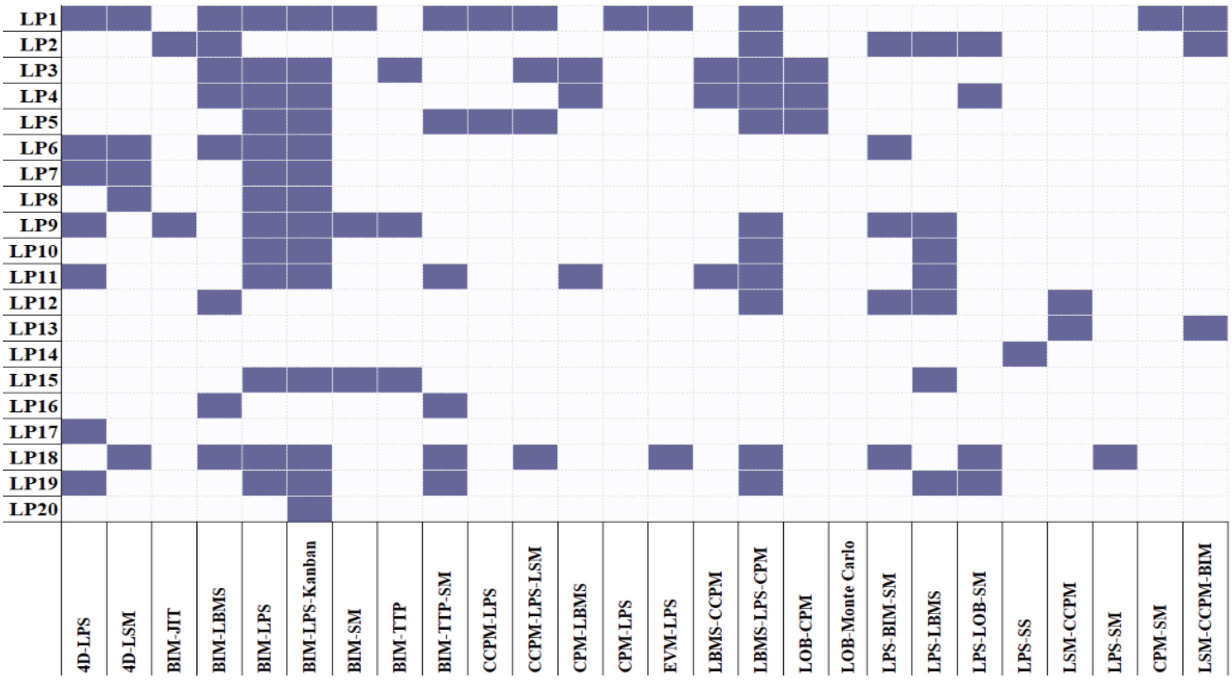

Figure 2: Mapping of studied integrated scheduling methods and the identified lean principles

QUANTITATIVE ANALYSIS OF LEAN PRINCIPLES

After conducting an in-depth analysis of the papers and identifying the lean principles, a reference matrix P was created based on those lean principles and integrated scheduling methods. The reference matrix P has a size of 20 by 26 and comprises 20 lean principles and 26 integrated scheduling methods. The following subsections describe the results.

Lean Principles Network

Using Equation 1, the authors created the adjacency matrix based on the reference matrix acquired from the literature analysis. The adjacency matrix's cell values indicate the weight of the edge connecting one node to another. The cells are color-coded based on the intensity of the edges between the pair of lean principles, illustrated in Figure 3. As can be seen, white-colored cells for a pair of lean principles imply that they have not co-occurred in any of the evaluated integrated scheduling methods. Consider LP2 (increasing productivity) and LP8 (schedule constructability analysis) for the latter. On the other hand, certain pairs of lean principles have dark orange cells, suggesting significant weights and, therefore, an abundance of co-occurrence in the integrated scheduling methods under consideration. This is represented in the edge weights between LP1 (improving the reliability of the planning) and LP18 (increasing transparency).

Moreover, as illustrated in Figure 4, the adjacency matrix is employed to visualize the lean principles network. The network diagram consists of 20 lean principles (nodes) linked by 266 directed edges or connections. The figure demonstrates that the network has several links between lean principles. In other words, the network of lean principles is dense, indicating numerous interconnections resulting from graph density equal to 0.778.

The degree of centrality (DC) is calculated and normalized to assess the interconnectivity among the lean principles in integrated scheduling methods. Table 4 displays the normalized DC results. In Figure 4, the dark purple colors correspond to lean principles with higher DC values, and the orange colors represent lean principles with lower DC values.

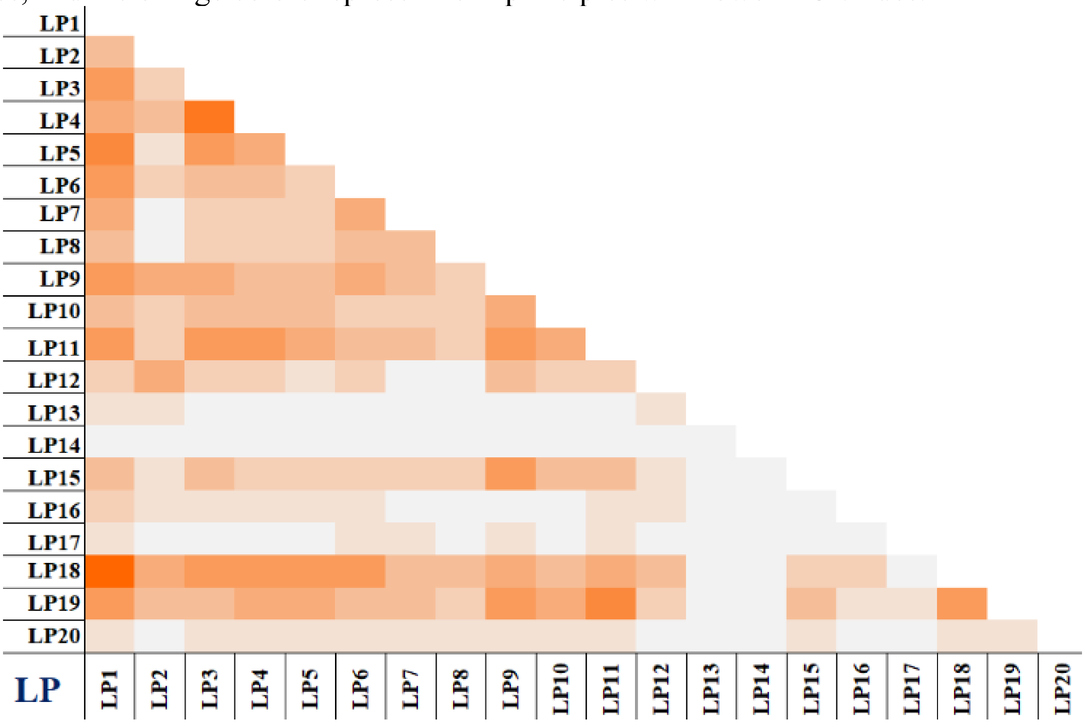

Figure 3: Color-coded adjacency matrix of lean principles

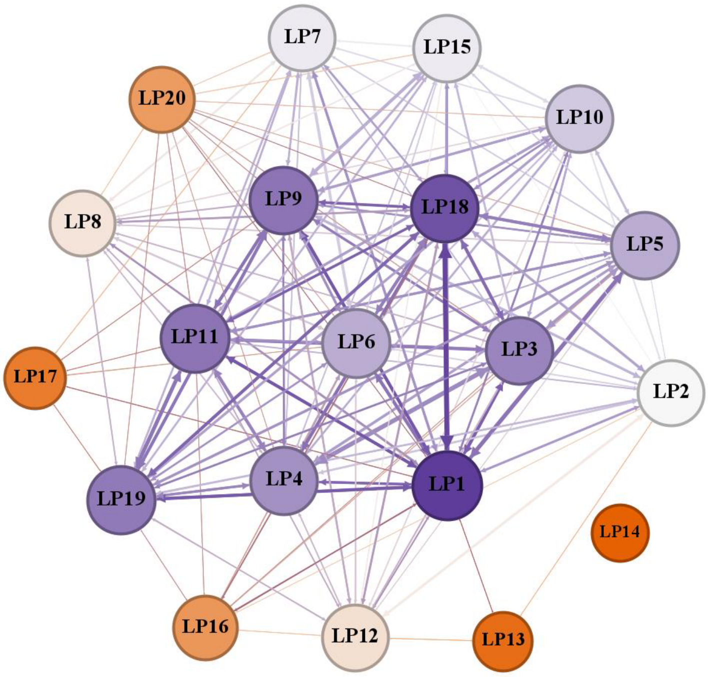

Figure 4: Lean principles network

Table 4: Normalized DC for lean principles

Code	Lean Construction Principles	Network P Normalized DC
LP1	Improving the reliability of the planning	1.00
LP18	Increasing transparency	0.94
LP9	Identification and elimination of waste	0.85
LP11	Detecting and solving spatiotemporal conflicts	0.85
LP19	Enabling the coordination of the look-ahead plans	0.83
LP3	Continuous flow of work	0.80
LP4	Decreasing workflow variability	0.77
LP5	More efficient constraints analysis	0.70
LP6	Visualization of schedules to understand and communicate content to a variety of stakeholders	0.70
LP10	Decreasing meeting durations	0.62
LP7	Avoiding omissions and sequencing mistakes	0.53
LP15	Reduction of production cycle time	0.53
LP2	Increasing productivity	0.50
LP8	Schedule constructability analysis	0.44
LP12	Maintaining continuity of resources	0.42
LP20	Implementation of pull flow control	0.20
LP16	Improving the usability of the 4D BIM for workflow analysis	0.18
LP17	Increasing safety on construction sites	0.09
LP13	Scheduling of modular and off-site construction	0.05
LP14	Eliminating the root causes of variability	0.00

Two perspectives on lean principles can be discussed: (1) the lean principles that have been employed most often in integrated scheduling methods, and (2) the lean principles that have been used the least frequently.

In regards to the first viewpoint, as shown in Figure 4 and Table 4, LP1 (improving the reliability of the planning), LP18 (increasing transparency), LP9 (identification and elimination of waste), LP11 (detecting and solving spatiotemporal conflicts), LP19 (enabling the coordination of the look-ahead plans), LP3 (continuous flow of work) have received the most attention in the integrated scheduling methods.

Following the second perspective, Figure 4 indicates that LP13 (scheduling of modular and off-site construction), LP17 (increasing safety on construction site), LP16 (improving the usability of the 4D BIM for workflow analysis), and LP20 (implementing of pull flow control) have been given the least importance by the integrated scheduling methods. Moreover, as seen in the network, there is no link for LP14 (eliminating the root causes of variability), indicating a lack of consideration for this principle in the integrated scheduling methods.

RESEARCH DISCUSSIONS

This section discusses the important results of this research in the context of identified lean principles in the integrated scheduling methods. This can be accomplished by highlighting areas that have gained considerable attention and those that have received little attention to determine future directions.

Understanding these integrated methods and the underlying concepts can enable project managers to optimize resources and processes more effectively. In support of this claim, several studies have discussed that a lack of knowledge and understanding of project scheduling methods, tools, and underlying concepts may lead to failures in project delivery (AlNasseri and Aulin 2015; Shash and Ahcom 2006). In this respect, this research investigated identifying and analysing the lean principles employed in integrated scheduling methods to assist project stakeholders in understanding the effectiveness of integrated scheduling methods. The findings indicated that the Last Planner System (LPS), Kanban, six sigma, Just-in-Time (JIT), and takt time were the most utilized lean tools in the integrated scheduling methods. Although many integrated scheduling methods, such as BIM-LPS, BIM-LPS-Kanban, LBMS-LPS, LPS-CPM, LPS-LSM, etc., have benefited from LPS advantages such as planning reliability, constraint management, continuous workflow, and continuous improvement, few integrated scheduling methods have focused on one of its shortcomings, which is the non-performance of root cause analysis and corrective actions (Aslam et al. 2020). In addition, the focus of some integrated scheduling methods, such as LPS-4D, LPS-BIM, and LPS-BIM-Kanban, on addressing one of LPS drawbacks, which is inadequate visualization capabilities (Aslam et al. 2020), demonstrates that there is a great deal of potential for the future of the industry, as well as research to focus on visual-based collaborative scheduling methods including Virtual Reality (VR)-LPS and metaverse-base LPS.

The results of the lean principles network illustrated that in the integrated scheduling methods, LP1 (improving planning reliability), LP18 (increasing transparency), LP9 (identifying and eliminating of waste), LP11 (detecting and solving spatiotemporal conflicts), LP19 (enabling coordination of the look-ahead plans), and LP3 (continuous flow of work) have were given the most attention. These results indicate that in line with efforts to increase productivity in the construction industry, the focus of research and industry for project planning and scheduling is beyond cost, time and quality management, which has been of concern for years. Areas such as reliability, transparency, waste management, coordination in mid-term planning, and flow and process management are considered more attention in integrated scheduling systems. Moreover, attention to workspace management through location-based scheduling methods, such as LOB, LBMS, and LSM, as well as object-based scheduling methods, including 4D and BIM in integrated scheduling methods, lead to focus has been directed at LP11 (detecting and solving spatiotemporal conflicts).

In the other hand, LP14 (eliminating the root causes of variability), LP13 (scheduling of modular and off-site construction), LP17 (increasing safety on the construction site), LP16 (improving the usability of the 4D BIM for workflow analysis), and LP20 (implementing of pull flow control) have received the least consideration in integrated scheduling methods. The findings show that although learning and eliminating the root causes of variability is one of the important principles in lean construction and extensively studied in the early days of lean construction, it has received little attention in integrated scheduling methods, this issue can also be found in Aslam et al. (2020)'s research. One possible explanation is that lean construction is a subset of the broader idea of lean thinking, which embraces various principles and activities to enhance productivity and quality while minimizing waste. Variability may be managed holistically and completely by combining lean construction with other principles, including, collaboration and communication management, continuous improvement and visual management. By focusing on these proactive actions, the need to address variability as a separate issue may be reduced or managed indirectly. In addition, little emphasis has been given to the scheduling of modular and off-site construction in integrated scheduling methods, despite the fact that one way to incorporate lean production into construction project delivery would be to enhance off-site construction levels from materials, components and sub-assembly to modular buildings (Pasquire and Connolly 2002). Furthermore, 4D BIM capabilities have contributed significantly to the use of lean principles, such as LP6 (visualizing of schedules to understand and communicate content to a variety of stakeholders) and LP11 (detecting and solving spatiotemporal conflicts), and LP8 (schedule constructability analysis), in integrated scheduling methods. However, little attention is paid to the usability of the 4D BIM for workflow analysis. This gap can be investigated in future research on integrated scheduling methods.

Analyzing the co-occurrence of used lean principles in integrated scheduling methods, based on Figure3, depicts the pairs of LP1 (improving the reliability of the planning) and LP18 (increasing transparency), LP4 (decreasing workflow variability) and LP3 (continuous flow of work), and LP19 (enabling the coordination of the look-ahead plans) and LP11 (detecting and solving spatiotemporal conflicts) have been recognized as the most frequent pairs in integrated scheduling methods. According to these evaluations, considering lean principles in integrated scheduling methods focuses mainly on mid (look-ahead) and short-term (weekly work) planning.

In integrated scheduling methods such as BIM-LPS, and BIM-LPS-Kanban, which combine LPS and BIM capabilities, lean principles have been covered to a considerable extent; however, in order to apply these concepts practically, one must utilize more integrated methods to overcome the challenges of mismatched LoD in BIM and the granularity of look-ahead (Lin and Golparvar-Fard 2021) and weekly work plans, covering all scheduling levels, and taking contract and management requirements into account. For this purpose, the authors propose using location-based scheduling methods, such as LBMS and Takt Time Planning (TTP), for work structuring and solving the mismatching LoD in BIM with look-ahead and weekly work plans granularity by associating BIM components to their locations. Moreover, since CPM-based scheduling is a contractual obligation for many projects, including it in integrated scheduling methods will also address managerial and contractual concerns.

CONCLUSION

As a result of poor productivity resulting from ineffective project planning and scheduling in the construction industry, not only have numerous studies examined the integration of conventional scheduling methods with each other, lean tools and principles, but also, in practice, project managers and planners put a greater emphasis on using integrated scheduling methods for more effective project scheduling and control. To better understand the lean principles used in integrated scheduling methods, this study followed a multi-step methodology to analyze 26 identified integrated scheduling methods and 20 lean principles. To this end, a systematic literature review is conducted on the planning and scheduling field of study. After that, a quantitative analysis was performed based on SNA. The degree of centrality (DC) is determined to assess the importance of lean principles used in integrated scheduling methods. The result indicated that BIM-LPS-Kanban, BIM-LPS, LBMS-LPS-CPM, and BIM-LBMS, as some integrated scheduling methods, have utilized the most lean principles in their structures that indicate the most focus of academia and industry is on the LPS and BIM for developing the integrated scheduling methods.

As lean principles, LP1 (improving the reliability of the planning), LP18 (increasing transparency), LP9 (identification and elimination of waste), LP11 (detecting and solving spatiotemporal conflicts), LP19 (enabling the coordination of the look-ahead plans), and LP3 (continuous flow of work) have gained the most attention in the integrated scheduling methods. In addition, the pair of LP1 (improving the reliability of the planning) and LP18 (increasing transparency) were detected as the most pairs in integrated scheduling methods. The findings illustrate that the construction industry's push for improving productivity has led to a shift in research and industry focus away from traditional concerns of cost, time, and quality management in project planning and scheduling.

In contrast, LP14 (eliminating the root causes of variability), LP13 (scheduling of modular and off-site construction), LP17 (increasing safety on construction site), LP16 (improving the usability of the 4D BIM for workflow analysis), and LP20 (implementation of pull flow control) have paid the least attention in integrated scheduling methods. Despite the potential benefits of incorporating lean production principles into construction project delivery through increased levels of off-site construction, integrated scheduling methods have overlooked the scheduling of modular and off-site construction. This represents a gap in the current focus, as enhancing the use of off-site construction - from materials, components, and sub-assemblies to modular buildings - could be a viable strategy for achieving this goal.

Finally, this paper contributes to the body of knowledge by enhancing knowledge and awareness of the lean principles used in integrated scheduling methods in the construction industry.

The limitations of this research are the lack of analyzing correlation between lean principles and considering the expert's points of view for evaluating lean principles. Moreover, focusing on collaborative visual-based scheduling using new technologies such as Virtual Reality (VR)-LPS and metaverse-base LPS could be one of the suggestions for further research. Future studies should also focus on several lean principles, such as root cause analysis and corrective actions, the usability of 4D BIM for workflow analysis, and modular and offsite construction scheduling for integrated scheduling methods.

ACKNOWLEDGEMENTS

This study was conducted at the Nancy Automation Research Center (CRAN) laboratory through the financial support provided by the National Research Agency of France (ANR-20-CE10-0011) for the ISoBIM project, whose support is gratefully acknowledged.

A NARRATIVE REVIEW OF WORKSPACE PLANNING IN CONSTRUCTION: CHALLENGES AND INSIGHTS

Diana Salhab[1], Fatima Alsakka[2], and Farook Hamzeh[3]

ABSTRACT

Space on construction sites is not abundant as may be thought. In fact, workspace planning could become increasingly challenging at times. Moreover, improper workspace planning may lead to congestion and, hence, potential safety and productivity issues. Workspace planning aligns with Lean thinking through reducing wastes in workers' productivity, waiting time, double handling, and different types of flow. Meanwhile, there is generally a scarcity of research studies in this area especially in industrial projects. As such, this paper presents a narrative literature review of research conducted on workspace planning in construction. Specifically, the review aims to answer the following questions: What is a workspace? What are some methods used for workspace planning? What are the challenges faced in workspace planning? What decisions are essential for workspace planning? The last question tackles fundamental concepts in workspace planning such as flow types, area patterns, workspace classification structure, and spatial-temporal conflict identification and resolution. The study concludes with considerations to be scrutinized and adopted during the process of developing a well-thought-off workspace planning system.

KEYWORDS

Workspace, planning, spatial-temporal conflict, flow, area.

INTRODUCTION

Generally, evaluating space requirements and positioning construction operations to predetermined locations on site are often left until the project starts. It may be believed that space is abundant in a way that eliminates the need for prior planning; however, this is a fallacy. Proper workspace planning is necessary to avoid needless material handling, prevent spatial-temporal conflicts, and reduce travel times (Tommelein & Zouein, 1993). A workspace is a shared resource among all participants on a project, and every person on a construction project needs a separate workspace to carry out their tasks. Accordingly, improper workspace planning might lead to interferences between different crews, creating congestion that results in safety and productivity issues (Hammad & Zhang, 2011; Mallasi, 2006). Workspace management aims to ensure that workspace demand and availability match, thereby avoiding spatial conflict (Igwe et al., 2020).

However, the available scheduling methods have proved to be less sufficient for workspace planning because they neglect the spatial feature of each task. For instance, the Line-of-Balance (LOB) method considers that only a single crew can occupy each work zone at once, and it treats the space as a scalar one-dimensional variable, which omits substantial complexity faced when managing 3D space (Choi et al., 2014). This complexity could explain why researchers have replaced 2D sketches and 2D computer-aided design models used for workspace analysis (e.g., Zouein & Tommelein, 2001, Guo, 2002) with 4D and 5D BIM models that better represent the actual complexity of the real workspace (e.g., Chavada et al., 2012; Moon et al., 2014; Rohani et al., 2018). However, most of the existing 4D (3D + time) simulations are static where objects are generated in the simulation at discrete points in time, such as at task start point. Still, in reality, construction is dynamic, and the products appear progressively as they are built (Heesom et al., 2003). Moreover, a construction activity might require more than one workspace of varying geometry throughout different stages (Su & Cai, 2014). Thus, the construction workspace constantly changes, but such change is poorly assessed in current literature, especially for industrial projects (Bannier et al., 2016). For a workspace modelling approach to be effective, it needs to convey the actual workspace usage accurately and flexibly. Although a variety of 4D simulation models allowing full navigation through the model across time is available in the market, none of them adequately supports the scheduler during schedule preparation. These models primarily focus on visualizing the already completed schedules (Tulke et al., 2008). Additionally, spatial-temporal conflicts can be prevented through employing rules to control the movement of workers, equipment, and material. However, developing the rules that govern how the cells behave is difficult, particularly when there are many rules (Hammad & Zhang, 2011).

In short, workspace planning is complex in nature and entails a variety of decisions that are contingent on the distinct requirements of each workspace. Specifically, evaluating the initial requirements of and the continuous spatial-temporal change in the location and dimension of each workspace (i.e., through time and across all three dimensions) could be a major challenge in workspace planning. Meanwhile, there is generally a scarcity of academic research, especially in industrial projects (Bannier et al., 2016), that provides detailed analyses of workspace requirements, dynamic behaviours of workspaces, and impacts of different tasks on a workspace. As such, this paper presents a narrative literature review of research conducted on workspace planning in construction. A narrative literature review intends to "assemble and synthesize extant literature and provide readers with a comprehensive report on the current state of knowledge in the area under investigation" (Templier & Paré, 2015). In this context, this study first presents the definition of workspaces in construction, a brief review of some existing workspace planning methods, a description of some of the challenges encountered in workspace planning, and then highlights a set of considerations that must be accounted for in construction workspace planning.

METHODOLOGY

This study followed a review procedure similar to the six-step procedure proposed by Templier & Paré (2015) for conducting literature reviews, which includes (1) formulating the problem, (2) searching the literature, (3) screening for inclusion, (4) assessing quality, (5) extracting data, and (6) analysing and synthesizing data. It should be noted that the quality assessment of the studies was limited to their relevance to the defined problem, their clarity, and their contribution to the body of literature found on the topic. As such, the research design and methods used in the studies were not evaluated. Moreover, given the limited size of research conducted on workspace planning in construction, the initially formulated problem in Step 1 was aimed to identify studies generally conducted on workspace planning in construction. The next step consisted of conducting an initial search for relevant studies published in reputable journals (e.g., *Automation in Construction*, *Journal of Construction Engineering and Management,* etc.) in order to determine significant research areas on the topic. Upon completing this initial search and screening the full texts of the identified studies, Step 1 was revisited to formulate more specific research questions in order to better direct the search process. As such, the following questions were formulated: *What is a workspace? What are some methods used for workspace planning? What are the challenges faced in workspace planning? What decisions or considerations are essential for workspace planning?* Next, for each question, the literature was searched for relevant studies (Step 2), and the studies were screened for data pertinent to the question of interest (Steps 3, 4, and 5). Finally, the data extracted for each question was synthesized to provide a summary that helps the reader understand the current state of knowledge on the topic (Step 6).

DEFINITION OF WORKSPACE

Construction crews need space to execute work and to move, fabricate, and store materials. They typically occupy space for predefined time intervals and move through the site in various patterns based on the type of their work and the material involved. Workspace is the 3D physical space needed to cater for a resource, characterized by its shape and volume, and governed by material quantities, dimensions, shape, and stacking ability (Riely & Sanvido, 1995; Riley & Sanvido, 1997). The common practice is to represent a workspace by a 3D bounding volume which can take different forms such as a bounding box, a bounding sphere, an oriented bounding box, an axis aligned bounding box (Choi et al., 2014), a rectangular box (Dashti et al., 2021), or a cylinder (Rohani et al., 2018). Another practice is the cell representation where the site layout is represented by a grid of numerous interconnected cells; this representation is mainly used for moveability analysis (Wang et al., 2019). A work envelope is defined as a 3D space volume enclosing a building component, and allowing a construction worker to be there and perform a construction task on this component, along with corresponding equipment and material (Bannier et al., 2016). Rohani et al. (2018) consider a transparent cylinder with a base area of 3.14 m^2 and a volume of 5.5 m^3 for representing the workspace needed by a static man-hour. Moreover, research has constantly revealed that productivity decreases when the threshold of one worker occupying 28 m^2 is crossed (Riley & Sanvido, 1997) . Su and Cai (2014) distinguish between two aspects to consider in workspace planning, namely workspace structure and the method of geometric modelling. The workspace structure determines the way the workspaces are arranged to correctly represent a construction task and the way they are managed for project participants to access the required information. As for the method of geometric modelling, it indicates how to generate workspace geometries.

