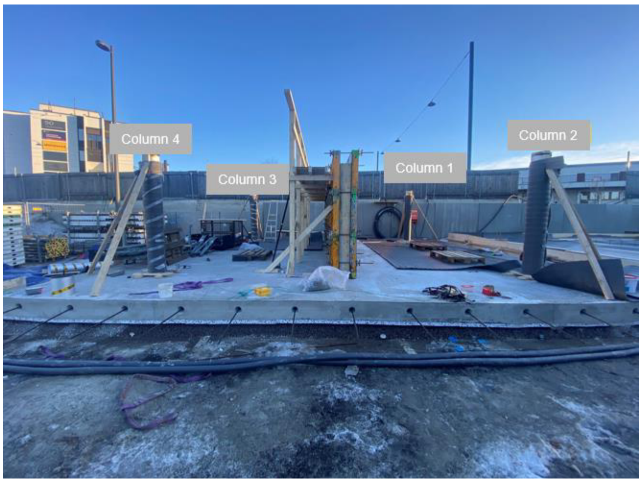

Figure 5: The four columns

Heating cables, either in the concrete or on the outside, seem to have a positive effect on the hardening process. For the two columns including this measure, it takes about half the time to reach the acceptable level of strength (8 megapascals) compared to the columns with only insulation.

The wall

The wall surfaces were split in two, where the upper parts included no measures while the lower parts included subsequently heating pipes containing glycol on one side and heating cables on the other (Figure 6).

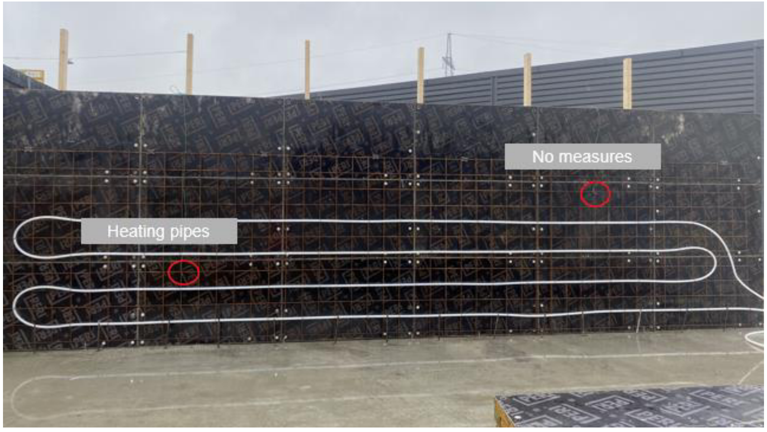

Figure 6: Wall surface, including heating pipes

The temperature development indicates a sudden and steep effect of both heating options. Furthermore, the hardening of the wall using heating cables or heating pipes seems to be all the same, both requiring between 15-18 hours to reach an acceptable level of strength (5 to 8 megapascals). In comparison, around 30 hours or more are required before the same level is reached when no measures are used.

The slab

Four different measures were tested to improve the hardening of the slab, which moreover was divided into several fields. The most comprehensive method applied was where the area underneath the slab was covered by insulation and hot air was pumped into it and circulated (Figure 7). Other actions underneath the slab included the use of infrared ovens and insulation plates, whereas heating pipes were tested in the slab.

Figure 7: Slab, with hot air underneath

Findings indicate that heating pipes in the slab are the most effective solution among those tested to improve the hardening process (Figure 8). Applying this measure, it takes 38 hours for the slab to reach the acceptable level of strength (25 megapascals). It also appears to give good results if insulation plates are used underneath the slab. On the opposite side, if no actions are taken underneath or in the slab, it may take 100 hours or more for the slab to reach the acceptable level of strength.

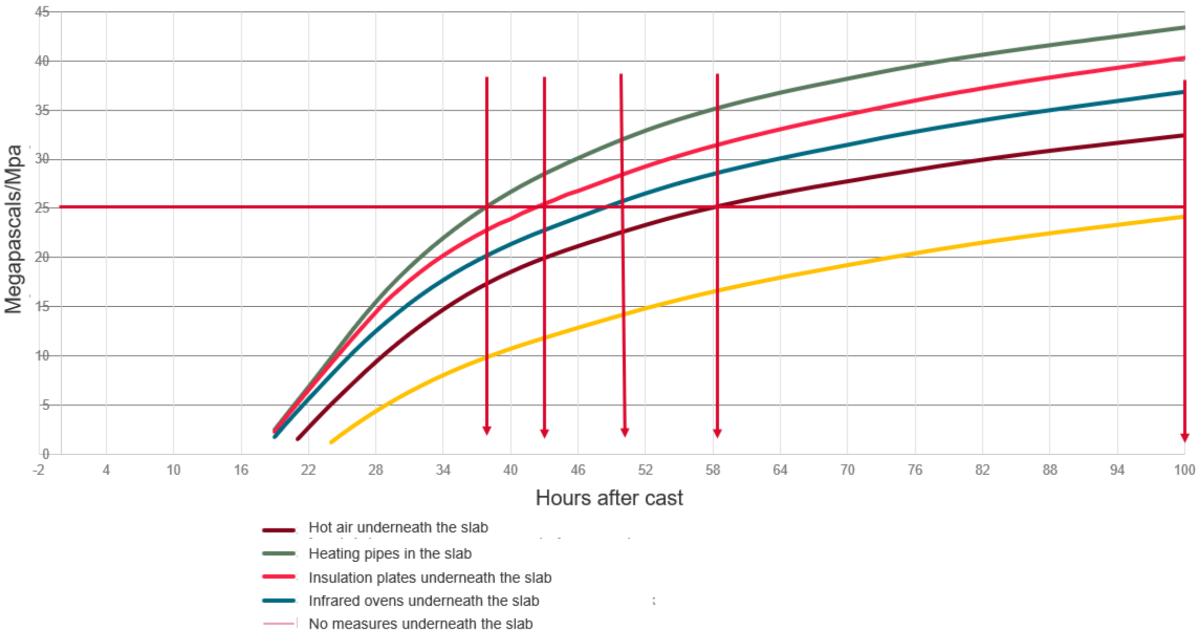

Figure 8: Hardening process of the slab

DISCUSSION

If using extremely low-carbon concrete, what would be the ideal measures to apply to improve the hardening process when erecting the structural envelope? Based on the results presented in this paper, different measures seem to apply to the various elements. Regarding the ground floor, the most effective combination is when insulation is placed underneath the cast, heating pipes in the cast, membrane curing, and covering up when the cast is ready to walk on. On the columns, heating cables on the inside or the outside have a positive effect. As for the wall, somewhat the same can be said about heating pipes and cables, whereas in terms of the slab heating pipes in the concrete seems to give the best results. On the opposite side, if no actions are applied using extremely low-carbon concrete, the findings presented here indicate a late hardening and substantially prolonged structural building phase. This is because the extremely low-carbon concrete develops no heat of its own. When having to deal with this substance, the simple answer to the question above is thereby to make use of all these actions.

Following this First Run Study is the office building constituting 11 000 square metres and consisting of 3900 m³ of concrete. While there is no calculation of the total costs of applying all the measures described, it will inflict additional expenses on the project. This would necessarily mean that the client needs to find it appropriate to spend the extra money. From a client's perspective, the cost of doing it will naturally be weighed against alternatives. For instance, how much will the project be delayed if no measures are used, weighed against the potential time savings of applying them? All the actions considered; this question seems particularly relevant to address to those meant for the hardening of the slab. If no or only simple measures are applied here, it takes a minimum of 100 hours before the slab has reached an acceptable level of strength (25 megapascals). A hardening process thus long would substantially delay the production progress.

This moreover triggers another consideration related to which actions should be prioritized if the focus was on choosing one or a few that would be the most effective. The actions meant for the slab seem particularly relevant in this respect. At the same time, all the rigging and equipment needed to apply at least some of these actions brings the cost concern into the equation. Then, the use of insulation plates underneath the slab might be the optimal choice. Even though heating pipes in the slab are slightly more effective in terms of hardening, it is also more expensive. Not necessarily due to material costs alone, but because of the power supply needed to be combined with the use of the pipes. At the same time, if the outdoor temperature falls drastically – which might very well happen in Oslo in February – then using heating pipes is likely the best alternative, even though applying it may cost more.

What if the process of erecting the structural envelope goes on in the summer instead of winter? Considering that extremely low-carbon concrete develops no heat of its own, it would seem a plausible strategy to do the cast in a period of the year when a much warmer atmosphere could help the hardening process go faster. What is more, it would save the project from additional expenses due to the various actions discussed above. Even more so, it would save the environment from emissions at the construction site, in form of material waste and energy consumption caused by the actions described. Since the mock-up was erected in the winter, there is no data to describe the effects of doing the cast at another time of the year. That said, the main problem seems to be the lack of heat inside the concrete, which delays the hardening process. Furthermore, when the substance is exposed to heat from external factors, it exhibits a positive response in terms of a more rapid hardening. After all, what can be more environmentally friendly than using the sun's warmth to make this happen? Ultimately, the solution must be to do the cast in the summer period if extremely low-carbon concrete is used.

Given the ultimate solution listed above, was the physical mock-up and all the testing a waste of time and money? No, because insight beats hindsight. Due to the use of a new substance, risks in the project's uncertainty analysis carried out were considered particularly high for the structural building phase. As a result of the first run study, the project's uncertainty was reduced from 4 to 2,5 percent of the total contract sum on 410 MNOK. A pilot production costing approximately 1,5 MNOK thereby paid off several times as uncertainty dropped from 16 to 10 MNOK.

CONCLUSION

This paper gives support to the hypothesis that introducing a climate-friendly building material to construction production may fundamentally impact project performance. Evidence is given for a prolonged, costlier process of erecting the building structure if an extremely low-carbon concrete combined with a 100 percent recycled aggregate is applied. A First Run Study (FRS) involving a physical mock-up proved very useful to uncover which actions are the most effective to accelerate the hardening process. The impact of this study was an estimated risk reduction of 1,5 percent in the context of the project it was intended to support. This type of experimentation should happen prior to actual performance, though, to prevent construction projects from falling short of time and finances caused by unexpected results. The outcome of this study is knowledge about how extremely low-carbon concrete appears in cold conditions. Without it, it would be less obvious that cast in the summer has clear-cut advantages. In fact, one can even imagine that cast in the winter could be initiated without further hesitations, with potentially devastating results. Additionally, while it is clear and obvious that doing the cast in the summer is the best alternative, this is not always a choice. A construction project evolves at the mercy of many conditions, whereof some are more difficult to control than others. To reach a timing in every project that fits perfectly with a schedule saying that the cast should only go on in the summer is a very naïve approach to handling the problem. Rather, it would seem a more passable way to go, to learn from the First Run Study presented in this paper which actions seem most appropriate to apply in your project and avoid experimenting too much once the production gets going.

EXPLORING HOW LEAN PROJECT DELIVERY SUPPORTS CARBON CAPTURE, UTILIZATION, AND STORAGE FOR INDUSTRIAL RETROFITS

Nicholas Heier[1], Anika Chakravarti[2], Anja Røyne[3], and Kristen Parrish[4]

ABSTRACT

The "lean construction ideal" is to maximize stakeholder value, minimize waste, and emphasize collaboration throughout the design, construction, and operating stages of a building project. In practice, lean construction relies on methods such as the Integrated Project Delivery (IPD) system to align stakeholder interests and share risks throughout the project lifecycle. IPD effectively enfranchises various project stakeholders as parties to one agreement, integrating their involvement throughout the design and construction process. While lean construction methods are evidenced to enhance project efficiency in cost and schedule while improving quality, the collaboration fostered by IPD also creates a project environment conducive to innovation and the adoption of new technologies. To that end, lean construction environments, and IPD projects in particular, may offer an opportunity to increase the adoption rates of more environmentally-conscious design alternatives, particularly as the construction industry continues to trend in a more sustainable direction. This paper explores how the lean project delivery system supports incorporating innovative design options on retrofit construction projects (i.e., on existing facilities), and leverages incorporating carbon capture, utilization, and storage (CCUS) systems on cement plants as a proof of concept.

KEYWORDS

Sustainability, environment, collaboration.

INTRODUCTION

Literature from the International Group for Lean Construction (IGLC) confirms that often, the leanest path to "green" is to retrofit an existing building rather than demolish it and begin from scratch (e.g., (Ladhad and Parrish 2013; Ding and Parish 2019; Soliman-Junior et al. 2022). Research from outside of lean construction further supports this claim. For example, Jagarajan et al. (2017) discuss the need to retrofit the existing stock of buildings and industrial facilities in order to achieve climate goals. Perhaps more relevant to this study is the nexus of lean and green shifts within manufacturing processes and facilities, e.g., Huang et al. (2022), a study that discusses the necessity of retrofitting manufacturing plants, equipment, and processes to ensure that production is as lean as possible (i.e., minimal labour, material, and time waste) and that the manufacturing process limits environmental impact to the extent possible. (2020) discuss the importance of lean project delivery systems for creating an environment where sustainability can thrive; they argue that leveraging building information modelling in a lean project team with sustainability goals is the best environment for BIM, lean, and sustainability goals to be achieved. This paper, similarly, argues that a lean project delivery system, and a team committed to lean, provides the right environment for green retrofits, and CCUS retrofits of cement plants specifically.

BACKGROUND

Lean Project Delivery System

Figure 1Figure illustrates the lean project delivery system, first introduced by Ballard (2000), and updated in 2008 (Ballard 2008). This system illustrates collaboration across project phases (i.e., project definition, lean design, lean supply, lean assembly, and use) as well as across project stakeholders, evidenced when triangles for different phases overlap, i.e., the "Design Concepts" node represents collaboration of owner representatives, designers, engineers, and contractors involved in project definition with the stakeholders involved in lean design. Such a system supports implementation of lean throughout the project lifecycle.

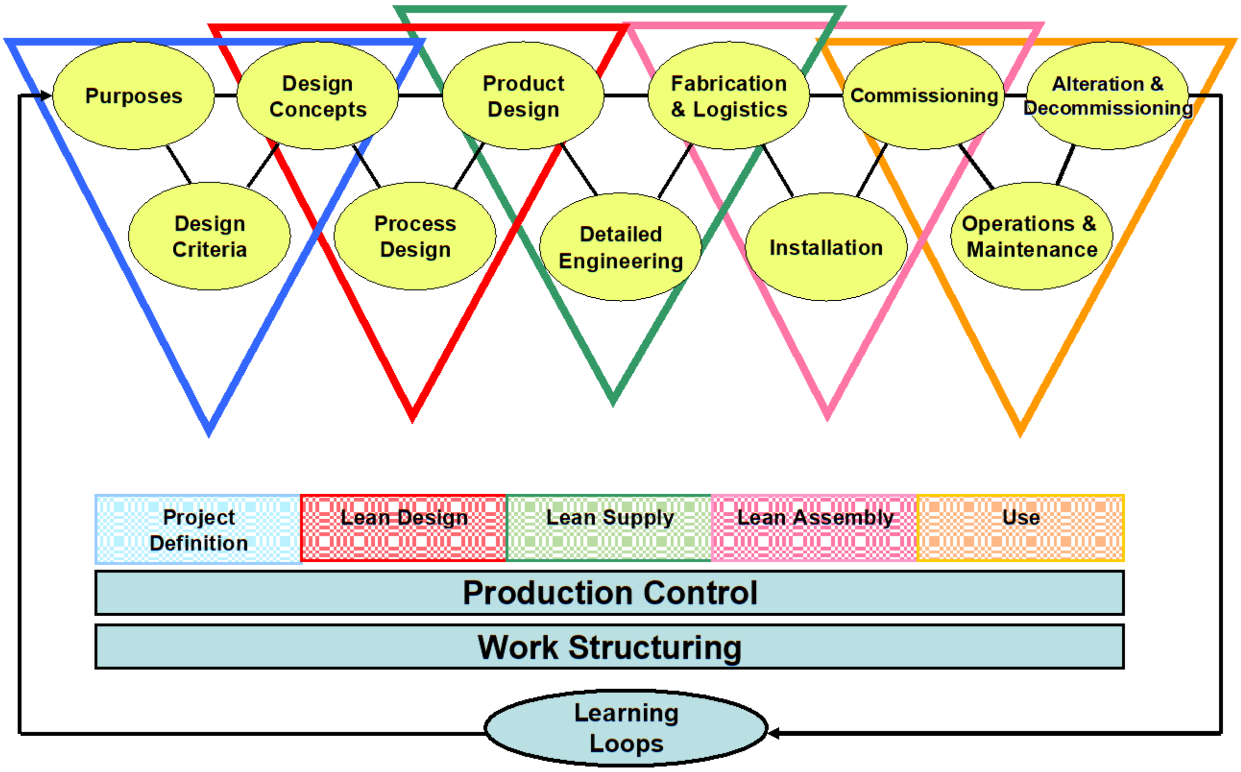

Figure 1: Lean Project Delivery System (Ballard 2008)

CCUS

Carbon Capture, utilization, and storage, or CCUS, refers to technologies that capture CO_2 from large point sources, i.e., industrial facilities, and then transport and utilize or store the CO_2 (IEA 2023). The number of retrofit construction projects involving CCUS installation will increase substantially over the next ten years. By the end of 2021, the global CCUS project pipeline contained 135 facilities, including 27 fully operational plants (Global CCS Institute 2021). The pipeline contained 51 facilities in 2020, with 21 operational (IEA 2023). Attaining the climate goals of the 2015 Paris Agreement requires construction of an additional 70-100 CCUS facilities globally, each year (Global CCS Institute 2021). CCUS represent the only group of technologies which at once abate end-of-pipe carbon emissions and offset past emissions. Given their capture capacity per area, CCUS technologies are the most direct path to a negative carbon effect.

For this reason, CCUS features prominently on sustainability roadmaps to net-zero and beyond (e.g., (GCCA 2022). Attaining net-zero in hard-to-reach sectors like power generation or cement and steel production is virtually impossible without CCUS technologies. Reflected in their sustainability commitments, Heidelberg Cement's carbon neutrality roadmap (Lenz 2023) features immediate and widespread integration of carbon capture technologies to reduce cement process emissions followed by intense development of capture and utilization technologies (Lenz 2023). Heidelberg showcases the retrofit of the Heidelberg Materials cement plant in Brevik, Norway as a first of a kind full-scale carbon capture demonstration (Brevik CCS 2023).

RESEARCH HYPOTHESES

Based on the background presented above, the authors developed the following research hypotheses:

- The collaborative nature of lean project delivery supports project teams' ability to implement CCUS technologies in industrial facility retrofit projects
- The lean project delivery system supports inclusion of innovative design alternatives in retrofit construction projects

METHODS

Testing the aforementioned hypotheses would require exploring a large number of "similar" retrofit projects, some delivered via LPDS and others not. Ideally, in order to conduct tests for statistical significance between the projects delivered with LPDS compared to those delivered without it, the authors would collect at least 30 projects delivered with each delivery system, for a total of at least 60 projects. Given that the total number of fully operational CCUS plants at the end of 2021 was 27, such a study is not feasible at present. Moreover, not all of the 27 operational plants represent retrofits, adding further difficulty to this experimental approach.

Given the limitations outlined above, the authors opted instead to illustrate how LPDS *could facilitate* the inclusion of sustainable design alternatives in retrofit projects. More specifically, the authors explore how the LPDS environment supports inclusion of one such sustainable design alternative, CCUS. To do so, the authors present the barriers to CCUS technology implementation and discuss how lean project delivery, and lean tools may be able to address these barriers. The barriers themselves are derived from a recent interview study conducted by the first author. The authors then suggest lean tools that may address these barriers based on IGLC and other lean construction literature.

INTERVIEW PROTOCOL

The authors developed the interview protocol to elucidate barriers in 2021 (Table 1), and conducted interviews from April 2022 – December 2022. The authors map each question to the most applicable phase of the LPDS, in order to best contextualize results.

The authors conducted interviews with 21 practitioners that spanned fields of basic research, applied research, technology development, innovation management, life-sciences, geophysics, civil engineering, construction materials, cement and concrete technologies, energy infrastructure, and innovation policy. The authors were transdisciplinary in their approach so they could learn about how innovative and sustainable design alternatives were developed and deployed in the cement industry. As important, they could understand the science that underpins CCUS technologies and how these scientific considerations impact CCUS adoption in the cement industry (e.g., how the chemical process of producing cement impacts the feasibility of deploying various CCUS technologies in cement plants).

Table 1: Interview Protocol

Number	Question	LPDS Phase
1	What types of new cement materials or technology have you worked with and how often do you work with them?	Lean Design
2	What needs to improve for the cement materials and technologies in use today?	Lean Design
3	What are some of the drawbacks of the green cement materials and technologies you have worked with so far?	Lean Design
4	What project delivery methods are best suited for green/regenerative projects or projects with novel technologies?	Lean Assembly
5	What are the impacts to cost (budget/schedule/productivity) when a new cement material or technology is brought on to a project?	Lean Assembly
6	What are the risks and benefits for taking on regenerative/green projects?	Project Definition
7	What innovations are most successful in the cement industry?	N/A
8	What innovations are most needed in cement materials and technologies?	N/A
9	When considering an innovation portfolio decision, what data and inputs are most useful?	N/A
10	What barriers do you perceive to innovation with cements and what would you suggest to overcome them?	N/A
11	What makes a regenerative or green innovation easier to adopt or spread within the industry?	N/A
12	What effect do sustainability and climate goals have on shaping your innovation portfolio?	Project Definition

All interviews were conducted via zoom. Interviews were recorded with the participant's consent (all participants consented to being recorded). The authors used the zoom transcripts for coding (Frey and Fontana 1991; Wengraf 2001). Specifically, the authors coded the responses for themes related to barriers to adopting innovative technologies in the cement industry. For the purposes of this paper, only barriers related to CCUS are presented.

RESULTS

Based on the interviews, the following barriers to CCUS implementation in the cement industry emerged:

Limited utilization potential for captured CO_2: Participants indicated that finding a local use for captured carbon was a challenge to achieving circular economy. Moreover, responses indicate that natural processing of CO_2 seems to favour storage, e.g., carbon deposits under the ocean floor.

Evaluation of technology readiness can impede implementation: Respondents discussed the Technology Readiness Level, or TRL, which influences those technologies that can be, and are, considered for inclusion in a capital project. In the context of the cement industry, the technologies with high TRL may not yet be cost effective over the expected lifetime of the plant.

Indeed, traditional cost assessments and their analytical methods do not accurately depict risks, costs, and benefits of CCUS projects in current and future markets. These evaluation models assess the cost of a CCUS install as a function of capital expenditures (CAPEX) and effects on operating costs (OPEX), accounted for in cost per unit of CO2 captured. Analysis includes baseline assumptions about the operating requirements of the carbon capture equipment, such as power requirements, maintenance, cost of compression, transport, and storage, and effects on plant productivity during and after construction (e.g., (Liang and Li 2012). Baseline assumptions rely on outdated performance data, typically from amine-based capture processes relying on coal-fired heat and power generation with overstated power requirements and carbon capture efficiencies around 70 to 80% of total plant emissions (Liang and Li 2012). Assumptions also incur oversized effect to indirect costs, such as technology readiness level (TRL) impacts on contingency planning costs (Gardarsdottir et al. 2019) and production impacts from simulated process flow models (Liang and Li 2012). Outside-the-gate factors assume fixed estimate rates for variable factors like future carbon pricing and energy supply types (Liang and Li 2012). Traditional assessments may also ignore market specific conditions like the availability of carbon transport and storage infrastructure or potential revenues for captured CO2.

Cement plants that are “new” are less likely to undergo an intensive retrofit: Given the relatively young age of cement plants discussed by interviewees, the interviewees indicated that taking on a capital-intensive retrofit would be unlikely unless such a retrofit was mandated by a local/state/national policy.

Cement plants have typical service lives of 30 to 50 years (Gardarsdottir et al. 2019). With the average age of plants in the U.S. at just under 20 years (IEA 2023), many existing plants could be considered for potential CCUS retrofit, provided they can sustain operations for the 20 to 25-year payback period (Gardarsdottir et al. 2019). CCUS installation can raise the costs of clinker production 50-90% (Gardarsdottir et al. 2019). The cost of captured carbon is a function of the cost of clinker divided by the total capture capacity of CO2 emissions. Cost of captured carbon varies widely according to the capture efficiency of each technology and the specific plant deploying it (Gardarsdottir et al. 2019). Total plant costs with carbon capture compared to potential revenues and incentives in each market determines the economic justification for retrofit.

DISCUSSION

The authors discuss herein how the barriers listed in the "Results" section can be addressed by lean project delivery.

LIMITED UTILIZATION POTENTIAL FOR CAPTURED CO_2

It is not immediately clear how lean tools, or the lean project delivery system, can address this barrier. However, one possibility would be to conduct a root cause/5 Whys analysis to understand exactly why the utilization potential is low. The authors do not expect that this analysis will yield a clear solution. Rather, the authors posit that this analysis will clearly frame future research directions that provide clarity about what makes utilization difficult. For instance, is the issue that there is not enough demand for CO_2 in the marketplace? This would seem reasonable, as many ongoing efforts work to reduce the CO_2 created, rather than use CO_2. If this is the root cause, then perhaps solutions for CCUS should focus more on storage of the captured carbon, without trying to develop a case for using the CO_2. If, however, the issue is that once carbon is captured, the transport to the utilization site (e.g., a soda plant) "costs" more CO_2 emissions than the CO_2 capture and utilization avoid, there is a clear opportunity to site new users of CO_2 proximate to cement plants with CCUS technologies installed. Indeed, the authors research suggests that if CO_2 has to be transported more than 100 km, the net CO_2 emissions are higher than if the CO_2 had simply been released at the plant.

EVALUATION OF TECHNOLOGY READINESS CAN IMPEDE IMPLEMENTATION

As discussed, evaluation of technologies and their applicability for a given plant should not be considered "one size fits all." Lean philosophies recognize the unique nature of construction sites and support developing the best approach for that specific site. Of particular note for evaluation is set-based design (e.g., (Ward et al. 1995; Sobek et al. 1999; Rekuc 2005; Parrish et al. 2007; Parrish et al. 2008a; Parrish et al. 2008b; Parrish 2009), which allows project teams to consider multiple design options longer than would be typical in a point-based design scenario. For the case of CCUS retrofits for cement plants, set-based design may involve considering multiple CCUS technologies, regardless of their technology readiness level. Indeed, the goal would be to allow each CCUS technology to persist in the design process until the last responsible moment, when failure to make a decision delays the overall project (Parrish et al. 2007). Project teams may elect to consider various CCUS technologies and explore their fitness for the cement plant at hand, in terms of leveraging incentives, meeting local/state/national or organizational CO_2 emissions reduction goals, and supporting site-specific production cost metrics, e.g., $\$/t_{CO2}$. When design alternatives are developed, project teams can make data-driven decisions about which CCUS technology is most appropriate using Choosing By Advantages (e.g., (Suhr 1999; Parrish and Tommelein 2009; Arroyo et al. 2015). CO_2 emissions reductions can be expressed as a 'must' or a 'want' criterion, depending on the requirements of the city or region where the plant is located.

NEWER CEMENT PLANTS ARE UNLIKELY TO UNDERGO A RETROFIT

The "Project Definition" and "Lean Design" phases of the LPDS offer clear opportunities to address this barrier. While it is understandable that a cement plant owner may not want to make a large capital investment in their relatively new plant, climate-related legislation and goals may warrant making such investments earlier than originally planned. Similar to the "evaluation barrier" described above, this barrier can be addressed by thoroughly understanding the context for the project. Assuming that a plant *must be retrofit* to comply with internal or external CO_2 emissions reduction plans, then lean project delivery offers the full project team an opportunity to collaboratively brainstorm potential solutions and assess them as a team. To address this barrier, a "big room" may be helpful (Ballard 2008). However, instead of using the big room during the design phase, the authors recommend implementing a big room meeting during an ownership meeting; that is, the plant owners could invite multiple designers and engineers to one of their routine meetings where they discuss plant operations. This big room would essentially offer a platform for brainstorming feasible CCUS solutions for each plant in the owners' portfolio. Then, the project teams can leverage set-based design and Choosing By Advantages to evaluate the most appropriate CCUS option for each site.

BROADER CONTEXT: EXISTING FACILITY RETROFITS

While this paper has focused on the barriers to implementing CCUS in cement plants, the barriers are likely not all that different than barriers facing any facility retrofit. As concern about the climate grows, and policies begin to be implemented that limit CO_2 emissions and mandate energy performance across sectors (e.g., (State of California 2018; New York City 2019), many facility owners will face a need to retrofit their facilities. The LPDS, and specific tools that enable it, can help owners identify the appropriate potential retrofits for their facility and decide from among these alternatives.

CONCLUSIONS

This paper explored how the lean project delivery system can support CCUS implementation in the cement industry. The authors highlighted specific barriers to CCUS implementation in the current marketplace, including limited utilization potential for CO_2, evaluation of CCUS technology, and unwillingness to invest in a relatively new asset. The authors discuss how the LPDS, and lean tools like set-based design, Choosing By Advantages, and big room meetings can help owners to overcome barriers associated with CCUS implementation. Indeed, the authors argue that these results extend beyond CCUS implementation in cement plants, and extend to any facility that requires a retrofit.

As discussed in the "Methods" section, the authors did not have enough data about enough projects to compare project outcomes for those projects using the LPDS versus those that did not. Such a study would be welcome in future research by the IGLC community.

THE CIRCU-LEAN REVOLUTION: A REVIEW OF THE SYNERGIES BETWEEN LEAN AND THE CIRCULAR ECONOMY

Nathan G. O. Johns[1], Saeed Talebi[2], Mark Shelbourn[3], Chris Roberts[4], and Mike Kagioglou[5]

ABSTRACT

Due to the impacts of industrialisation on the planet's environmental systems, industrial practice has had to evolve. Sustainable development goals have been set by the United Nations to limit industrial impacts on the environment. At the core of the development goals are the efficient use of materials and the reduction of waste. Two common production philosophies are becoming prevalent within the literature as a solution to consumption and waste within the construction industry, Lean and the Circular Economy (CE). Both provide aspects of green supply chain management that are required to meet the goals set by governments. There are clear synergies between the two philosophies though there are few investigations into their likeness within the literature. This paper aims to further investigate the synergies between Lean and the CE within the construction industry to develop the extant body of knowledge. The findings of the research identified that the majority of interactions between the concepts were positive although not entirely explored in construction. The core similarities surround waste reduction whereas the key differences are Lean's human management and the CE's closed-loop value retention. Therefore, it is suggested that a complimentary mixed Circu-Lean philosophy will be the future of production and construction.

INTRODUCTION

Since the early innovations of man, the analysis of the economic system and its activities have brought forth knowledge for the advancement of the production process. Revelations in economic and production theory have revolutionised countries and humanity's way of life. Allowing production activities to produce higher quantities, higher quality, and in a shorter timeframe (Liker, 2004; Ghisellini *et al.*, 2016). By increasing these aspects of production, economies, and organisations have created competition for the best system structure (Shah and Ward, 2003; Liker, 2004). The creation of Mass and Lean production proposed differing

philosophies which focus on aspects of the supply chain in order for improved outcomes such as quantity or value (Liker, 2004). Since the late twentieth century, the rhetoric has refocused on the impacts of the economy on organic life and the biological systems that support it (Huovila and Koskela, 1998; McDowall *et al.*, 2017; Ogunmakinde *et al.*, 2022). This is due to the analysis and understanding of the environmental impacts produced by economic activities. The results of which identified an unsustainable future for humanity without industrial change. Sustainable development goals set to limit the impact of humanity's expansion have been created by the United Nations (UN, 2022). The targets set by the United Nations commonly aim to reduce the number of resources consumed and the wastes concurrently produced in the development and maintenance of economies (UN, 2022). In this effort, the improved management of resources within the construction industry is proposed through waste-focused production philosophies and Supply-Chain Management (SCM) (Carvajal-Arango *et al.*, 2019; Hossain *et al.*, 2020; Ogunmakinde *et al.*, 2022).

Green Supply Chain Management (GSCM) is becoming more popular within academic literature (Kalemkerian *et al.*, 2022). In the development of a green philosophy of production to reduce waste, the benefits of Lean production in reducing waste and environmental impacts were identified (Huovila and Koskela, 1998; Marhani *et al.*, 2013; Carvajal-Arango *et al.*, 2019). The Lean philosophy's promotion of value through the reduction of waste in all its forms has provided a basis for green production. However, a more recent philosophy has grasped similar attention for the reduction of waste within the economic supply chain, the Circular Economy (CE) (Adams *et al.*, 2017; Geisendorf and Pietrulla, 2018; Chen *et al.*, 2021). The CE production philosophy creates a closed-looped flow of materials within the supply chain (MacArthur, 2013). The value of the original material input is the core focus of the philosophy and is therefore maintained throughout the supply chain (MacArthur, 2013). Thus, the CE reduces waste through the informed design and conservation of resources (Benachio *et al.*, 2020). Both the Lean and CE philosophies of production reduce waste within the supply chain to meet the demands of a modern sustainable industry. However, the synergies between the concepts are scarcely investigated in the literature with publications only appearing from 2021 (Benachio *et al.*, 2021; Schmitt *et al.*, 2021; Silva *et al.*, 2022). Furthermore, publications specifically looking at the synergy between the two concepts within the construction industry is limited to one pertinent journal publication by Benachio *et al.* (2021). This gap in knowledge requires addressing though as of yet the extant knowledge is yet to be coalesced. This paper aims to investigate extant literature surrounding the synergies between Lean and the CE within both manufacturing and the construction industry to coalesce and contrast current knowledge to guide future investigations into the synergies within construction.

RESEARCH METHODOLOGY

The research conducted was in the form of a systematic literature review, in which data was collected using Scopus, Web of Science, and Google Scholar by using keywords to search for the titles, abstracts, and keywords of extant literature. The following keyword strings were used; **String 1 (CE):** ("Circular Econom*" OR "Circular Practice" OR "circular manage*") AND ("construction industry" OR "construction" OR "built environment") ; **String 2 (Lean): (**"Lean Philosophy" OR "Lean Production" OR "Lean Principle") AND ("construction industry" OR "construction" OR "built environment"); **String 3 (Synergies) (**"Circular Econom*" OR "Circular Practice" OR "circular manage*") AND ("Lean Philosophy" OR "Lean Production" OR "Lean Principle"); **String 4 (Synergies in Construction): (**"Circular Econom*" OR "Circular Practice" OR "circular manage*") AND ("Lean Philosophy" OR "Lean Production" OR "Lean Principle") AND ("construction industry" OR "construction" OR "built environment"). Twenty papers were identified for String 3 and five papers were identified for String 4 within the literature, String 1 and 2 have large bodies of extant literature from which only core literature had to be selected for context. The sampled papers were manually reviewed and excluded if they were not a journal article or were deemed irrelevant to the research or of a low quality. The final sum of papers for String 3 and 4 included eight journal articles on the synergies between the two topics, four of which were construction related. An interpretivist philosophy and deductive reasoning guided this study to review and compare the synergies within the literature (Saunders *et al.*, 2009). The selected literature from String 4 was analysed through content analysis to identify the core principles of the two concepts and their synergies (Saunders *et al.*, 2009; Patton, 2014). A qualitative research synthesis analysis was conducted to compare and contrast the results of the literature on the synergies using a matrix of the identified synergies within literature (Patton, 2014). The identified Lean principles have been numerically coded, and the CE practices have been assigned alphabetical codes for cross examination. The synergies within the literature were analysed individually and then overlayed to view the density of relationships. The synergies identified are shown within Table 6 to highlight commonalities, differences, and gaps within both topic areas as identified within the extant literature. Finally, the results of the matrix will be observed and discussed to understand the nature of said results and areas for future research to guide researchers and practitioners.