OVERVIEW OF WORKSPACE PLANNING METHODS

Tommelein and Zouein (1993) presented MovePlan as a 2D interactive dynamic layout planning model. It is a construction schedule augmented with data required to establish layouts, such as resources and their dimensions, and which positions temporary facilities and movement of material and equipment on site. The model output can be additionally refined by integrating geometric detail and advanced graphical packages. Akinci et al. (2002) presented a mechanism for automating the process of generating workspaces and creating a space-loaded production system. Superintendents were asked to describe the workspaces needed generally based on the construction method they are intending to use. Such generic descriptions address the size and position of every workspace qualitatively as being oriented with reference to an object. Dawood et al. (2005) developed the virtual construction site (VIRCON) as a set of assisting tools for project planners to do informed and accurate planning decisions when allocating activities' execution spaces. However, several limitations were noted with the developed system, such as lack of visual representation of spatial overload simultaneously with the project plan, difficulty in allocating space, not being user friendly, and need for manual optimization. Spatial overload occurs when the aggregated space demand matches or exceeds available space. Su and Cai (2014) tackled workspace planning and modelling via a life-cycle approach. The study investigated workspace evolution patterns through an object-oriented data structure. Different life cycle stages of a task are identified along with corresponding needed workspaces which are then arranged into sequences. The developed model proved to be more accurate than models with single workspace representation. Moradi et al. (2015) developed a 4D-BIM system to dynamically detect spatial-temporal conflicts and quantify the corresponding impact on project performance. A workspace is generated and assigned by identifying four parameters which are orientation, width offset, length offset, and extension value. The proposed model allows more accurate detection of conflicts and determination of conflict severity. Kumar and Cheng (2015) presented a framework that makes use of BIM in creating dynamic layout models for construction sites. This is done through estimating the dimensions, size, and number of interim facilities needed at various stages of construction. Their results show through a demonstrative example that the developed model could achieve 13.5% reduction in travel distance as compared to traditional methods. Bannier et al. (2016) presented a framework for integrating information pertaining to work envelope needs among the steel and piping trades in order to support space planners during preconstruction phase. Superintendents on industrial projects were interviewed to define conventional work envelopes. Their results showed that the anthropomorphic characteristics of a population considerably affects work envelope requirements. Mirzaei et al. (2018) presented a 4D BIM model that dynamically detects and quantifies spatial temporal conflicts and their effect on project performance. The crew movement is taken into consideration by simulating four different execution patterns with four distinct starting points. Workspace planning is also looked at from a safety perspective. For instance, Choe and Leite (2017) developed a 4D planning process for construction safety that considers site-specific spatial and temporal information. Their findings revealed that risky zones, activities, and days could be prioritized when information relating to number of workers, occupation type, and zoning plan is included in project schedule.

All that being said, workspace planning studies mainly address building construction and are scarce for industrial construction.

CHALLENGES WITH WORKSPACE MODELLING

Dynamic workspace modelling is faced by two major challenges during construction planning, which are modelling the workspace's geometry and capturing its accurate dynamics. The term "workspace dynamics" simply refers to the dynamics occurring from change in geometry to position of workspaces across time. Since an activity can occur at different locations throughout different stages, one workspace falls short of representing such progressive series of workspaces. Moreover, each task impacts the workspace differently. For instance, a slab construction task increases the floor area as construction progresses, whereas a drywall construction task divides or partitions the existing space into reduced units (Riely & Sanvido, 1995). Commonly, actual workspace variations go unnoticed in planning and even in control (Wu & Guo, 2014). Figure 1 illustrates an example based on Riely and Sanvido (1995) of how a construction site constantly changes with time. Beginning at time t, no construction work takes place. After a while at time $t1 > t$, a slab construction task is in place. Further ahead at time $t2 > t1$, masonry works take place which encloses the space and reduces access. Finally, at time $t3 > t2$, drywall installation task occurs, altering the site layout. Failing to consider the dynamic progression of workspaces reflects negatively on planning as it may yield imprecise information to planners (Su & Cai, 2014). Another challenge is that generally, people who are given the task of space planning, such as field engineers or superintendents, might lack the skill and knowledge of assessing the precise geometric parameters of workspace needed by each task. Especially in industrial projects, academia efforts pertaining to identifying and representing the piping activities' workspaces are scarce (Bannier et al., 2016). In other words, research focusing on extracting and translating the semantic information relating to workspaces from superintendents is still behind.

Poor space planning will eventually lead to overlaps in workspaces among various trades and to workspace clashes, resulting in potential safety hazards and congestion that impacts productivity and creates waste (Hammad & Zhang, 2011; Mallasi, 2006). Research showed that congested workspaces suffer losses in productivity amounting to 65% and delay in project duration reaching 30% (Hosny et al., 2020). Moreover, people not abiding by the workspace allocated for them creates issues. For instance, at times, project participants such as individual subcontractors set up their temporary storage areas, causing obstructions to other subcontractors. Another example of bad practices is leaving shelves and other products in space and having to relocate them several times which adds to transport and waiting times (Binninger et al., 2018).

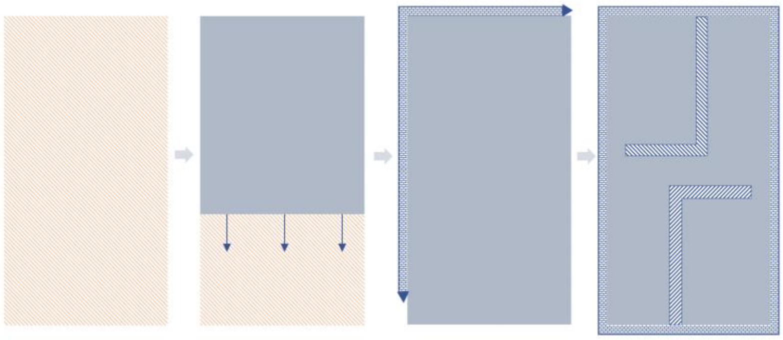

Figure 1: Evolution of workspace with time

FINDINGS: COMPONENTS OF WORKSPACE PLANNING

This section presents the main components required, but not exclusively, to formulate a workspace planning system as found in the literature. The first sub-section lists the different flow types in construction, followed by discussions on area patterns, workspace classification structure, conflict identification, and finally conflict resolution studies.

FLOW TYPES

When modelling workspaces on construction sites, it is integral to first identify all the entities that may occupy or "flow" within the workspace at any point in time. The verb "to flow" herein means "to move freely and continuously" as per the definition quoted by Kalsaas & Bolviken, (2010) and later adopted by Tommelein et al. (2022). Tommelein et al. (2022) distinguishes different types of flows in construction as depicted in Figure . Most studies focus on workflow, worker flow, and trade flow (Hosny et al., 2020; Kassem et al., 2015; Mallasi, 2006; Moon et al., 2014; Rohani et al., 2018; Su & Cai, 2014). A less number of studies considers additionally material, equipment, and tool flows (Choi et al., 2014; Dawood et al., 2005; Guo, 2002). As for the remaining flow types, they are mostly disregarded. Generally, each flow type gives rise to a specific pattern for workspaces, prefabrication areas, storage areas, and product space areas which are explained in the following sub-section. Also, each flow type might need specific workspaces. A workspace classification structure in presented in the sub-section following the area patterns.

AREA PATTERNS

Space behaviour patterns refer to the way a crew typically moves in a space across time to execute work elements. Such behaviour must be modelled to identify the links between tasks with distinct patterns and to forecast the workspace needed for task work elements. Riely and Sanvido (1995) distinguished between four area patterns which are work area, prefabrication area, storage area, and product space patterns.

A work area pattern refers to the directions and locations where different work units are achieved for various tasks and materials. An example is following a linear pattern to perform ductwork and install conduit. A prefabrication area pattern describes positions of prefabrication areas on site that are needed for different tasks or types of material. An example of such an area pattern is having one prefabrication area per floor for conduit assemblies. A storage area pattern refers to locations where material is kept from the time it is delivered until the time it is used. An example is having bulk storage where material is stored in a single location per floor, then distributed to work areas as required. Finally, product space pattern describes the impact that completed work will have on the existing space for upcoming tasks. An example pattern is creating space for following activities such as slab construction. A direct impact is when work resulting from a task directly conflicts with space required by other tasks, generating thereby sequential dependencies between the tasks. If a task is completed without putting into place material that directly impacts the available space for upcoming activities, then the result is no impact (Riely & Sanvido, 1995).

Figure 2: Flow types in construction based on Tommelein et al. (2022)

WORKSPACE CLASSIFICATION STRUCTURE AND GENERATION PROCESS

Understanding the structure and function of a workspace is crucial for proper workspace modelling. Table 1 is compiled based on a study by Choi et al. (2014); it provides a workspace classification structure that can be used in formulating a workspace modelling system. A workspace can be classified as direct or indirect based on its function. For instance, a workspace is said to be direct when it is associated in a direct way with activity execution such as workspace for installing a window. Object space (product), working space (working, tool and equipment), and storage space (staging) are classified as direct workspaces. An indirect workspace is either indirectly related to the execution of an activity or is needed for execution of several activities such as a corridor for personnel path. Unavailable space (hazard, protected), set-up space (unloading, layout, prefabrication), and path space (debris, personnel, material) are all indirect spaces. Furthermore, a workspace is categorized based on its moveability which can be fixed like window installation workspace or flexible like storage areas. Various considerations play a role in determining the size and location of a workspace; such considerations include the components' geometric features, construction method, management plan, facility layout, etc. Finally, workspace generation and expiration follow certain rules as Table 1 shows. Generally, generating a workspace requires three steps. The first step is to determine a task necessary for constructing an element or product. The second step consists of identifying individual workspaces required in each stage of the task's life cycle. The third step calls for associating the identified workspaces with the product or element (Su & Cai, 2014). By assigning precedence relationships between the generated workspaces, a standardized sequence of workspaces can be attributed to each construction task.

Table 1: Workspace classification structure based on Choi et al. (2014)

Type	Function	Movability	Size & Location	Generation	Expiration
Direct space	*Object Space:* Product	Fixed	Determined by components' geometric features	At activity's starting point of activity	Until completion of project
Direct space	*Working space:* Working Tool, equipment	Fixed	Determined by construction method definition of spatial relationship with object	At activity's starting point	At activity's ending point
Direct space	*Storage space:* Staging	Fixed or flexible	Size determined by material's quantity and geometric features, Location determined by material management plan	At activity's starting point	At activity's ending point
Indirect space	*Unavailable space:* Hazard Protected	Fixed	Determined by protection condition of object and construction method's definition of hazardous condition	Preserved through activity duration or protection duration controlled by feature of object protected	
Indirect space	*Set-up space:* Unloading Layout Prefabrication	Fixed or flexible	Determined by temporary layout of facility	At activity's starting point	At activity's ending point
Indirect space	*Path space:* Debris path Personnel path Material path	Fixed or flexible	Min height and width of path determined by activity's construction method and material's geometric features	During duration of activity	

SPATIAL-TEMPORAL CONFLICT IDENTIFICATION AND EVALUATION

When a workspace overlaps with another or more during construction, a dynamic short-term clash called a spatial-temporal clash occurs. Site planning, project features, management concerns, logistic and resources, and external environment are all categories of potential reasons causing workspace conflicts (Hosny et al., 2018). A variety of tools are proposed in the literature to detect and evaluate spatial-temporal conflicts as summarized in Table 2. The early research used sketches to visualize conflicts. With the advancement in CAD systems and virtual reality modelling, conflict visualization became easier, and more aspects were added to the analysis such as cost. A conflict is mainly evaluated with respect to its severity which is calculated by assessing overlapping areas ratios, overlapping durations ratios, required and available spaces ratios, etc.

Table 2: Conflict visualization and evaluation

Study	Tools for visualization	Conflict Evaluation
(Zouein & Tommelein, 2001)	Sketch	-
(Guo, 2002)	2D CAD	$ISP^4 = \frac{interference\ space\ size}{original\ size} \times 100$ $IDP^5 = \frac{interference\ duration}{original\ duration} \times 100$
The VIRCON project (Dawood et al., 2005) (Winch & North, 2006)	2D CAD 4D-CAD (3D CAD models + time) 4D Virtual Reality Modelling Language (VRML) format	$Spatial\ loading = \frac{required\ space}{available\ space} \times 100$
(Mallasi, 2009)	4D-CAD and VRML	Geometrical adjacency algorithm
(Chavada et al., 2012)	5D (BIM + time + cost)	$CS^6 = \frac{conflicted\ duration}{current\ activity\ duration} \times 100$
(Moon et al., 2014)	4D-CAD (BIM)	$WCR^7 = \frac{adjacency\ distance}{expanded\ interval\ distance}$
(Kassem et al., 2015)	4D	$CS = \frac{conflicted\ duration}{current\ activity\ duration} \times 100$
(Rohani et al., 2018)	5D-CAD	-

SPATIAL-TEMPORAL CONFLICT RESOLUTION STRATEGIES

Whether planners develop schedules first and then resolve any identified spatial conflicts (i.e., follow a reactive approach) or attempt to directly generate conflict-free schedules (i.e., follow a more proactive approach), a set of commonly used conflict resolution strategies have been identified based on a review of relevant literature. Table 3 summarizes these strategies and highlights the ones considered or discussed in each of the reviewed studies. As suggested by Rohani et al. (2018), these strategies could be generally classified into two categories; The first category includes strategies that help resolve spatial conflicts without impacting the total project's duration and cost and, hence, can be considered less intrusive. Examples of such strategies include modifying the direction of work execution (e.g., north to south instead of south to north) or modifying activity start time within its float time. It is important to note, however, that even though certain strategies that are typically classified under this category may not have a direct impact on the project's duration or cost, they may have an indirect effect. For instance, modifying space size has been thought not to affect the schedule's critical path (Chavada et al., 2012) or the direct/indirect costs of the project (Rohani et al., 2018). However, reducing the size of a workspace may adversely affect the productivity of the corresponding activity (Guo, 2002), which, in turn, may lead to increased project's duration (if the activity is

[4] Interference Space Percentage
[5] Interference Duration Percentage
[6] Conflict Severity
[7] Workspace Conflict Ratio

critical) and cost. Hence, when selecting strategies to resolve spatial conflicts, careful consideration of their potential consequences must be taken even if the strategies are deemed non-intrusive. The second category includes strategies that are more intrusive and likely impact the project's duration and cost. Modifying the number of resources assigned to a critical activity in order to reduce the number of space users is one example of such strategies. Plainly, researchers recommend resorting to the second category only when certain spatial conflicts cannot be resolved using the first category strategies.

Table 3: Conflict resolution strategies

	Strategies \ Studies	(Zouein & Tommelein, 2001)	(Guo, 2002)	The VIRCON project (Dawood et al., 2005)	(Winch & North, 2006)	(Mallasi, 2009)	(Chavada et al., 2012)	(Moon et al., 2014)	(Kassem et al., 2015)	(Rohani et al., 2018)

CONCLUSION AND ADDITIONAL CONSIDERATIONS FOR WORKSPACE PLANNING

The common practice in construction is to create schedules then resolve spatial-temporal conflicts. Workspace planning has not achieved diffusion in practice, especially in industrial projects that face lack of academia efforts in this regard. This paper presented a narrative literature review on workspace planning and summarized major findings from leading research studies. The study offers an overview of the existing workspace planning methods, challenges faced with workspace modelling, and general components that form the base for workspace planning such as flow types, area patterns, classification structure, and conflict identification and resolution. Moreover, this study offers below general considerations to examine when developing a space planning system. One thing to note is that a construction project goes through various phases from feasibility studies to construction, and operation and maintenance. Each phase is characterized with a distinct level of development (LOD) for the 3D models and project schedules. Such LODs strongly impact the 4D simulation's purpose and quality. Guidelines for defining and selecting LODs appropriate for project needs and progress are discussed further in a study by Guévremont and Hammad (2020). The considerations are:

- What is the level of abstraction sought? What is the unit of analysis: project level, industry level, company level, team level, area level, etc.?
- What LOD the system will tackle?
- What level of complexity can the system handle?
- What types of flow will the system consider?
- Who will use the system (i.e. foremen, superintendents, planning engineers...)?
- What will the system look like to help engineers better manage the space?
- How to align the system with the Last Planner System (LPS)?
- What kind of simulation is most suitable for the type of projects at hand?
- How to perform solution evaluation of the developed system?
- How to integrate BIM with the model?
- What input should be included in the system?
- How to define the parameters required for the system?
- What templates are suitable for accommodating the modelling process?

Finally, some limitations are associated with this study. First, the paper is based on a narrative literature review, which means that the results are limited to the studies and sources that were included in the review. Therefore, the findings may not represent the complete picture of the field of workspace planning. Second, the paper provides general considerations for developing space planning systems, but it does not provide a detailed framework or methodology for implementing such systems. Third, the paper mentions the Last Planner System (LPS), which is a production planning and control system used in construction projects. However, it does not provide sufficient information on how to align space planning systems with LPS. In conclusion, if we can accurately assess the space requirements, patterns, and impacts of each task on the construction site, we can simulate different plans and generate optimized, conflict-free schedules. This research advocates taking a step back to look at planning from a different perspective, and then adopting the general considerations presented as a guide to develop space planning systems that meet the specific needs of each project.

A SYSTEM DYNAMIC MODELLING APPROACH FOR INTEGRATED LEAN-BIM PLANNING AND CONTROL METHODS

Mahmoud Karaz[1] and José Manuel Cardoso Teixeira[2]

ABSTRACT

Traditional planning and control methods do not accurately reflect the construction reality and lack feedback loops. The Last Planner System (LPS) and Location-based Management System (LBMS) have been suggested as socio-technical systems to generate practical and actionable real-life data based on production theories and logic. This data can be effectively communicated, analysed, and managed using the capabilities offered by Building Information Modelling (BIM) workflows. However, a true integration between Lean Construction-BIM is not yet matured, where parallel use of both concepts is still more common. This paper presents a conceptual framework based on a system dynamic modelling approach to elaborate a causal loop diagram (CLD). The CLD explores the interactions between basic management functions and waste, on this basis this paper proposes how the integration between LPS, LBMS, and BIM can be harnessed to apply waste elimination strategies. The results of this study can be applied as lean policy analysis for new lean adaptors to understand the impact of Lean-BIM for planning and controlling various wastes across the construction supply chain.

KEYWORDS

Last Planner System, Location-Based-Management, System Dynamics, Casual Loop Diagram, Building Information Modelling, Construction Waste

INTRODUCTION

The construction industry is highly fragmented, has low productivity, and is a slow adopter of new techs. Most construction projects are waste-prone, resulting in delays, defective products, accidents, material waste and cost overruns. The production is traditionally managed, which relies on ad hoc decisions directing site activities with low-resolution and unreliable plans without channels for feedback from downstream players, therefore encapsulating production tasks in black boxes (Sacks et al., 2018). That challenges the construction stakeholders to extract useful and reliable information on a weekly and daily basis about the production.

About 54% of root causes of project delays and poor productivity are attributed to unreliable planning and control Ballard & Howell (1998). In Koskela's (1992, 2000) theory of the Transformation-Flow-Value (TFV), it is explained that these inefficiencies are attributed to the Transformation (T) view because it hides the propagated waste across the construction supply chain and ignores the value chain between project actors and the final customer hence suggesting the Flow (F) and the Value (V) views to complement the T view. The Flow (F) view

is an essential concept in lean philosophy that decomposes the construction processes into Value-Added (VA) and Non-Value-Added (NVA) activities (i.e., work-in-progress, rework, defects, unfinished products, and waiting) (ibid). At the same time, the Value perspective stresses the importance of actively pulling requirements from the final and internal customers to avoid non-value activities.

A practical implementation of the F is planning and control systems, namely, Last Planner System (LPS) and Location-Based Management (LBMS). LPS is a socio-technical system that increases the planning resolution collaboratively to shield downstream from the upstream variability (Ballard, 2000). LBMS is a technical Flow-based method that calculates forecasts, production rates, quantities, and resource consumption for each task and trade according to their physical location (Kenley & Seppänen, 2010). Both systems complement each other in attempting to bring the production problems to the surface by targeting continuous, reliable, and one-piece flow (Seppänen et al., 2010). The combination of both systems could establish production planning that addresses bottlenecks through structuring, sequencing, managing handoffs, and visualising the construction flow, and proactive control that aims at identifying, analysing and removing constraints while alerting people about potential interference in the production system (Seppänen et al., 2015). That would increase production flexibility and credibility through detailed, measurable, reliable, and stable plans (Frandson et al., 2014).

Construction production is information intensive, and planning accuracy requires consistent information models which can be accessed across organisation boundaries. Building Information Modelling (BIM) is a visual, computational, and analytical process that enhances the communication of integrated production information (process and product) (Dave & Sacks, 2020). According to the LC-BIM matrix provided by Sacks et al. (2010), 56 positive interactions could support value and waste elimination concepts. The application of LPS becomes potent by incorporating automated BIM workflows where decisions and feedbacks rely on information streamlined from BIM models during performing constraint analysis, task definition, sizing, and sequencing (Gerber et al., 2010). The development of software as a service and tools based on LPS-BIM is growing as an independent research area; examples of provided prototypes are KanBIM (Sacks et al., 2010), VisiLean (Dave, 2013), LPS-based BIM (Heigermoser et al., 2019), and Beam! (Schimanski et al., 2021). The application of LBMS requires BIM workflows to perform and manage extensive calculations of quantities, durations, resource consumption and production rate (Kenley & Seppänen, 2010). A commercial example of this integration is presented in Vico software which automates LBMS logic using BIM functionalities and extends 4D logic from CPM to LBMS (Trimble, nd).

Conversely, the current BIM solutions did not fully integrate LPS and LBMS functions. Instead, they are performed in parallel, which misses the full potential of both planning and control systems. Also, no research discussed construction waste explicitly using the three concepts. Therefore, this paper provides Casual Loop Diagram (CLD) to illustrate the waste propagation across a construction production system based on the work of Formoso et al. (2015, 2020) and then proposes a conceptual framework that applies LPS, LBMS and BIM to tackle the construction wastes. The first two steps of the SDM method are to define the research problem and conceptualise this problem using CLDs, which will be the focus of this paper.

The subsequent sections are structured as follows: a brief literature review on construction wastes, an explanation of LPS and LBMS, and a discussion of the existing BIM functionalities for planning and control purposes. The next section presents CLD for waste networks combined with functional areas of lean-BIM for planning and control. The final sections discuss the research contributions and conclude this paper's major elements.

LITERATURE REVIEW

CONSTRUCTION WASTE

Construction waste is a high-level concept that hinders productivity and incurs capital loss which is challenging to measure systematically (Formoso et al., 2020; Viana et al., 2012)—causing massive negative impacts on environmental, economic, and social dimensions. According to Horman and Kenley's (2005) meta-analysis, 49.6% of construction operations are NVA (Non-Value Adding) activities. The literature has approached construction waste using various definitions, including rework (Love and Li 2000), product defects (Josephson and Hammarlund 1999), re-entrant flow (Sacks et al. 2017), transportation (Belayutham, González and Yiu, 2016), and institutional waste (Sarhan et al. 2017). This disparity in waste measures shows that it is challenging to formulate a holistic framework and attempt to complete an analysis of the root causes of construction waste (Formoso, Bølviken, and Viana 2020).

The construction waste propagates in complex networks. Those cycles can be modelled using causal loops that relate wastes in unidirectional and bidirectional ways. The propagation of waste cycles inherits the same properties of construction processes (i.e., pooled, sequential, or reciprocal) (Koskela et al., 2013). Also, waste can be understood as discrete (task-level), synergistic (project-level) and systematic (organisational and contractual level) (Fernández-Solís & Rybkowski, 2012). Formoso et al. (2020) categorised the construction waste into previous stages (design, planning and control, material supply, and training); production wastes (quality deviation, making-do, transportation, waiting, work-in-progress; inventories), and terminal waste or traditional waste metrics (rework, defects, material waste, safety issues, gas emissions). The literature shows various similarities in taxonomies of production waste, but it is difficult to grasp their applicability without a series of case studies to provide a holistic view.

THE LAST PLANNER SYSTEM© (LPS)

The LPS is the most applied from LC methods; sometimes, the LPS term is used interchangeably with LC. The key goal of LPS is to shield downstream from the upstream variability to increase planning reliability and workflow stability (Ballard, 2000). The second feature is providing commitment planning which focuses on facilitating conversation between planners to identify activities, their sizes, sequence, and related constraints. The third feature is to increase planning details based on Kanban planning; LPS breaks down the construction planning into four to five stages, namely master planning, phase planning, look-ahead planning, weekly planning, and learning, as illustrated in Figure 1. LPS uses social-technical measures that steer people to communicate project activities in detail with their constraints and requirements. Through a higher level of planning detail, planners can filter and pull ready (non-constraint) activities from the collaboratively developed backlog. The control function of LPS is enabled through PPC (Plan Percent Complete) and RNC (Reasons for non-compliance) metrics. They can be used to track the construction's progress and constraints to production—examples of analysis methods that can be used are 5whys and A3.

	SHOULD	CAN	WILL		DID
Planning Stage	Master	Phase (Pull)	Lookahead	Short-term	Learning
Planning Window	Milestones	Phases	4-6 weeks	Weekly/Bi-Weekly/Daily assignments	
Planning detail	Rocks (Milestones)	Rocks (Phases)	Boulders (Processes)	Pebbles (Operations)	Pebbles (Assignments)
Main activities	• Define key milestones • Identify critical path (CPM) • Assign start-finish relations	• Apply reverse planning • Identify handoffs, durations, and overlaps • Define delivery conditions	• Constraint analysis • Breakdown Processes • Design for operations	• Make reliable promises	• Measure PPC* • Investigate RNC** • Standardize
Addressed wastes	• Budget overrun • Schedule overhead • ENV measures • Value measures • Defects	• Budget overrun • Schedule overhead • ENV measures • Value measures • Defects	• Making-do • Work-in-Progress • Inventory • Crews absent, injuries • Transportation • Information delay • Rework	• Idle (waiting) • Unfinished works • Rework • Moving	• PPC Failures
Actors	• Owner • Portfolio Managers • Project Managers	• Project Managers • Site/production Manager	• Project Managers • Site/production Manager	• Project Managers • Site/production Manager • Crew managers	• Project Managers • Site/production Manager • Crew managers

*PPC = Plan Percent Complete; RNC = Reason for Non-Compliance

Figure 1: The structure of LPS stages, related activities, addressed wastes and actors.

LOCATION-BASED MANAGEMENT (LBMS)

LBMS is a system of preplanning, planning, scheduling, and controlling production according to units of physical locations. That is based on locations by calculating the quantity of work to be accomplished and the production rate (Kenley & Seppänen, 2010). LBMS breaks down the project into Location Based Structure (LBS), using the same Work Breakdown Structure (WBS) logic but applied to physical locations (Kenley & Seppänen, 2010). LBS divides the project into interdependent structures that can be built separately and narrowed to manageable locations where one trade can operate continuously without waiting. According to LBMS logic, reducing the interdependencies provided by CPM, removing float between tasks, and synchronising production rates is possible. The control indicators applied in LBMS can forecast production capabilities and provide information about the root causes of cascading delay (i.e., work-in-progress, waiting, rework, and congestion) (Kenley & Seppänen, 2010). LBMS reduces production complexity by streamlining continuous flow across location, which steers planning targets towards stable and interrupted production, gives clear directions for trade crews, and reduce trade risk and waiting time (Biotto & Kagioglou, 2020).

REFLECTION ON LPS AND LBMS

Although the wide acceptance of LPS, many gaps have been reported regarding PPC metrics, automation level, and cost management. Firstly, PPC does not measure or reflect any flow parameters, such as variation in production rates, trade discontinuities, out-of-sequence work, product CTs, WIP levels, bottleneck production rates, and levels of non-value-adding work (Maraqa et al., 2021). That can be partially addressed using LBMS, which provides metrics of flow quality, and actual flow line charts, which show the locations, and the movement of trade crews across spatial-temporal dimensions (Maraqa et al., 2021). However, focusing on productivity metrics offered by LPS and LBMS can lead to counterproductive behaviour by steering the production towards results instead of managing by means. Secondly, a major gap shows that LPS and LBMS are still lagging in supporting real-time flow monitoring, which is a challenging lack of automation, as Ratajczak et al. (2017) indicated. Thus, adopting more tracking and tracing technologies, such as IoT sensors, is envisioned for autonomous data entry for BIM-based production planning and control systems (Dave et al., 2016). Regarding the cost management function, there is little evidence of cost control supported by LPS (Schimanski et al., 2021), which can be complemented by the measures supplied by LBMS in calculating quantities, resource consumption and production rates.

BUILDING INFORMATION MODELLING

BIM becomes a de facto technology in AECO industries which brings various actors to use a shared digital representation of a built asset to facilitate design, construction, and operation processes to form a reliable basis for decisions (ISO, 2018). BIM functionalities can overcome major information problems such as design inconsistency, errors, and duplications caused by conventional design workflows (Sacks et al., 2018). Successful implementation of BIM stands on three pillars, process, people, and technology (Hardin & McCool, 2015). Lean construction can complement the former two pillars, while the latter relies solely on extensions to the existing BIM functionalities. These functionalities include parametric modelling, interoperability, clash detection, 4D simulation, functional analysis, and documentation (Sacks et al., 2018). Thanks to interoperability functionality, it is possible to seamlessly exchange design information between different BIM systems and design speciality (e.g., by Industry Foundation Classes (IFC)) (Sacks et al., 2018). 4D planning encourages discussion of several plan alternatives, increases process transparency, and improves planning reliability (Bortolini et al., 2019).

However, 4D planning is not fully exploited in production planning (Schimanski et al., 2021) because short-term planning is not considered in commercial 4D planning (Ardila & Francis, 2020), which is mainly programmed for documenting and analysing production plans according to activity-based logic. Thus, most BIM solutions are not fully developed for lean data processing; instead, they are used in parallel with LPS and LBMS (Schimanski et al., 2021). Therefore, lean planning and control systems and BIM integration exist, but their full potential is not realised yet.

RESEARCH METHODOLOGY

This study aims to enable lean stakeholders to identify the effect of LPS, LBMS and BIM on waste elimination by micro-mapping objects and spaces using the Casual Loop Diagram (CLD) according to the theory of System Dynamic Modelling (SDM). The SDM measures the effect of change in a system over time with a high level of abstraction and minimum level of detailing. SDM was coined in the 1950s by Jay Forrester to depict the change in socio-economic systems' behaviour over time as a broad evolving methodology to conceptualise, describe, analyse, and manage feedback systems (Sterman, 2002).

Figure 2 illustrates the research methodology used in this paper, representing four steps of developing SDM. The scope of this paper is to conceptualise the problem (step 1) by formulating a Casual Loop Diagram (CLD) for production wastes and construction management functions (including material delivery, production planning and control, site layout planning, and product design using BIM). CLD can explain the dynamic hypothesis by visualising a complex system's cause-and-effect relationships between variables. Constructing a CLD involves six activities 1) research question definition, 2) variables identification, 3) links between variables, 4) polarity identification, 5) assigning feedback loops, and 6) determining delays (not included in this paper). The main use of CLDs is communicating with stakeholders and constituting a framework that captures expert knowledge, and a main drawback of SDM is that a high level of abstraction works with averages that cannot be used at operational and tactical levels. Also, it has limited animation capabilities compared with Agent-Based Modelling (ABM) and Discrete Event Simulation (DES).

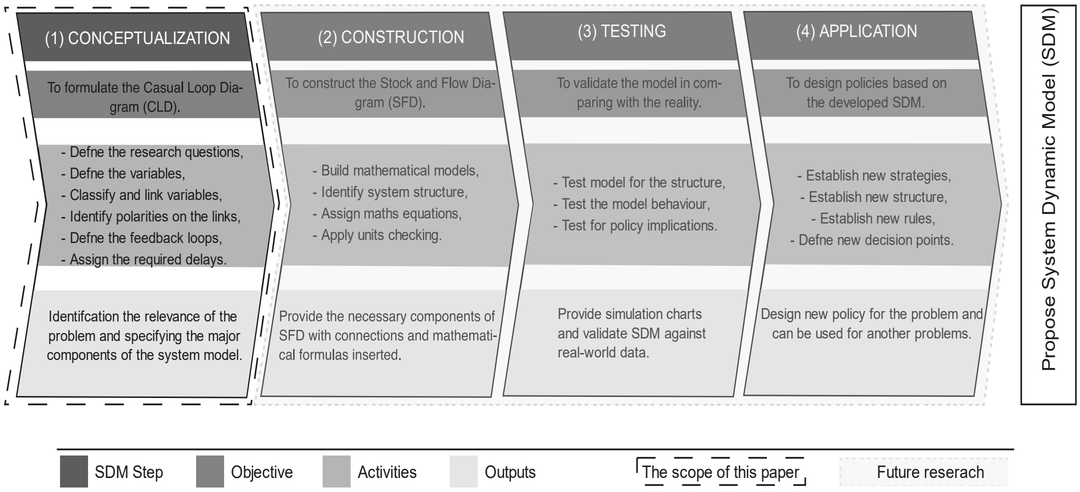

Figure 2: The research methodology

CAUSAL LOOP DIAGRAM (CLD) FOR WASTE ELIMINATION

CLD is a conceptual tool that shows dynamic and complex problems related to their solutions and reveals a chain of cause and effect. Such a diagram consists of a set of nodes representing variables connected, the relationship between these variables, represented by arrows, can be labelled at the arrowhead as either positive or negative. The CLD presented in 3 is based on (Formoso et al., 2015, 2020), who proposed a network analysis that could depict the patterns of the construction wastes by drawing links among taxonomies of wastes and between the construction waste and the production system stages. This CLD also adopts the components of Integrated Lean Project Delivery (ILPD) presented by (Ballard & Howell, 2003), lean design, lean supply, lean production planning and control. In addition, BIM processes and Quality management were added to the CLD to investigate the relationships between all mentioned concepts and production waste concepts. By analysing the diagram of Figures 3, the following loops can be clearly recognized:

Loop R1 highlights the effect of material delivery and site layout planning on the inventory, where inventory is a temporary facility that should be planned in the site layout. The more frequently delivered materials, the bigger inventory on site is needed when the resource consumption may not meet the delivery rate. Additionally, the more parts are delivered, the more complex inventory management is required to reduce inventory accumulation. Loop B2 concerns material waste as an outcome of damaged materials due to storage and movement, excess inventory, and rework. Other causes of material waste indirectly arising from Production Planning and Control (PP&C), for instance, improper allocation of materials, poor site layout plans, damage during transportation (as shown in Loop R4), poor handling, and improper material staging and among others (For more about material waste, check (Formoso et al., 2002). In loops B1 and R3, the labour movement across physical locations is affected by the material delivery, the routes and site layout design and planned activities by Production Planning and Control (PP&C). Information about labour routes across the physical locations can be scheduled and controlled through LBMS with the support of BIM for obtaining quantities and geometrical analysis for the site layout.

In loop R2, the PP&C actions about work are streamlined from collaborative efforts to prepare work to be structured, sized, sequenced, scheduled, communicated, and controlled, which appears to play a central role in the CLD PP&C is essential for releasing pull signals for the whole production system about crews' resources, production progress, resource consumption, production rates, constraints, etc. LPS and LBMS can provide this kind of information, which can be considered a real-life data generator about the production system, which helps stakeholders streamline informed decisions about production instead of traditional ad-hoc methods. A proper PP&C system should consider the role of variability in the production system (e.g., the parade of trades), where work chunks should be sequenced, and handoffs between trades should be negotiated and harmonised to prevent starvation or overproduction of planned tasks. As well as, PP&C has to provide proactive measures to eliminate the root causes of cascading delays (i.e., interference between the trades in tasks or locations can cause flow interruptions).

The impact of information availability is a prerequisite for PP&C functions, as well as this variable limit the likelihood of making-do emergence and request for information (RFI) (as shown in Loops R14 and R6). A well-defined BIM execution plan should match the Level of Development (LOD) with PP&C details. Information availability variables can be streamlined through tracking and tracing technologies such as indoor positioning, cloud points, and Internet of Things (IoT) techs. These provide real-time control for the construction site conditions that can be connected to the BIM process for further visualisation and analysis steps.

Several policies could be applied to regulate the effect of material delivery on project performance. On the site, by inserting measures of PP&C associated with planned site layout planning (SLP) (Cheng et al., 2015). These functions send ‘pull’ signals for materials to be timely ordered and delivered under the just-in-time (JIT) concept. In the PP&C, the materials should be quantified and allocated before execution. Thus, in any process that commences without the perquisite materials, a making-do waste arises, which is responsible for other wastes such as Work-In-Progress (WIP) and unfinished works and hinders labours' productivity. Another waste not communicated in Figure is substitution waste, a phenomenon that urges to substitute unavailable materials with other materials to meet schedule deadlines; this waste is similar to making do but hinders productivity due to reworks and defects.

The material delivery also impacts the reliability of production planning and control (e.g., when the required materials are not available when the planned work is released, a making-do effect could be raised, which can be snowballed to the emergence of rework and defects). The role of SLP (site layout planning) is necessary to coordinate physical locations between the demand of the production system and temporary facilities, delivered materials, crew movements, machine setups and truck traffic.

BIM processes positively reduce design changes, variability, rework and RFIs (Sacks et al., 2018), as shown in Loops R11, R12, and B4. BIM functionalities such as quantity-take-off, 4D planning, visualisations, clash detection, and interoperability are available in commercial software, bringing valuable information control to the PP&C systems. A true interaction between BIM functionalities and lean-based PP&C is not mature, the literature actively proposed different prototypes, but a real impact on waste elimination is not presented yet. However, the potentials of BIM functionalities' impact on waste reduction are evident even on final wastes such as rework, material waste, and capital waste.

B3, R9, and R10 concern the quality management to control variability using quality control charts and continuous improvement methodology based on the PDCA cycle (Deming, 1982). Construction variability is the main source of product defects and process discontinuity, leading to reworks, poor productivity, and eventually to, capital waste and cascading delays. Loop R7 illustrate the causality of Making Do with WIP and unfinished works. The impact can be explained by working on activities without its prerequisites (e.g., trades that focus on local optimisation are reluctant to pick the easiest available work packages at the beginning, “a low-hanging fruit phenomenon”, crews move to open spaces until a problem appears, leave unfinished work behind them, and prevents WIP to be progressed. Eventually, this phenomenon led to interruptions in workflow and interference with other trades' schedules, leaving labours to wait until the problem is resolved, where overtime strategy would be a solution to compensate for the delay, which can lead to labour fatigue and labour productivity to be negatively impacted

(Loop R8). Again, the impact of making-do waste is complex and cannot be modelled in a unidirectional causality link (Formoso et al., 2020), which contradicts CLD principles (As shown in loops R7 and R8, the link between making-do and unfinished-works is bidirectional). Thus further investigation is needed to explore intermediate variables between making-do and other wastes.

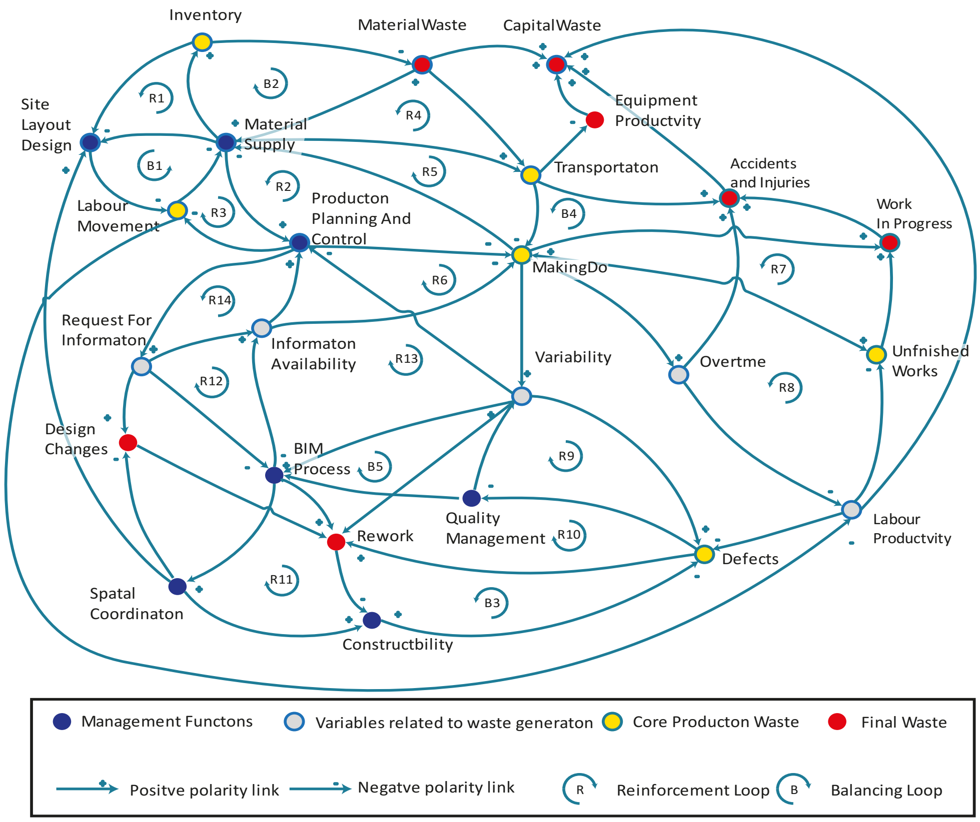

Figure 3: A CLD of wastes and production system functions adapted from (Formoso et al., 2020)

BIM-BASED INTEGRATED PLANNING AND CONTROL

BIM workflow is in the middle of the proposed framework in Figure 4 because BIM is considered as single truth source and because it supplies the necessary data for the variables governing LPS and LBMS (i.e., start and finish time, production data, geometry, and resource quantities). LPS can apply different scheduling methods, but this research applies LBMS forecasts for scheduling, planning, and controlling the production and alarms LPS stakeholders about upcoming and ongoing production problems, and supplies them with locations, crews' consumption (manhour/unit), production rates, and quantities (Kenley & Seppänen, 2010). While the site teams' feedback suppliy information about quantities, constraints and commitments during look-ahead planning and weekly planning (Seppänen et al., 2015). Thus, the deficiencies of LPS will be complemented using LBMS countermeasures (Tommelein & Emdanat, 2022).

During the master scheduling stage, milestones are determined, and the master schedule is defined using LBMS scheduling techniques. BIM is at schematic design, which approximates estimations, identifies main phases and primitive tasks, and provides geometrical analysis for defining a rough Location Based Structure (LBS). The outputs are milestones, phases, flow line schedule and Gant chart schedule. In this stage, high-level waste elimination can be targeted (i.e., capital waste, environmental waste, safety issues, rework and defect rates, and inventory). In phase scheduling, collaborative backwards (pull) planning from defined milestones in the master schedule is applied, where work chunks and handoffs can be determined without defining durations. LBMS functions are divided into scheduling and optimisation (Seppänen et al., 2010). The first targets the setting of LBS (i.e., units of equal size of work in locations that assures trades to work until they get work completed in a location before moving to another location). Collaboratively, LBMS also seeks optimisations in phase scheduling (including adding more resources, splitting tasks, accepting discontinuous work, decreasing crew size, and adding more scope) (Seppänen et al., 2015). The spatial coordination stage of BIM can provide 4D schedules for better visualisation and clash detection to identify the product systems interference. The aimed waste in phase scheduling are design changes, reduction of Request for Information (RFI), schedule overrun, movement, transportation, and defects.

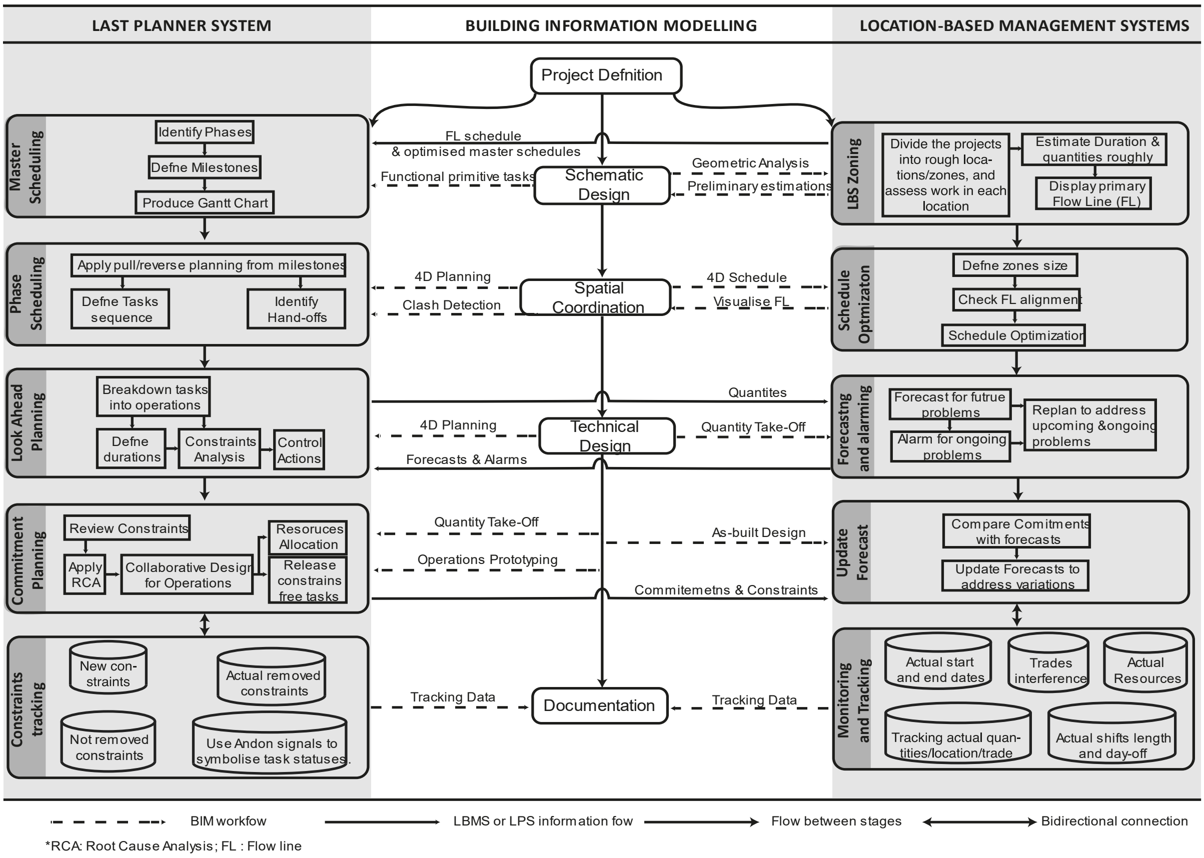

Figure 4: Assembled sub-systems of LPS, LBMS, and BIM.

The control functions commence with the look-ahead planning stage. A social process of LPS breaks operations into tasks, and a technical process of LBMS breaks operations into locations. In LPS, stakeholders apply constraint analysis to identify, diagnose, assign, and remove potential constraints for each task in a phase when durations are determined for each task. LBMS collects the required data about crew consumption, quantities, and production rates from trades, BIM take-off, and LPS. This information is used to forecast future problems and alarm ongoing production problems. Root Cause Analysis (RCA) is applied to seek systematic control actions that remove constraints supplied by LPS and mitigate the schedule risk provided by LBMS.

In the commitment planning stage, the LPS teams review the constraints and commitments in short-term windows. A collaborative effort is applied to design for operations, and the simulation functionality in BIM would be useful for providing prototyping at the operational level (Seppänen et al., 2015). At this stage, LPS functions are more applied than LBMS, but the LPS commitments are to be compared with LBMS forecasts to adjust exceeded plans (Seppänen et al., 2010). Finally, Production tracking is necessary to pull information from the site to planning and control systems, as shown in Figure . This function can detect the status of commitments, constraints, tasks progress, bottlenecks information, interference, actual resources, start and finish dates, shifts, and other quantities. The literature suggested various technologies to track and monitor the production information (e.g., (Dave & Sacks, 2020; Zhang et al., 2015). Tracking and monitoring function is essential to close the feedback loop of the suggested system, increase the situational awareness of trades and planners about the production, and bring management attention towards critical issues that generate waste and hinder value delivery.

CONCLUSIONS

This paper applied the System Dynamics theory to investigate the impact of production planning, control, and BIM on waste elimination. Based on a literature review, a Causal Loop Diagram (CLD) was illustrated to highlight the dynamicity of waste propagation and the interactions and feedback loops among BIM and planning and control functions. Then a generic framework was proposed to assemble the flows between Location Based Management System (LBMS), Last Planner System (LPS), and BIM. Waste measures should be used as guidance and actionable language when applying LBMS and LPS-based BIM. LBMS and LPS provide systematic, preventive, and proactive waste elimination measures from the early stages of the project, while BIM provides enormous data collection, analysis, and exchange on the elaborated wastes. By harnessing BIM functionalities, lean practitioners could communicate potential production wastes at different planning and control stages.

System dynamics may be viewed as the initial methodology to analyse waste accumulation across a specific timeline. Thanks to the clarity a dynamic system model provides, stakeholders can identify and resolve planning and control issues and measure the impact of countermeasures on waste elimination efforts. The combination between the LPS and LBMS in association with BIM functionalities streamlines powerful improvement for the construction production systems. Regardless of the ease of understanding, CLDs can be communicated with stakeholders with diverse backgrounds and experiences. The proposed CLD requires additional concepts, such as delays which enhance the system behaviour by adding waiting time measures when necessary.

Moreover, the elaborated CLD is limited because it is abstract and conceptual, which may not build a reliable judgement to be implemented on a real-world project. This paper is part of ongoing research that aims to model lean thinking using system dynamics. The future research will collect experts' views based on the case study research method on the elaborated casual loops diagrams and transform them into operable stock and flow diagrams, which allows the researchers to simulate the system by manipulating the model's major variables and compare runs among the different scenarios across a specific timeline.

A MECHANISM FOR SMART CONTRACTS TO MEDIATE PRODUCTION BOTTLENECKS UNDER CONSTRAINTS

Gongfan Chen[1], Chuanni He[2], Simon M. Hsiang[3], Min Liu[4], and Huaming Li[5]

ABSTRACT

Central project managers devote massive efforts to monitor, track, coordinate, and take actions to diagnose and prognose governed constraints and remove them to enable a reliable workflow. The blockchain-enabled smart contract can streamline the work process by predefining "intelligent" consensus to facilitate central managers' jobs. However, the inability of smart contracts to handle unexpected events under complicated environments posited challenges in realizing it automatically. This study aimed to develop adaptive mechanism to mediate production bottlenecks caused by constraints. First, the research identified the four main types of constraints and their levels of variability from a prefabricated project. Then, a simulation model was established to quantify the impacts of different constraints and determine the fair payment rules. Lastly, different constraint-bundled scenarios and execution policies were developed and encoded in the smart contracts for automated executions. Smart contracts can assist construction managers to motivate reliable production and minimize waste caused by bottlenecks in the system.

KEYWORDS

Constraint, simulation, smart contracts, Shapley value, modular construction

INTRODUCTION

This study aims to improve production flow by modeling potential scenarios integrated with smart contracts during planning to assist the team in making informed decisions that lead to a reliable flow. Enabling a reliable construction workflow requires timely identification and removal of constraints under dynamic construction scenarios (Javanmardi et al., 2020). Koskela (1999) identified that at least seven types of constraints must be removed during the planning stage: design and working method, components and materials, laborers, equipment and tools, space, prerequisite work, and external conditions. However, such a task requires central project managers to be proactive and increasingly detailed iterative planning actions to identify and

remove constraints to make ready before the tasks are released into production (Sacks et al., 2020).

The recent advance of blockchain-enabled smart contracts showed great promise to streamline the construction process by infusing “intelligent” consensus in smart contracts to facilitate central managers’ jobs (J. Li et al., 2019; Mason & Escott, 2018). However, various research pointed out the difficulties of establishing such a consensus. For example, Hunhevicz et al. (2021) argued that complicated construction environments posited various uncertainties in smart contract executions. Therefore, ensuring the flexibility to handle unexpected events when designing smart contracts was crucial for successful implementation. Hamledari & Fischer (2021a) mentioned that smart contracts heavily rely on individuals who design the underlying consensus to enable its “smart” in automation. Nevertheless, Lu et al. (2021) stated that construction resources (e.g., workers, equipment, materials) could be turned into smart construction objects with properties of awareness, communicativeness, and autonomy to enable communications between the construction process and blockchain networks. Such a theory indicated the supporting flows (e.g., workers, equipment, materials) could be used as a “Check” mechanism in smart contracts to decentralize and enhance production. However, there are research gaps in converting intangible process-level constraints into tangible smart contract manageable consensus explicitly to enable automation and enhance the intelligence of a decentralized governance mechanism.

This study aimed to develop an adaptive smart contract by encoding constraints and quantifying their interactive relationships as management consensus. First, this study identified the four main constraints for a construction project and defined various levels of variabilities for each constraint. Then, a simulation model integrated with the Shapley value algorithm was developed with permutation and combination to quantify the impacts of different constraints and determine the fair payment rules. Lastly, different constraint-bundled scenarios and related payment policies were encoded in the smart contracts for automated executions. Test scenarios were generated to validate and verify the smart contract implementations. The developed smart contracts provide a solution to automatically handle dynamic constraint events with minimum central managers’ efforts. The developed smart contract prototype can be extended to model Koskela (1999)’s seven types of constraints with suitable adjustments to project needs.

LITERATURE REVIEW

CONSTRAINT MANAGEMENT

In construction management, Koskela (2000) developed a systematic transformation-flow-value (TFV) production theory to streamline the construction production process. Here, the transformation focuses on converting inputs to products; the flow theory emphasizes construction task, material, and information hand-offs; and the value theory stresses customer satisfaction. Specifically, the flow perspective treats production as flows of processes to improve their reliability and eliminate waste. Koskela (1999) suggested that at least seven types of constraints should be removed during construction planning: construction materials, tools and equipment, laborers, prerequisite work, design and working methods, space, and weather. While the constraints widely exist in practice, it takes construction professionals significant time and effort to identify and eliminate them to achieve the desired production pace and reliable workflow (Javanmardi et al., 2020).

In the past decades, it has been shown that constraint removal has a significant relationship with workflow reliability (Jang & Kim, 2008). Hamzeh et al. (2016, 2015) identified constraint removal during make-ready impacts construction lookahead plans and eventually affects project duration. Liu et al. (2011) further revealed a positive relationship between workflow reliability and constraint removal through a case study. In recent years, research was also developed to visualize various constraints and integrate constraint removal efforts (He et al., 2023; He, Liu, Zhang, et al., 2022). Although research on constraint removal is abundant, there has been a lack of research on quantifying the interrelated relationships between different constraints in terms of project schedule and cost. This research will fill this gap.