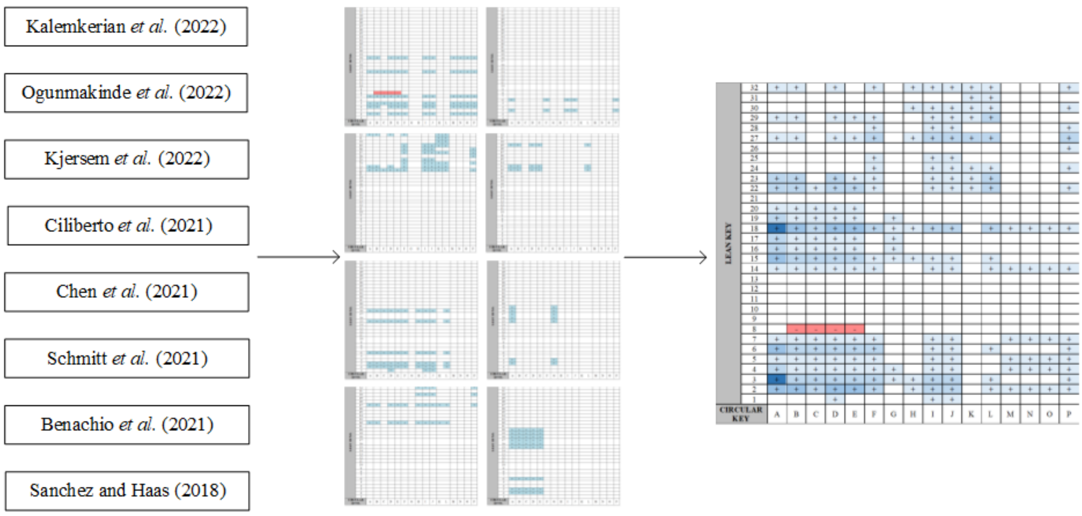

Figure 1: Development of qualitative research synthesis analysis matrix

THE LEAN PHILOSOPHY OF PRODUCTION

The TPS system established 14 management principles to improve the workplace and seven wastes (Table 1) which created the Lean philosophy of production (Liker, 2004). The Lean philosophy of production aims to promote value within the production process and reduce waste that hinders those efforts (Shah and Ward, 2003; Liker, 2004). The pull system utilised by Lean allows for the reduction of several wastes such as overproduction, waiting time, and inventory expenditure by drawing demand from the consumer (Liker, 2004). Lean principles create a consumer-led production with the “pull” system, whilst refining the process to ensure the quality of the product, and the effective management of the workers and their knowledge, well-being, and skills (Shah and Ward, 2003; Liker, 2004). Lean principles are made to be used together to form focussed multi-method strategies such as Just-In-Time (JIT), Total Quality Management (TQM), Human Resource Management (HRM), and Total Productive Maintenance (TPM) (Shah and Ward, 2003; Liker, 2004). The incorporation of the Lean philosophy within the production and construction industries has shown an improvement in the performance of the system in terms of cost, time, quality, and in turn the environmental impact of the process (Hines *et al.*, 2004; Liker, 2004; Marhani *et al.*, 2013; Carvajal-Arango *et al.*, 2019). Due to the positive impacts of Lean within production, it has become a popular philosophy within manufacturing and construction. Ultimately, it has become intertwined with modern methods of production management.

Table 1: Lean Principles from Liker (2004)

ID	MANAGEMENT PRINCIPLE
1	Base your management decisions on a long-term philosophy, even at the expense of short-term financial goals.
2	Create continuous process flow to bring problems to the surface.
3	Use “pull” systems to avoid overproduction.
4	Level out the workload (Work like the tortoise, not the hare.)
5	Build a culture of stopping to fix problems, to get quality right the first time.
6	Standardized tasks are the foundation for continuous improvement and employee empowerment.
7	Use visual control so no problems are hidden.
8	Use only reliable, thoroughly tested technology that serves your people and processes.
9	Grow leaders who thoroughly understand the work, live the philosophy, and teach it to others.
10	Develop exceptional people and teams who follow your company’s philosophy.
11	Respect your extended network of partners and suppliers by challenging them and helping them improve.
12	Go and see for yourself to thoroughly understand the situation
13	Make decisions slowly by consensus, thoroughly considering all options; implement decisions rapidly
14	Become a learning organization through relentless reflection (hansei) and continuous improvement
15	Over Production - Producing more than the customer demands
16	Inventory - Related to Overproduction, inventory beyond that needed
17	Transportation - The material be shipped directly from the vendor to the location in the assembly line
18	Waiting - Material is not being transported or processed
19	Over Processing - eworking, deburring, and extra work undertaken
20	Defects - Production defects and service errors waste resources i. Materials ii. Labour iii. Time vi. Reworking labour
21	Motion - This waste deals with ergonomics and health issues with respect to the workers and their job

LEAN CONSTRUCTION

The 11 Lean Construction (LC) principles were derived by Koskela (2002) (Table 2) to adjust for the differences within the construction industry’s lifecycle structure. The priciples of Lean construction utilise those of the Lean philosophy within a construction context to better suit the structure of the industry. It was identified within construction that there are activities that create process flow within the system preparing resources and conversion activities that transform resources into products of value (Alarcón, 1997; Koskela *et al.*, 2002). The flow and conversion activities within construction are a complex mix of materials, components, and discipline-specific labour (Alarcón, 1997; Babalola *et al.*, 2019). Thus, the application of the Lean philosophy is increasingly difficult as opposed to manufacturing due to the size and complexity of construction (Alarcón, 1997; Koskela *et al.*, 2002). Koskela’s (2002) LC principles focus on managing the complexity of the construction system in order to better apply Lean production principles (Alarcón, 1997; Koskela *et al.*, 2002). Communicating information, benchmarking, and evaluating activities are key in understanding the flow and conversion of resources to reduce the wastes identified by Lean (Koskela *et al.*, 2002). Furthermore, simplifying the process assists in the application of management strategies (Alarcón, 1997; Koskela *et al.*, 2002). LC aims to lower the complexity of the system with standardisation and simplification in order to reduce the waste caused by complex systems (Alarcón, 1997; Koskela *et al.*, 2002). Within construction the application of the Lean philosophy has shown similar promises of value as those found in manufacturing (Babalola *et al.*, 2019; Carvajal-Arango *et al.*, 2019). In summary, LC advances upon Lean production in an attempt to increase adoption within the vast and complex industrial system that is construction.

Table 2: Lean Construction Principles by Koskela *et al.* (2002)

KEY	LEAN CONSTRUCTION PRINCIPLE
22	Reduce the share of non-value-adding activities
23	Reduce the cycle time
24	Reduce variability
25	Simplify by minimizing the number of steps, parts, and linkages
26	Increase output flexibility
27	Increase process transparency
28	Increase value through the consideration of customer's requirements
29	Focus control on the complete process
30	Build continuous improvement into the process
31	Balance flow improvement with conversion improvement
32	Benchmark

THE CIRCULAR ECONOMY

The Circular Economy (CE) is a new structure for construction and production, becoming popular around the millennium (Govindan and Hasanagic, 2018). Now the CE is being proposed around the globe by organisations and governments as a solution to economic waste (McDowall *et al.*, 2017; Huang *et al.*, 2018). The CE is part of the most recent industrial revolution, Industry 5.0, the human-centric focus of industrial practice (MacArthur, 2013; Geisendorf and Pietrulla, 2018). The CE aims to reduce waste within the lifecycle of products by promoting value and reducing waste (Geisendorf and Pietrulla, 2018; Govindan and Hasanagic, 2018). This is achieved by creating a pull-system and closing the loop on linear waste removing value from the system (Geisendorf and Pietrulla, 2018; Govindan and Hasanagic, 2018). The CE has several principles in which to reduce waste and promote value within the lifecycle known as the 3Rs, 6Rs, or the 12Rs (MacArthur, 2013; Geisendorf and Pietrulla, 2018). The 3Rs are simply reduce, reuse, and recycle (MacArthur, 2013; Huang *et al.*, 2018). These outline the aims of the CE, to reduce the quantity of resources consumed, to reuse products and components, and finally, recycle waste back into the system to gain the maximum value from resources (MacArthur, 2013; Huang *et al.*, 2018). The 6Rs and 12Rs go further into detail, elaborating on the 3Rs with refuse, reduce, repair, reuse, repurpose, regenerate, rethink, remanufacture, recycle, recover, rot, and re-evaluate (MacArthur, 2013). Overall, the principles of the CE aim to consider the implications of the supply chain to avoid, manage, evaluate, and recover material waste within the supply chain.

Table 3: Circular Economic Principles

KEY	CE PRINCIPLE	DESCRIPTION
A	Reduce	The reduction of resources and waste at every stage possible. From design through to the end-of-life stage.
B	Reuse	The reuse of materials and components in new products or projects.
C	Remanufacture	The restoration of materials or components.
D	Recover	The collection of materials in their end-of-life period.
E	Recycle	The incorporation of recovered materials in new products.
F	Redesign	The reduction of waste and incorporation of recovered materials through product design.

CIRCULAR CONSTRUCTION

The CE within the construction industry is still relatively new, only appearing significantly within the literature since 2015 (Adams *et al.*, 2017; Benachio *et al.*, 2020). The construction industry has naturally developed a human-centric pull-system in some sectors as the requirements of the client are stated for the function of the project (Ghisellini *et al.*, 2016; Hart *et al.*, 2019). Though a higher level of consideration for the human element in the built environment is emerging in the fifth industrial revolution (Geisendorf and Pietrulla, 2018; Çimen, 2021). However, the manufacturing of materials and components for the construction industry still follows a linear mass production structure to supply projects (Hart *et al.*, 2019; Hossain *et al.*, 2020). Furthermore, the construction industry is one of the largest waste producing industries, making construction a target for CE innovation (Adams *et al.*, 2017; McDowall *et al.*, 2017; Benachio *et al.*, 2020). The practices used by the construction industry to implement closed-loop circular economic flows have been coalesced in Table 4. The practices utilized by the construction industry are focused on communication within the industry, simplification of the systems processes and components, and design according to the 3Rs. In totality, the CE within the construction industry collaborates, evaluates, and redesigns.

Table 4: Circular Economic Practices in Construction

KEY	CE PRACTICE	DESCRIPTION
G	Pull-system	Produce the number of products to the required demand to avoid materials and products requiring inventory space or being wasted.
H	Lifecycle Analysis	Evaluation of the activities and events in the lifespan of a given process or material.
I	Design for Maintenance	The consideration of maintenance within the design of the product to reduce depreciation of the value.
J	Design for Recovery	The consideration of resource and component recovery to reclaim value lost from the linear wasting of products.
K	Standardisation	The use of common designs, materials, or processes to reduce the amount of variation within the market. Overall, it simplifies the application of higher strategies.
L	Modularisation	The design of a product in sections to allow for the interchangeability of components/modules.
M	Supply-chain Management	The collaboration and management of members of the supply chain for better synchronisation of the project's supply.
N	Knowledge Management	The management of data and knowledge in regard to the project for a better understanding of the completed work and the proposed.
O	Stakeholder Management	The management of stakeholders for better communication and direction for the project's operational functionality.
P	Material Passports	The creation of passports for resources to communicate the resource's information and designed lifecycle strategy.

The initial practice for CE innovations is the analysis of the lifecycle to view the waste produced by industrial activities (Benachio *et al.*, 2020; Çimen, 2021). This evaluation is key to understand the problem within the system (Hossain *et al.*, 2020; Munaro *et al.*, 2020). Once identified, the waste can be considered within the design stage (Adams *et al.*, 2017; Benachio *et al.*, 2020). The waste can be designed out and reduced, designed for reuse, and designed for recovery (Adams *et al.*, 2017; Benachio *et al.*, 2020). Material passports are used to communicate the designed strategy for maintenance and recovery to enable its application (Hossain *et al.*, 2020; Munaro *et al.*, 2020). Designing for maintenance and recovery can be assisted by practices such as modularisation and standardisation of components to reduce complexity within the design (Adams *et al.*, 2017; Hossain *et al.*, 2020). These methods of production are also less wasteful as components are prefabricated in factory conditions (Hart *et* *al.*, 2019). Additionally, collaboration with the wider supply chain better enables the creation of a closed-loop CE structure within the industry (Govindan and Hasanagic, 2018; Çimen, 2021). SCM is therefore a core practice of the CE to design for and recover materials in the lifecycle (Govindan and Hasanagic, 2018; Munaro *et al.*, 2020). The management of stakeholders is also key to create a uniform direction for the design and application of the given strategy (Govindan and Hasanagic, 2018; Çimen, 2021). Altogether, the knowledge generated through the communication within the supply chain and stakeholders requires management and evaluation to further apply the 3Rs, 6Rs, or 12Rs (Munaro *et al.*, 2020). Ultimately, creating more value from the production and operation of the product.

CIRCU-LEAN SYNERGIES

The popularity of Lean and the CE in literature as solutions to unsustainable consumption naturally brought forth comparisons to determine their qualities. However, the topic is not yet saturated within the literature with only eight papers identified with both topics mentioned in the title, abstract, or keywords. Of the eight papers identified within the literature, four were based on manufacturing. Firstly, Ciliberto *et al.* (2021) conducted an initial study creating a series of matrixes comparing Lean and the CE finding strong correlations in the reduction of waste through evaluation and collaboration. Kjersem *et al.* (2022) found that Lean and the CE have many similarities within the process and production stages in terms of waste reduction and environmental/economic impacts. Schmitt *et al.* (2021) investigated the synergy with the aim of creating a three-level system for the strategies to be combined and incorporated into the product, process, and system levels of the economy. Schmitt *et al.* (2021) found that Lean compliments the process level of the CE strategy whilst the CE promotes long-term value. Kalemkerian *et al.* (2022) found similar results as Schmitt *et al.* (2021) in their investigation into Green Lean management which had limitations compared to the long-term environmental and economic gains of the CE. Overall, the initial investigations into the synergy between Lean and the CE are positive.

Within the construction industry the investigation of synergies between LC and the CE are fewer still. Several papers mention Lean and the CE though do not investigate or elaborate on the relationship. Sanchez and Haas (2018) suggested some initial benefits from the application of a CE with the Last-planner system. Sanchez and Haas (2018) proposed that Lean's last-planner pull-system and management strategies provided a beneficial structure for the application of a CE though did not specifically focus on investigating the relationship. Chen *et al.* (2021) found that the use of Lean can benefit the CE in the construction stage by mitigating the waste produced by activities and process. Furthermore, Ogunmakinde *et al.* (2022) hypothesised the use of modular prefabrication within LC can assist in developing CE methods within construction supply chains. Benachio *et al.* (2021) investigated the interactions between the two strategies within the construction lifecycle finding seventy-four positive and four negative interactions. Benachio *et al.* (2021) found the highest number of interactions surround off-site construction and prefabrication where Lean is better applied. Benachio *et al.* (2021) also investigated the interactions based on the stage in the construction lifecycle. Benachio *et al.* (2021) found that the construction stage has the highest number of interactions between the strategies. In summary, some synergies between Lean and the CE have been identified within the literature but only Benachio *et al.* (2021) conducted an investigation specifically into the synergy within the construction sector.

FINDINGS AND DISCUSSION

This research found that the synergies identified between Lean and the CE within the literature are positive overall but still in the early stages of investigation. The sample of literature identified for the study was minimal and largely focused on manufacturing and production over construction specific investigations of the synergy. The eight papers used within the matrix were analysed individually to understand the identify the synergies discussed within the literature, then coalesced in Table 5 for cross-examination.

Table 5: Synergies between Lean and the Circular Economy. Positive Interactions (Light Blue to Dark 1-4), Negative Interactions (Red).

The in the cross-examination of the literature on CE and Lean synergies, it was identified that the largest number of interactions were identified within the waste reduction principles and practices. This is supported by Benachio *et al.* (2021), who identified the most interactions between the two concepts which are within the manufacturing and construction stages. This further supports waste reduction as the core similarity between the topics. This further suggests that manufacturing and construction are perceived the most immediate stages in which waste can be reduced. In this effort, the pull system is utilised for the reduction of waste such as overproduction and inventory space in both strategies but was originally developed within Lean's philosophy (Liker, 2004). The human-centric pull-system of both strategies creates consumer-led value and was commonly identified as a similarity between the two strategies. The considerations present within both strategies for the consumers requirements assist in reducing waste caused by unwanted or unneeded products or elements. This is underpinned by another similarity between the two topics, the focus on long-term value and prioritisation of the big picture. By prioritising the long-term outcome, both strategies increase value, sometimes at the cost of short-term performance (Liker, 2004; Govindan and Hasanagic, 2018). In this regard, both strategies evaluate practice to improve the system. The Lean philosophy creates continuous improvement, benchmarking, and aims to increase transparency in order to identify and understand inefficiencies or wastes within the system for redesign. Similarly, the CE aims to analyse the impacts of the lifecycle with LCA to understand the material wastes produced and their impacts for redesign and reduction or strategic recovery of the waste. Overall, the reduction of waste is largely similar in terms of output though differs slightly in methodology.

There are also several differences between the two strategies. The distinct difference identified within the literature are the well-defined principles and wastes within the Lean philosophy that are more developed than the CE. The advantage of Lean's established practice enables granular waste reduction within the system's processes and activities whilst cultivating the workforce. The CE on the other hand is a more recent strategy that is still developing and therefore has not yet reached a level of maturity to specifically target wastes on a granular level. However, the CE also provides innovations to the Lean philosophy that can further increase waste reduction and value promotion within the system. The closed-loop structure of the CE strategy adds value from waste that cannot be designed out or reduced. The longitudinal nature of the CE strategy adds a system level consideration for value and waste which increases value retention over the lifecycle. The holistic closed-loop nature of the CE lifecycle compliments the Lean philosophy by elucidating on the long-term benefits of managing value and waste. Both points highlight deficiencies in which the other compliments. This suggests that not only are there significant similarities between the two strategies but complimentary difference in which the strategies support and develop one another. Furthermore, the Lean philosophy also aims to promote value from the workforce and their experience, knowledge, and skills. The management of human resources has shown to further increase value within the production and construction of products. In comparison to Lean, the CE has few practices for the enrichment of the human resources within the system. Additionally, Lean aims to educate and advance the workforce to better the overall organization and the extended supply chain. Thus, it is suggested that the use of Lean's human resource management could support the development of the CE's management philosophy. In summary, Lean's principles of collaboration between management and the workforce could help promote a culture of closed-loop recycling within management for construction and production and are not negative differences between the strategies. Overall, there are some differences between the strategies, though they are not necessarily negative and could be used to develop a new Circu-Lean philosophy for economic production. One study highlighted negative interactions between the CE and Lean strategies conducted by Ciliberto *et al.* (2021). Which identified the CE's innovative use of materials for new sources of value contradicted Lean's desire for thoroughly tested and simplified systems (Ciliberto *et al.*, 2021). There are no doubt further negative interactions between the two topics however there is no extant studies investigating this factor and therefore should be the focus of future studies.

The investigation into the literature for synergies between Lean and the CE found that there are many similarities and differences (Table 6). Primarily, a human-centric pull-system, the promotion of value, the reduction of waste, the simplification of processes, the long-term focus of the strategies, and evaluation for redesign. Through cross examination of the similarities within Table 6, areas in which the two strategies differ are highlighted by the lack of interactions between the strategies. Initially, the infancy of the CE management philosophy in contrast to Lean's, which has developed several management principles for the extraction and promotion of value from management and the workforce. Secondly, both strategies approach value promotion and waste reduction differently. Lean's reduction of process waste within flow and conversion activities provides a granular approach. Whereas the CE focuses on general material waste reduction and recovery through a holistic closed-loop approach. This suggests that where the strategies are lacking interactions within Table 6, said differences could be beneficial to the developing the opposing strategy.

CONCLUSION

In totality, the literature specifically on Lean and the CE in the construction industry is still within its early investigation of the synergy between the management strategies. Benachio *et al.* (2021) have conducted the most sophisticated study into the synergy and have identified multiple areas where positive interaction between the strategies exists. However, within the literature there is yet to be a publication of sufficient quality to support or contradict the study conducted Benachio *et al.* (2021). Furthermore, if the initial findings within the literature for production and construction are correct. The synergy between Lean and the CE could be extremely valuable for construction in the effort of meeting SDGs. Overall, the similarities between the strategies within the design and production/construction stages are vast and positive. Likewise, the differences, although stark, suggest a complimentary contrast if combined. Ultimately, providing guidance and structure for one another to innovate where the other is successful.

The novelty of this work is twofold, a review to coalesce and critique of the extant knowledge on the Circu-Lean synergy, and guidance for future research into the synergy between Lean and the CE. Future research would continue the investigation into the strategies' synergies within the construction industry to better understand the similarities and differences. Furthermore, the investigation into the similarities between waste reduction can provide an interesting platform for researchers to identify the best practice for waste reduction in the construction industry. Moreover, further research into the differences between the two strategies can elucidate on the shortfalls and areas in which the contrast between the two strategies can complement one another (E.g., HRM in the CE). The limitations of this study are largely due to the lack of construction specific research on the synergies between Lean and the CE. As the literature progresses the qualitative synergy within the matrix would become richer as the sample increases in size. Furthermore, at present there is little contradictory literature for the review of contrasting opinions within the research community

In summary, this research reviewed a newly founded body of knowledge on the synergies between Lean and the CE. The vast majority of interactions between the two strategies are positive and concentrated on waste reduction. And finally, it is suggested that the development of the literature surrounding the synergy between CE and Lean could converge into a Circu-Lean philosophy of economic production and construction.

León William. & Guevara, Jose. (2023). "Semantic network analysis of lean construction literature." In: *Proc. 31st Annual Conference of the International Group for Lean Construction (IGLC31), Rybkowski, Z. K., Liu, M., and Sarhan, S. (eds)*, Lille, France, pp. 559–570. doi.org/10.24928/2023/0152. Available at: <https://iglc.net/Papers>

SEMANTIC NETWORK ANALYSIS OF LEAN CONSTRUCTION LITERATURE

León William[1] and Guevara Jose[2]

ABSTRACT

Lean Construction is a philosophy grounded in production theory that play a crucial role in promoting efficient, sustainable, and cost-effective practices across the Construction and Engineering Management (CEM) sector. To understand its impact, it is important to analyze the related concepts, synergies, information gaps, potential research paths, and new terms associated with such domain. Therefore, this research paper aims to develop a graphical and quantitative analysis of the LC literature using Semantic Network Analysis (SNA). The analysis builds a large network of interactions between concepts related to the implementation of the LC philosophy in construction projects, offering a novel perspective on reviewing the LC literature. It provides metrics and graphical tools to characterize, quantify, and interpret LC concepts such as Building Information Modelling (BIM), Integrated Project Delivery (IPD), Last Planner System (LPS), and Sustainable Construction, and enables the observation of emerging relationships with opposing concepts such as Earned Value Management (EVM) or information gaps related to Risk Assessment, Decision-Making, or Planning Reliability, which are equally crucial for the implementation of CEM. Overall, this study offers valuable contributions to the IGLC community by providing new perspectives on potential research routes and emerging concepts in the LC literature. It achieves this by synthesizing the relationships between LC ideas and concepts that are not traditionally connected to LC principles, such as Earned Value Management (EVM).

KEYWORDS

Lean construction, construction and engineering management, and semantic network analysis.

INTRODUCTION

Researchers in the field of Construction and Engineering Management (CEM) have developed useful methodological tools by leveraging quantitative and graphical analysis of bibliographic reviews (Herrera et al., 2020). While Lean Construction (LC) has been thoroughly studied over the past decades, there is a notable gap in the CEM domain when it comes to the integration of LC with other essential concepts in the construction industry (Heigermoser et al., 2019). Based on that, this study aims to address this gap by examining the relationships between LC studies and other relevant investigations focused on concepts, such as Building Information Modelling (BIM), Integrated Project Delivery (IPD), Earned Value Management (EVM), and sustainability.

In order to develop a quantitative and graphical synthesis of LC and its connection with other relevant concepts in the CEM domain, the study utilizes Semantic Network Analysis

[1] Ph.D. research assistant, Civil and Environmental Engineering Department, Universidad de los Andes, Bogotá, Colombia, wm.leon10@uniandes.edu.co, https://orcid.org/0000-0002-2533-853X

[2] Associate Professor, Civil and Environmental Engineering Department, INGECO research group director, Universidad de los Andes, Bogotá, Colombia, ja.guevara915@uniandes.edu.co, https://orcid.org/0000-0002-3485-9169

(SNA) (Salazar et al., 2021). This analytical tool allows for the development of networks between associated concepts in a literature review, making it possible to analyze LC and its synergies with other important ideas (Wen & Qiang, 2016). By characterizing, quantifying, and interpreting concepts that are commonly associated with LC and other terms with wide application in the construction sector, this analysis aims to provide a set of metrics and graphical tools that researchers can use to gain a deeper understanding of LC (Castelblanco et al., 2021). Thus, examining the integration of LC and CEM ideas.

POINTS OF DEPARTURE

LEAN CONSTRUCTION

Lean Construction is a philosophy grounded in production theory that play a crucial role in promoting efficient, sustainable, and cost-effective practices across the Construction and Engineering Management (CEM) sector (Koskela et al., 2002). The main focus of this philosophy is on improving the management and administration of construction projects by continuously improving processes, reducing waste, and increasing the final value of the construction product for the customer (Koskela et al., 2002). The adoption of this philosophy leads to higher productivity in processes, which in turn results in increased profitability of projects while minimizing the processes associated with the loss of value of the final product (Aslam et al., 2020). Hence, LC is considered a vital tool for optimizing resources and eliminating waste (Igwe et al., 2020).

SEMANTIC NETWORK ANALYSIS

SNA is a methodological approach for the analysis of dense networks between associated concepts, provides a quantitative, qualitative, and rigorous analysis of the existing synergies between concepts in literature (Motter et al., 2002; Pishdad-Bozorgi et al., 2017). Based on the development of networks of related words, this association analysis enables the extraction of metrics and the production of clear objectives and complex analyses related to the general structure of the relationships (Motter et al., 2002). The structure of this methodology involves creating a network of interconnected nodes from a set of words. If words are not associated with other nodes, this methodology reveals isolated connections or relations of interdependence between them (Herrera et al., 2020; Motter et al., 2002).

Using SNA allows for quantitative analyses of keywords from different articles and provides graphic and mathematical results (Zhai et al., 2014). Moreover, this technique enables the analysis of large databases with low computational requirements, making literature reviews more complex and comprehensive (Han et al., 2018). Therefore, this study employs SNA in evaluating and analyzing the LC and CEM literatures.

CONTENT ANALYSIS

Content analysis (CA) is a valuable technique that complements the SNA methodology. It involves a set of methodologies that allow researchers to extract information from a qualitative or quantitative interpretation of texts (Yearworth & White, 2013). By filtering, categorizing, and classifying information, researchers can carry out objective analyses that are suitable for graphic and mathematical analysis (Elo et al., 2014). In this study, the authors used content analysis to group themes, select fundamental concepts, evaluate trends, establish recurrences, and facilitate the SNA study of LC. In combination with SNA, content analysis enables a comprehensive and in-depth analysis of the literature on LC.

COMMUNITY ANALYSIS

Community analysis is a quantitative strategy used to understand and analyze the behavior of related concepts within a small group compared to the main network being studied (Newman, 2004). This tool helps researchers observe the grouping of sets of nodes that share similar characteristics. Community analysis is highly useful for characterizing underlying communities in large databases (Blondel et al., 2008). It also provides graphical complements that aid in understanding the overall network of nodes (Newman, 2004). By combining SNA, CA, and community analysis, this study analyzed LC and identified associated concepts and main networks from a rigorous selection of 500 research articles from bibliographical resources.

RESEARCH METHODOLOGY

The integration of SNA, CA, and community analysis in this study provides a synthetic view of the key concepts associated with LC. This methodology generates quantitative metrics that reveal significant relationships between LC and other concepts, while graphical representations visually demonstrate the density of these connections. The approach comprises six steps, as presented in Figures 1 and 2, and discussed below.

First Step – Paper Selection Strategy

This stage involved the search for relevant articles on the Web of Science database. From the selected articles, a set of core concepts were extracted to establish the scope of the SNA network and to guide the search patterns used in the Web of Science and Scopus search engines (Doerfel & Barnett, 1999). This search yielded approximately 1,800 records. For the first search cycle only the term Lean Construction was used. After finding a first group of high-recurrence keywords, the search was supplemented with a second cycle that included keywords as Building Information Modelling, Last Planner System, Integrated Project Delivery, and Sustainability.

Second Step – Paper Filtering and Categorization

After obtaining an initial total of 1,800 records in the Web of Science database, only the highest quartiles (1, 2) and records related to CEM were selected, resulting in a final set of 500 articles based on citation rates (de Castro e Silva Neto et al., 2016). The objective of this selection was to define the scope of the research and obtain a set of highly relevant articles for the SNA study. Moreover, this set of 500 articles was classified based on their type and central theme to identify research trends and recurrent thematic nuclei in academic research (Castelblanco et al., 2021). This exercise enabled the observation of the most recurrent themes in LC academic research, with the involvement of peer reviewers.

Third Step – Keywords Selection

This phase focused on extracting keywords from the 500 research articles (Bao et al., 2018). Titles, abstracts, and introductions of each article were analyzed, along with keywords suggested by the author, journal, and database. The extracted keywords were then filtered based on their significance and recurrence within the article. A maximum of 10 keywords were selected from each article to enhance SNA analysis by concentrating computational efforts on the most relevant and representative words (Eteifa & El-adaway, 2018). A standardization process was carried out to eliminate keyword redundancies, leading to a final set of 975 keywords across all 500 articles. This standardized approach improved the interpretation of the research articles by highlighting their core ideas, communicative intent, and content, and provided greater clarity for the subsequent SNA and CA analyses.

Fourth Step – Matrix Development

This step involved a quantitative analysis to determine the recurrence ratio of each keyword in the 500 articles. A matrix was constructed with 975 rows and 500 columns, where each row represented a keyword and each column represented an article (Castelblanco et al., 2021). A value of 0 was assigned to the intersection of a keyword and article if the word was absent from the article and 1 if it was present. Subsequently, the transposed matrix was created, with the number of articles in the rows and the total number of keywords in the columns (Hanneman & Riddle, 2005). This matrix allowed for the identification of the recurrence relationship between pairs of words. Finally, the multiplication of the keyword adjacency matrix and its transposed matrix was carried out to complete the process. This methodology enabled the identification of the most important and recurring keywords in the literature related to Lean Construction (LC) and their relationships with other concepts.

FIFTH STEP – NETWORK DEVELOPMENT

A general network was built, and it was possible to observe the geometric configuration of concepts, density of the network, key concepts, and the periphery of the network. This graphical analysis can show isolated or less relevant concepts. A specific network was built for specific subgroups (sub-communities) with high relevance in the main network.

SIXTH STEP – SNA METRICS AND VALIDATION

The collected data was analyzed for coherence and consistency, and validated using UCINET, Gephi, and Microsoft Excel software. It is important to acknowledge that the methodological categorization of keywords can be subjective, leading to limitations in generalizing the state of the art in LC (Bao et al., 2018). However, this article followed a rigorous validation process, including peer review to filter keywords, and verification of connection nodes across different software platforms.

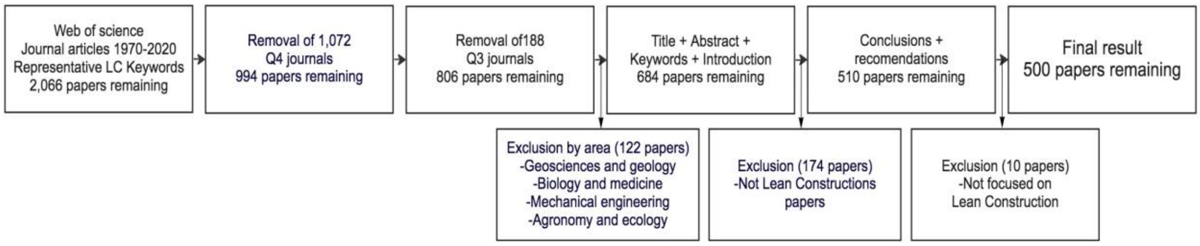

Figure 1: Paper filtering and categorization

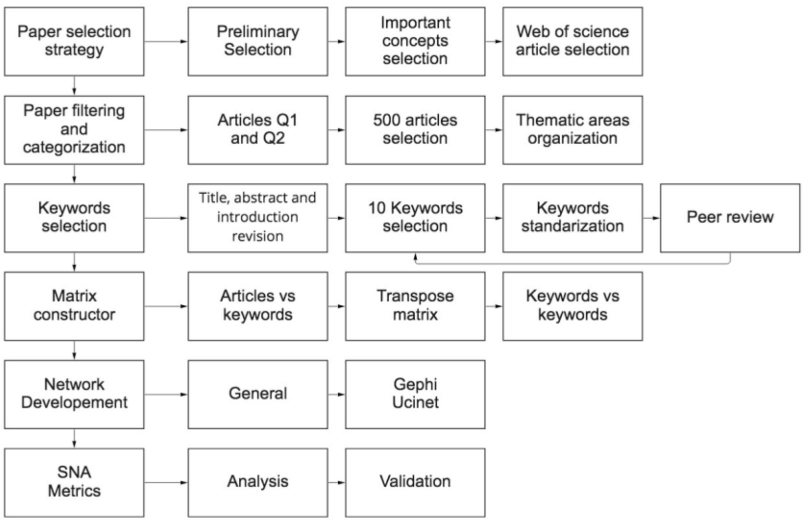

Figure 2: Methodology

RESULTS

The methodology stage yielded a set of networks (1 general structure and 5 sub-structures) that reflect the overall behavior of the LC-related literature and its primary relationships with recurring keywords within the CEM domain. It is noteworthy that the primary outcome is the creation of a semantic network between the 975 filtered keywords and a specific analysis of the sub-communities identified in the modularity coefficient analysis. To fully comprehend the significance of the centrality and cohesion metrics acquired in this study, several concepts have been defined in Table 1, as shown below.

Table 1: SNA Metrics

SNA metric	Meaning
Density	The number of co-occurrences between all keyword pairs as a percentage of the total number of coexistences between all keywords is referred to as density. (Hanneman & Riddle, 2005).
Clustering Coefficient	Metric used to quantify how closely related concepts are to one another. It is higher when particular thematic groups show strong internal interconnection (Freeman et al., 1991).
Modularity	The density of links within communities as opposed to links between communities is measured by a scalar value between -1 and 1, which is known as modularity. (Blondel et al., 2008).
Number of Connections	The quantity of connections between nodes serves as a measure of connectivity and the significance of each individual node inside a network. (Eteifa & El-adaway, 2018).

GENERAL NETWORK

Table 2 summarizes the cohesion metrics found in the semantic network of LC. The general network consists of 975 nodes and is formed by several sub-communities. These communities share common characteristics and are grouped based on color patterns to facilitate separate study. The analysis of communities provides valuable insights to researchers into the interrelationships between different concepts across the field of LC.

The network presented in Figure 3 shows the principal concepts observed in the center of the graph and less important concepts observed in the periphery. A summary of the nodes with the greatest impact is shown in Table 3, along with some of the most relevant centrality measures for this study.

PROJECT MANAGEMENT AND ORGANIZATIONAL CULTURE

The first sub-community identified on the main network is Project Management, as shown in Figure 4. This network comprises a high number of nodes, representing approximately 28.7% of the total network. The next community identified within the main network is Organizational Culture, which is the largest community, accounting for 36.5% of the nodes, as shown in Figure 5. Table 3 group the main nodes, which exhibit high level of density for both structures.

PRODUCTION PROCESS AND MODEL ANALYSIS

Production Process is the smallest community in the whole network. It includes 10 nodes and 17 relationships, comprising around 1% of the main network, as shown in Figure 6. On the other hand, Model Analysis entails roughly 8% of all keywords with 75 nodes and 149 connections. It shows few relationships per node despite exhibiting strong modularity indicators, low density, and high fragmentation as shown in Figure 7.

CONSTRUCTION PROCESS

This community is a medium-sized network with 77 nodes and 139 relationships. Metrics indicate high modularity and low density, with nodes exhibiting few relationships, as compared with other communities. Furthermore, this community also presents a small number of relationships, as shown in Figure 8, but it still represents a sizable portion of the total nodes, comprising about 8% of them.

Table 2: Network-based Measures

		Nodes	Number of Connections	Density	Clustering Coefficient	Modularity
	General Network	975	11852	0.025	0.774	0.226
Sub-Community	Project Management	280	4137	0.106	0.749	0.148

DISCUSSION

The review of literature derived from the SNA model yielded important results regarding the current state of art of Lean Construction (LC). The analysis shed light on concepts of greater proximity, the intensity of the interrelationships, and most importantly, the existing knowledge gaps between LC and some of the most recurring concepts aimed at optimizing and improving processes in the CEM domain.