SMART CONTRACT IN CONSTRUCTION

The term "smart contract" was coined by Szabo (1994). He defined the smart contract as "a computerized transaction protocol that executes the terms of a contract." The smart contract runs on a blockchain and can execute predefined consensus automatically once certain events are detected. All the transaction data will be recorded in a distributed ledger, namely blockchain, to track conditioned events and executions. Smart contracts showed a 200% improvement in information-sharing accuracy compared with traditional digital payment tools (Hamledari & Fischer, 2021a). Smart contracts demonstrated great potential in streamlining the construction business, such as assigning progress payments (Hamledari & Fischer, 2021b), coordinating supply chain orders (Lu et al., 2021), and triggering rework where defects occurred (Wu et al., 2021). The introduction of smart contracts in the construction industry can remedy the deficiencies of centralized control (Yang et al., 2020) and enhance process automation (Mason & Escott, 2018).

Construction projects are characterized by dynamic and uncertain processes that involve tangible and intangible constraints interrelated with each other. Although smart contracts have been widely adopted in the construction industry, they are not inherently "intelligent" enough to handle different uncertainties ex-ante, and their design heavily relies on individuals who construct the underlying consensus. Poorly designed smart contracts may lead to irreversible financial loss (Hamledari & Fischer, 2021a). Hence, ensuring the flexibility of smart contracts in handling unexpected events is critical for their successful implementation in the real world (Hunhevicz et al., 2021). Various research efforts have been made to facilitate the practical adoption of smart contracts by modeling constraints in their design. For instance, Wu et al. (2021) proposed a formal ontology to represent constraints in construction quality regulations, aiming to improve blockchain's interoperability and support the auto-generation of smart contracts by strengthening the reasoning ability of ontology. Another study by X. Li et al. (2022) highlighted the challenges in developing adaptive smart contracts that can provide solutions for constraints, risks, uncertainties, and disturbances. They acknowledged that including them in each transaction leads to redundancy and low latency for the blockchain network. Furthermore, Chen, Liu, Zhang, et al. (2023) conducted a simulation study to elaborate on various levels of prerequisite work readiness as the primary constraint for smart contracts to enforce a reliable critical path workflow. Simulating different "what-if" scenarios and conducting cost-benefit tradeoffs in real-time demonstrated significant implications for robust smart contract consensus design. Dounas & Lombardi (2022); He, Liu, Wang, et al. (2022) emphasized the importance of standardized smart contract design to enhance context awareness. However, the design of smart contracts barely considered the seven types of constraints that are the leading factors of construction "waste." This study aims to investigate the interactive constraint relationships to present a situation-awareness smart contract.

DATA COLLECTION

Data was collected from a high-rise residential building project in Singapore that utilized the modular construction method for Prefabricated Bathroom Unit (PBU) installation. The project aimed to complete 120 PBU installations, with equal distributions of three different types: 40 PBUA, 40 PBUB, and 40 PBUC. The project had three major participants: a PBU fabricator responsible for off-site fabrication and delivery, a crane and operator responsible for platform installation and lifting, and workers responsible for installation. The major constraints included uncertain and out-of-sequence PBU arrival due to the fabricator's preference for producing PBUs in a large batch, crane unavailability due to fully scheduled lifting activities, and a minimal number of workers assigned for installation to maximize profitability. This worsened the vicious cycle of arrival-lifting-installation. Besides, heavy rainfall was frequent in Singapore (Shen et al., 2018), which can significantly hinder installation productivity. Therefore, considering external conditions (e.g., precipitation intensity) as the fourth constraint is also crucial during the project planning stage.

RESEARCH METHODS

Figure Figure 1 presents the research framework, which involves six main steps. First, the study identified four key constraints for the real case project, namely external conditions (EC), material availability (MA), equipment availability (EA), and labor availability (LA). In step 2, the research defined three levels of variability for each constraint and used them to construct a simulation model that generated 81 possible scenarios. The scenarios were evaluated based on cost, and a Shapley value approach was used to determine fair reward/penalty sharing rules. In step 5, the researchers programmed all the scenarios and payment terms into smart contracts to incentivize collaborations and ensure high reliability. Finally, the framework's validity and effectiveness were tested through various scenarios input.

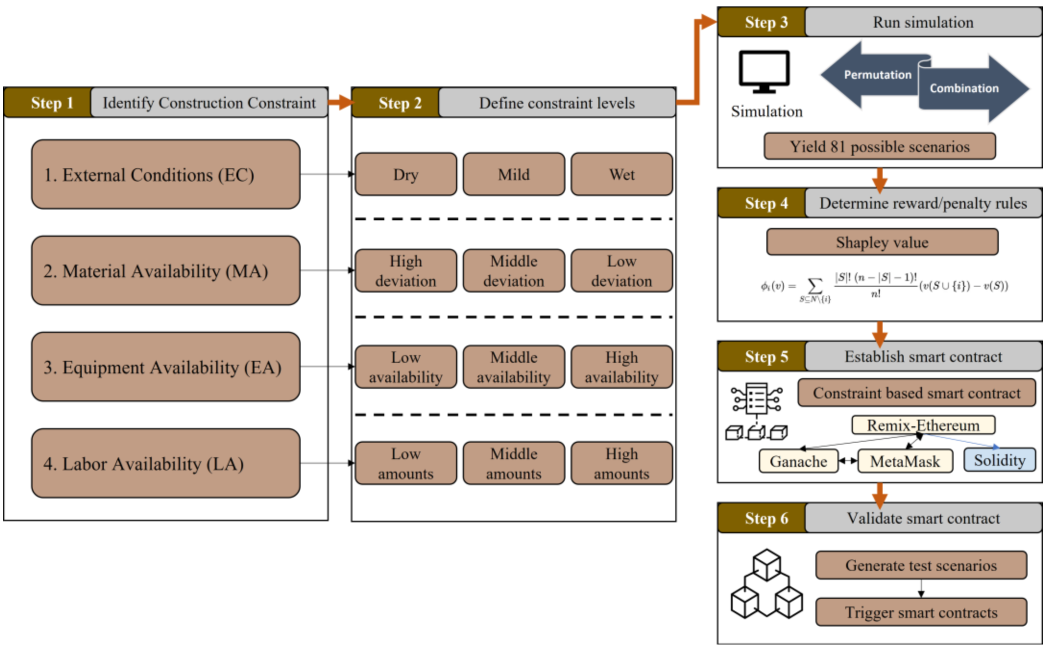

Figure 1: Research framework

Simulation Modeling

The research collected data on 74 PBU loading platform assemblies and 139 PBU hoisting activities. The productivity distribution processing can be referred from previous work (Chen et al., 2022). Productivity distribution is used used to build a simulation model that considers four main constraints: precipitation intensity (EC), PBU delivery reliability (MA), crane availability (EA), and assigned worker amounts (LA). These variables were used to evaluate the impacts on the project's overall outcomes.

The weather in Singapore can be categorized into dry, wet, and mild seasons, as reported by the National Environment Agency (2009). The historical daily precipitation data for 2017 was obtained by web scraping from the Meteorological Service Singapore (2023), which provided 151 daily precipitation intensity records for dry weather and 91 and 123 records for mild and wet weather, respectively. Larsson & Rudberg (2019) identified that different levels of precipitation intensity affect work efficiency, with the efficiency decreasing as precipitation intensity increases. Based on their findings, different weather conditions have varying precipitation intensity probability distributions, which are displayed in Figure 1. The reliability levels for PBU, crane, and workers, as well as the simulation workflow, can be found in our previous work (Chen, Liu, Li, et al., 2023; H. Li et al., 2023), which also outlines the three different levels of reliability for each constraint as summarized in Table 1. These different levels of variability can be combined and permuted to produce 81 possible scenarios.

The simulation recorded the project duration of 120 PBU installations, and the wait time for the crane and installation workers. The project cost includes PBU material costs, crane rental costs, workers' salaries, and indirect costs. Each PBU costs \$5,400 to fabricate, \$648,000 for 120 PBUs in total. Crane costs \$1,200/day, one installation team costs \$1,000/day, and the indirect cost is \$2,000/day. The project outcomes will be quantified in terms of cost to evaluate the marginal contributions from each constraint.

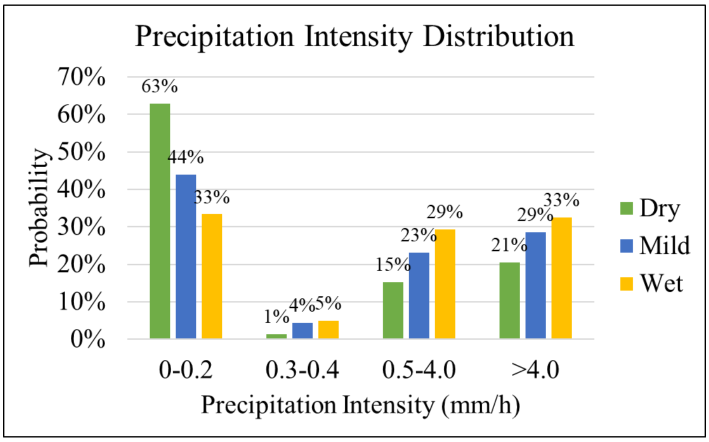

Figure 2: Influence of Precipitation on Construction Efficiency Based on Different Weather Conditions

Table 1: Reliability Level for Four Constraints

Reliability	Measurements	
EC	Precipitation Intensity	Distribution
High	Dry	DISC(0.63, 1, 0.64, 0.6, 0.79, 0.5, 1, 0.3)
Middle	Mild	DISC(0.44, 1, 0.48, 0.6, 0.71, 0.5, 1, 0.3)
Low	Wet	DISC(0.33, 1, 0.38, 0.6, 0.67, 0.5, 1, 0.3)
MA	PBU Delivery Deviation	Distribution
High	(0,8]	DISC(1/3, PBU_x, 1/3, PBU_y, 1, PBU_z)
Middle	(8,14]	DISC(11/18, PBU_x, 15/18, PBU_y, 1, PBU_z)
Low	(14,24]	DISC(15/18, PBU_x, 17/18, PBU_y, 1, PBU_z)
EA	Crane Availability	Distribution
High	>= 80%	80%
Middle	(60%, 80%)	70%
Low	<= 60%	60%
LA	Assigned Worker Amounts	Distribution
High	(7, 10]	U(66, 76)
Middle	(4, 7]	U(80, 90)
Low	<= 4	U(100, 111)

Note: DISC(Cumulative Probability, Value, ...) : discrete probability distribution; U(a, b) : Uniform Distribution

Shapley Value Calculation

The Shapley value method is a way to fairly and efficiently share benefits among a group of players (Parrachino et al., 2006). It assumes that a collaboration of n players can be represented by a set of players N, and a coalition of players S, with $v(S)$ measuring the sum of payoffs from members of S due to cooperation. Each player's contribution to the coalition can be measured using the formula:

$$\varphi_i(v) = \sum_{S \subseteq N \setminus \{i\}} \frac{|S|!(n-|S|-1)!}{n!}(v(S \cup \{i\}) - v(S)) \quad (1)$$

Where n is the total number of players, $v(S \cup \{i\}) - v(S)$ is the difference of worth when adding player i in coalition S, and $S \subseteq N\{i\}$ is the subsets S of N not containing player i. This formula can be used to calculate the fair reward or penalty for each player.

For example, suppose the objective is to determine the equitable reward for PBU fabricators in a scenario where all players (MA, EA, and LA) take part in a High (H) reliability collaboration, where the benchmark is Middle (M) reliability collaboration. The Shapley value method can be employed in the following manner:

1. Calculate the marginal value of adding each player (MA, EA, and LA) to the coalition, which can be represented as $[\Delta v_{\emptyset,MA}, \Delta v_{EA,MA}, \Delta v_{LA,MA}, \Delta v_{(EA,LA),MA}]$, and their values are [$1,722, $630, $504, $42].
2. Determine the scaling factor for each subset size, which averages the effect of the rest of the team members, ignoring their composition and focusing solely on the player's marginal contribution. The scaling factors for $[\Delta v_{\emptyset,MA}, \Delta v_{EA,MA}, \Delta v_{LA,MA}, \Delta v_{(EA,LA),MA}]$ are [1/3, 1/6, 1/6, 1/3], respectively.
3. Calculate the fair reward for each player by multiplying the scaling factor for each subset size by the marginal value of adding that player to the coalition and summing the results. The fair rewards for players PBU fabricator (responsible for MA) are 1/3 × $1,722 +1/6 × $630+1/6 × $504 +1/3 × $42 = $777.

Therefore, according to the Shapley value method, PBU fabricators, crane, and workers should receive benefits of $777, $861, and $21,672 when all players participate in the High collaboration. Shapley values can be negative if a player's participation causes a decrease in overall project performance, indicating that the player should be penalized for their contribution. For example, once (M, M, M) has been set as benchmark, the penalties for case (L, L, L) can be calculated by forming the following eight combinations: (M, M, M), (L, M, M), (M, L, M), (M, M, L), (L, L, M), (L, M, L), (M, L, L), (L, L, L).

Table 2: Sample of Shapley Value Calculation

Case	(MA, EA, LA)	Duration	Total Cost	Difference	PBU SV	Crane SV	Worker SV
1	(M, M, M)	44.24	$ 833,808	$ -	$ -	$ -	$ -
2	(H, M, M)	43.83	$ 832,086	$ 1,722	$ 1,722	$ -	$ -

SMART CONTRACT DEVELOPMENT

Eighty one possible scenarios formulated "management intelligence" and were translated into smart contract codes in Solidity language (version 0.8.14). This research developed smart contracts in Remix-Ethereum (version 0.29.2), which has an online Integrated Development Environment (IDE) that is a powerful toolset for developing, deploying, debugging, and testing Ethereum and Ethereum Virtual Machine (EVM)-compatible smart contracts. The IDE also has the desktop version for programmers who prefer the performance or security on their own hard drives. Besides, this study utilized Ganache (version 7.2.0) to create a private Ethereum blockchain and created accounts for three parties: PBU fabricator, crane, and installation workers. Ganache enables setting a personal Ethereum blockchain on the local network for testing and development so that the smart contract programmer can simulate different blockchain nodes in one computer before practical implementation. Ganache provides a Remote Procedure Call (RPC) link that allows smart contracts to run on the fetched blockchain network. The Remix-Ethereum can enter the PRC link in the "Environment" tab to deploy developed smart contracts in created blockchain. Once the blockchain is deployed, project participants can use MetaMask 10.11.3 (a decentralized crypto wallet) as a tool to interact with the blockchain and smart contract. Once all the settings have been settled, different scenarios can be generated to test the validity and effectiveness of proposed smart contracts.

RESULTS

The simulation outputs are summarized in Table 3. The results of non-weather consideration were also included in the table. Without weather considerations, the average project duration for 27 scenarios is 32.27 days, and the wait time for the crane and installation worker team are 0.97 hours/PBU, and 0.34 hours/PBU, respectively. While with weather (dry) considerations, the project duration is 46.17 days, showing a 43.08% increase. Figure 2 indicates that even during dry weather, there are precipitation intensities >4.0 and 0.5-4.0 mm/h, which cause a decrease in production efficiency, ultimately resulting in a significant increase in overall durations compared to situations without weather considerations. The crane and installation workers' wait times were 1.81 hours/PBU and 0.21 hours/PBU, respectively. This led to an 87.63% increase in crane wait time and a 37.52% decrease in installation worker team wait time under weather assumptions. The crane had more idle time, while the installation workers were busier. Project duration increased by 14.95% for mild weather (53.07 days) and by 23.62% for wet weather (57.08 days) compared to dry weather. Crane idle time increased by 23.07% (2.23 hours/PBU) for mild weather and by 36.18% (2.47 hours/PBU) for wet weather, while workers' wait time decreased by 18.43% and 26.05%, respectively. These results suggest that severe weather (increased precipitation intensity) can increase project duration and crane idle time, while putting more pressure on installation workers. Weather affects task productivity, and the worker installation capacity cannot match the high PBU delivery and crane capacity during turbulent weather. According to the Goldratt & Cox (1984), a bottoleneck operation is the operation that limits the capacity of the entire production process, and it can be identified by high levels of capacity utilization of the resources. Therefore, the activities of installation workers became the bottlenecks in this production process.

Table 3: Comparisons of 108 Scenarios from Simulation

	Without Weather (Chen et al., 2023)			With Weather (Dry)			With Weather (Mild)			With Weather (Wet)

*WT: Wait Time (Hours/PBU)

Table 4 presents the rewards and penalties under 81 scenarios for PBU fabricators, crane operators, and installation workers responsible for MA, EA, and LA under different weather conditions. Each value is aggregated using generated cost from simulation and Shapley value calculation described previously. The value corresponds to the marginal contributions of this responsible specialty under that scenario. Figure 3 visualizes the Shapley values based on the marginal contributions from each participant, with the height of each bar column indicating the Shapley value payments or contributions of each participant. Figure 3 (a) showed that without considering the impact of weather, PBU delivery excelled over than other two factors in contributing to successful project outcomes. With weather considerations and as weather conditions got worse, the installation workers dominated the project contributions. During wet weather, the contributions from higher reliability of crane and PBU delivery are minimum. It is essential to prioritize installation worker assignments either by assigning an extra installation team or extending the working time to overcome extreme external conditions. These 81 payment rules will be encoded into smart contracts as an incentive mechanism to enable reliable constraint removal for decentralized production planning.

VALIDATIONS

Test scenarios are generated to validate the smart contract executions, as shown in Figure 4. In this study, smart contracts can only be triggered by a mutual-agreed database. The database can be integrated with various platforms, representing the physical state of the current construction performance. To facilitate data input, this study encoded “2”, “1”, and “0” as the high, middle, and low reliability level, respectively. The environment was be set up as Ganache Provider with four initiated accounts. The first step involved inputting participants’ information and corresponding constraint levels. Given a scenario in that wet weather, high reliability for PBU delivery, crane, and worker involvement was detected from the database, the decoded labels were “0”, “2”, “2”, and “2,” correspondingly. According to the simulation results, the PBU fabricator, crane, and installation workers should receive 427, 123, and 26,320 ether (1 ether = $1 in this study), respectively. In step 2, once the smart contract was successfully activated, the “SendNotice” function would broadcast to the blockchain network regarding the payment amounts for each participant. Step 3 showed that smart contracts could successfully recognize the situations and will assign the correct amounts of payments under this scenario. Solidity provides *transfer()* function that can easily transfer the ether to targeted accounts. Once the transactions were performed, all the information was updated and stored in the blockchain simultaneously, where project participants could view the transactions through Ganache or their digital wallet. The results demonstrated the validity of the developed smart contracts.

CONCLUSIONS

Smart contracts hold immense potential in streamlining the construction process by specifying detailed task planning and enforcing consensus executions. Nonetheless, the dynamic and uncertain nature of construction projects, coupled with tangible or intangible constraints, poses challenges to the effectiveness of smart contracts in dealing with uncertainties ex-ante, relying heavily on individuals who design the underlying consensus. To enhance situation awareness in a decentralized constraint removal system, this study modeled the interactions of constraints in the smart contract consensus, developing a simulation model by permutating four constraint levels to generate 81 scenarios. An equitable payment method based on the Shapley value algorithm was established to incentivize reliable constraint removal. The findings revealed that installation workers dominated project contributions during adverse weather conditions, as installation speed is slower than PBU delivery and crane activities. Consequently, the installation capacity fails to keep up with the delivery and lifting capacity, thereby underscoring the importance of ensuring sufficient installation workers/teams on-site to guarantee project success during extreme weather conditions. Notably, the smart contract executions attested to the accuracy and validity of the developed framework.

This research makes two contributions. Firstly, it quantified the dominant constraints in the face of interactive uncertainties. The flow of constraints is challenging to model and quantify in terms of project outcomes. However, the simulation, which integrated the Shapley value algorithm, exhaustively evaluated all possible scenarios and identified the marginal contributions of improving each constraint. Consequently, project managers can determine the most effective sequence to remove constraints. Secondly, the study integrated blockchain and lean constraint removal theory to enhance smart contracts' situation awareness in dynamic construction environments. Decentralizing construction management requires smart contracts to be "intelligent" enough to function similarly to centralized project managers. The developed smart contract anticipated the governed constraints before the tasks were released into production. Thus, the smart contract focuses on the make-ready process, proactively avoiding situations where crews wait for conditions to mature instead of reactively resolving them with centralized control intervention.

LIMITATIONS

This study has several limitations. First, due to the limitations of the available data, this research only considered the four major constraints that impacted the projects in smart contracts, whereas Koskela (1999) suggested that at least seven types of constraints should be removed during construction planning. Future research can investigate modeling seven constraints and their interactive relationships in smart contracts. Second, this study assumed the extracted information from a database could be used to activate smart contract executions. However, it is difficult to establish a comprehensive database as well as construct contextualization that guarantees reliable smart contract execution. The deployment in the test environment represents another limitation.

CASE STUDY – LEAN PROJECT MANAGEMENT IN A MULTI-PROJECT ENVIRONMENT

Maximilian R.-D. Budau[1] and Tobias Juchum[2]

ABSTRACT

Lean project management approaches such as the Last Planner System (LPS) have already been proven their worth in numerous case studies. Lean project management generally contributes to the optimization of schedule execution and the project-related resource utilization. However, this often ignores the fact that a company usually strives to optimize its use of resources at the corporate level. Therefore, a specific approach was developed and tested in a case study in cooperation with a medium-sized company. This study utilizes the Design Science Research (DSR) approach, drawing on existing approaches to problem solving. The developed Multi-Project LPS (MPLPS) approach shows significant potential for cross-company resource optimization after only a few weeks of application.

KEYWORDS

Last Planner® System, collaboration, pull planning.

INTRODUCTION

A major challenge for construction companies is to optimize the allocation of resources across projects. Large construction companies frequently use software to support this process. Medium-sized companies often have to find another way for cost reasons. In the company considered in this case study, one employee is responsible for resource allocation. This person must try to find an optimum in exchange with the individual construction sites. By optimizing the use of resources in the form of machines, materials and personnel on one construction site at the expense of another, this can lead to a situation where, at the end of a fiscal year, the company's results do not correspond to what would have been possible in the best case. The company in question recognized this problem and attempted to find a solution that would at least identify bottlenecks in resource planning at an early stage. Such an approach would be a first step towards the cross-project optimization of resource utilization within a company. To develop this in the present case study, the so-called Design Science Research (DSR) approach is used. The basic procedure is shown in Figure 1.

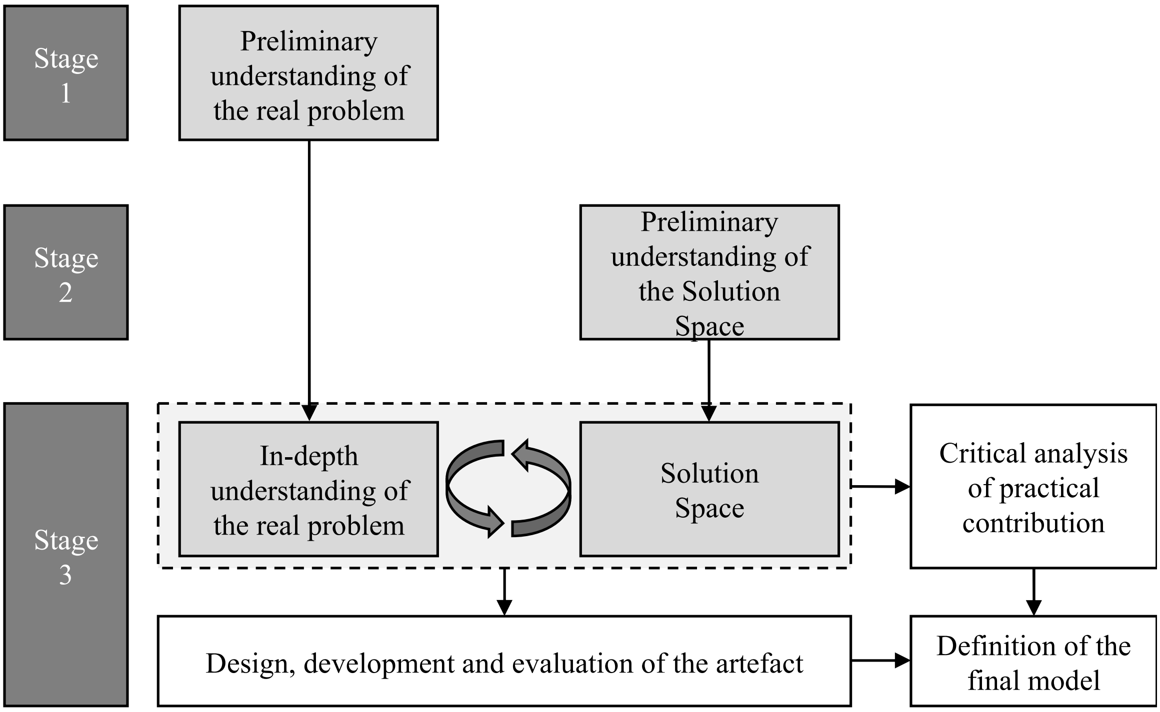

Figure 1: A visualization of the method and structure of this paper (Dresch et al. 2015; Hamerski et al. 2019).

As the figure shows, the first step in DSR is to identify the problem and break it down into its core components. To do this, this case study examined individual projects of the construction company as well as the distribution of resources within the company.

A literature search was conducted in the second step to form the so-called solution space. In particular, the IGLC served as a platform for the research. The approaches identified in this way formed the solution space alongside fundamental approaches to lean construction, such as the LPS.

In the third step, the extent to which the solution space provides solutions for the problem under consideration was tested in an iterative process. The aforementioned medium-sized company, which agreed to participate in the cross-company test, served as the data supplier. Within the framework of individual projects, it was possible to test the benefits of individual approaches from the solution space before these could gradually be put together to form a holistic solution approach. This process results in a multi-project management approach according to lean principles.

This study summarizes the development process results and presents the results of the first applications, the so-called Multi-Project Last Planner System (MPLPS). Finally, the results are summarized, and possible limitations of the investigation are pointed out.

STAGE 1: PROBLEM SPACE

PROJECT OVERVIEW

The research began in early 2022. The construction company considered here had 10 ongoing projects at that time. Table 1 provides an overview of these projects. The projects were mainly high-rise construction projects and a large part of them were in the remodeling sector. The company provided access to all of the projects as well as access to all of the documentation. Access consisted of the authors being able to attend all resource planning meetings and were given access to all data associated with this.

Table 1: project overview

Project	Project size (Million €)	Project art
1	3	new building
2	5	rebuilding
3	3	rebuilding
4	1	rebuilding
5	11	new building
6	5	new building
7	8	new building
8	1	rebuilding
9	2	rebuilding
10	4	rebuilding

IDENTIFIED PROBLEMS

The first weeks of the development process were used to analyze the main problems and to understand the problems identified, as provided for in the DSR. In many cases, problems cannot be reduced to a single cause. It was therefore necessary to focus on individual aspects. The results of this analysis process are the following problems, which need to be solved, as far as possible with the help of the model developed here:

- Problem 1: Resource bottlenecks are often not recognized until they have already occurred.
- Problem 2: Resource allocation requires a lot of coordination work by the resource manager.