Firstly, as expected, LC is the term with the highest recurrence in the main network. Concepts such as the Last Planner System (Ballard, 2000), Integrated Project Delivery (Eckblad, 2007), and Building Information Modelling (Sacks et al., 2010) are the closest concepts to LC in current literature, which aligns with Lean principles (Power & Taylor, 2019). In contrast, concepts such as Target Value (Gomez & Rameson, 2019), Flow Value, and choosing by advantages (Schöttle et al., 2019) are concepts that not appear because they are within the principles of LC and are a type of redundance inside the SNA model.

Secondly, the network analysis mathematically confirms the existing relationship between LC, Integrated Project Delivery, Last Planner System, and Building Information Modelling, but it also identifies new terms that are not conventionally associated with LC. Particularly, the emergence of Green Building (Pasquire & Ebbs, 2017; Sarhan et al., 2018) within the five most important nodes around LC is an interesting discovery. While LC is commonly associated with value generation, waste reduction, or continuous improvement (Landim et al., 2022), its association with sustainable development and environmental responsibility concepts is relatively novel. This reveals a new avenue of research that delves into understanding the synergy between LC and the implementation of sustainable projects (Sarhan et al., 2018). Recent construction projects have shown a trend towards coordinated implementation of LC principles and environmental impact mitigation strategies, which is compatible with the findings in this research article (Francis & Thomas, 2019). Furthermore, terms such as Green Building (Ruiz & Guevara, 2021) are shown to be more prominent than terms such as Project Performance, Productivity, or Process Optimization. This highlights the dynamic nature of LC and its ability to adapt to the new requirements and needs of the environment.

Thirdly, while the network analysis confirms the quantitative relationship of LC with traditional and new concepts, it also highlights gaps in literature regarding LC philosophy. Issues such as risk assessment and mitigation (Andenaes et al., 2019) are not extensively documented in relation to LC, and concepts such as Planning reliability or Decision-Making (Abdel-Jaber et al., 2022) are not explicitly linked to LC, but are undoubtedly critical to the structuring and execution of construction projects. Similarly, the lack of connection between LC and quality or innovation indicates gaps in knowledge and presents opportunities for new lines of research aimed at continuing to refine, understand and implement LC. In this way, the proposed SNA methodology enabled the verification of relationships, identification of new synergies, and characterization of knowledge gaps.

In addition, it is important to mention that despite the existing relationship between EVM and LC, EVM has been characterized as not being fully compatible with LC implementation (Kim & Ballard, 2010). However, the relationship between these two concepts exists and is strong due to recurring research that criticizes, compares, and/or combines EVM with LC principles (Cândido et al., 2014). Accordingly, this study not only finds LC linkages with compatible concepts that present synergy and complement each other but also finds terms or concepts that, despite seemingly going against LC postulates, are necessary to explain and deepen the existing knowledge. This also denotes that researchers around the world are examining the possibility of combining EVM with Lean, which is a preliminary indication of how construction projects are being developed worldwide (Cândido et al., 2014).

Finally, the results highlight the importance of variability in the execution of construction projects and their relationship with LC. For example, the process-oriented philosophy of LC, which emphasizes continuous improvement, is closely linked to reducing variability in processes, durations, and methods (Fischer et al., 2021). Therefore, investigating the relationship between LC implementation and variability reduction through performance metrics and indicators could provide valuable insights for future research.

IMPLICATIONS

The current research has practical implications for academics and practitioners in the CEM domain, as the employed methodology improves transparency and highlights semantic connections in a synthetic manner. As demonstrated in Table 3 and Figures 3-8, this study establishes links between LC keywords and critical CEM concepts. This is particularly relevant for those who are not familiar with the LC philosophy.

Results show that Machine Learning has emerged as a powerful tool in LC research (Pasquire & Ebbs, 2017). Technological innovations and computational developments have opened up new avenues for research that complement traditional methods and have provided new opportunities to study and deepen LC principles through modelling or numerical analysis tools. This development suggests that LC is increasingly being analyzed through data-based reasoning, a trend that is likely to gain more popularity in the years to come.

Furthermore, this study highlights the close association between non-linearity and complexity in the context of construction, which is a significant knowledge gap in LC literature (Murguia & Urbina, 2018). This gap indicates the need for future research to explore the complexity of construction projects, their uncertainty, and dynamics in greater detail through emphasizing LC ideas. It is found that LC has a determinant impact on the construction industry, as other economic sectors such as the mining industry have been interested in adopting LC philosophies for the execution of their processes (Castillo et al., 2015).

The analysis also reveals that the term "construction system" is commonly used in LC literature, implying that future research can focus on a systemic view of construction processes (Vásquez-Hernández et al., 2022). This view emphasizes construction as a large system with elements that are interconnected, interdependent, and constantly evolving.

CONCLUSION

The literature review presented in this study provided a visual and quantitative analysis of the linkages between LC and CEM concepts. The study reveals significant knowledge gaps that are linked to the interior of construction projects but are absent in their relationship with LC. These findings have the potential to reveal a new landscape for LC research, with knowledge gaps that are likely to continue existing due to the evolution of LC.

The proposed literature review highlights the significance of LC in the CEM domain and the close synergies it shares with essential concepts such as IPD, LPS, BIM, and Green Building. The SNA offered the authors the opportunity to visualize the nodes associated with LC and the communities underlying this large network. The study reveals approximately 975 keywords grouped in a network with high values of clustering coefficient, density, and modularity.

The fragmentation of nodes in smaller communities with similar characteristics suggests that concepts associated with LC exhibit modular behaviors. This indicates that there are groups of nodes that tend to be more related to specific groups of keywords, making it difficult for a node to connect with other communities. However, terms such as LC, LPS, IPD, and Green Building tend to have low modularity and are often related to more than one community. This implies that most communities have low density values because they are not significantly related to each other.

The also study shows that there are critical gaps in academic research related to LC and concepts such as Risk Assessment, Decision Making, Artificial Intelligence, Planning Reliability, and Innovation in Technology. This finding highlights the importance of utilizing graphical and quantitative tools to identify current relationships, discover new links, and identify information gaps to further advance researchers' understanding and application of LC in the construction industry.

Overall, this study offers valuable contributions to the IGLC community by providing new perspectives on potential research routes and emerging concepts in the LC literature. It achieves this by characterizing the relationships between LC ideas and concepts that are not traditionally connected to LC principles, such as Earned Value Management (EVM).

UNTANGLING THE CONCEPTS OF VALUE AND VALUES

Frode Drevland[1] and Jardar Lohne[2]

ABSTRACT

The concept of value is widely used in lean construction (LC) literature, but researchers and practitioners lack a common understanding of the term. This is partially due to confusion between value (singular) and values (plural), which are two different concepts. This paper aims to provide a clear and concise understanding of the two concepts of value and values, separating them from each other and explaining their relationship. Furthermore, the paper discusses and exemplifies what these two concepts themselves entail. In doing so, the paper also introduces new terminology relevant for understanding and describing value and values in construction projects. Finally, the paper concludes that value and values research should be more precise in terminology than current literature.

KEYWORDS

Value, values, lean construction

INTRODUCTION

Value is a fundamental concept within lean construction (LC) and is one of the most commonly used terms in all LC-related literature. For example, the word value appears in the title or abstract of nearly a third of all IGLC papers (*IGLC.Net*, n.d.)

In 2010, Salvatierra-Garrido et al. (2010) critically reviewed the concept of value in LC theory, concluding that neither researchers nor practitioners had reached a common understanding. Since then, several authors have tried to lock down the concept of value (Drevland & Lohne, 2015; Drevland & Svalestuen, 2013; Khalife & Hamzeh, 2019). However, the concept of value is still very much fuzzy in the LC community.

Contributing to this fuzziness of value is the concept of values. While one could intuitively believe that values are not the plural of value, this is not so. Instead, they are entirely different – albeit related – concepts. As we will expand upon later in the paper, value (singular) is the specific result of an evaluative judgment of an object; values (plural) are general and fundamental beliefs about what is right and important in life.

Values and value are often confounded (Sánchez-Fernández & Iniesta-Bonillo, 2007). In the LC community, Some authors have covered the difference between the concepts (e.g., Drevland & Lohne, 2015; Khalife & Hamzeh, 2019; Schöttle et al., 2020). However, our impression from the recent IGLC conference is that value and values are still often confused. Moreover, both concepts on their own still seem very fuzzy within the LC community.

We would argue that one issue with previous LC authors' coverage of values as a concept is that it has been superficial – sufficient to broadly distinguish the term from value but not sufficiently for the reader to understand the concepts of values in depth.

[1] Associate Professor, Norwegian University of Science and Technology (NTNU), Trondheim, Norway, +47 920 64 262, frode.drevland@ntnu.no, orcid.org/0000-0002-4596-1564

[2] Norwegian University of Science and Technology (NTNU), jardar.lohne@ntnu.no, orcid.org/0000-0002-2135-3468

The purpose of this conceptual paper is to untangle the concept of values and values, and to make them easier understandable. That is, we seek not only to separate the concepts from each other but also from themselves. As shown later in the paper, both concepts have different definitions in the literature.

However, while the paper, to some extent, considers differing definitions of these concepts, we do not present a literature review of the topic. Instead, the aim is to create a to-the-point understanding of the concepts relying on a few select sources. We seek to pierce the veil of fuzziness that seems to surround both concepts of value and values, and make them understandable to the LC community members.

The paper starts by tackling the concept of values – explaining how values are beliefs about what is important in life and how one should behave. After that, the paper moves on to value, explaining how value results from an evaluative judgment and considers what elements play a role in this judgment, including how values play an essential role. Finally, the paper argues and concludes that research relating to the concepts of value and value should be a lot more stringent concerning terminology than what can be observed in the current LC body of literature.

VALUES

In the introduction, we wrote that there is a difference between values (plural) and value (singular). This statement is a truth with modifications. Values (plural) have to be the plural of something. In the seminal work, "The Nature of Human Values", Rokeach (1973) distinguishes between an object having value and a person having *a* value. However, people never have only one value; instead, they have several organised in *value systems*. Therefore, human values are seldom referred to in the singular. To avoid confusion, this paper explicitly uses the term human value when referring to such values in the singular.

Different authors have presented different definitions of values (Hofstede, 1985; Rokeach, 1973; Schwartz & Bilsky, 1987). However, the difference lies mainly in the wording. Most definitions of values found are conceptually the same (Schwartz & Bilsky, 1987). This paper mainly adopts Rokeach's (1973) conceptual framework, finding it superior to others regarding understanding the difference and relationship between value and values.

The literature commonly agrees that values are concepts or beliefs of what is important in life (Hofstede, 1985; Rokeach, 1973; Schwartz & Bilsky, 1987). Furthermore, what is important in life encompasses both the end states one seeks in life and how one should behave. In other words, there exist both ends-values and means-values.

Rokeach (1973) explicitly distinguishes between terminal and instrumental values. Terminal values are the end-states one seeks to achieve. Rokeach places them broadly into two categories. The first is social values. That is, the end states one seeks to achieve at the societal level – for example, "world peace" and "equality". The second category is personal values – for example, "a comfortable life" and "happiness". As for Rokeach's instrumental values, they are values that guide behaviour. Examples of these are "honest", "responsible", and "polite".

Human values are more or less constant over one's lifetime and are primarily learned in childhood (Rokeach, 1973). Initially, values are taught and learned individually, without considering their relation to other values, in a definitive and absolute way. However, once one matures, one will increasingly face situations where these values can conflict. For example, if you observe a friend doing something bad and you are asked to tell what happened, should you be loyal to your friend and lie, or should you be honest and tell the truth? Once a value is acquired, it becomes part of a structured system of values where each value is ranked in relation to the others based on its priority – a *value system*.

This value system organises one's values hierarchically (Rokeach, 1973). For example, two fundamental human values are self-preservation and protecting others. Say you find yourself in a burning building. You have two alternatives, evacuate yourself immediately or help others escape. The value you assign to each option depends on how you rank the abovementioned values.

A person typically has a relatively small number of values (Rokeach, 1973). While different individuals and cultures will have different hierarchies in their value systems, most human values are shared across the globe (Rokeach, 1973; Schwartz, 2017; Schwartz & Bilsky, 1987). Several authors have developed standardised frameworks for these values – for example, Rokeach's (1973) Value Survey or Schwartz's Theory of Basic Values (Schwartz, 2012).

While Schwartz's Theory of Basic Values is more widely acknowledged and used in modern times, the level of abstraction is also higher. That is, Schwartz employs higher-level concepts, such as *hedonism* and *achievement,* compared to Rokeach's more straightforward ones, such as *happiness* and *social recognition*. Therefore, for pedagogical purposes, the example values we use in this paper are primarily based on Rokeach's Value Survey as they are more concrete – and thus more relatable.

Organisational values

In this section, we have so far discussed human values, which relate to individual people. However, in construction projects, we seldom deal with individuals. Even with single-family homes, there will be several family members, each with their values. Related to human values, there exists the concept of *organisational values*.

According to (Liedtka, 1991), organisational values "take the form of guiding principles and beliefs perceived to exist by organisational members as a whole" – in other words, they are essentially the same as human values, but for organisations. However, organisational values are not as straightforward as the statement by Liedtka suggests. For example, according to Zhang et al. (2008), corporate values are often formulated by those in leadership positions, leading to a gap between the values of the organisation and its employees.

It is beyond the scope of this paper to explore the topic of organisational values thoroughly. However, related to understanding the concept of values, we believe it essential to understand that organisations have values like individuals. Furthermore, we would like to point out that similar to the frameworks categorising human values, frameworks exist for mapping values at the organisational level, for example, the Competing Values Framework (Cameron & Quinn, 2011).

VALUE

Back to the disambiguation made at the start of the previous section, value (singular) relates to an object having value. Therefore, properly understanding value as a concept entails understanding how the value of an object is determined. However, before dwelling on this matter, we must point out that value (singular) is not a singular concept.

As with values, there are many different definitions of value in the literature across various fields (Drevland et al., 2018). Most of them are variants of value being the relationship between what you get and what you give – or cost/sacrifice and benefit. However, different value concepts still exist within this notion of value. For example, market value – a term from economics – is the price one has to pay to acquire a good or service on the open market. With this value concept, value is objective and measurable. Thus, this value is very distinct from value as a concept within lean.

The lean concept of value concerns customer value (Drevland et al., 2018). Since, within the lean philosophy, all project stakeholders are considered project customers, this equates to stakeholder value. There are many stakeholders in a construction project, all of whom will have different notions of what is valuable (Drevland & Tillmann, 2018). Value for one stakeholder will not be value for another stakeholder. In other words, value is subjective or particular for a given stakeholder and cannot be objectively measured (Drevland et al., 2018). Indeed, value in our context is the result of an evaluative judgment.

While evaluative judgment is another term with various definitions across fields, we here use it as commonly used in the fields of psychology and neuroscience. There, evaluative judgment is a fundamental aspect of human cognition that allows individuals to assess the degree of liking or disliking towards a stimulus (Clemente et al., 2021). This evaluation process helps people compare and choose alternatives, make decisions and prioritise actions.

When making evaluative judgements, people draw on various processes and sources of information. (Musch & Klauer, 2003). In the following, we will expand upon how the value of an object is determined through an evaluative judgment. This explanation is anchored in and built upon our previous research. In Drevland et al. (2018), we defined value on a fundamental level by developing nine tenets on the nature of value. Together, these tenets yield a more comprehensive definition of value than found elsewhere. For discussion of how our definition of value differs and compares to other definitions found in the lean construction literature and other fields of research, we defer to Drevland et al. (2018).

In Drevland et al. (2018), we included a rather lengthy definition of value that incorporates all nine tenets. The explanation and discussion of value in this section include all elements of this definition and the tenets; however, we will here use a cut-down and modified version of the definition for pedagogical purposes.:

> *Value is the result of an evaluative judgment of the relationship between what someone gets from an object and what they must give to obtain and use it.*

Figure 1 illustrates the above definition and shows three main elements of value: 1) the value object, 2) the value subject – for whom is the value, 3) and the evaluative judgement itself.

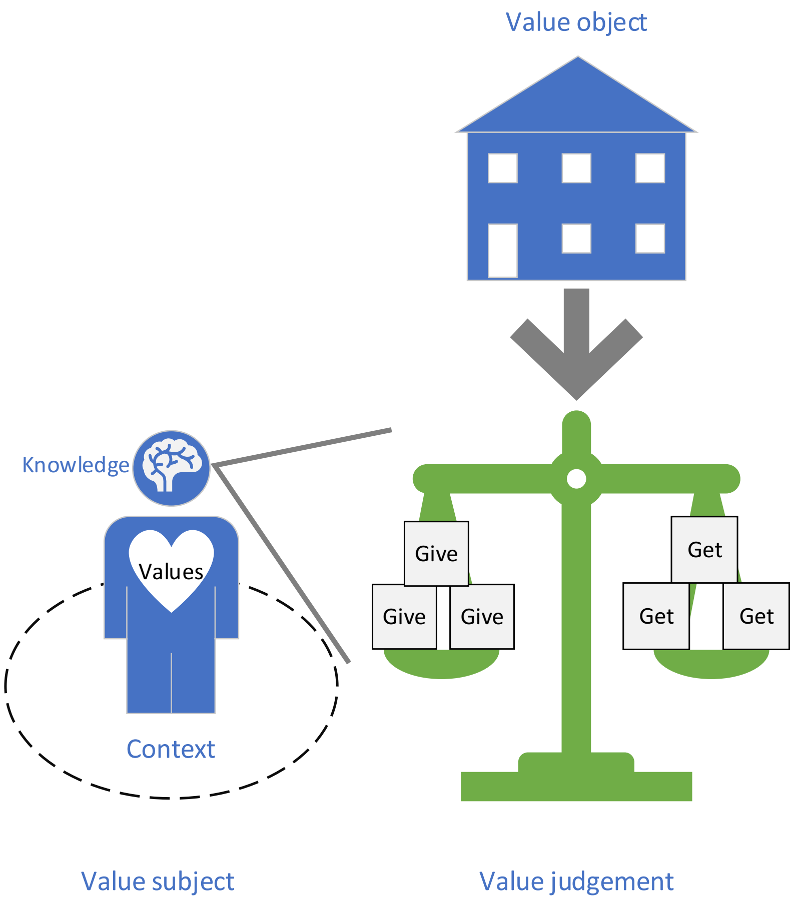

Figure 1: Graphical Definition of Value

THE VALUE OBJECT

We will here introduce the term *value object* to denote the object that is the target of an evaluative judgment to determine its value. The value object can be a physical object – like a building – or an immaterial product or a service. It matters not; what matters is what about a value object, in general, we consider when making a value judgment. In our context, the value object is the project – encompassing both the final built facility and the design and construction process delivering it.