In the following, the so-called solution space will be discussed first. This is the result of a literature research on similar and related problems. In the following step, an artifact is proposed based on the presented solution space, which solves the problems presented here, if possible.

STAGE 2: SOLUTION SPACE

PROJECT-SPECIFIC RESOURCE OPTIMIZATION: LAST PLANNER SYSTEM

The Last Planner® System (LPS) is a method for increasing productivity and stabilizing workflows. It was developed by Glenn Ballard and Gregory Howell and involves all project stakeholders in schedule and subcontractor control. The idea of LPS is to take a backward look at scheduling. (Ballard 2000)

First, the entire project is considered and milestones are defined for individual process phases. In a second step, a week-by-week phase schedule is used to define tasks to maintain the flow of work in the coming weeks. (Fiedler 2018) Last Planner meetings are used to check the targets set in the work plans, identify any errors and their causes, record the reason, and include the consequences in schedules and milestone plans. The interval of the meeting depends on the size of the project (e.g., weekly). When errors occur, such as incomplete or faulty work, the affected project participant can stop production. "This person is referred to as the Last Planner." (Heidemann 2011)

CROSS-PROJECT OPTIMIZATION

There are numerous lean approaches for optimizing individual construction sites, such as the LPS. The application of these approaches has already been tested and their efficiency has been proven. For the holistic optimization of an organization, there have been initial publications including case studies in recent years. In this context, the three-level approach by Dlouhy et al. (2018), which will be discussed in more detail here, and the multi-project lean management approaches by Bellaver et al. (2022) and Hamerski et al. (2019) are particularly worth mentioning.

Figure 2 shows the 3-level model of customer-oriented construction production according to Dlouhy et al. (2018). According to the authors, the model provides a transparent regulatory framework for structuring construction processes. It organizes an organization's resource and work planning processes into three hierarchical levels, with the level of detail increasing from top to bottom. The processes are closely linked. The following work steps must take place at the three levels:

Macro level: The macro level of the 3-level model represents the basis for communication with the client. The level of detail is reduced to a level that it is sufficient for strategic decisions relating to the entire construction process. The information for this level in turn comes from the levels below it.

Standard level: The standard level has a medium level of detail. It is used to map the construction coordination processes. The macro level provides information and specifications that are adapted to the project at this level. Construction processes are in turn planned and coordinated at this level. Individual processes and their interfaces are optimized. In this way, a stable execution flow can be ensured.

Micro level: The micro level represents the lowest and most detailed level of the 3-level model. Its purpose is to represent the processes that actually take place at the value creation level and to help control and monitor the work performed on a short-cycle basis. It receives instructions from the standard level and, conversely, passes on data and information to the two upper levels.

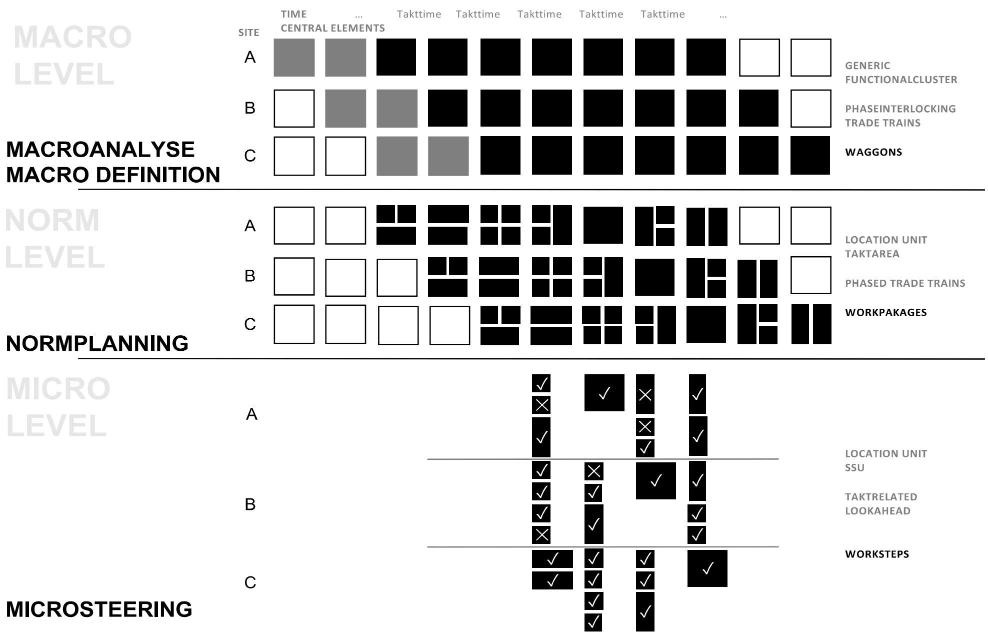

Figure 2: The three-level model (Dlouhy et al. 2018).

These approaches to the cross-project level first show at the principle level how such optimisation could take place. What is missing, however, is a concrete solution or implementation approach, which is the focus here.

INTEGRATED PRODUCTION SYSTEMS (IPS)

The implementation of lean construction often leads to problems in companies. Through various reorganization projects, companies are to be adapted to the Japanese model, and expectations are very high. In many cases, these innovations do not produce any real improvement, which ultimately leads to demotivation of the entire workforce. (Lay et al. 2005)

However, the fault lies not in the nature of the projects or their tools, but in the way they are implemented. Two fundamental problems can be identified that are responsible for the false start of Lean Systems. The first is the lack of stabilization of the new projects. If they do not bring success, they are immediately replaced by other projects. The second mistake is the lack of coordination between different approaches. For example, new types of production systems can strongly influence existing systems. The individual projects within the TPS concept must also be coordinated so that they do not work at cross-purposes. (Lay et al. 2005)

IPS are therefore introduced at the point of implementation. Its goal is to bring together all the concepts of the company in a meaningful way and to eliminate conflicting goals. An IPS is thus not a stand-alone tool. Rather, it is a regulatory instrument for coordinating the introduction of an existing production system. On the one hand, it creates transparency; on the other hand, it combines the strengths of all structures in order to improve the economic efficiency of the company. (Lay et al. 2005)

Every company has a different history and combines different concepts and structures. Therefore, an IPS does not offer a one-size-fits-all solution. Instead, it responds individually to the existing systems, technologies and the associated corporate culture. (Lay et al. 2005)

The IPS is therefore not limited to manufacturing. It tries to extend the new ideas to all relevant areas. (Lay et al. 2005) This applies in particular to upstream and downstream areas such as planning, control and logistics. So, it covers the entire manufacturing process. (Spath 2003)

In addition, IPS has a modular structure. It can be clearly seen what the task of an element is and how it relates to the overall system. This creates transparency and facilitates the operation of the elements. (Lay et al. 2005) To reinforce this effect, it is necessary to define the business objectives. In this way, the modules can be built up more purposefully and, if necessary, linked together. (Spath 2003)

The components of an IPS can be divided into methods and tools. The methods form the basis of the system. They are working techniques, which consist of planned and comprehensible working steps. They specify how a specific tool must be used to reach the desired goal. (Gorecki et al. 2014)

Since a IPS is modular, it can consist of different methods and tools. If a company chooses the components that make the most sense for itself and assembles them into an individual IPS. Since there are many different methods and tools, only the most important ones will be described in the following chapters.

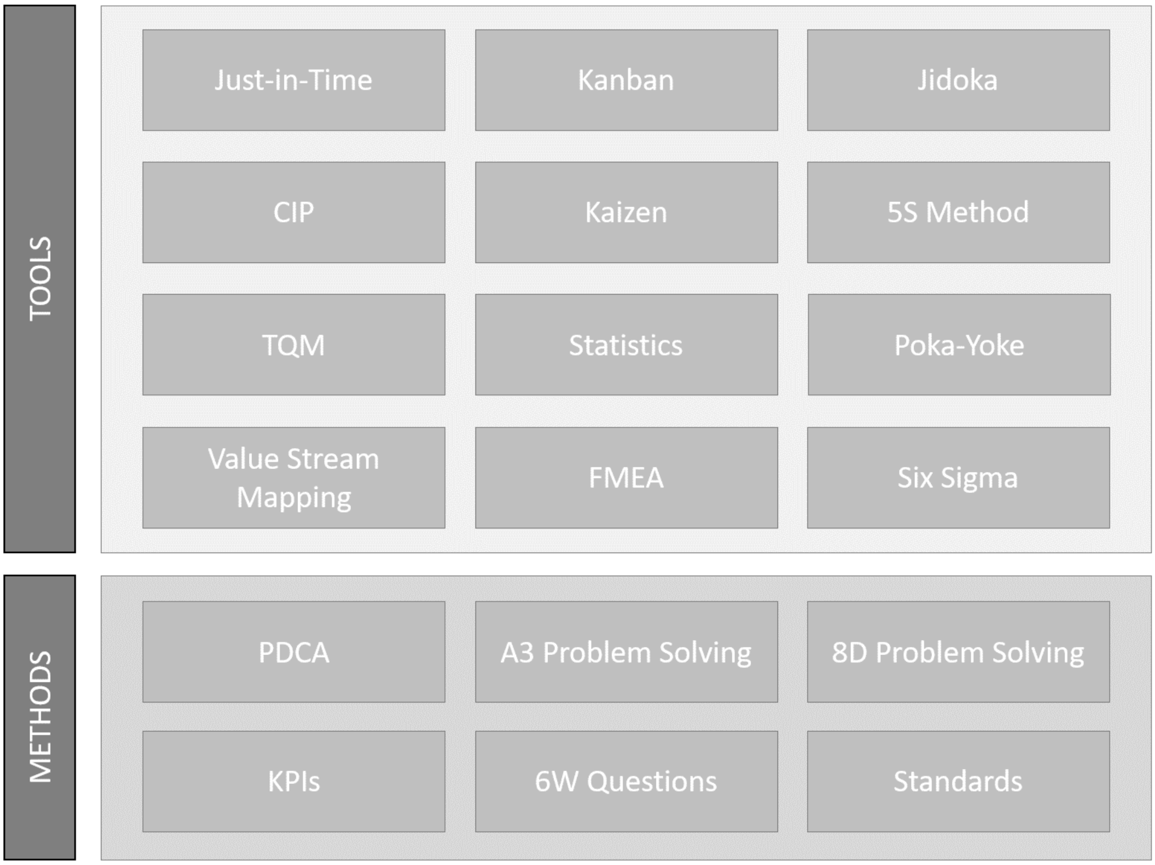

Figure 3: Tools and methods of IPS (Gorecki et al. 2014).

STAGE 3: ARTEFACT

RESULT OF DESIGN AND DEVELOPMENT OF THE ARTEFACT

Initial implementation

A fundamental distinction must be made between the initial setup and the short-cycle adjustments to the planning as the project progresses. In the following, the initial process of setting up the planning of a project will be discussed first. The basic idea of the 3-level model is that it can be used to control a large number of individual projects. In order to take advantage of the strengths of the approach, the following process must be implemented for all construction measures of the company in question.

The initial setup of resource planning for an individual measure is essentially based on the 5-step approach of the Last Planner system in the approach examined here. A special feature here is that the individual planning levels of the LPS are integrated into the levels of the 3-level model by Dlouhy et al. (2018).

According to the LPS, the first step is to perform an overall process analysis for the specific project. Framework data such as completion dates, lock-in periods, etc. are determined, and necessary work steps as well as initial dependencies are identified. The goal of this step is a master plan (milestone plan) with project-specific phase and area classification as well as process steps for each area and possible trade.

In the next step of phase planning, a schedule is created based on the master plan (milestone plan) using common scheduling software such as MS Project. A prerequisite for the functioning of the model presented here is that the software used allows the linking of several phase plans and the allocation of resources. Scheduling should be done on a weekly basis and not more precise.

This phase planning in turn forms the basis for the make-ready planning (6-week preview planning) in the next step. If possible, this should be done at the construction site by the respective trade managers. The 6-week preview can in turn be further specified at the start of the project in the form of weekly work planning (2-week detailed planning).

The make-ready planning (6-week preview planning) and the weekly work planning (2-week detailed planning) are to be integrated at the micro level of the 3-level model, since the optimization of the use of resources takes place here at the project level. At the standard level, the phase planning of the company's individual projects is combined again. By allocating resources, resource conflicts can be identified at this level and adjustments can be passed on to the micro level. Similarly, resource planning at the micro level allows for the automatic derivation of metrics that can be used at the norm level. The same is true for metrics that can be derived from master resource planning at the norm level to support strategic decisions at the macro level. The system used here does not provide for any further information at the macro level beyond key figures such as adherence to schedules.

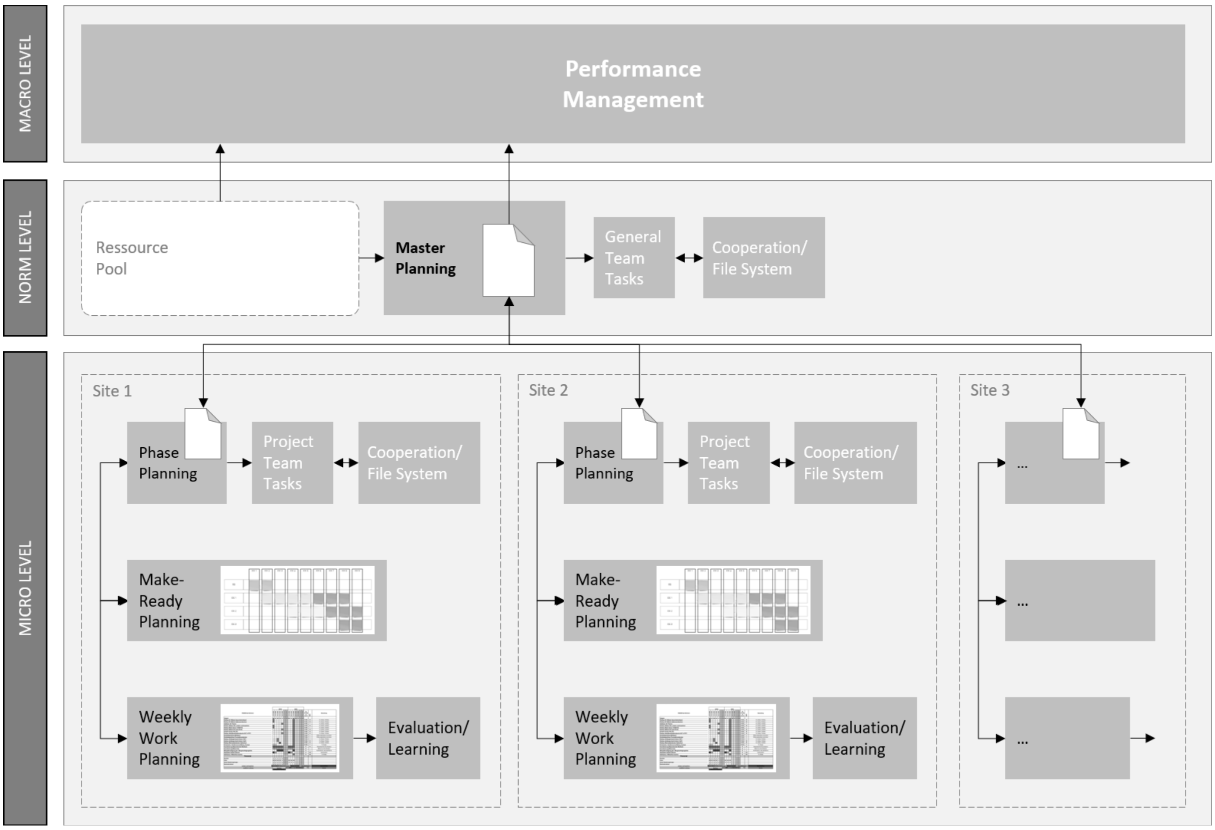

Figure 4: Initial implementation.

Adaptation process

The MPLPS provides that, where possible, a new week is added to the make-ready planning (6-week forecast schedule) and the detailed weekly work planning schedule, or the existing schedules are adjusted. This adjustment process continues to occur as part of the approach presented here. As presented above, this is part of the micro level. The specifics of the process presented here relate in particular to feedback to the norm and macro levels. The basic adaptation process is shown in Figure 4.

After the adjustment of the make-ready planning (6-week forecast plan) and the detailed weekly work planning according to the MPLPS takes place in the first step, the resource master planning on the norm level must take place in the second step. The adjustment of the resource planning must be carried out by the respective site manager. In order to keep the workload as low as possible, the level of detail of the resource master plan at the standard level has been limited to an accuracy of one week. Changes in the phase planning that occur at the micro level should also be identified in order to further reduce the workload. Once the resource master planning is synchronized with the already existing enterprise resource plan, information about resource conflicts is obtained. If this occurs, this information needs to be passed down to the micro level to make appropriate adjustments.

Adjustments to the macro level are automatic. The macro level can use the current metrics to make strategic decisions. The actions that result from these decisions are not standard processes and therefore are not directly addressed in the adjustment process.

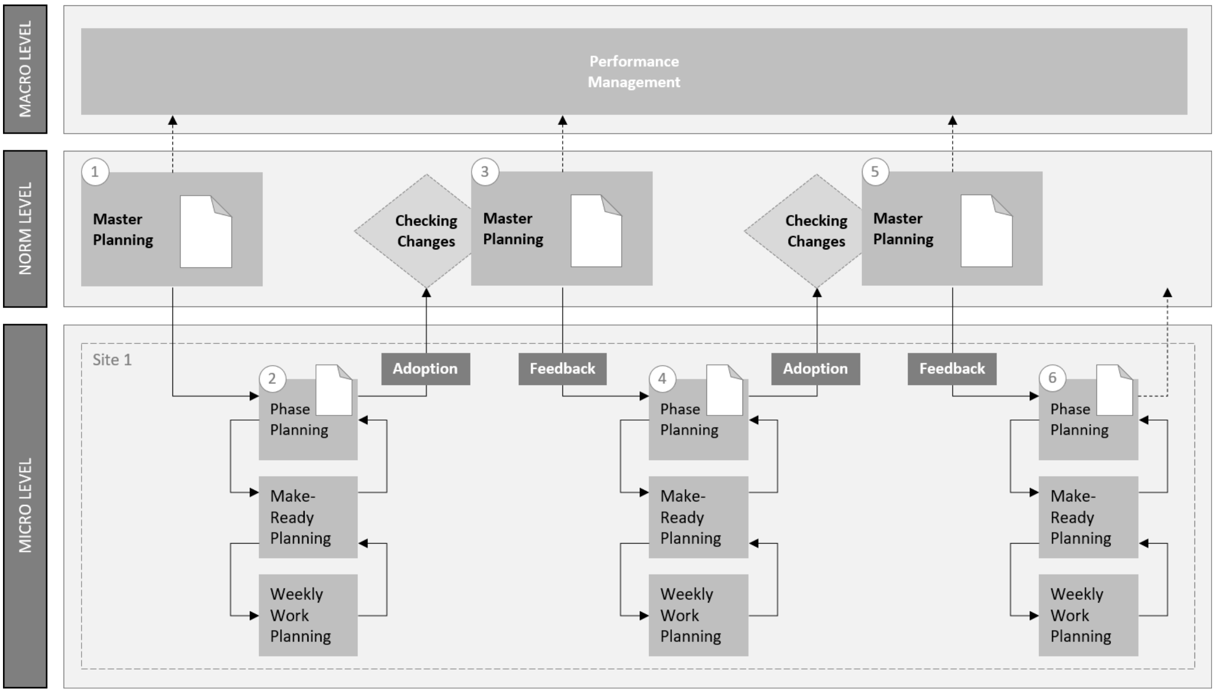

Figure 5: Adoption process.

PRELIMINARY EVALUATION OF THE ARTEFACT

The artefact is still being optimized. A final model could not yet be created. Nevertheless, the artefacts and the current state of the artefact presented here have been repeatedly evaluated in the course of the DSR with respect to solving the problems of the problem space. This can be summarized as follows:

- Problem 1: The developed artefact can effectively identify resource bottlenecks with sufficient lead time.
- Problem 2: Resource allocation is structured by using this artefact. This does not reduce the effort but transforms it into an orderly process.

Only gaps regarding the resources that are the subject of the resource pool can be identified. A resource pool that is too large may lead to too much administrative work. Therefore, the user must weigh up how much administrative effort is reasonable.

The benefit with regard to problem 2 cannot be quantified directly. A structured process does not directly lead to more effectiveness. However, it is the first step on the way to process optimization.

LESSONS LEARNED

The main innovation of the approach considered here is the linked application of LPS on several projects. It is therefore not necessary to report on the experience gained in applying LPS, but to focus in particular on the experience gained at the norm-level. The points that are of importance for the application beyond this are discussed below in bullet points:

- Currently, there is no software solution available that automates the interfaces. The current software solutions that can be used to manage resources do not allow pull planning. As a result, the interfaces must be transferred manually.
- In order to reduce the need to adjust the standard level resource planning when micro-level changes occur, the accuracy of standard-level planning has been reduced to one week.
- One person in the organization is required to take primary responsibility for managing and verifying compliance. The approach developed here helps to find a solution for resource allocation that does not have resource bottlenecks. What it does not do is find the optimal resource allocation solution. This still requires the expertise of the users.

The next step could therefore be to formalize this process further. The individual work packages could then be combined into an optimum overall process with the aid of a production planning system such as is used in stationary industry.

CONCLUSIONS

Optimizing resource utilization across multiple sites is a problem that is too rarely addressed. Approaches such as LPS often only aim to optimize the use of resources on one construction site. Alternative approaches such as the 3-level model help with cross-company optimization. In order to test this, a proprietary approach combining both methods was developed and tested in a medium-sized company. The approach showed great benefit in the context of the company, although its use is associated with considerable effort due to the numerous interfaces that have to be maintained. Therefore, an attempt should be made to find a software solution that digitizes the model.

DAILY HUDDLES' EFFECT ON CREW PRODUCTIVITY

Søren Wandahl[1], Cristina T. Pérez[2], Stephanie Salling[3], Cecilie H. Hansen[4], Magnus K. Nielse[5], and Tom Nissen[6]

ABSTRACT

Construction labor productivity has always been a key focus point in construction management, particularly for the operational part of the management, i.e., the site managers. Nonetheless, it seems that research on the site managers' tasks and time use is sparse. In the large lean toolbox, several approaches to improving labor productivity and management efficiency are present. One is the Daily Huddle. The objective of this research is to investigate the relationship between Daily Huddles and crew productivity. The research design is case-based, as two cases are analysed, one without and one with Daily Huddles implemented. Data based on Work Sampling of both crew and site manager are collected and analysed. The results show a remarkable distinction in the two cases in both site manager time use and crew productivity. However, a scientifically valid conclusion cannot be reached based on two cases only, thus limitations in the current research design and suggestion for future research are discussed as a contribution to the lean construction society. The practical implication of this study is that the benefit of Daily Huddles has been showcased.

KEYWORDS

Daily huddle, Flow, Productivity, Work Sampling

INTRODUCTION

The interest in understanding labor productivity on the national, project, and individual levels in construction has existed for decades (Abdel-Wahab & Vogl, 2011; Neve et al., 2020a). However, measuring productivity requires data from both earned value (output) and the value of resource use (input), which makes it highly resource-demanding to collect productivity data. Therefore, researchers are searching for other variables that can be used as predictor variables for construction labor productivity. One of these is Direct Work (DW), which is the share of work time that is used for value-adding activities (Handa & Abdalla, 1989; Wandahl et al., 2021). Neve et al. (2020b) investigated this relationship on a project level and found in detail the relationship between value-adding and non-value-adding activities and how these impact productivity through the lenses of transformation-flow-value (Koskela, 2000).

The Work Sampling (WS) technique has been used for decades to collect data on the amount of value-adding work time, referred to as DW (Gong et al., 2011; Salling et al., 2022). WS is a quantitative approach where data is obtained through direct observations of how workers use their time on the construction site. In general, WS has been applied to improve, often single construction projects regarding efficiency, construction labor productivity, and construction cost and time. In this research, WS is used as an indicator for efficient production.

Lean construction promotes a mindset and provides an extensive toolbox that can be adopted in the management, planning, and production control of construction projects to improve efficiency. One tool is Daily Huddles (DH). A DH is when a team meets before production begins to follow up on yesterday's production and talk about the production of the day. This is typically done in the morning, either in the work zone or at the site office. The purpose of the huddle is to improve alignment and solve problems efficiently, thus making sure that the crew can produce efficiently during the day and particularly improve the startup of the production. In industrial production and manufacturing, short DH plays an important role in day-to-day management and is widely adopted.

Neve et al. (2020b) demonstrated five system behaviors for "low performing" construction production systems, where one was a low share of DW around the start and stop of production, particularly at the start of the workday and at the end of the workday. A vast amount of research has identified and ranked factors influencing construction productivity in general, e.g. (Hamza et al., 2022; Hasan et al., 2018; Naoum, 2016). The results often mention planning systems, communication systems, leadership style, and team integration as high-ranked enablers/disablers for productivity. This is aligned with the purpose of the DH. When reviewing the literature on productivity enablers, it shows that the role of the site manager is under-researched. Site managers are responsible for the operational planning and running of construction activities and have a large interface and communication with the crew. The tasks of the site manager can have a significant impact on crew productivity (Binninger et al., 2018). Therefore, it is relevant to investigate how the site manager spends their working hours at the start of the production and to investigate a potential relationship with construction productivity.

RESEARCH OBJECTIVE

The objective of this research is to investigate the relationship between the site manager's time use and crew productivity in the first two hours of the day. The investigation is based on two case studies, one where DH was implemented and one without DH.

Before explaining the data collection and data analytic methods, a short theoretical introduction to the site manager and DH are presented.

SITE MANAGERS

In the construction industry, site managers are responsible for the day-to-day on site running of a construction project. Site managers are also referred to as construction managers, contract managers, or building managers. They are often responsible for a sub-part of the construction tasks, often divided by trade, i.e., carpenter, foundation, mason, etc. Site managers are required to keep within the time and budget and are involved in both quality control, health and safety checks, and inspection of work carried out. Thus, site managers have a large interface and communication with crew, and the way the site manager plans, manages, and supports the construction project can have a huge influence on crew productivity (Binninger et al., 2018; Fraser, 2000; Koskenvesa & Sahlstedt, 2012). Neve et al. (2020b) argue that the site manager often has a position and holds the insight necessary to be able to overcome daily problems and positively affect both crew and project productivity.

Research addressing site managers in the construction industry is one of the most marginalised fields of interest in construction management studies (Styhre & Josephson, 2006), and most literature has a negative slant. Site managers are depicted as a professional group exposed to conflicting demands and objectives, operating in a complicated environment. For instance, Djebarni (1996) writes: "*Site managers carry out one of the toughest and hardest jobs in the construction process. Site management is characterised by a high work overload, long working hours, and many conflicting parties to deal with, including the management, the subcontractors, the subordinates, the client, etc. This trait of the job makes it very prone to stress*" (Djerbarni, 1996, p. 281).