Value is the relationship between what one gets and gives; thus, when making an evaluative judgment, one considers what one must give or sacrifice to obtain – and possibly operate – the object and what doing so will provide one with.

One may consider a host of different factors when judging a value object. Authors have used differing terms for these underlying factors. For example, Drevland et al. (2018) refer to them as get-and-give factors, while (Kliniotou, 2004) calls them value drivers. In this paper, we will refer to them as value factors. We will revisit value factors later in the section. However, before doing so, we must first cover some central aspects of the value judgment and how the characteristics of the value subject play into this judgment.

THE VALUE SUBJECT

Value being subjective entails the value of an object is always for someone. We will here introduce the term *value* subject to refer to this someone. When a value subject judges the value of an object, three attributes of the value subject matter (Drevland et al., 2018): Their knowledge, values and context – or metaphorical speaking, their heel, heart, and their head.

Heel – What context are one's feet planted in

What someone considers valuable depends on where they – metaphorically speaking – stand, that is, the context in which they find themselves. For example, someone living in a country with high-quality tap water will typically not see much value in bottled water. However, if they were to find themselves in the desert dying of thirst, they would judge the same bottle of water very differently.

Context encompasses the value subject's current needs and goals. Drevland (2021) relates an example from hospital projects in the Mission District of San Francisco, where a demographic shift in the neighbourhood caused the client to want to provide different services at the hospital and thus needed other physical infrastructure. In other words, what they saw as valuable changed because their context changed.

Hearth – One's values: what one cares about

As previously explained, values are general beliefs of what is important in life. An example of such a human value would be "protecting the environment". Someone who cares about the environment will always prefer "greener" products and assign a higher value to a green building, everything else being equal. However, everything else is seldom equal. Making a greener building could also make it more expensive. For an individual buying a home, the human value of "protecting the environment" could potentially come into conflict with values such as "having a comfortable life" and "taking care of one's family". Whether they prefer a cheaper non-green home or a more expensive green home would then depend on their value systems and how their values rank internally. Thus, the value judgment is highly dependent on the values of the value subject.

Head – What one knows

When people judge an object's value, they depend on the knowledge they possess (Drevland et al., 2018). Knowledge not only about the value object but also its context, alternatives, etc. The knowledge that someone has can very well be flawed or lacking, leading to an erroneous perception of what value is. For example, recent history is fraught with cases of sustainable initiatives initially considered valuable that – in hindsight – have turned out not to be sustainable and of little value, such as biofuel (Antwi-Bediako et al., 2019).

In addition to the perceived value – the value someone perceives given the knowledge they possess – Drevland et al. (2018) introduces the term *true value* to represent an ideal notion of the value that would be perceived had the value judge had perfect knowledge.

While the concept of true value is purely abstract and theoretical – we can never know the true value of an object – it is helpful in our context. In some fields, the perceived value is all that matters Drevland et al. (2018). For example, marketing is only concerned with the value the customer perceives when making the buy/no buy decision. In construction projects – especially with newer value-centric project models – the goal is to maximise the value for the customer at project delivery, not just deliver what they perceived as valuable at the beginning. In other words, although we do not know the true value for a project stakeholder, we strive to achieve it.

When the value subject and the value judge are not the same

The head, hearth and heel metaphor above assumes that the value judge and the subject are the same entity; however, this is not necessarily the case. The value judge may not be the same individual as the value subject. For example, a designer makes value judgments when making design decisions to optimise the value for the owner – the primary value subject of a building.

In addition to true value, Drevland et al. (2018) introduced a third term related to the perception of value: *Estimated value* – the value for the value subject by a second party judge – e.g. a designer for a client – given the judge's knowledge – both general and their knowledge of the values and context of the value subject.

THE VALUE JUDGMENT

We will use the term *value judgement* to refer to the evaluative judgment made to determine value. While the term is typically related to making moral judgments or people's behaviours, often the negative connotations, most dictionaries define the term broader. For example, the APA Dictionary of Psychology defines value judgment as "an assessment of individuals, objects, or events in terms of the values held by the observer rather than in terms of their intrinsic characteristics objectively considered" (American Psychological Association, n.d.). This definition aligns with what we already have covered on how people assess value. However, it assumes that the judge and the value subject are the same, and it goes beyond judging objects. Thus, here, we define value judgment as the evaluative judgment a value judge makes to determine the value of some object.

Referring to Figure 1., the value judgment is a matter of determining what value factors a value object provides on both the get and give sides of the scale and how they balance. However, doing so is less straightforward than it seems. We will discuss several aspects of the value judgment that make it so.

Value judgments consider experiences – not attributes or money

A fundamental aspect of value is that it is experience-based (Drevland et al., 2018; Holbrook, 1981). While people might sometimes express value factors in terms of object attributes or money, they will typically be placeholders related to the experiences they get from the value object. Say, for example, someone is buying a home. Superficially, they are giving up money and getting an asset in the form of a house or apartment. However, when it comes down to it, what factors people consider will be based on the experiences they envision having living there. For example: Will they sleep well there? Will they feel safe? Can they play loud music without annoying the neighbours? Can they host lavish dinner parties? How much time will they spend getting to and from work?

These examples are all factors impacted by the qualities of the home – i.e., the get side of the equation. However, similar considerations are related to the give side. Superficially they are giving up money. However, with few exceptions, money only matters if you do not have enough. For most people, what is important is how the mortgage payments will affect their life experiences. Can they dine out and go on vacations as often as they would like? Can they afford to keep up their hobbies? Will they feel safe financially with the burden of a mortgage?

With some twists, companies will make similar considerations as individuals (Drevland et al., 2018). First, people will consider what experiences they will have doing (or not doing) the activities that matter in their lives. Likewise, companies will consider their experiences doing the activities that matter to them – their business and production processes. Second, for companies, money can be of more direct interest. Typically, the *raison d'etre* for a commercial entity is to earn money for its owners or shareholders. In other words, one of the terminal values for a commercial entity is wealthy owners. For an individual, money is only ever a means to achieve their terminal values. However, being wealthy will directly support many terminal human values such as "freedom", "family security", and "social recognition".

The value judgment is comparative

One of the nine tenets of Drevland et al. (2018) is that value is comparative. They anchor this tenet in Kahneman & Tversky's (2000) seminal works on the human psyche, tying value to choices. However, they do not expand upon the implications of value being comparative.

Unlike objective value concepts – such as market value – our value concept does not have an absolute measurement. Value is the result of an evaluative judgment of what someone gets from an object and what they must give to obtain and use it. That result only ever makes sense in comparison to other such results. However, people make these comparisons in a broad sense. That is, one does not only compare apples to apples but also apples to oranges.

To take a more concrete example, when someone considers buying a specific home, they will compare it to other homes on the market; however, they will also compare it to alternatives such as renting or continuing to live at home with their parents. Regarding the previous point of value judgments considering experiences, the comparison is not between different objects but different sets of experiences.

The value judgment is holistic

People judge value holistically, not piecemeal (Drevland et al., 2018). Piecemeal judgment would entail judging each value factor individually, assigning them a weight, and then tallying them up. Doing so would be nonsensical for two reasons. First, assigning value factors a weight would require some measurement scale – thus, being incompatible with comparative value judgment, as described above. Second, how someone will weigh different factors is not linear. How much the various value factors weigh down on the scale will often depend on a complex interplay between them.

One caveat is that construction projects deliver complex objects with multi-faceted use. Here, one can, to some extent, consider the marginal value of distinct features such as a separate bedroom.

VALUE FACTORS

Having described and discussed the characteristics of the value subject and the value judgment that impacts value, it is time to revisit value factors. What factors do people put on the scale when making a value judgment of an object?

We would argue that the concrete factors one will consider will depend on both the value object and the value subject. For example, one will not consider the same factors when buying a car versus a home. There might be some overlapping ones related to, for example, financial aspects; however, the complete set of factors will differ widely.

Furthermore, for any given value object in our context – i.e., construction projects – there will be several stakeholders and thus value subjects. What an owner gives to and gets from a project is very different from what a contractor, user or neighbour does – and they can be in direct conflict with each other. For example, a developer might want to build an apartment building as tall as possible to maximise the monetary gain they experience; however, this might severely negatively impact the view of the neighbours and, thus, the experiences they have in their homes or places of business.

Experiences and placeholders

Value factors are grounded in experience. However, as pointed out, this might not be evident. People tend to describe placeholders rather than actual value factors. They relate desired object attributes that would provide them with some experiences rather than describe the desired experiences themselves. For example, someone buying a home might say they want a large backyard. However, nobody wants a large backyard for the sake of having a large backyard. They might want it because they enjoy gardening, want room for the kids or pets to play, or any other number of other experience-related reasons. Thus, “a large backyard” is, in this case, a placeholder for these experiences that the yard would support.

Regarding placeholders, money is a generic one (Drevland et al., 2018). Money can buy a lot of different experiences. One can go to the movies, dine out, vacation, etc. – or for a company; they can have various experiences through alternate investments.

While we have not conducted any in-depth study on the subject, with the advent of new value-centred delivery models, it is seemingly becoming more usual to explicitly link value factors to experiences rather than using attribute-related placeholders. For example, we know of one school project where one of the stated value factors was to reduce bullying and a psychiatric hospital where they wanted to reduce the use of force by 50%.

For an individual or a family buying a home, the use of placeholders is not a problem. However, in the domain of commercial and public projects, we would argue it can be. For example, an individual saying they want a large backyard is also the one making the decision on which home to buy. In a construction project, the people making the decisions can be several steps remove from those who describe the value factors.

An interesting example to illustrate the issue could be observed during the construction of St. Olav’s Hospital in Trondheim, Norway. When designing the doctor’s offices, they first asked the doctors what size offices they needed – and got back wildly varying size requirements. Then, they went back and asked what they needed to do office and what equipment they needed to do so. The doctors then explained that they, for example, would examine patients and needed an examination table. This experience-based description enabled the designers to develop office designs that fulfilled the doctors’ needs without being unduly large.

Classification schemes

Several authors have tried to establish classification schemes to aid in describing and understanding value factors in construction projects (Construction Industry Council, 2002; Drevland & Klakegg, 2017; Drevland & Svalestuen, 2013; Emmitt et al., 2005; Khalife et al., 2022). However, such frameworks all have their limitations. As discussed above, the factors considered in value judgment highly depends on both the value object and the value subject. Thus, such generic schemes are limited to relatively broad categories. They can serve as starting point to point one in the correct direction for describing value factors; however, they are in no way, shape or form fully fleshed-out tools able to adequately describe value factors in a given project.

SUMMARY OF TERMS

In the previous sections, we covered many different terms related to value and values. Terms we would argue are essential to understand the concepts of value and values properly. However, while the text explains all the terms, not all are given succinct and precise definitions. Furthermore, given how the paper presents the terms, we realise that getting a good overview of them can be difficult. Therefore, we have included Table 1 below to give an overview of the terms related to value and values the paper has presented.

Table 1: Summary of Terms

Term	Definition
Values / Human values / Organisation values	General beliefs about what is essential in life and how one should behave.
Terminal human/organisation values	Desired end states of an individual or organisation
Instrumental values	Beliefs that guide the behaviour of an individual or organisation
Value	The result of an evaluative judgment of what someone gets from an object and what they must give to obtain and use it
Value subject	The individual or organisation for whom the value of an object is considered
Value judgement	The act of determining the value of an object for someone through an evaluative judgment
Value object	The object that is considered when making a value judgment
Value judge	The person or group making a value judgement
Value factor	Factor considered on the get or give side of the scale when making a value judgement.
Perceived value	The value a value subject arrives at through making a value judgment themselves, given the knowledge that they possess
True value	The value that a value subject would arrive at through a value judgement if they possessed perfect knowledge
Estimated value	The value for a specific value subject judged by a second party with the knowledge that they possess

DISCUSSION AND CONCLUSIONS

The paper's purpose has been to untangle and clarify the concepts of value and value. In doing so, we have treated value and values – and the other introduced terms – as very stringent concepts. However, value is a common word in English, and everyday use does not abide by any such stringency. So, for example, someone might say some building feature provides great value for the owner. However, relating to the terms this paper has introduced, they actually mean that said feature supports one or more experiences that are significant value factors for the owner.

Enforcing such stringency and precision in everyday speech would be futile and counterproductive. People will still get their message across without any language policing. However, while low precision and ambiguous terms in everyday speech are acceptable, vague terms do not yield any precision in academic analysis and create poor foundations to build tools or more advanced theoretical constructs. Therefore, we would like to caution researchers who write about value or use the concept of value in their papers to be conscious of the difference between value and values, as well as different value concepts. We have too often seen authors trying to summarise what value is by picking various characteristics from papers dealing with vastly different concepts – often confounding value and values. Some of these authors end up concluding that value and multi-faceted concept. We would argue value should not be considered as such.

Take, for example, value, as this paper defines it, compared to the previously described concept of market value from economics. The two concepts are clearly related. Both centre on the relationship between what one gives and gets. However, the two concepts vastly differ in how one evaluates that relationship. Thus, we would argue that they cannot be considered facets of the same concept but are instead different concepts rooted in the same abstract root concept.

This paper has not gone into great depth on value and values in projects, mainly deferring to use examples at the personal level. There are two reasons for this: 1) To make it easier and understandable for the reader, and 2) we lack the appropriate knowledge.

The paper's purpose has been to foster the readers' theoretical understanding of the concepts, not to expound upon their real-world usage. Projects are complex sociotechnical systems. In addition to having a wide variety of stakeholders whose value must be considered, many stakeholders are, in effect, multi-headed trolls. They are not monolithic entities with a singular perception of value but a collection of individuals with many different value perceptions. Thus, discussing value in such a context complicates matters. The same holds for values. Therefore, we would argue that one must thoroughly understand the concepts at the individual level before one can grasp them at the organisational or project level.

Regarding not knowing enough about real-life values and values in projects, there is a shortage of empirical research on these matters – especially regarding what value factors are considered, how value judgments are made, and by whom. While a third of all IGLC papers mention value, very few go into detail on such matters. Those that do are not very useful due to a lack of terminological stringency.

We would argue that empirical data gathered from projects need to be analysed relating to a solid theoretical framework with unambiguously defined terms, such as what we have presented in this paper. Given how haphazard and ambiguous the everyday use of value-related terms is, any empirical statements gathered from projects need to be viewed and interpreted through such a lens to ensure internal consistency.

We are not as pompous as to believe that what we have is the end-all and be-all of the theoretical frameworks for value and value. However, we would strongly argue that research into value or values needs to relate to clearly defined terminology with a precision that is on the level of what we have presented in this paper. Otherwise, the results will be ambiguous mush, not serving to bring our field forward.

CREATING CO-LOCATION CONCEPTS UNDER CONSIDERATION OF HYBRID APPROACHES IN CONSTRUCTION PROJECTS

Leonie Szyperski[1], Maximilian R.-D. Budau[2], Gernot Hickethier[3], and Shervin Haghsheno[4]

ABSTRACT

During the COVID-19 pandemic, across industries many project teams started working from home instead of their (co-located project) office, thus relying on virtual teamwork. This shift prompted the use of hybrid or virtual co-locations, whose purpose is to improve communication and collaboration in the project team. However, there is limited research on the effectiveness of these hybrid and virtual co-locations. A co-location can be implemented in both traditional and partnering delivery models, however, this research focuses on co-locations within partnering projects. To address this gap, interviews were conducted with co-location participants in Germany, Switzerland, and the US to gather a wide range of experiences, as well as supplement and validate the literature review. From this information, a co-location requirements catalog was created, and five concepts of co-location setups were identified and developed with varying degrees of hybridity. The research showed that trust and communication are crucial for collaboration, which is one goal of installing a co-location. Therefore, the implementation of a hybrid or virtual co-location must take this goal into account. In-person events play a key role in building and maintaining trust. As technology continues to advance, research on hybrid and virtual teamwork is becoming increasingly relevant.

KEYWORDS

Co-location, big room/obeya, collaboration, hybrid co-location, integrated project delivery (IPD)

INTRODUCTION

The COVID-19 pandemic sent many workers into home-office and virtual teamwork, including workers from the construction industry. The pandemic has resulted in the implementation of virtual and hybrid co-locations. The co-location is a procedure teams using collaborative project delivery models, such as IPD, implement (Lahdenperä, 2012). A co-location aims to foster communication, trust, and collaboration and can be implemented in traditional or partnering construction projects. However, there is a need to further understand co-locations, including hybrid and virtual variants, and their implications to have clear vocabulary for implementation

and further research. This research seeks to address this gap in knowledge by investigating traditional co-locations, as well as hybrid and virtual derivatives, with a focus on the construction industry. The motivation for this research stems from the significant changes in work practices caused by the COVID-19 pandemic and the need to adapt to new modes of teamwork.

Figure 1 shows the structure of this paper. Each blue box represents a chapter, and the hexagons depict key points covered within the chapters. The introduction contains a brief overview of the paper. The results of the literature review covering the existing definitions of the co-location, goals, purpose, requirements, and concepts of a co-location. The method chapter explains the procedure of the literature review, as well as the gaps found, leading to the need for interviews. The following two chapters discuss the results of this paper: the five co-location concepts and the co-location as a method. Based on the interview results, the five identified co-location concepts found in the literature review were supplemented and explained in further detail. Additionally, in this research, we define the co-location as a method to encompass all five concepts. Finally, the closing remarks and conclusions wrap up and summarize the contents of this paper.

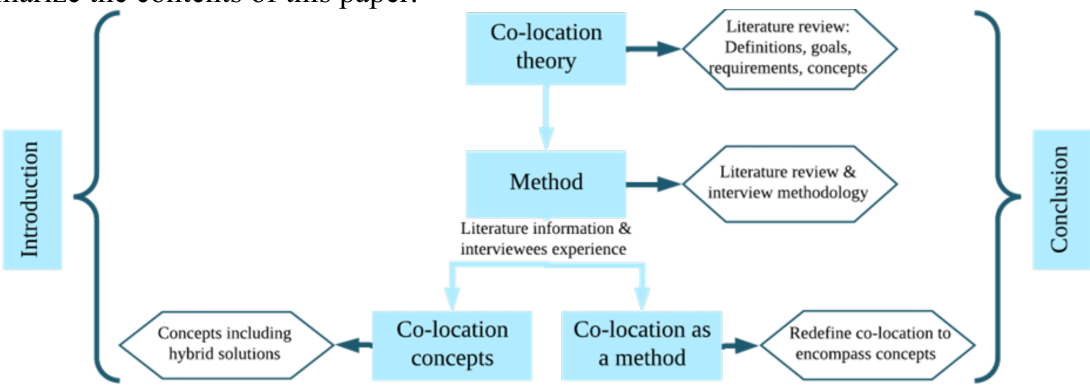

Figure 1: A Visualization of The Structure of This Paper.

CO-LOCATION THEORY

DEFINING CO-LOCATION

Often literature uses co-location, big room, and Obeya room interchangeably. However, they have different meanings and need clear differentiation.

A co-location in the construction industry refers to the practice of key members of a project working together in a shared space, usually a construction project office, to facilitate communication, teamwork, and productivity (Allison et al., 2018). This shared physical space, is designed to bring the team together to foster collaboration, create a group identity, and reach the goals of the project (Allison et al., 2018; Ashcraft, 1996; Fischer et al., 2017; Lazarte, 2020). Allison et al. (2018) mention it can be a physical or a virtual space. The co-location is not a universal requirement for all IPD projects, but research has found it to be an important factor in successful IPD projects (Haghsheno et al., 2022; Rodrigues & Lindhard, 2021). Although Hosseini et al. (2018) found the co-location to be the fourth most important partnering element in their research, only 6 of 43 projects observed implemented a co-location in Norway. Haghsheno et al. (2022) found three out of 13 international papers examined to believe a co-location is a must-have, and a further two mention the co-location as an optional element.

Obeya is an environment designed to facilitate the free flow of information and communication among team members and stakeholders, not a physical room (Dalton, 2019). It often includes visual management tools like charts, schedules, and trend lines to display the current status of a project (Liker & Morgan, 2006). Visual information management (VIM) is a tool used in Obeya to create transparency and transport relevant information to team members and display their work (Björnfot et al., 2012; Dalton, 2019). Obeya is derived from the Japanese word for "big room" and was originally used in the Toyota production system (Liker & Morgan, 2006).

The big room is a physical space where team members can come together to discuss and work on a project. The big room is designated as the design and coordination office of the project (Temel et al., 2019). Its purpose is to facilitate communication, collaboration, and innovation (Staun, 2020; Temel et al., 2019). The concept of the big room, however, is not clearly defined in the construction industry (Alhava et al., 2015). Obeya is a similar concept, but it specifically refers to an environment that supports the free flow of information and communication, not coordination. The big room is a part of the co-location and can contain visualizations inspired by the Obeya concept.

THE GOALS AND PURPOSE OF A CO-LOCATION

The co-location has a positive effect on integration and collaboration, which helps projects run more smoothly (Adamtey, 2019; Galvin et al., 2021; Mesa et al., 2019). The co-location aims to create a space that promotes collaboration and addresses challenges such as a large group of interdisciplinary people and the need for fast decision-making and information exchange (Allison et al., 2018). Figure 2 illustrates how the co-location facilitates collaboration, with the following paragraph containing the explanations of the connections.

The co-location enables fast decision-making and problem-solving through the exchange of ideas and discussions in the co-location (Allison et al., 2018; Bygballe et al., 2015; Galvin et al., 2021; Gomez et al., 2018). Effective communication and information exchange, aided by the physical proximity and presence of key partners in the co-location, is a factor in building relationships, trust, and collaboration (Adamtey, 2019; Ashcraft, 1996; Rahim et al., 2015; Thompson & Ozbek, 2012). Being present in the co-location allows for relationships to develop and for partners to gain an understanding of each other, leading to an increase of trust over time (Galvin et al., 2021; Olson & Olson, 2010). Trust is a prerequisite of teamwork, crucial for IPD projects, and needs to be consciously built from the start (Majava et al., 2019; NASFA et al., 2010). Performance indicators such as the percent plan complete (PPC) trend line can be tracked in the co-location to increase the team's reliability and commitment to project goals (Andary et al., 2020).

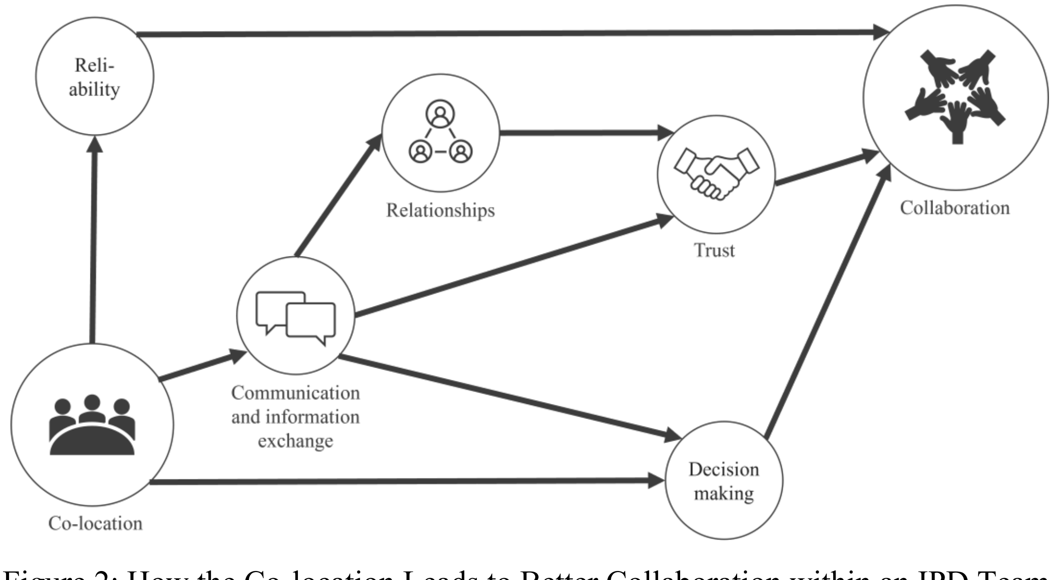

Figure 2: How the Co-location Leads to Better Collaboration within an IPD Team.

CO-LOCATION REQUIREMENTS CATALOG

Allison et al. (2018) outline a large list of considerations, attributes, and characteristics of a co-location. Knowing the requirements helps to fulfil the potential of a co-location. A co-location requirement can be a hard factor, like a conference room or a coffee machine, as well as a soft factor such as teamwork. The list created by Allison et al. (2018) is validated and supplemented during the literature review and interviews. Table contains the complete list and can be found in the appendix. The goal of this list is to aid those who want to set up a new co-location, so they can use this as a checklist throughout the creation of the co-location.

Not all requirements need to be considered at the same time, the categories are listed chronologically when which requirements need to be considered. The categories *Team/culture* and *Project organization* can begin in parallel to the remaining categories.

THE FIVE CO-LOCATION CONCEPTS

There are five overarching co-location concepts identified in the literature, sorted here by the amount of physical presence:

- *Full-time co-location*: completely in-person, 4-5 days a week at the co-location. Allow for the telecommuter (Fischer et al., 2017).
- *Part-time co-location*: 1-3 days a week at the co-location (Allison et al., 2018).
- *Pulsed co-location*: every other week or one week per month in the co-location. Focus on releasing work when in the co-location (Fischer et al., 2017).
- *Part-virtual*: an almost completely virtual co-location except for workshops which are done in-person (Hosseini et al., 2018).
- *Virtual co-location*: a virtual co-location with options for virtual or augmented reality (Fischer et al., 2017; Wolfartsberger et al., 2020).

A concept that can be combined with the above, is the *rotating co-location*. This is when the co-location is at one of the partner's offices and rotates between the various offices depending on the phase and needs of the partners (Fischer et al., 2017). The co-located *telecommuter* is when partners are allowed to work on other projects while present in the co-location (Fischer et al., 2017). For all concepts, except full-time, office hours need to be set. Establishing a clear schedule of when partners need to be present is imperative for a part-time and hybrid co-location to function (Fischer et al., 2017).

METHOD

The literature review covers the definition of co-location (A), existing co-location concepts (B), as well as the requirements and goals of a co-location (C). By using a Boolean search, numerous combinations of keywords were entered into various academic websites, such as sciencedirect.com and emerald.com. An example of a Boolean search being: (requirements OR characteristics OR value OR advantages) AND (co-location OR big room) AND (lean OR lean construction OR IPD). From the literature found, the sources that each author cited were also combed through for additional articles and potential sources. Publications include English and German articles. Literature was sorted into three categories listed above (A, B, C), and only included when within the context of the construction industry.

During the literature review, it became clear there are significant gaps in the available information regarding the co-location. To begin, co-location has several competing definitions and does not encompass the five co-location concepts, which we identified. Additional gaps found included points summarized here into six categories: (1) hybrid communication, (2) teamwork regarding hybrid co-locations, (3) co-location requirements, (4) digital solutions and alternatives, (5) reasons for a hybrid co-location, and (6) information on the degree of hybridity (DOH) within a co-location concept. Further gaps found that will not be covered further in this paper are as follows:

- Key performance indicators (KPIs) in a hybrid co-location
- Pedagogic view and psychological analysis of teamwork in hybrid co-location
- Minimum project size for a physical co-location
- Creating a co-location on a budget as well as co-location cost suggestions
- Social networks analysis (SNA) of the project team for co-location decisions
- Project quarterback rating (PQR) for assessing hybrid co-location performance
- Analysis of space needed in co-location based on people and budget size
- Effectiveness of concepts concerning collaboration, productivity, and planning using case studies

To address the gaps found in the literature review as well as supplement and validate the information found, a survey and subsequent qualitative interviews were conducted with co-location participants in Germany, Switzerland, and the US. Detailed interviewee responses to the six categories will not be covered in this paper. The goal of the interviews was to explore different perspectives and understand how participants tackled the challenges of the COVID-19 pandemic regarding the co-location. The interviews were semi-structured, explanatory interviews and structured into three blocks: introduction, main questions, and conclusion (Bogner & Menz, 2009; Gansen et al., 2011; Meuser & Nagel, 2009). This allows for the structure to keep the dialogue goal-orientated, but enough freedom to ask additional or clarifying questions.

A total of 41 people were contacted based on their experience with co-locations in the various project phases, 26 of whom agreed to participate in an interview in the months of February, March, and April of 2022. The participants included designers, builders, project owners, users, and coaches. Table 1 lists the project identity, position, and country of each interviewee. The German and Swiss interviewees represent seven IPD projects. Therefore, the results cannot be generalized to address traditional project delivery methods. The US interviewees were not based on a specific project, but rather on their general experience. Most of the interview partners were in the project management team (PMT), and some were in the senior management team (SMT) of their project. PMT and SMT definitions as well as corresponding names e.g. core team and alliance team will not be addressed in this paper. To ensure anonymity, the names, and companies of the participants, and their IPD projects, are not disclosed. The interviews were transcribed and analyzed using the qualitative content analysis method from Mayring (1991).

CO-LOCATION CONCEPTS

OVERVIEW OF THE FIVE CONCEPTS

With the information and experience of the interview partners gathered during the interviews, the five concepts found in the literature review were elaborated on and described in further detail. An overview of these five concepts can be found in Table 2. Due to limited space the results of the interviews will not be outlined, but rather the further development based off the interview results.

A co-location is hybrid when one or more team members are not physically present, and the rest is physically present. The DOH peaks when there are several participants in the co-location but also several working remotely on the none-core days. A co-location becomes virtual when all members are joining in virtually. The concepts have varying degrees of hybridity, beginning with a full-time face-to-face (F2F) co-location with close to zero hybrid components. Then the hybridity is increased and peaks at concept 3, the pulsed co-location. In concepts 4 and 5, hybrid components are replaced by virtual components. Components are processes that happen within the co-location, such as meetings and workshops, as well as requirements listed in the requirements catalog.

Table 2: An Overview of the Co-location Concepts with Varying Degrees of Hybridity.

Concepts	Concept 1 Full-time	Concept 2 Part-time	Concept 3 Pulsed	Concept 4 Part-virtual	Concept 5 Virtual
Picto-grams					
Physical presence in days a week [d/w]	4-5 d/w	1-3 d/w	Every other week or one week per month	Select processes in person, everything else is virtual	0 d/w Completely virtual
Options	Tele-commuter		Possibility for a rotating co-location	Virtual or augmented reality	Virtual or augmented reality
DOH	Low	High	Medium	Low	Low

The goal of a hybrid or virtual co-location is to maintain at least the same level of collaboration as a traditional F2F co-location. This section covers the created concepts proposed to reach this goal.

The process of choosing a concept depends on different project framework conditions such as the size of the project both in costs and complexity, as well as the phase of the project. Due to the diversity of project conditions in the construction industry, there is no one size fits all solution for choosing a concept. The decision on which co-location concept depends on the project framework, such as budget, complexity, duration, and the current project phase. It also depends on the chosen team and if they are compatible with a high DOH.

CONCEPT 1: FULL-TIME CO-LOCATION

This concept encompasses the traditional F2F co-location. This is where all project partners come to the co-location in-person, 4-5 days a week. This concept has a low DOH. The *telecommuter*, as described above, is when project partners can work on other projects while at the co-location. Note that it is not recommended to force partners to come five days a week as this goes against the new normal. If five days a week are needed, create a shift system where the first half of the team is there Monday-Thursday and the second half Tuesday-Friday. To implement this concept, the full standard co-location requirements catalog is required. Table in the appendix contains the catalog, including both requirements found in the literature review as well as during the interviews. The full-time co-location is suggested mainly during the construction phase for large and complex projects. During the construction phase, the co-location should be as close to the construction site as possible, in the earlier phases it can be located closer to the team's offices.

CONCEPT 2: PART-TIME CO-LOCATION

The second concept is a part-time co-location averaging 1-3 core days a week in-person and the rest in a hybrid or virtual setup. Team members are allowed to work in the co-location on the non-core days if this is what they prefer, but they are not required to be present. This concept is by far the favored concept based on the interviews. This concept is the sweet spot between F2F and virtual. It allows for the benefits of a physical co-location while still giving the flexibility of a concept with a higher DOH. Here a physical co-location is necessary that follows the same requirements and steps as in Concept 1. Additionally, to the full-time requirements, the part-time co-location needs hybrid components. For this concept, it is recommended to do LPS in person but have a digital copy so that on the days away from the co-location participants can still access this information, especially when only using the co-location 1 or 2 days a week. The team should either use software that allows interactive work in the big room or have the physical post-its copied into a digital version after each LPS meeting, which could be as simple as uploading photos. This depends on the team and whether they chose to invest in software and how affine they are with technology. VIM should be present in the co-location; however, the project should have an additional dashboard online as well to quickly access the current project status. Most meetings, including SMT, PMT, and PIT meetings are all in-person at the co-location. Organizational and simpler topics can be held in a hybrid or virtual format. Meeting rooms need to be equipped with appropriate hardware such as microphones, screens, and cameras to be able to hold hybrid meetings.

CONCEPT 3: PULSED CO-LOCATION

The third concept is the pulsing co-location. This means that a team is either at the co-location every other week or one week per month. The week where presence is mandatory are the so-called core days for this co-location. Depending on the team it may only be 3 days a week, once a month. It is possible to have a rotating co-location, which, as described above, is when the co-location rotates between the partner's offices and does not have a separate location. If there is a separate co-location and not a rotating co-location, each team member can choose for themselves whether to be present on the non-mandatory weeks. Due to the low amounts of mandatory presence, other processes increase in importance and must compensate for the time missing in the physical co-location. It is important to have a cohesive virtual dashboard to maintain VIM even when not present in the co-location, this can be a virtual whiteboard software or integrated with the BIM model. LPS meetings are done in a virtual format. Note that due to the large number of participants in a LPS meeting, it is suggested to be completely virtual to avoid miscommunication. The importance of LPS meetings increases with the DOH as it allows for the whole team to come together and communicate what is currently being worked on. This concept has the highest DOH, meaning most of the co-location aspects are in a hybrid format.

CONCEPT 4: PART-VIRTUAL CO-LOCATION

The part-virtual concept is ideal for smaller projects or project phases that require less collaboration. The team should meet in person for select processes that enable the team to still build trust and relationships that in turn allow for open communication and collaboration. In-person events, like team building events and the kick-off, are even more vital for this concept as they are the few times the team comes together. Team building events need to be reoccurring to maintain the level of collaboration. These events can either be done at the partner's offices, or in event rooms rented for those specific occasions. All other processes are done virtually. This includes SMT and PMT meetings, as well as LPS meetings. Facilitation and leadership skills are of higher importance here to ensure the team is still collaborating and getting along. The team needs to have clear communication and meeting rules, as well as more discipline than using a traditional co-location. This co-location form is almost completely virtual, and therefore, the DOH sinks.

CONCEPT 5: VIRTUAL CO-LOCATION

The last concept is the completely virtual co-location. This has no in-person or hybrid aspects. The virtual co-location is currently not recommended. Due to the missing in-person interactions, it is difficult to build trust, communication, and therefore, collaboration. This concept should only be implemented if the team is a small tight-knit group that has experience working together. Due to chance communication missing entirely, other communication channels as well as VIM need to carry more weight. Set importance on video calls with the camera and microphone on, rather than chat platforms. This maximizes the number of communication styles in use. Options for virtual or augmented reality can help further increase the number of communication styles being transmitted. A virtual dashboard that is clean, structured, and contains all important project status information in one accessible place is vital. Software needs to be intuitive and available to all team members. Ideally, a communication platform is used that encompasses everyday communication, the project dashboard, the LPS, the BIM model, the master schedule, and other relevant information.