As described, site managers' tasks are very versatile, as they include dealing with problems arising daily, planning ahead, and accounting for changes that have happened. Thus, some tasks are focused on past production (e.g., claim management, accounting), others are future oriented (e.g., planning, purchasing), and some tasks are focused on present time (e.g., logistics, information, unforeseen events). There is a trend that more and more of the site manager's time is spent on administrative tasks, and less time is spent on facilitating the crew on site. Johansen et al. (2021) report on the site manager's role and defines the concept of visible site management as when the site manager spends time on site assisting the crew with, e.g., answering questions, clarifying production, coordination with other crews, etc. In other words, visible site management is when the site manager focuses on the present time, i.e., the production of the current day, instead of past or future production.

In addition, Johansen et al. (2021) concluded that, especially during the morning start-up, it had a large effect on crew productivity when site managers were visible on the site. Neve et al. (2020b) and Neve et al. (2021) confirm that construction labor productivity is particularly low in the morning and after breaks. Therefore, if the site manager can better facilitate production in the time around production start, it is likely that this could improve productivity. This points towards the implementation of DH, where the site manager assembles his crew every morning.

DAILY HUDDLES

The definition of huddle is to gather or pile together, in this context meaning that people, often in a crew, meet in an informal way. Huddles are also recognized in sports, e.g., during time outs, before starting a play, etc. Daily refers to the frequency, i.e., on a daily basis. It is common to experience different frequencies, like weekly huddles or huddles every two weeks.

The Lean Construction Institute (LCI, 2022) defines a Daily Huddle as "*A daily huddle is a daily check-in for members of a team. It is a method to communicate and measure progress of a team's work plan. Daily huddles allow members to tackle problems prior to missing goals. They also allow the team to review accomplishments from the previous day and to set expectations for the coming day.*" Sometimes, the daily huddle is named differently, e.g., as morning huddle, stand-up meeting, foreman meeting, or even weekly work plan meeting. The important part is not the time of the day, or whether participants are standing or sitting, rather, it is the focus of the activity. In a DH, the focus is on alignment, proactive planning of the day's production, and agility in solving short-term problems fast. The DH meetings are reported to have a short duration of 5 to 20 minutes (Jimenez et al., 2020; ThinkProductive, 2023).

Research on the topic shows a range of purposes for DH. ThinkProductive (2023) defines the content of the huddle as to check in on one another and outlining plans for the day, and to achieve alignment. The communication aspect of the huddle is also stated by Oladiran (2017) and Mastroianni and Abdelhamid (2003), who describe the purpose as improving the communication between the project manager and the foremen, resulting in a high level of commitment from workers on-site. Others report that DH meetings are used in construction to develop and improve assignments (Salem et al., 2004) and to plan and coordinate tasks (Noorzai, 2022). Paez et al. (2005) further add that DH meetings look for immediate actions that ensure the completion of highly variable assignments. Fuemana and Puolitaival (2013) describe the DH as an important part of production planning and control, as the follow-ups on plans are accompanied by DH, where the team control, plan, and rearrange production to minimize waste. This is aligned with Jimenez et al. (2020), who describes that DH is applied to identify disturbances in the production flow to then rearrange tasks and minimize time losses. Time loss is by Kalsaas (2010) and Wandahl et al. (2021) linked directly to crew productivity. Thus, a causal link between DH and onsite productivity is present via the reduction of time waste.

Several studies report on the benefits of implementing DH. Salem et al. (2004) investigated the effect of implementing different lean construction tools and found that DH had the largest positive effect. In addition, they applied a survey among workers, where 67% reported that they found daily huddles to be value adding. Mariz et al. (2019) implemented DH in a civil engineering project and found that team involvement was a key factor in deploying daily management. Many problems were reported at the DH. Simple problems were solved with immediate team action and larger problems that needed further analysis were forwarded to the engineering team. Consequently, they reported that cost reduction of 7% was achieved. Johansen et al. (2021) reported from a project where, among other lean elements, DH was implemented. In this project, waste time was reduced by 19%. Noorzai (2022) described that the most effective lean technique to improve success factors in the construction phase is DH meetings.

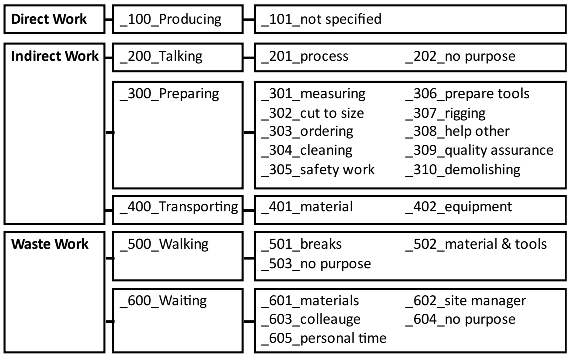
It is clear that DH is a part of the Lean philosophy and the Lean Construction application. Salem et al. (2004) argue that DH is part of the continuous improvement philosophy as it enables team members to improve collaboratively over time. Mariz et al. (2019) argue it can be viewed as part of the go-Gemba movement, as the site manager often conducts these huddles in the work zones or walks onto the construction site with the workers after the huddle. Several studies connect DH with the Last planner system, as DH focuses on achieving weekly planning for daily control through quick meetings with team members (Ballard et al., 2009). This view is aligned with Paez et al. (2005), who write, "*while Last Planner is a tool for managing operations, there is a need in construction for effective follow-up of highly variable events that affect assignments*" which then is referred to as the DH.

METHOD

The data collection is based on detailed Work Sampling (WS) as described in Salling et al. (2022). The WS technique has been used for decades to collect data on the amount of value-adding work time, often referred to as Direct Work (DW) (Gong et al., 2011). WS is a quantitative approach deploying direct observations to obtain data on craftsmen's time consumption on the construction site. In general, WS has been applied throughout time to improve single construction projects regarding efficiency, construction labor productivity, and construction cost and time. In this research, WS is applied both on the crew and on the site manager responsible for the crew. It is conducted with two different categorizations of observations. Moreover, as outlined by the research question, the data collection is narrowed to only collecting data in the first two hours of each day.

WORK SAMPLING – CREW

Step one is to clarify the categories of the activities to be measured: in this empirical study, the activities can be direct work (DW), indirect work (IW), and waste work (WW). This study followed the classification of Salling et al. (2022) with six categories for DW, IW, and WW: (1) Production as DW; (2) Talking, (3) Preparation, and (4) Transport as IW; and (5) Walking and (6) Waiting as WW. For each category, subcategories are defined, representing the actual activities of the observed crew on the site. The observations were conducted by an observer following the site crew and for every 1-2 min noting what each worker of the crew was doing including four types of information: a timestamp, a location, the work category, and the subcategory from the activity list shown in Figure 1, left side. The observer used an electronic form in Excel to collect the data (Figure 1, right side).



Number	Time	Category	Activity	Comment
1	07.01.03	_200_Talking	_202_no purpose	
2	07.03.59	_500_Walking	_501_breaks

WORK SAMPLING – SITE MANAGER

Very little research has been published on work sampling for site managers. Therefore, the authors developed a new taxonomy that suits the purpose of investigating the effect of DH. Several pre-studies were conducted to identify the most suitable taxonomy. First, the two case site managers were interviewed to understand their work. Based on this information, it was decided that the taxonomy should include a time dimension, i.e., whether the task of the site manager focused on past or future work (categorized as IW) or on today's work (categorized as Present Work (PW)). Second, a pre-observation round was conducted on case 1, and the results were discussed with the site manager. Thereafter, the final taxonomy, as depicted in Figure 2, was decided. The observations were conducted using the same procedure as for the crew observations.

Figure 2: Left: Taxonomy of categories; Right: Example of site manager observations.

This study collected data for 5 days and used a 95% confidence interval. The guideline of CII (2010) was followed to calculate the minimum number of observations needed to obtain the confidence interval based on the number of workers in the crew. This was calculated for each of the two cases and for crew observations and site manager observations, respectively.

CASE ONE – NO DAILY HUDDLE

The construction project is a combined renovation and extension of a commercial and residential building in the centre of a large city in Denmark. The contract form is a general contractor, and the project has a budget of 6 million EUR. The project started in 2021 and is expected to finish medio 2023. The subjects for observation were the carpenter crew and the site manager responsible for the crew from the general contractor. The carpenter crew consisted of 4 workers, and the observed tasks were mainly flooring, installing windows, and gypsum panel installation. The site manager's approach did not include any lean methods and was mainly reactive as opposed to proactive with regard to the crew.

CASE TWO – DAILY HUDDLE

The construction project was a deep renovation of a large campus facility with offices, lecturing rooms, and large genetic lab facilities, totalizing 11.000 m2, awarded as a general contract. The contract is 83 million EUR with a timeframe from 2021 until ultimo 2024. The subjects for observation were the carpenter crew (around 15 workers) and the site manager responsible for the crew. The contractor was the same company as in case one. Crew tasks were mainly roofing work, mounting doors and windows, and gypsum panel installation. On this project, the site manager was very proactive and engaged in the crew's work. He facilitated DH every morning in the site office. The duration was 10-15 minutes, with the following topics: follow up on yesterday's work, talking about today, organising materials, informing about changes, etc.

RESULTS

In the following, WS data will be presented for each case respectively.

CASE ONE – NO DAILY HUDDLE

In case one, the site manager did not implement DH. Table 1 describes the data collected during the one week of WS for the carpenter crew, and Table 2 shows the data for the site manager responsible for the carpenter crew.

Table 1: Work Sampling data for the carpenter crew

		Direct Work	Indirect Work			Waste Work	
$\bar{p}$	(%)	8.0%	72.2%			19.8%	
n		91	823			225	
		Producing	Talking	Preparing	Transport	Walking	Waiting
$\bar{p}$	(%)	8.0%	20.0%	41.0%	11.2%	14.5%	5.3%

Table 2: Work Sampling data for the site manager

		Present Work	Indirect Work	Waste Work		
$\bar{p}$	(%)	12.5%	74.0%	13.4%		
n		115	679	123		
		Present	Past & Future	Walking	Waiting	Personal
$\bar{p}$	(%)	12.5%	69.9%	4.1%	1.4%	12.0%

As learned from the tables, the DW of the crew and the PW share for the site manager are both relatively low. A DW share of 8% is not uncommon but low compared to other studies. Wandahl et al. (2021) investigated 474 cases of work sampling data in construction, and only 2% has a DW share of less than 10%. The carpenter crew has a very high share of IW, 72.2%. In other words, the crew spends more than 2/3 of their time to understand, prepare and make ready to produce. In the same time frame, i.e., the two first hours of the working day, the site manager spends more than 2/3 of his/her time on work activities concerning past work, like claims and quality management or future work, such as planning, coordinating, or purchasing. He spends 12.5% of his time on today's production. Table 3 shows the most frequent subcodes in the observations.

The crew has most observations of talking about the process (16.3%) and measuring (7.73%). This clearly indicates that there are parts of the production which is not clear for the crew.

Table 3: Most frequently observed activities for the crew and the site manager.

Sub codes for crew		Sub codes for site manager	
_200_Talking_201_process	16.3%	_200_past/future_201A_talk own	3.05%
_200_Talking_202_no purpose	3.69%	_200_past/future_201B_talk other	8.29%
_300_preparing_301_measuring	7.73%	_200_past/future_201C_talk general	11.9%
_300_preparing_302_cut to size	7.55%	_200_past/future_202A_phone own	1.20%
_300_preparing_304_cleaning	2.55%	_200_past/future_202B_phone other	4.91%
_300_preparing_305_safety work	5.88%	_200_past/future_202C_phone gener.	6.76%
_300_preparing_306_prepare tools	5.00%	_200_past/future_203A_pc own	1.96%
_300_preparing_307_rigging	3.51%	_200_past/future_203B_pc other	1.42%
_300_preparing_308_help others	2.19%	_200_past/future_203A_pc general	24.1%
_300_preparing_310_demolishing	6.41%	_200_past/future_2004_meeting	6.32%

For the site manager, the most frequently observed category was using the computer (24.1%). It is also clear that the site manager spends more time on other contractors and general topics than on own contracts, both for talking (cat. 201), phone (cat. 202), and computer (cat. 203).

Both Direct Work for the crew and Present Work for the site manager is stable after approximately 700 observations, and with good 95% confidence intervals. The confidence interval shows that for the carpenter crew, DW = 7.99 ± 0.97%. A DW interval of [7.02-8.96] has been observed from data point no. 651 and onwards. For the site manager's PW share (Figure 3, right), the confidence interval is equally good with PW = 12.54 ± 1.37%. A PW interval of [11.17-13.91] has been observed from data point no. 590 and onwards.

Average day curves illustrating the time distribution for the carpenter crew and the site manager are depicted in Figure 3 to show variation over time, and to identify possible trends.

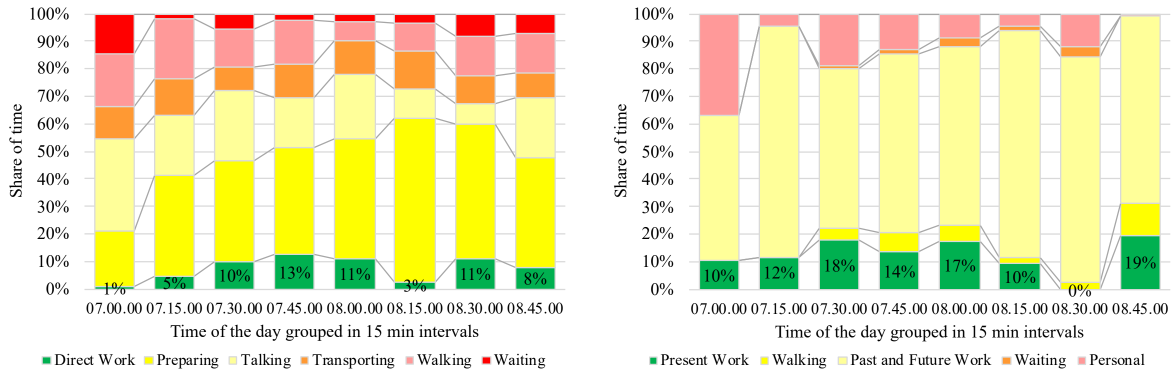

Figure 3: Left: Day curves for the crew; and Right: the site manager.

Figure 3 confirms the descriptive data from Table 1 and 2, showing that the performance, both in terms of DW and PW, is low. Moreover, two distinct patterns are observed. For the carpenter crew a pattern of DW starting very low at the beginning of the day and then slowly rising, is identified. The second pattern is seen on the curve for the site manager, who has a low and uniform distribution of PW. Most of his work time is spent on past or future work.

CASE TWO – DAILY HUDDLE

For case two, the site manager conducted DH every morning with the carpenter crew as described in the method section. Table 4 describes the work sampling data for the carpenter crew, and Table 5 shows the data for the site manager responsible for the carpenter crew.

Table 4: Work Sampling data for carpenters.

		Direct Work		Indirect Work		Waste Work	
$\bar{p}$	(%)	28.2%		56.4%		15.4%	
n		791		1584		431	
		Producing	Talking	Preparing	Transport	Walking	Waiting
$\bar{p}$	(%)	28.2%	16.0%	23.5%	17.0%	13.0%	2.3%

Table 5: Work Sampling data for the site manager.

		Present Work	Indirect Work		Waste Work	
$\bar{p}$	(%)	28.1%	61.2%		10.7%	
n		224	487		85	
		Present	Past & Future	Walking	Waiting	Personal
$\bar{p}$	(%)	28.1%	49.0%	12.2%	1.5%	9.2%

As learned from the two above tables, the DW of the crew and the PW share for the site manager are both high, and around industry average Wandahl et al (2021). The carpenters spend around 1/3 of their time on preparing and talking about the work before producing. The site manager uses 49% of his time on dealing with past and future work. Compared to case one, the site manager on case two uses three times as much time on walking. This is because he spends time on the construction site among the crew. Based on the detailed codes of the WS, Table 6 shows the most frequently observed subcodes.

Table 6: Most frequently observed activities for the crew and the site manager

Sub codes for crew		Sub codes for site manager	
_200_Talking_201_process	14.3%	_200_past/future_201A_talk_own	5.15%
_200_Talking_202_no purpose	1.71%	_200_past/future_201B_talk_other	11.8%
_300_preparing_301_measuring	6.91%	_200_past/future_201C_talk_general	0.00%
_300_preparing_302_cut to size	6.52%	_200_past/future_202A_phone_own	0.25%
_300_preparing_304_cleaning	2.64%	_200_past/future_202B_phone_other	1.76%
_300_preparing_305_safety work	0.43%	_200_past/future_202C_phone_gener.	0.00%
_300_preparing_306_prepare tools	5.31%	_200_past/future_203A_pc _own	26.1%
_300_preparing_307_rigging	0.64%	_200_past/future_203B_pc _other	2.26%
_300_preparing_308_help others	0.14%	_200_past/future_203A_pc _general	0.00%
_300_preparing_310_demolishing	0.68%	_200_past/future_2004_meetings	1.38%

As in case 1, the crew has most observations on talking about the process (14.3%) and measuring (6.91%). The most observed categories for the site manager are also similar to case 1; working in front of computer (26.1%) and talking about other contracts (11.8%).

Based on the data from Table 4 and 5, stabilization of both crew and site manager are analyzed. DW for the carpenter crew stabilizes after 2,000 observations and with a good 95% confidence interval. The high number of observations (compared to case 1) is due to the larger size of the carpenter crew. Direct Work ends with DW = 28.16 ± 1.80%. The PW category for the site manager is less stable. The Present Work share ends at PW = 28.14 ± 2.06%. Since observation no. 718, PW has been inside this confidence interval. Nonetheless, the data is considered valid and stable enough for further analysis.

Average day curves illustrating the time distribution for the carpenter crew and the site manager are depicted in Figure 5 to show variation over time, and to identify possible trends.

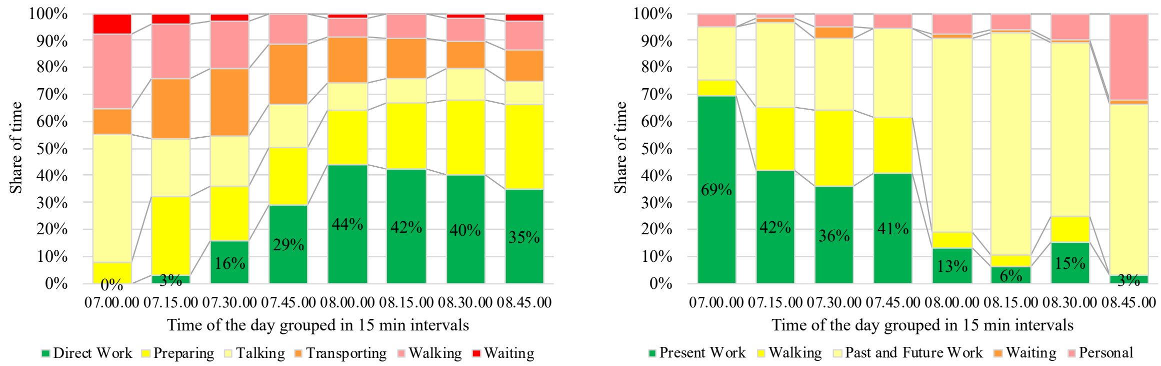

Figure 5: Left: Day curves for the crew; and Right: the site manager.

From the day curve of the carpenter crew (left side of Figure 5), it is visible that the workers take part in the DH from 07.00 to around 07.15. Their participation is registered as either preparing or talking (at the huddle meeting), depending on the crew is talking about work or talking in general. Some days, the Huddle was concluded faster than 15 minutes, whereafter the crew started walking and transporting material and tools to the production zone. For the site manager (right side of Figure 5), his engagement in DH is also visible. His participation in the DH is registered in the Present Work category. As mentioned, the huddle some days ended faster which creates indirect work from 07.00 to 07.15. After the Huddle, the site manager often walks to the construction site and joins the crew to assist and answer questions and address problems that might occur. After the first hour, the site manager typically concludes that work is running well (which can be confirmed from the DW=+40% from the crew), and he then starts planning for future work or follow-ups on past work, quality management, etc.

DISCUSSION

Case one and case two clearly show different results. Case two applied DH, and case one did not. Most interesting is the difference in how the site manager uses his time in the first two hours of the day, cf. figure 3 and 5. In case two, the site manager uses around 50% of his time to be productive and focus on present time activities. This is very different from case one, where the site manager uses 50% or more of his time on past and future activities and only uses 10-20% of the time on present activities. One reason for the difference is the DH applied every morning on case two. Another difference that provides insight is they sub activities the site manager is using his time on and how this is distributed over time. In case one, the site manager's time use is relatively uniform over time cf. figure 3, which is not the case for case two. Here the time use changes significantly during the day, cf. figure 5. In the first hour, the site manager uses around 50% of the time on today's activities, and after the first hour, the time use shift towards a focus on planning future activities and following up on past activities. The interesting result is that there seems to be a causal relationship between the site manager's time use and the crew's share of time on DW. This is most visible in case two. Comparing the left side (crew DW) of figure 5 with the right side (site manager's time use) shows an opposite pattern. This pattern is likely a consequence of the DH. The crew starts with a low DW, in fact, zero, because they use time on the DH. It is then seen that soon after the DH, the crew's productivity increases to a high and steady level.

The above results must be considered with some limitations. Firstly, only two cases are the basis for the result. This is insufficient to draw a scientifically valid conclusion, however, it indicates a clear tendency that is worth further investigating. However, this study has developed a methodology that allows for collecting more case studies to further examine the trend. The use of detailed WS increases the validity and paves the road for arguing for a causal relationship between DH and crew DW rates. A second limitation is that the analysis shows a delayed effect of the DH. This can be explained with a causal explanation, that improved production conditions will improve the share of time used on DW, however not instant. Conducting ad DH will not immediately improve crew share, the effect might be delayed. The results from case two show that the effect is visible after some hours, but the effect on the rest of the day is not investigated in this study, which calls for further investigation. A third limitation is that the DW share of the crew and the site manager cannot be isolated, with DH being the only variable. Other and unknown variables could influence DW shares, however, these variables cannot be excluded from the analysis. For instance, the effects of social constructs and trust, in general, will likely influence DW. A fourth limitation is that the two cases were very different in crew size, and the effect of large vs small crew cannot be isolated in this analysis. More studies with various crew sizes are needed. However, methodologically, crew size does not influence DW rates, or stabilization of DW, as smaller crew sizes just require a longer duration of data collection to achieve the same amount of data points.

The relevance and impact of this study are both related to academia and industry. For industry this research demonstrates the benefit of DH, even taking the above-mentioned limitations into account. Previous research has also concluded positively about the use of DH, however, few studies have succeeded in quantifying and measuring this cause-and-effect relationship. For research purpose this study can serve as a first run study on how to measure the effect of DH. The dissemination of the learnings from this study is of value for designing future studies on measuring the effect of DH. Moreover, DW data is not Construction Labour Productivity, however, DW is a valid indicator for Construction Labour Productivity as it shows the resource use, i.e., the denominator of the Construction Labour Productivity equation.

CONCLUSION

The objective of this study was to investigate the site managers' time use and its impact on crew productivity. For that purpose, the study conducted a review of both site managers and their time usage and on Daily Huddles, as one prominent approach for improving crew productivity. The review concluded that scarce research has focused on site managers and their impact on project success. Several studies report on the effect of Daily huddles, however, often the reports are based on logical arguments rather than data.

In continuation of the above, this research designed a method based on a case study to investigate the effect Daily Huddles has on crew DW shares. An adaption of the work sampling method to suit site manager data collection was designed and tested. The result of the two case studies, one with and one without Daily Huddles implemented, clearly show a difference in site managers time usage and crew’s share of time spent on DW activities. Conducting Daily Huddles seems to have a measurable effect on crew DW rates, even though the study includes some limitation.

ACKNOWLEDGEMENT

This research was supported by grant 0217-00020B from Independent Research Fund Denmark. The authors are thankful for the economical support. Also, the authors are thankful to the contractor, the site manager, and the carpenter crew on the two case studies for allowing data collection.

A COMBINED DIGITAL TWIN AND LOCATION-BASED MANAGEMENT SYSTEM

Manuel Jungmann[1], Timo Hartmann[2], Rahul Tomar[3], and Lucian Ungureanu[4]

ABSTRACT

As the coordination of resources' flow during location-based construction is complex due to limited space and simultaneous movements, management systems have been extended by adding a control stage to handle deviations from the initial schedule. However, a suitable information system has yet to be established. Therefore, a combined digital twin and location-based management system was developed. The digital twin concept relies on continuous, real-time data collection to provide information about the project's status. The combination of both methods facilitates effective, data-based production planning of the resources' flow over time and space. The proposed system offers the ability to proactively manage real-time information for ongoing location-based work through discrete event simulation. For improved understanding among stakeholders, the simulated processes are visualised in a 4D game engine. In an exploratory study, the system's effectiveness was demonstrated by using literature-based changes in productivity rates during the construction of finishing work in a high-rise building. The discrete event simulation results indicate that by ordering reasonable actions in response to construction deviations, a high level of resource efficiency can be maintained. This highlights the importance of using real-time data in location-based construction projects.

KEYWORDS

Digital Twin Construction, Discrete Event Simulation, Location-Based Management System, 4D Process Visualisation.

INTRODUCTION

As many different interacting trades are involved in the construction phase, appropriate coordination before and during the works is essential for successful sequences (Trebbe et al. 2015). A well-organised planning phase, which includes all stakeholders, before the construction start helps to reduce subsequent conflicts. However, during construction, unexpected issues arise, such as delays or disruptions, that lead to process deviations. Process deviations refer to any changes during production that deviate from the initial planned schedule and may cause time-space conflicts on site. During time-space conflicts, at least two activities must be executed simultaneously at the same location, which impedes continuous workflows (Akinci et al. 2002). The location-based management system is an approach used for efficiently

planning trades' workflows to avoid clashes between participants. In comparison to previous location-based methods, the location-based management system extends the planning process by a controlling stage during construction. Currently, the control process is enabled by weekly planning meetings according to the Last Planner System® (LPS) (Seppänen et al. 2015). However, for efficient planning within weekly meetings and for managing ongoing construction works, reliable information regarding current site conditions and processes are required. Insufficient communication and information exchange among trades is a prevalent issue in current construction practice (Dallasega et al. 2018), which hinders efficient construction work and results in wasted time for staff. The digital twin concept can remedy these shortcomings, as it aims to provide data-based status information in real-time. It is crucial to use the information gained to proactively manage ongoing works through modelling and simulation while considering Lean Construction principles (Jiang et al. 2021). This approach is called digital twin construction (DTC) (Sacks et al. 2020). One essential aspect of digital twins is the appropriate visualisation in an intuitive and understandable manner (Rogagae et al. 2022).