CO-LOCATION AS A METHOD

Due to the terms co-location, big room, and Obeya room being used interchangeably, as well as the definitions not encompassing hybrid or virtual co-locations, we expand the definition of the co-location. To create clarity, we define co-location as follows:

The co-location is a method of transforming a space to bring a team together and foster collaboration through coordination, visualization, and transparency. It is the space where interdisciplinary teams come together to collaborate, communicate, and work as an integrated team side-by-side. This includes all hierarchies, e.g., in IPD projects the project implementation teams (PITs), PMT, and SMT. The co-location uses visualizations to inspire the team, using the principles of the Obeya room throughout the space. The co-location does not have to be a permanent physical space in the case of a hybrid or virtual co-location.

By defining the co-location as a method, rather than a physical space, hybrid and virtual co-locations can be considered. For smaller projects, the physical co-location may just be a big room including the workstations of the team. Larger projects will encompass the big room as well as meeting rooms, a coffee corner, and an open co-working space.

CONCLUSIONS

Creating a high-performing team of interdisciplinary, cross-functional people in a complex construction project needs trust and open communication. The co-location is a tool that improves collaboration and communication in construction projects. A co-location includes various components such as VIM and LPS, as well as elements like acoustics and the Internet. Due to the COVID-19 pandemic and the parallel transformation of technology, it has become the new normal for companies to offer employees more flexibility to work from home (Raghavan et al., 2021). A hybrid approach to co-location has become increasingly important, combining in-person and remote work. A co-location must have the fitting components and be used effectively to be successful. Based on the literature review, supplemented, and validated through the interviews, a comprehensive requirements catalog was created and can be used as a checklist for future co-locations.

We defined co-location as a method to transform a space to bring an interdisciplinary team together and foster collaboration through coordination, visualization, and transparency. The co-location does not have to be a permanent physical space in the case of a hybrid or virtual co-location. Depending on the size of the project, a co-location can be as small as the big room or large enough to include the big room as well as smaller meeting rooms, a coffee nook, and an open co-working area. The co-location actively uses visualizations to inspire and guide the team, using concepts of the Obeya room throughout the space.

Five co-location concepts were identified in the literature review and developed further with clear definitions, three of which are hybrid. By defining each concept clearly, future discussion over the concepts will have fitting vocabulary. The second concept, being the most recommended in the interviews, is a part-time co-location where participants are present 1-3 days a week depending on project size and preference. These concepts should be seen as suggestions and need further examination to understand their impact on collaboration, teamwork, and the project. They are based on 26 interviews and a literature review. The interviews were held mainly with co-location participants in Germany, findings here cannot be generalized for international purposes.

In conclusion, interviews showed hybrid co-location concepts can be successful, however, none recommended the long-term implementation of a virtual co-location. Interviews showed that in-person events need to be at the beginning and throughout the project to build and maintain trust. As the DOH increases, communication channels such as chance communication decreases. Interviewees argue other communication channels such as LPS need to compensate for the missing communication.

The co-location concepts need to be further analyzed and tested in practice to ensure their accuracy. Each project is different, and no co-location is the same. Further differentiation needs to be taken based on the project's size, both in volume as well as in the number of project participants. Additional sources of information could be included in the future, such as case studies and large-scale surveys to gain more practical data. Further international interviews should be held to ensure the accuracy of these findings and to remove cultural biases.

A process and research of a topic are never complete. As lean methods would say, one needs to constantly plan, do check, and act (PDCA). This paper covers one iteration of co-location concepts that are built on prior research and practical implementations. We recommend that in the next iteration, these concepts be, implemented, checked, and further improved.

ACKNOWLEDGMENTS

We would like to express our gratitude to everyone who helped and supported us during the process of creating this paper. Specifically, Yukon Projects GmbH, who gave access to their pool of contacts and knowledge. Finally, we wish to acknowledge all the interview partners for taking the time out of their day to answer our questions openly and honestly.

FLEXIBLE ROBOTIC PRODUCTION IN OFF-SITE CONSTRUCTION: A LEAN APPROACH

Jennifer Alejandra Cardenas Castaneda[1], Beda Barkokebas[2], Pablo Martinez[3], and Rafiq Ahmad[4]

ABSTRACT

The integration of robotics into flexible manufacturing systems (FMS) has been identified as a potential strategy for increasing modular construction flexibility. The purpose of this paper is to present a conceptual framework for investigating the relationship between FMS and robotics in modular construction. The framework proposes that by incorporating robotics into FMS, prefabricated building component manufacturing systems will gain flexibility. The two key variables of the framework are robotics (as the independent variable) and FMS (as the dependent variable). Moderator variables such as controlled environment and variability are also considered, as are mediator variables such as real-time adjustments, productivity, equipment utilization, set-up times, varying speeds, and reduced manpower. The purpose of this paper is to set the theoretical foundation for further studies on robotics integration into FMS in modular construction. The paper concludes with a discussion of the proposed implications of the framework for modular construction practitioners and researchers.

KEYWORDS

Construction 4.0, modular construction, robotics, flexible manufacturing systems.

INTRODUCTION

Modular construction is a method of manufacturing and construction that involves prefabricating building components in a controlled environment before assembling them on-site. It is based on the concept of modular product architecture, which entails designing products in such a way that they can be easily customized and configured using pre-designed modules (Bertram et al., 2019). However, the industry's main problem is a mismatch between the need of large type batch sizes in fabrication and the needs of small type batch sizes in assembly. This results in excess inventory or missed opportunities to meet customer demand, both of which can negatively impact the company. In the absence of robotics in modular construction fabrication, the industry faces one of the major challenges of manufacturing, the inability to adjust production time to meet changing demand for a product (Wadhwa, 2012).

Flexible Manufacturing Systems (FMS) is a collection of manufacturing technologies that allow for the quick and efficient production of a wide range of products in small batches. FMS technologies such as computer-controlled machining centers, automated material handling

systems, and robotics are designed to work together to enable the efficient production of a wide range of products with minimal changeover time. FMS offers a cost-effective option for small-batch production while retaining the efficiency and productivity of mass production (Kostal et al., 2014).

The use of robotics in modular construction fabrication can help to address this issue. Robots can work around the clock by automating production processes, increasing productivity and reducing the need for manual labor. Robotics also allows for the quick and easy adjustment of production schedules to meet changing demand, making it easier to respond to market demands. Furthermore, the use of robotics can improve the consistency and accuracy of the manufacturing process, resulting in higher-quality products (Tilley, 2017).

The ability to adapt to fluctuating demands has become a critical factor for success in the 4.0 Industry era (Enrique et al., 2022). This requires production lines to be able to adapt to the demand changes. These changes in product demand occur in the market as a result of customer requirements changes (Yadav & Jayswal, 2018). The modular building industry has to deal with lean implementation challenges such as product customization flexibility and variable market demand (Innella et al., 2019). Companies must prioritize flexibility and the ability to respond quickly to changes in demand in order to remain competitive.

Despite the increased productivity brought by offsite construction involving efficiency, there is still improvement to be done. A lot of focus has been placed on using various methods for improving productivity but there have been a few emphases on incorporating automated systems into the offsite manufacturing process (Tehrani et al., 2022). The World Economic Forum has created three scenarios for the future of construction, each of which addresses a different megatrend, including the integration of robotics and pre-fabrication (Pan et al., 2022). Additionally, legislative bodies like European Parliament have emphasized the importance of robotics as a key piece for the digital transformation of the construction industry (European Parliament, 2019).

While there are challenges associated with implementing robotics in modular construction fabrication phase that is illustrated in Figure1, the benefits of increased productivity, reduced dependence on labour, improved responsiveness to changing demand, and improved product quality make it a promising technology for the future of the modular construction industry. The purpose of this paper is to present a conceptual framework for investigating the relationship between modular construction and flexible manufacturing systems (FMS). The paper also intends to provide the theoretical groundwork for future research on robotics integration into FMS in modular construction.

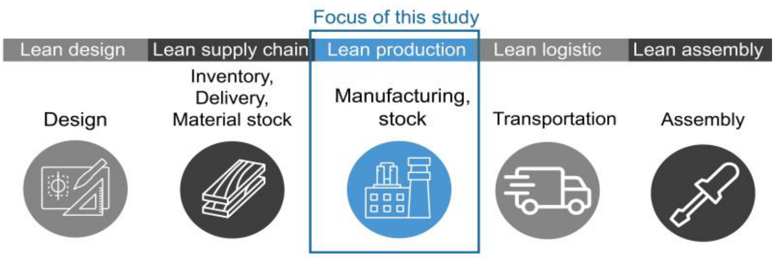

Figure 1: Production Stages in Modular Construction (Innella et al., 2019).

SYNERGIES BETWEEN FLEXIBLE MANUFACTURING SYSTEMS AND ROBOTICS

BENEFITS AND CHALLENGES OF FLEXIBLE MANUFACTURING SYSTEMS

A flexible manufacturing system (FMS) is regarded as an essential component in the realm of Industry 4.0, as it has the potential to improve system performance and thus boost the system's overall competitiveness (Priyadarshini & Gupta, 2023). As the name implies, it is characterized by its flexibility, which allows it to respond quickly to changing production requirements and conditions. An FMS is made up of adaptable machines such as robots, multi-purpose machines, or workstations, an automated transport system, and a decision-making system, also known as a scheduler, that determines which tasks will be executed and on which machine at any given time (Eloundou et al., 2015).

One of the most significant advantages of an FMS is that it allows the system to adapt to changes in demand, reducing downtime and increasing productivity (El-Khalil & Darwish, 2019). A manufacturing system's adaptability allows it to handle varying levels of product variety and quantity (Priyadarshini & Gupta, 2023). Considering that flexibility is highly important when producing for a fluctuating demand, FMS concept aims to bridge that gap. Other benefits include increased capital and equipment utilization, shorter work-in-process and set-up times, faster throughput and lead times, smaller batches and lower inventory, and fewer manpower requirements (Magalhães et al., 2022).

However, there are some challenges associated with implementing flexible manufacturing systems, such as low equipment utilization, a lack of technical expertise, and a lack of understanding on the part of senior management, all of which can have a negative impact on the FMS's implementation and execution (Priyadarshini & Gupta, 2023). Furthermore, the cost of implementing and commissioning a flexible manufacturing system is high, and the anticipated savings are difficult to quantify (Magalhães et al., 2022).

BENEFITS AND CHALLENGES OF ROBOTICS

Another key driver for Industry 4.0 is robotics (Bahrin et al., 2016), which is a rapidly growing field that has the potential to revolutionize the way products are manufactured and produced. The implementation of robots in various industries is gaining widespread recognition for its ability to improve productivity, efficiency, and reduce the need for manual labor, particularly in repetitive or hazardous tasks. Robots come in a diverse range of shapes, sizes, and functionalities, which can range from highly flexible and autonomous to being limited to performing a single or set of predetermined tasks (Smids et al., 2020).

There are two important types of robots that are relevant to this research: industrial robots and collaborative robots. Industrial robots are heavy rigid bodies that perform a complex series of actions that for a human would be very difficult and dangerous to do, such as for example carrying a huge load and are normally placed in a human-isolated workspace. On the other hand, we have collaborative robots, also known as cobots, that are smaller, more flexible and designed to operate close to humans within the same space (Sherwani et al., 2020).

The benefits of robotics in manufacturing and production are numerous. For instance, robots are capable of mass customization through the production of lots as small as single unique items because of the ability of rapidly configure machines to adapt to customer-supplied specifications. Furthermore, robots provide a high flexibility feature to the production, since they can produce new products quickly without complicated re-tooling or setup of new production lines (Bahrin et al., 2016). Additionally, robots bring the benefit of working 24/7 without breaks, leading to increased productivity and reduced downtime (Naveen Reddy et al., 2019). Furthermore, robots can perform complex tasks with a high degree of accuracy, reducing the likelihood of human error and improving product quality. Additionally, robots can work in hazardous environments, reducing the risk of injury to human workers.

However, there are also some challenges associated with the implementation of robotics technology. For instance, the high cost of acquiring and maintaining robots can be a barrier for smaller businesses, additionally the total costs are often no completely predictable during the beginning stage of the project, which might increase due to unexpected follow-up costs, for example for employee training (Flechsig et al., 2022). Moreover, the lack of technical expertise related to the operational side of the robots can limit their widespread adoption.

In conclusion, while robotics technology holds great promise for the manufacturing and production industries, it is important to carefully consider the benefits and challenges of implementing robotics, in order to maximize its impact and minimize any negative effects.

FLEXIBLE MANUFACTURING SYSTEMS WITH ROBOTICS IN MODULAR CONSTRUCTION

Modular construction has a strong connection with manufacturing as it involves the production of prefabricated building components in a controlled environment (Bertram et al., 2019). These components are then transported to the construction site and assembled, reducing the time and effort required for traditional on-site construction methods (Kamali & Hewage, 2016). This approach aligns with the principles of Industry 4.0, which prioritizes the use of advanced automation and technology to increase efficiency and quality in the manufacturing process (Bahrin et al., 2016).

Modular construction uses panels that are cut to the desired shape and size using CNC (computer numeric control) tools that can cut in almost any direction with high precision to form openings, service voids, etc. A CNC system is designed to perform specific tasks by following precise instructions. Figure 2 illustrates how the CNC system for manufacturing components for modular construction works, following a set of steps that are already programmed. However, the main drawback of this type of system is its inflexibility, since it lacks the ability to adapt to changes in its environment, modify its process, or make independent decisions (Virasak, 2019). This is the main distinction between flexible systems and a CNC sysstem.

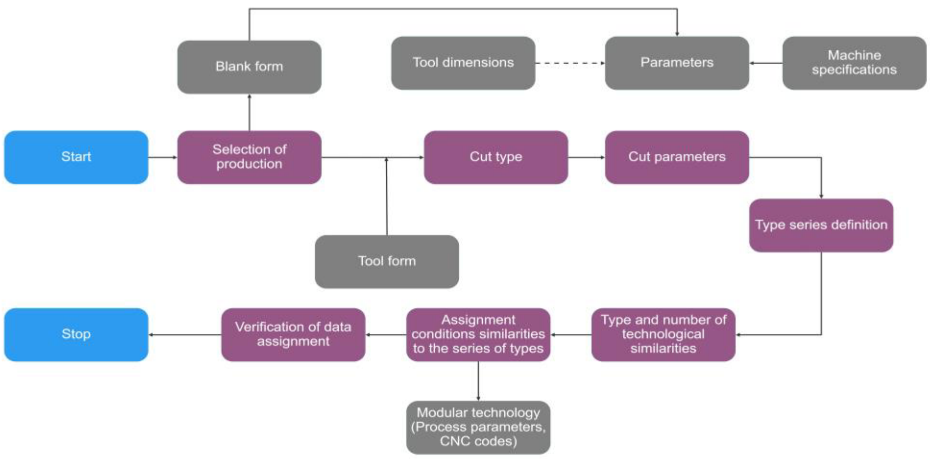

Figure 2: CNC Manufacturing Process of Modular Construction (Rząsiński, 2018).

A flexible system can alter its process, change its instructions, and make decisions based on input or feedback (Lafou et al., 2016) while a CNC only follows the instructions that have been programmed into it. On the other hand, robotics systems are considered to be more flexible compared to other manufacturing processes. One reason is robotics systems can be programmed to perform a wide range of tasks (Graetz & Michaels, 2018), making them adaptable to changing manufacturing needs. Furthermore, robotics systems often feature sensors and feedback systems that allow them to make real-time adjustments to their operations.

Production fluctuations are a common occurrence in manufacturing as illustrated in Figure 3. The graph depicts the fluctuations in demand for prefabricated components in the modular construction industry. The graph shows how demand for prefabricated components has changed over time, with peaks and troughs. Understanding these fluctuations is critical for industry stakeholders because it can help inform production, inventory management, and pricing strategies. This graph is a useful visual representation of the industry's demand patterns that can be used to represent demand fluctuations.

The demand for a manufacturing plant can vary from day to day (Ojha et al., 2013), making it unnecessary to have a 100% production capacity all the time. A low-demand rate is translated to high-demand variability, which leads to an inefficient manufacturing process as a consequence of high tooling and setup costs (Knofius et al., 2016). From a lean perspective, demand fluctuations during the production of modular construction components result in overproduction, known as an example of waste in the lean approach. Longer lead times, higher carrying costs, and extra inventory can all be the effects of overproduction (Aziz & Hafez, 2013).

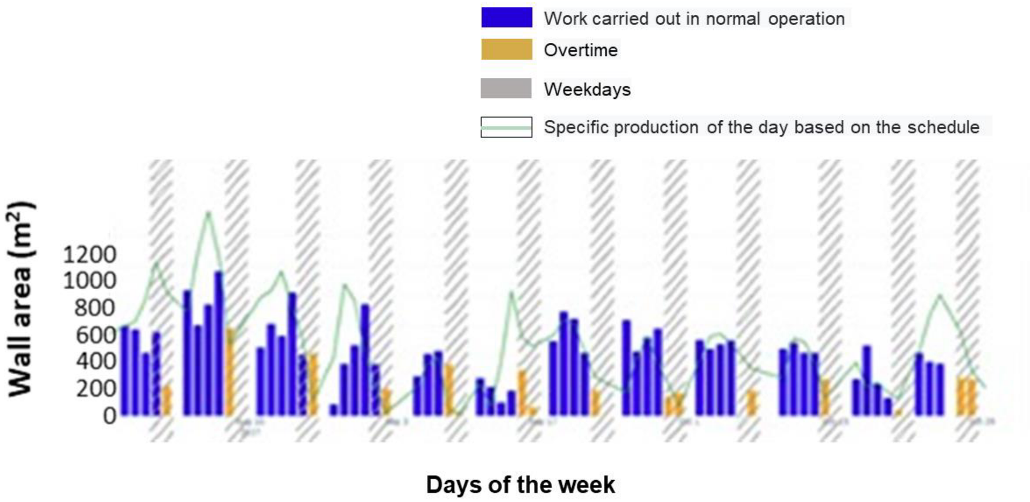

Figure 3: Fluctuation in Modular Construction Industry Demand for Prefabricated Components.

This is why flexibility in production is a key challenge in the industry. By understanding the demand variability, manufacturers can adjust their production processes to accommodate these fluctuations, reducing the need for maximum efficiency at all times. This can help save costs and resources, while still meeting customer demands. To maintain the principles of Lean, it is essential to have a flexible and responsive manufacturing system that can adjust to changing demand and avoid overproduction.