In this paper a combined digital twin and location-based management system was developed (DTLMS) as an advanced method. By integrating DTC, the location-based management system benefits from continuous, real-time information regarding ongoing construction processes. Real-time knowledge can enable data-driven management of trades' workflows and more efficient construction execution. In a previous study, the authors demonstrated how machine learning classification can be used to extract reliable, stochastic activity durations from real-time data and calibrate a discrete event simulation (DES) model (Jungmann et al. 2022). This paper focuses on the usage of gained information in a DES to ensure efficient construction by investigating possible what-if scenarios. To support the planning, a 4D process visualisation tool was added to the system. The simulated construction processes are illustrated in a game engine for improved communication among stakeholders in planning meetings. The paper presents the DTLMS as a business process model and notation (BPMN) and aims to demonstrate efficient project planning according to process deviations in a case study. The paper is structured as follows: The following section presents a theoretical framework of the topics location-based management system, DES, and DTC. Next, the developed DTLMS is described by a BPMN followed by the application of the developed DTLMS approach on a finishing works case study. The final section summarises the findings, limitations, and future research.

THEORETICAL FRAMEWORK

Modelling and simulation is an effective method for supporting construction planning and control (Altaf et al. 2018) by efficiently testing different scenarios and their estimated impacts. DES has proven its usefulness in supporting the decision-making process in location-based production flow research (Brodetskaia et al. 2013) by investigating construction processes and resource allocations (Liu et al. 2015). DES can be used prior to the start of construction to determine the master schedule and during construction to generate and investigate control actions. To produce reliable simulations of process flows, DES requires meaningful input parameters that represent current productivity rates from the construction site. Therefore, it is essential to receive data about production processes during the construction phase to update input parameters according to current site conditions. To this end, a digital twin is required, which offers reliable data-based information in a timely manner. It is important to ensure that data-driven information integration adds value to production management (Dave et al. 2016). Real-time data enable the determination of reliable activity durations, which can be used within DES to plan location-based resource flows based on the simulation results. The results of the DES need to be visualised to enhance the understanding of the sequences and their impact on time, space, and resources. Traditional 2D plans are often difficult to understand in short meetings, but 4D visualisations enable a superior visual project representation (Crowther and Ajayi 2021). The different approaches – Location-based management system, DES, DTC, and 4D visualisation – complement each other and exploit the potential benefits of the combined system.

LOCATION-BASED MANAGEMENT SYSTEM

Location-based management methods focus on the flow of resources across different work zones provided by a location breakdown structure (LBS) of the construction site to support the planning process by considering time and space. Due to the adjustment of resource allocations, productivity rates of different trades become similar. Thus, continuous resource workflows over locations can be achieved and waste can be minimised (Seppänen et al. 2014). This method is particularly useful for repetitive construction works, but planning the distribution of resources over time and locations while avoiding idle time remains a major challenge (Ungureanu et al. 2019). A technique within location-based management systems is to delay the start of activities at the first location to consider a sufficient time buffer between tasks (Seppänen et al. 2014). For lean production planning, control, and the location-based management system, it is essential to visualise problems as early as possible (Seppänen et al. 2015). Within location-based management systems, flowline diagrams – a visual representation of crews' movement over time on the X axis and over locations on the Y axis – are used as 2D visualisations. A recent study demonstrated that a significant amount of time is wasted during mechanical, electrical, and plumbing work due to communication issues among workers caused by insufficient plans and schedules, as 2D plans are often confusing and unsuitable (Görsch et al. 2022). 4D models add a time dimension to digital 3D models, such as a BIM model, making them more intuitive for providing an overview and identifying project conflicts. Research has shown that 4D visualisations significantly improve the planning process and project reliability by facilitating collaboration among project partners (Crowther and Ajayi 2021). Hence, there is a need for research on 4D visualisation based on schedule simulation and automated progress monitoring (olde Scholtenhuis et al. 2016).

The location-based management system strives to manage deviations as early as possible to adapt trades' productivity rates in scheduling to prevent any time-space conflicts or adverse impacts on the construction execution. Changes in resource allocations could be applied as control actions (Seppänen et al. 2015). The LPS is a Lean Construction method that proposes weekly lookahead meetings to control current processes on a construction site (Ballard 2000). Therefore, location-based management system and LPS complement each other to improve production management during construction works (Kenley and Seppänen 2010). However, approaches for information flow between these two systems and its appropriate usage are needed. Thus far, discussions in lookahead meetings regarding changes in construction sequences have been based on separate, paper-based project documentations (olde Scholtenhuis et al. 2016) or the subjective experiences of different stakeholders who are often unwilling to compromise due to financial concerns (Ballard and Tommelein 2021), rather than site data (Hartmann 2021).

DISCRETE EVENT SIMULATION

DES enables the simulation of real-world events in a virtual environment. The effects of management-decisions and what-if scenarios can be modelled and investigated in a cost-effective and risk-free way (Wainer 2009). In recent years, DES has been increasingly employed in lean construction research (Shou et al. 2019) as a suitable method for handling the management of complex construction interactions by dividing the schedule into discrete events (AbouRizk 2010; Martinez 2010). DES simulates a list of separated events over time and the system's state changes according to the occurrence of discrete events. The simulation is proceeded according to a provided activity duration, which can be either deterministic or stochastic. Based on the activity duration, required resources are seized. If the required resources are already seized for another activity, the activity has to wait in a queue until the resources are released. Hence, DES enables the description of the resources' flow in a system. DES functions as an input-output transformer by taking input parameters and outputting process durations and resource usage. While the potential of DES is acknowledged in the construction sector, its usage is limited due to a lack of meaningful input data (Abdelmegid et al. 2020), resulting in unrealistic outputs (Abbasi et al. 2020). Nevertheless, Shou et al. (2019) provided a systematic review of DES application in lean construction research.

DIGITAL TWIN CONSTRUCTION

For the usage of a digital twin, it is essential to determine its purpose beforehand (Brilakis et al. 2019) as digital twin models have to be used for a target service (Jiang et al. 2021). In general, it can be stated that a digital twin for the construction phase consists of three elements: a physical system, a digital model, and its bidirectional data, information, and knowledge exchange (Tao et al. 2019). Real-time data are collected using different technologies, such as sensors or cameras, on the physical asset and sent via the internet to an Internet of Things (IoT) platform, where the data are accessible from everywhere. The collected data are analysed by artificial intelligence to gain information about current conditions. This provides reliable project status information (PSI) and the digital model, the digital twin, can be updated according to the physical system and knowledge is created by comparing the PSI with the as-designed building and the as-planned process. This results in project status knowledge (PSK). Precise PSI and PSK enable the use of the digital twin for data-driven simulation of ongoing construction works. The DTC paradigm is a mode to apply the digital twin concept for proactive management of production processes by considering lean construction principles (Sacks et al. 2020). In general, enormous positive potential is anticipated for the digital twin concept (Delgado and Oyedele 2021). However, the digital twin concept is still seldom applied in the building sector, especially in the construction phase (Sacks et al. 2020), although digital twins can promote smart construction. The implementation of digital twins in the construction industry is very complex, as many interacting resources move continuously on large-scale sites influenced by uncontrollable uncertainties. Therefore, there is an urgent need to develop common frameworks and demonstrate use cases for digital twins in the construction sector (Jiang et al. 2021; Pregnolato et al. 2022).

COMBINED DIGITAL TWIN AND LOCATION-BASED MANAGEMENT SYSTEM

A BPMN for the application of DTLMS by DES was developed (Figure). Before construction begins, a BIM file for the intended building is modelled. The BIM file is used to derive the required activities. The construction site can be structured into different zones according to a LBS so that for each zone information about required material amounts is available. By having different zones, the activities are structured in a work breakdown structure (WBS) for the management of the different tasks. Hence, due to the structuring into a WBS and LBS there is a final list of events, which is modelled in a DES. The productivity rates, which represent the activity durations, are derived of a historic database based on data collection from previous projects. Additionally, the number of resources needs to be stated. Within the DES, different options can be compared based on automatically calculated key performance indicators (KPIs). The following KPIs were determined: total construction duration, resource efficiency for the trades (i.e. the active time divided by the total time the trade is on site from the first day until the last day of work), idle days on the separate locations (i.e. the duration when construction works are not finished in a zone, but no works are executed in this zone), and total personnel costs for resources (the duration resources are on site multiplied by personal costs per day). It is aimed at achieving continuous workflows for all trades and avoiding time-space conflicts. If decision-makers decide on a construction option, the master schedule for long-term execution is stated. The before construction start available information from the BIM model, databases, and simulations builds the basis for creating the master schedule.

According to the master schedule, construction starts and sequences are executed. During construction, data collection technologies automatically collect real-time raw data and store it on an IoT platform. The data are analysed by artificial intelligence to determine the as-built and as-performed status, the PSI. E.g. time lapsed images can be taken and analysed by deep learning to track progress at certain intervals or sensors attached to the workers can provide data that are analysed by machine learning classifiers to track works. The PSI is used for control in comparison to the initial planning information. If deviations from the initial planning are detected, the productivity rates can be updated and stored in a database for use in following construction projects. Furthermore, this updated information can be input into DES to investigate realistic short-term what-if scenarios. The results offer the basis for managing ongoing works in the weekly lookahead meetings. Within these weekly meetings, it is aimed to maintain equal productivity rates for all trades to avoid idle time. If there is an urgent case, an earlier intervention than weekly is possible. The whole procedure is based on the plan-do-study-act (PDSA) cycle for continuous improvement of management processes. Due to the continuous data collection and the control actions, it is aimed to learn about processes and apply these gained findings for further improvement of the production sequence. This process must be repeated until all works are completed.

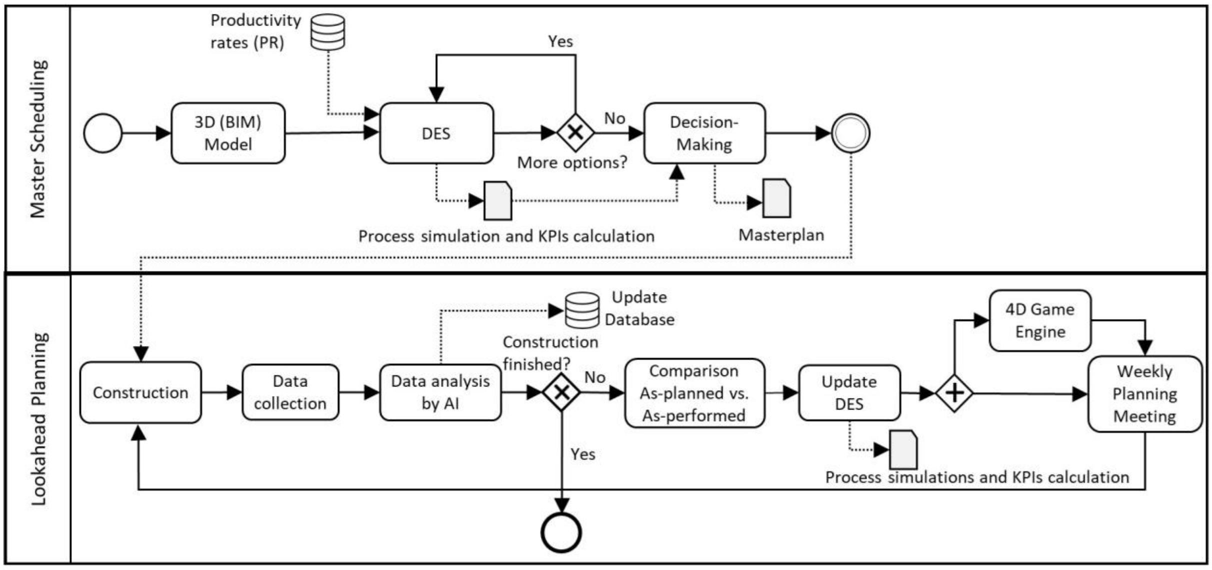

Figure 1: BPMN for a combined digital twin and location-based management system

A developed Digital Twin-platform, which is based on the game engine Unity, visualises the simulated processes of the trades. The BIM model as an IFC file is converted to a Unity file using a Python script to retain the geometry and metadata for import onto the platform. The start and end times for each process resulting from the DES are provided to the game engine as a JSON file. The information is interpolated to enable continuous process visualisations of the discrete events on the Digital Twin-platform. A colour is assigned to each trade and the construction site is divided into different zones. The zones are coloured according to the period during which an activity is executed by the trade. A Gantt chart timeline presents the activities at the bottom, which proceeds when the play button is clicked. Additionally, navigating back and forth is possible to investigate a situation in detail for better comprehension. By using a split screen, it is possible to compare the processes of different options next to each other.

DEMONSTRATION SITE

The demonstration site for the application of the developed system is a high-rise building in Gothenburg, Sweden. The future hotel and office building will have a total floor area of around 30,000 m². The floor area for each of the 27 floors ranges between 960 and 1,400 m². As most of the floors have similar floor plans, the finishing works will be executed in a similar sequence across all floors. The simulation of labour-driven operations executed by human resources, such as finishing works, is especially important, as the coordination is riskier due to the simultaneous execution by different trades (Bokor et al. 2019). A case study found that only 27% of the working time during equipment installation works is value adding and recommended research to minimise the wasting time (Görsch et al. 2022). Because finishing works are repetitive, it is possible to continuously learn from completed works and use the PSI and PSK for DTC management of ongoing works. The 16th floor, which will be used as a hotel, has a size of 1,200 m² and was chosen for an exemplary investigation (Figure).

Within this study, the execution of the following finishing activities by different trades was investigated: dry wall first side, wall installation of ventilation, plumbing, and electricity, dry wall second side, dry wall ceiling, painting, floor, and doors (Figure). The works are executed consecutively for each location by the following trades: dry constructor, heating, ventilation and air conditioning (HVAC), plumbing, electrician, painter, floor layer, and carpenter. Some activities require teams of two workers for the execution.

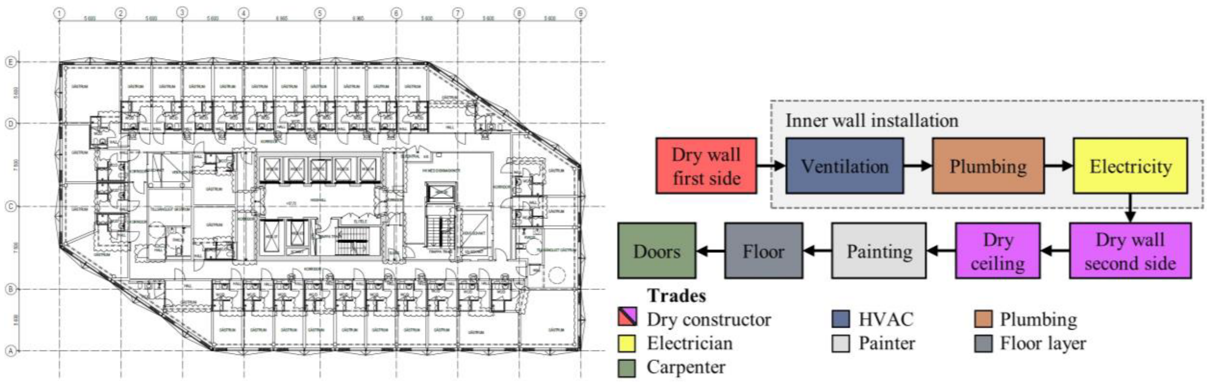

Figure 2: Floor plan 16th floor and process of finishing activities

APPLICATION

The execution of the finishing works for the 16th floor was modelled in a DES in R according to the process in Figure 2. The whole floor was divided into three zones of similar sizes. Due to the floor plan, the material quantities and the zone sizes differ slightly. According to the LBS and the WBS, there are 24 tasks as the dry wall work on the second side and the dry ceiling work were combined into one task. The productivity rates for each activity were derived from the construction company's provided schedule and the material quantities were gathered from the BIM file. The resulting activity durations were rounded up into whole days so that there would be a time buffer for the case processes proceeded more slowly than initially planned. If a higher number of resources is used, the execution of the activity is faster, however, at some point, there is a turning point and more resources hinder the execution (Ng et al. 2013). Therefore, a constraint of five simultaneous executed works of one trade in a zone was specified. To avoid time-space conflicts, subsequent activities can only begin after the previous activities are completed.

The stated KPIs were forecasted automatically in the DES to compare three different options. The two main principles of synchronisation – similar productivity rates among trades – and pacing – continuous process of activities across the zones – for location-based scheduling were integrated. As production management is especially complicated, if a trade returns to the same location (Brodetskaia et al. 2013), for the mounting of the second dry wall side and the ceiling, a second crew of dry wall constructors was introduced. Hence, one crew can focus on the mounting of the first dry wall side and the second team can work on the second side of the dry wall and on the ceiling. Thus, the whole sequence can be repeated subsequently on different floors. Option 1 is the initial planning before construction starts. Within Option 2, changed productivity rates during execution are considered, but no control actions are performed. Option 3 assumes the application of the DTLMS and the changed productivity rates are stated, followed by control actions to handle the deviations from initial planning. The results for the three options according to the DES are listed in Table 1.

Table1: DES results for different options

	Option 1	**Option 2**	**Option3**
Duration [days]	52	52	48
Efficiency trades [%]	100	100	100
Idle days on site	21	32	19
Personnel costs [€]	125,300	110,400	109,200

In Option 1, the resource allocations were adjusted before start to achieve continuous flows for each trade without any idle time. Therefore, the start of the plumbing trade was delayed by one day. Figure 3 presents the usage of the different zones. This results in an efficiency of 100% for all trades. Six floor layers working in two-person teams are commissioned and no idle time occurs, but the three zones are not occupied continuously. During construction, 21 days occur when no work is executed in one of the three locations, although the works have not been finished in the respective zone. In the first zone, there is almost no idle time, only the delayed start of the plumbing trade, but in the second and third zones, some several short-term interruptions occur. However, such short interruptions can also function as buffers, if a trade proceeds slower than expected. Option 1 results in a construction duration of 52 days and leads to personal costs of around 125,328€.

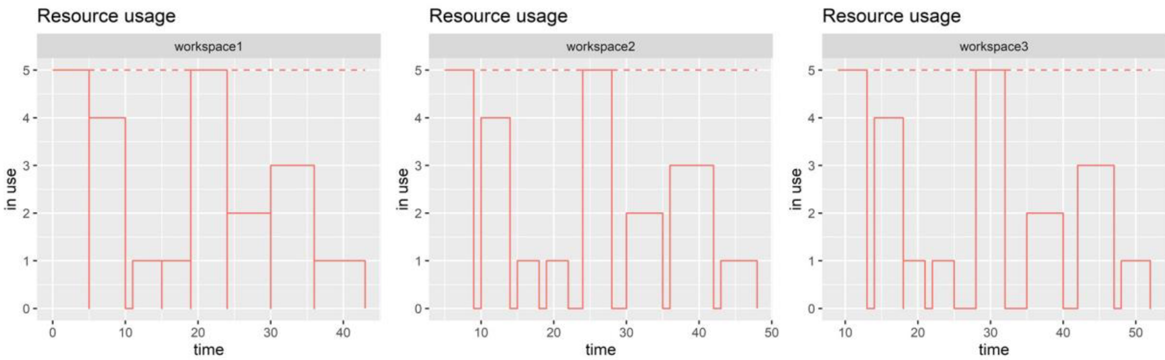

Figure 3: Option 1 - Zone usage

Option 2, the initial planning was based on Option 1, but a deviation in the actual productivity rate for the dry walls was assumed. The updated productivity rates were based on a study that investigated the productivity rates for dry wall work in a similar construction project in Sweden (Brosque et al. 2020), as no site measurements were possible. The mounting of the second side of the dry walls was faster in the construction company's assumptions, but the field investigation revealed that the construction of the first side was faster. The productivity rate for the first side changed from 0.200 h/m² to 0.106 h/m² and for the second side from 0.165 h/m² to 0.140 h/m². However, within Option 2, no change from the initial planning was made and the start date of the different activities was not amended. As the drywall work are executed faster, there is no change in the end date. Personnel costs fall slightly to around 110,400€ as the staff is required on fewer working days. No change in the efficiency of the different trades is observed, but the zones were used inefficiently as the duration of the idle periods increased as presented in Figure 4. On 32 days, no work was executed in one of the three zones, although the work in that zone was not completed. This is an idle time increase of more than 50% in comparison to Option 1. As the productivity rates for the first dry constructor team was faster, idle times occurs that sums up for all three zones. Additionally, the idle periods are of longer durations.

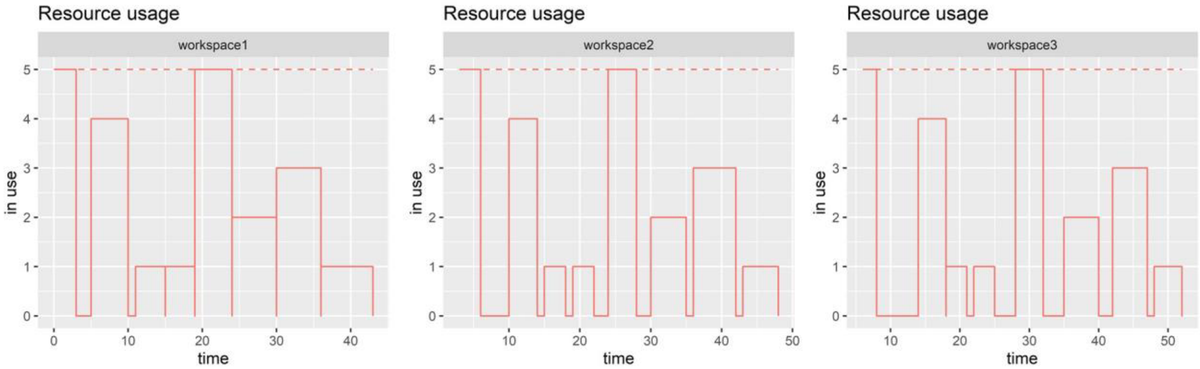

Figure 4: Option 2 – Zone usage

Within Option 3, it was assumed that the DTLMS was applied and the deviation of the productivity rates was stated by the digital twin concept. Subsequently, the gained PSI and PSK were used to adjust the initial planning and scheduling after the first week. On the one hand, the start dates for the following activities were brought forward. On the other hand, due to the faster productivity rate for the dry wall construction on the first side, another HVAC team was introduced to achieve a similar PR. As only a small deviation occurs for the mounting of the second dry wall side, this does not significantly affect the execution due to the simulation in whole days. Option 3 resulted in an estimated construction duration of 48 days. This is four days less than initially scheduled and the efficiency of 100% could be kept for all trades. Additionally, the idle days on the construction site were reduced to 19 days, an improvement of around 10% compared to option 1 and of more than 40% compared to Option 2. Figure 5 displays that the idle days were minimised and no idle days occurred in the first zone. The costs declined by around 15% to around 109,214€ compared to Option 1.

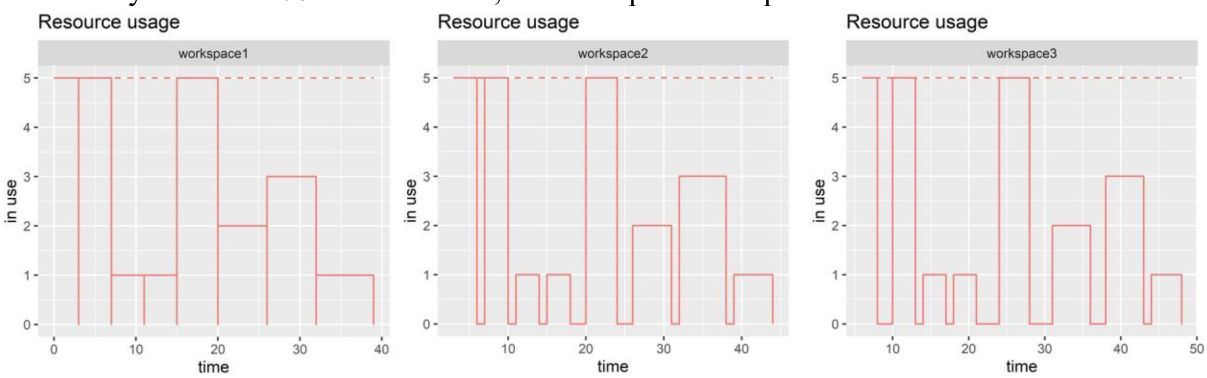

Figure 5: Option 3 – Zone usage

An image of the 4D process visualisation tool is presented in Figure 6. By clicking on arrow buttons, the different options can be selected. While the processes simulated for Option 1 are on the left side, the processes for Option 2 are visualised on the right side. The three zones are coloured differently depending on the activity performed and a Gantt chart provides an activity overview. Thus, the differences can be detected. By applying the developed approach, the impact of the construction execution can be improved in comparison to the initial planning. In all three options, a theoretical resource efficiency of 100% can be achieved. But in Option 3, the zones are used much more efficiently, as around 40% fewer idle days occur. Furthermore, the personnel costs could be reduced. If considering a larger case study and all floors of the investigated building, the positive impacts would increase even more.

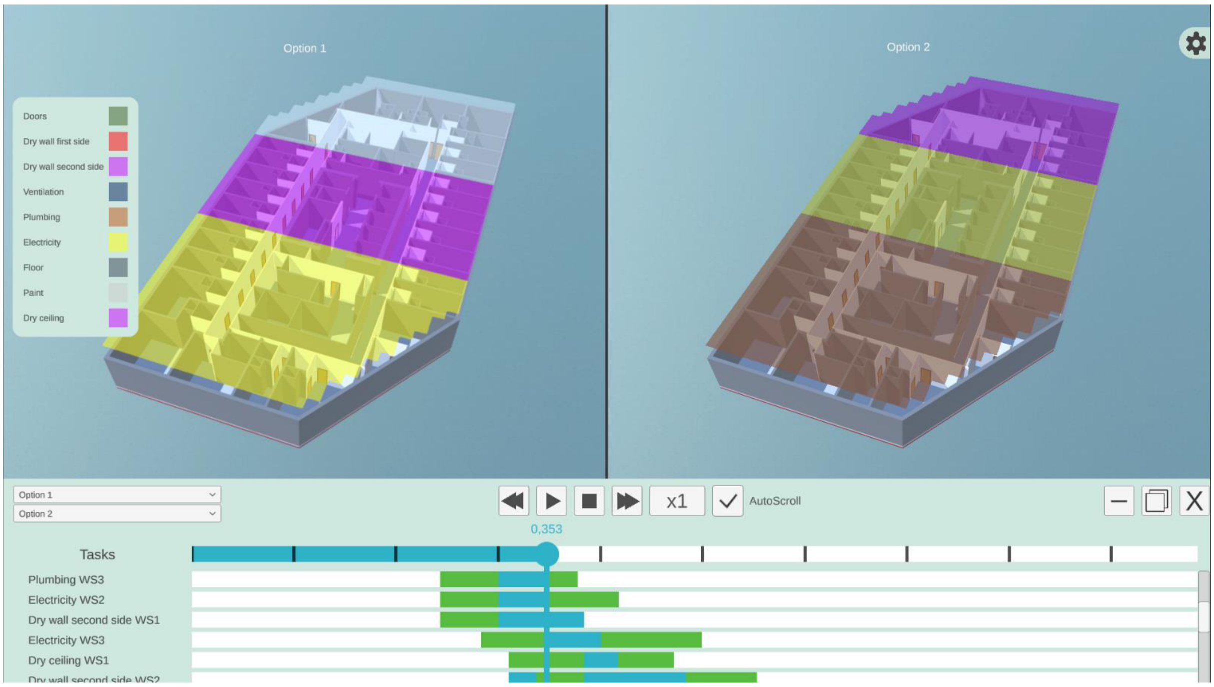

Figure 6: DES-based 4D process visualisations

CONCLUSIONS

The DTLMS presents a systematic approach for using real-time data during construction works for project management in consideration of Lean Construction. The paper provided evidence that using gained PSI and PSK can enhance the management of ongoing construction processes by ensuring continuous workflows and high efficiency during finishing works. However, in real projects, an efficiency of 100% remains a theoretical maximum (Ungureanu et al. 2019). Deviations from the initial master schedule should not necessarily represent an obstacle, but can also offer an opportunity to learn and improve ongoing processes. In the case study, it was possible to improve the estimated KPIs resulting in shorter durations, lower costs, and less idle time due to the intervention. The reason is the faster execution of dry wall work, which is uncommon in construction, as slower productivity rates are more frequently reported during production control (Seppänen et al. 2014). Nonetheless, this paper emphasises the need for real-time data-based construction control and, if necessary, control actions for handling deviations to hinder adverse impacts and shift away from subjective decision-making. The 4D visualisation assists due to an improved presentation of construction sequences and helps to identify conflicts in a timely manner. The extension of conventional 2D methods by the 4D process visualisation enhances the basis for discussion in weekly planning meetings. For successful management and execution, a common information basis and understanding of processes is required among all stakeholders, which also strengthens confidence.

A major limitation of this study was the use of literature-based measurements instead of data-based findings. The analysis of real-time data to gain reliable information for stochastic simulation was presented in a previous work (Jungmann et al. 2022). The focus of this paper was on the application of simulation for enabling control actions according to a literature-based deviation. Other than dry wall work, the productivity rates of different activities will vary from initial assumptions during construction. Hence, the investigation of an extended, more complex construction process will be expedient. Additionally, future research has to investigate the gap between the intended performance and the real performance, which will unavoidably differ. Future research should also consider the material deliveries via real-time data-based information in the DES to consider further uncertainties during construction. Furthermore, the game engine visualisations will be extended to a dashboard to enable information provision regarding past works.

PREDICTIVE SIMULATION FOR AUTOMATED DECISION-SUPPORT IN PRODUCTION PLANNING AND CONTROL

Timson Yeung[1], Jhonattan Guillermo Martinez Ribón[2], Li-Or Sharoni[3], Rafael Sacks[4], and Tomi Pitkäranta[5]

ABSTRACT

Production system design, planning and control are limited both by the incomplete situational awareness of planners and by their inability to predict the range of possible outcomes of their planning and control decisions. With the development of information technologies for monitoring products and processes on construction sites, it is increasingly possible to provide detailed status information describing the as-built products 'as-built' and processes 'as-performed'. This opens the door to applying predictive analytics to provide decision-makers with frequent predictions of the outcomes for a range of changes they might contemplate to the production system design, even during construction. Within the BIM2TWIN project, we are designing and implementing an agent-based simulation engine that is a core component of an Automated Decision Support System. Currently, the simulation can be calibrated to accurately predict the range of likely project durations for a residential construction project. However, certain aspects of the trade crews' performance, particularly with respect to the completion of tasks, appear to differ from the behaviours described by industry experts and encapsulated in the crew agent behaviour tree in the simulation.

KEYWORDS

Production system design, production planning and control, agent-based simulation, decision-support.

INTRODUCTION

The design of a production system plays a critical role in determining its overall performance. A well-designed system not only ensures efficient production processes but also provides the foundation for effective planning and control. However, if the system's configuration is not optimal from the outset, even the most sophisticated planning and control techniques may not achieve the desired outcomes (Schramm et al. 2006).

The status quo in production system design (PSD) is that it is primarily performed until construction begins, at which point the production system configuration becomes largely static,

and actions are limited to the scope of production control. This often leads to suboptimal solutions as the planners struggle to find the optimal configuration among the exponentially increasing solution space due to the large number of interconnected and interdependent variables at play. Without automation, planners must rely on known best practices, trial-and-error and their intuition and experience. This results in static production systems that are suboptimal with respect to the dynamic circumstances of construction sites, as opposed to the relatively stable environment of manufacturing plants.

An alternative approach is to apply automation to explore continuous optimisation of the production system configurations and parameters within the degrees of freedom of the system. This implies a shift from PSD as a planning exercise performed exclusively before construction to being an integral layer of production planning and control during construction. In this scenario, an automated decision support system (ADSS) would search the solution space to optimise the process, enabling the identification of multiple feasible alternatives. Additionally, it would provide forward-looking situational awareness (Lappalainen et al. 2021; Martinez et al. 2023), allowing planners to understand how the current production system configuration, as well as any alternative configurations, are likely to perform in the near future. Thus, planners could make better-informed decisions about the production system.

ADSS systems leverage the power of modern machines and information technologies to process data, optimise solutions, and analyse results (Bucklin et al. 1998; Payne 2000; Power and Sharda 2007). The core function of an ADSS is to predict the future behaviour of the production system based on its configuration and current status using digital simulation or statistical methods such as machine learning. The goal of an ADSS is to perform objective, comprehensive analyses of current and alternative production system configurations in very short times by virtue of automation, thus making continuous PSD through construction possible.

We present a novel predictive agent-based simulation framework for use within an automated decision support system (ADSS) for production planning and control. The framework is driven by 15 production system design parameters and generates 17 types of output data for performance evaluation. The capabilities of the simulation are demonstrated through the use of a real-world construction project in Finland, highlighting its current prediction capabilities and limitations. Furthermore, the paper outlines areas for improvement to further enhance the simulation's prediction accuracy and usefulness in real-world scenarios.

BACKGROUND

Automated decision-support systems (ADSS) are computer-based systems that augment decision-making by leveraging computer power to process data, make calculations, and generate information and knowledge to enhance situational awareness (Feng et al. 2009). ADSS can explore larger and more precise solution spaces than traditional trial-and-error-based planning approaches. This is achieved using advanced algorithms, such as mathematical optimisation, machine learning, and simulation, that can generate multiple solutions in a short period of time. With access to a large solution space, planners can identify feasible options, including some that may not have been considered previously, and select the most optimal for the project (Beynon et al. 2002; Marakas 2003). Thanks to automation, this can be done in much shorter times and with minimum effort (Gonzalez 2005).

Additionally, the use of computer algorithms helps ensure that solutions are not only optimal but also consistent, thus reducing the impact of human error and bias, which is especially relevant in the context of rapidly changing and uncertain construction environments. Future ADSS for construction may leverage data collected onsite, such as through digital twin and automated progress monitoring technologies (Kunath and Winkler 2018), to make evidence-based, explainable decisions that can improve the transparency and accountability of the planning process, as well as enhance trust and collaboration among project stakeholders (Coelho et al. 2021; Yeung et al. 2022).

Researchers have developed decision-support tools and systems for PSD. Draper and Martinez (2002) evaluated alternative production system designs for selected building construction processes with discrete event simulation (DES) to expose waste and artificial constraints hidden in the production system. Schramm et al. (2008) applied DES models in the decision-making process for the design and operation of house-building projects. The simulation models identified configuration options that reduced the total construction time. This, in turn, provided construction company production managers the ability to evaluate different scenarios and develop more efficient construction sequences, which led to a reduction in non-value-adding activities. Jadid and Badrah (2012) implemented a decision-support system for material selection based on value engineering to enhance interdisciplinary knowledge-sharing. These solutions have shown that proper decision-support systems can facilitate continuous improvement in all projects to improve their performance (Dave and Koskela 2009) and enhance the competitiveness of organisations with high absorptive capacity (Cohen et al. 1990).

Many existing decision-support systems use computer simulation as the mechanism for optimisation (AbouRizk 2010). Production systems in construction involve many heterogenous and interdependent components with stochastic behaviours, making it difficult to describe them with mathematical models without oversimplification (Abdelmegid et al. 2020). Simulation modelling allows for the description of a production system's components and their interactions, leveraging computer processing power to project and analyse the performance of the system. Additionally, a simulation can be used to optimise different aspects of the production system, such as resource allocation, scheduling, and process design, by changing the input parameters and observing the resulting output (Martinez 2010).

Of the main modelling approaches, agent-based simulation (ABS) particularly excels in producing explainable results (Bonabeau 2002). ABS uses a bottom-up, actor-oriented approach to represent systems as collections of autonomous agents interacting with each other and the environment. The interactions between agents give rise to emergent phenomena that can be observed at system-wide levels. Faithful reproduction of the behaviours of the individual agents within the system supports a comprehensive understanding not only of the overall system performance but also of the contributions of individual components (Macal 2016).

In recent years, researchers have applied ABS to investigate various aspects of construction production systems. Ben-Alon and Sacks (2015) developed the EPIC simulation tool to assess the impact of production control methods and information flow on production. Shehab et al. (2020) simulated construction crew performance using a hybrid ABS-DES model to facilitate weekly work planning in the Last Planner System. Barazi et al. (2021) proposed using ABS to study how parameter changes in vertical logistics systems can impact production performance in high-rise building projects.

SYSTEM DESIGN AND IMPLEMENTATION

The proposed system aims to assist planners in promptly exploring and optimising PSD at multiple points in a project by using project status and intent information. Specifically, by using parametric agent-based simulation, the ADSS can explore and evaluate a set of decision parameters, including changes in labour and/or resource allocations and in production control policies.

To design the system architecture, define the PSD decision parameters and outline the parametric agent-based simulation, we conducted a four-step process that included a literature review, gathering information from an expert panel, interviewing production planners, and observing and mapping agents' behaviours on construction sites. An expert panel of eight construction professionals from Finland, Spain, and France were consulted to specify the system features and functionalities. To define typical decision parameters used to make changes in production plans, we conducted 18 semi-structured interviews with production planners (Martinez et al. 2022). Through a behaviour mapping exercise on construction sites, we identified and mapped the behaviours of crews, supervisors, and site engineers in traditional building construction projects using decision trees. To design the overall system architecture, we applied a backward design approach and used a BPMN diagram to illustrate the system components and process flow, considering the functional requirements specified in the first step (Sacks et al. 2020).

The ADSS system comprises five main modules: 1) the User Input Module, 2) Simulation Module, 3) Alternative Plan Evaluation Module, 4) Alternative Plan Optimisation Module, and 5) Recommendation Dashboard Module. These modules work together to provide comprehensive decision support for construction production planning and control. The User Input Module receives the user's input information and selects the most suitable set of alternative production plans for simulation. The Simulation Module, designed according to agent behaviour specifications and implemented in AnyLogic® software, simulates the sets of alternative plans. The Alternative Plan Evaluation Module receives the raw outputs from the Simulation Module, evaluates alternative plan performance, and compiles decision aid elements and KPIs. The Alternative Plan Optimization Module enables users to generate additional alternative plans and simulation iterations based on optimisation algorithms. The Recommendation Dashboard Module presents the simulated production plans and their decision aids, allowing users to make informed decisions on the production plan to be applied in the next production cycle. The ADSS system includes two databases: 1) a Local Database that contains the baseline production plan, the constructed complete alternative production plans, their evaluation results and visualisation data, and 2) a Digital Twin Platform, which is a graph-based online repository for storing up-to-date project information.

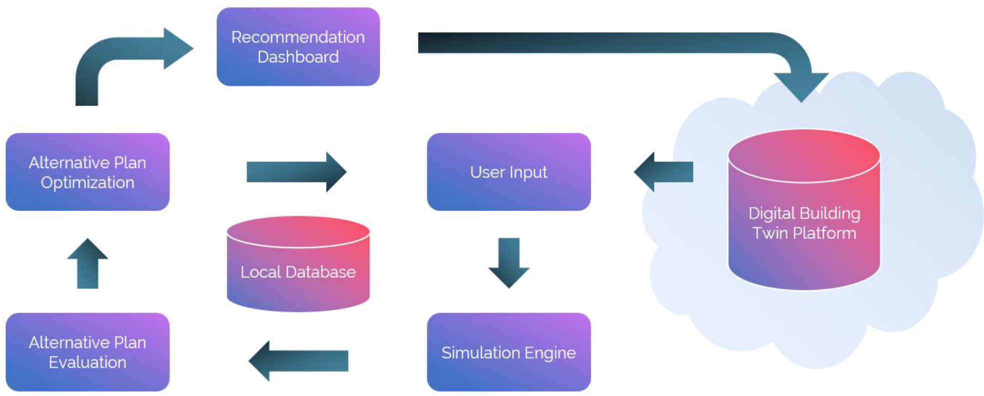

Figure 1: Overall System Architecture.

Table 1 details the 15 production system parameters that users can explore in the proposed ADSS. If a user decides to explore alternative production systems by modifying some of the parameters, such as adjusting crew sizes, the simulation engine can interpret the changes and apply them to the simulation before each run. In any given situation, there are multiple agents (managers, crews, equipment, materials, locations, suppliers, designers, etc.); each agent has multiple parameters, and each parameter can have some set of discrete values. For example, a 'drywall crew' agent may have a 'crew size' parameter, which may range from 4 to 6 workers. As such, the potential solution space is a complex product of the number of agents, parameters and possible parameter values. This yields combinatorially large numbers of production system configurations.

The predictive simulation engine in this ADSS uses the agent-based modelling approach. Agent-based modelling is a computational approach that simulates the behaviour of individual agents within a complex system. These agents have their own attributes, behaviours, and decision-making processes. They interact with one another in a decentralised fashion to create emergent system-level outcomes. In agent-based simulation models, agent classes are used to represent the general types of entities in a system, and specific instances of these agents are generated during a simulation run based on input data. This allows the model to represent the system at the individual level while also capturing the collective behaviour and interactions that arise between the agents.

Figure 2 gives an overview of the agent-based simulation engine's structure which includes the five classes of agents in the agent-based simulation model developed for this study: Work Crew, General Contractor Management (GC), Subcontractor Management (SC), Supplier, and Design Firm. The colour-coded rectangular boxes represent the different behaviours that each agent possesses, and the dotted lines show the interactions between these behaviours. This visual representation provides an overview of the behaviours and interactions of the different agents within the model and helps to understand how the system functions as a whole. For more details on the parametric generation framework, please refer to our recent paper (Yeung et al. 2022).

Table 2: Production system parameters.

Category	Parameter	Description
Labour	Production rate	The production rate for the specific crew (probabilistic-deterministic)
	Crew size	The crew size for each specific crew
	Number of crews	Add or remove a crew
	Crew calendar	Adjust the crews' calendars
Equipment	Maintenance rate	The equipment maintenance rate
	Number of equipment	Assign or remove equipment for a specific Work Package
	Equipment availability	Modify the availability time of equipment
Material	Material batch size	Change the material batch size for any material
	Material delivery frequency	Vary the material delivery frequency
	Material's buffer quantity	Vary materials' buffer quantities (percentage)
WBS	Task sequence	Change the task sequence
	Prerequisite tasks	Vary the prerequisite tasks
LBS	Construction site zones	Modify the construction site zones (Location-Based Schedule (LBS))
Production Control Policies	Material arrival strategy (pull or push)	Defines the material arrival strategy (push or pull)
	Work Package or location selection based on production planners' preference	The system gives priority to work packages where the largest quantity of productive work is available
		The system gives priority to spaces where work has already begun
		The crews assign the highest priority to spaces with the smallest amount of remaining work (Constant Work in Progress (CONWIP))
	Logistics Policy	The user changes the logistics supply chain type for a certain material

Each of the behaviours shown in Figure 2 was first defined in a behaviour map by construction experts and then coded as software routines in the simulation model. As an example, **Error! Reference source not found.** shows a behaviour map for the task assignment behaviour of the GC Management agent. A section of the corresponding logic tree in the AnyLogic software is shown in Figure 4.

Table 3 lists some of the result data that the simulation engine produces per simulation run. Each output is time series data, meaning that it is recorded at a specified frequency. This data is provided for each activity and resource, allowing diagnosis of the performance of the system at a fine-grained level. The abundance of high-resolution output data can be used to boost the ADSS's explainability to users, giving them confidence in the recommended solutions. It also enables calibration and validation of the simulation engine's prediction capability with high precision.

Table 3: Result data provided by the simulation engine.

Category	Output	Description
Trans-formation	Productivity	Work quantity completed per unit of resource input
	Resource Consumption	Quantities of material, equipment and labour effort consumed
	Earned Value	Accumulated value of work completed
	Project Progress	Percentage of work completed out of the whole project
Flow	Cycle Time	Amount of time it takes to complete a unit of product (e.g., apartment, floor)
	Throughput	Number of products completed within a given period
	Work In Progress	Amount of work in progress at a given time
	Non-Value Adding (Idle) Time	Amount of time a crew has been initiated but is not actively working on a task
	Space Conflicts	Number of times two or more crews require the same work location
	Material Buffer Size	Amount of material stored at a location at a given time
	Delivery Delays	Number of material deliveries delayed
	Equipment Capacity Utilisation	Percentage of total available time an equipment was utilised
Value	Material Delivery Date	Timestamp when a material order was fulfilled
	Resource Consumption	Quantities of material, equipment and labour effort consumed
	Rate of Rework	Percentage of tasks/products requiring rework
	Quality Control	Percentage of tasks/products containing defects
	Handover Date	Timestamp when a unit of product was handed over to the customer

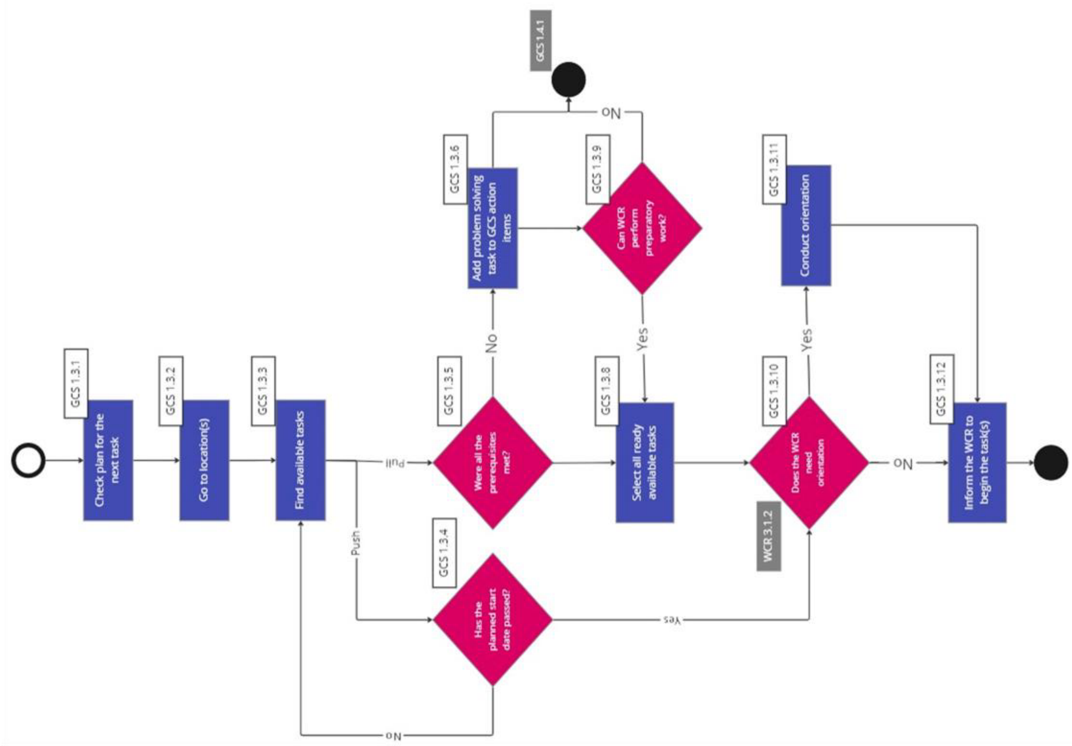

Figure 2: Behaviour map for GC Management task assignment behaviour as defined by experts.

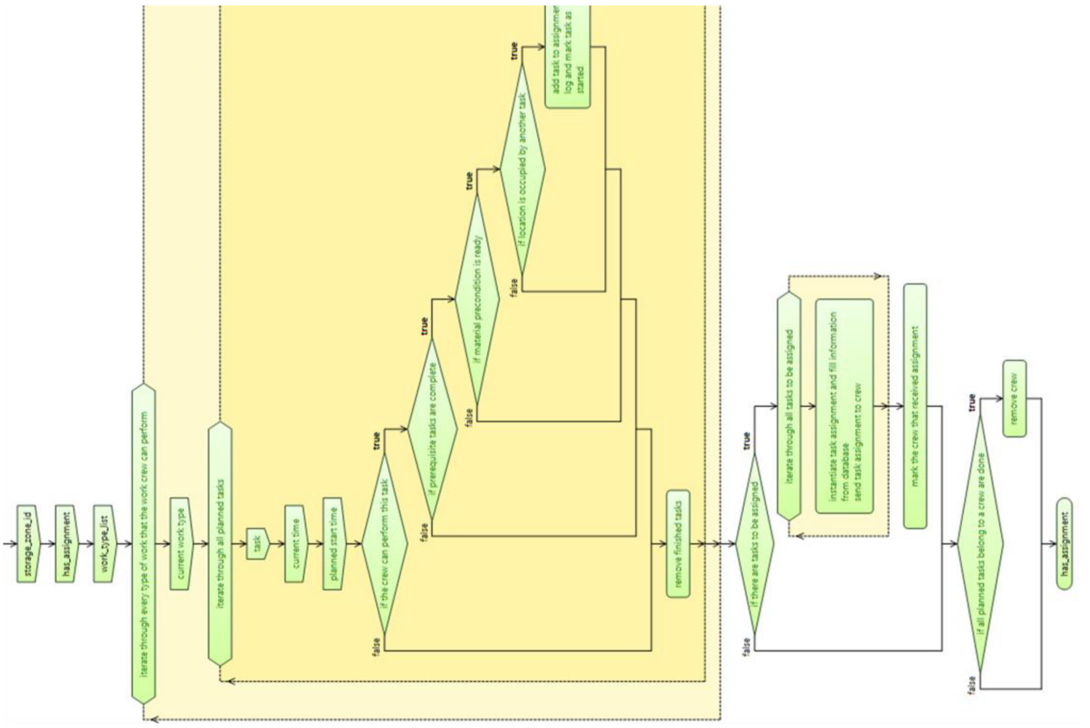

Figure 3: Behaviour map for GC Management task as programmed in the simulation.

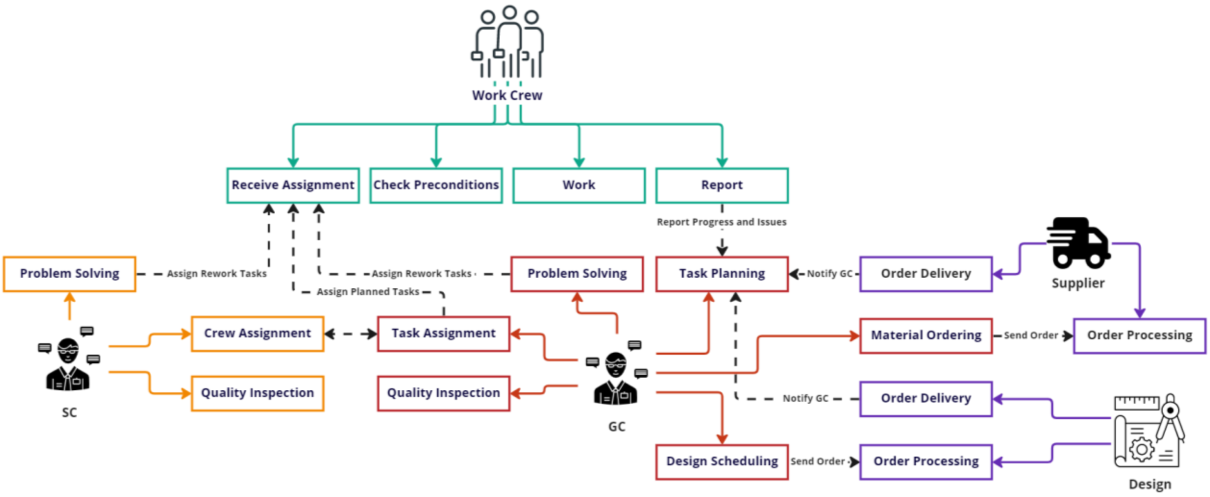

Figure 4: Agent classes and their behaviours in the ABS model.

CALIBRATION AND VALIDATION

To test and demonstrate the forecasting capabilities of the simulation engine, we apply it to an as-performed project dataset captured in a construction project of an eight-story prefabricated concrete residential building in Finland. The dataset covers the interior finishing phase of the project. It includes as-planned and as-performed progress, work quantities, planned production rates, a detailed work breakdown structure, and a location breakdown system. We used the progress data for validation and the rest of the data to set the initial production system parameters for the simulation. We ran 500 simulation runs using a Monte Carlo sampling method where the variance in supply chain reliability fluctuates randomly.

Figure 5 visualises the trajectory of project progress through time as a percentage of total tasks completed from the chosen start point (day 60 of the project). The as-planned progress curve is plotted in black, and the actual progress curve is plotted in red. The trajectory of each simulation run is plotted in a green spectrum, where lighter greens indicate earlier project end dates and darker greens indicate later dates. The figure shows a) that the actual progress deviated significantly from the planned schedule and b) that the actual trajectory falls within the range of the simulation's predictions.

Note that the planned trajectory lies at the left side of the distribution, suggesting that it was highly improbable, as would be expected in the case of a plan prepared using the Critical Path Method (CPM). This can be seen clearly in the histogram of project end dates presented in Figure 7. Here, we see that the actual end date and the planned end date are more than 30 working days apart, while the mean of the distribution of end dates is just ten working days earlier than the actual end date. The planned end date intersects the cumulative distribution curve at around 0.2 (i.e. a 20% probability of completing the project as planned).

Although the simulation results are promising in terms of projecting progress, a careful analysis of operational flow in these runs reveals that there is still much room for improvement in accurately simulating the actual flow patterns in real-world projects. Figure 8, a histogram of average cycle time per floor, shows that although the simulation results are closer to the actual results than are the actual outcomes for cycle times, they do not capture the actual patterns of flow. This discrepancy is also apparent in Figure 7, where the planned line of balance schedule is plotted against the actual status and against a representative simulation run. Towards the end of the project, there are multiple independent finishing activities scheduled in a tight time window. According to the actual record, these activities overlapped and intersected with one another in every location. In contrast, in the simulation run, the activities were performed in a relatively ordered way despite being scheduled tightly together.

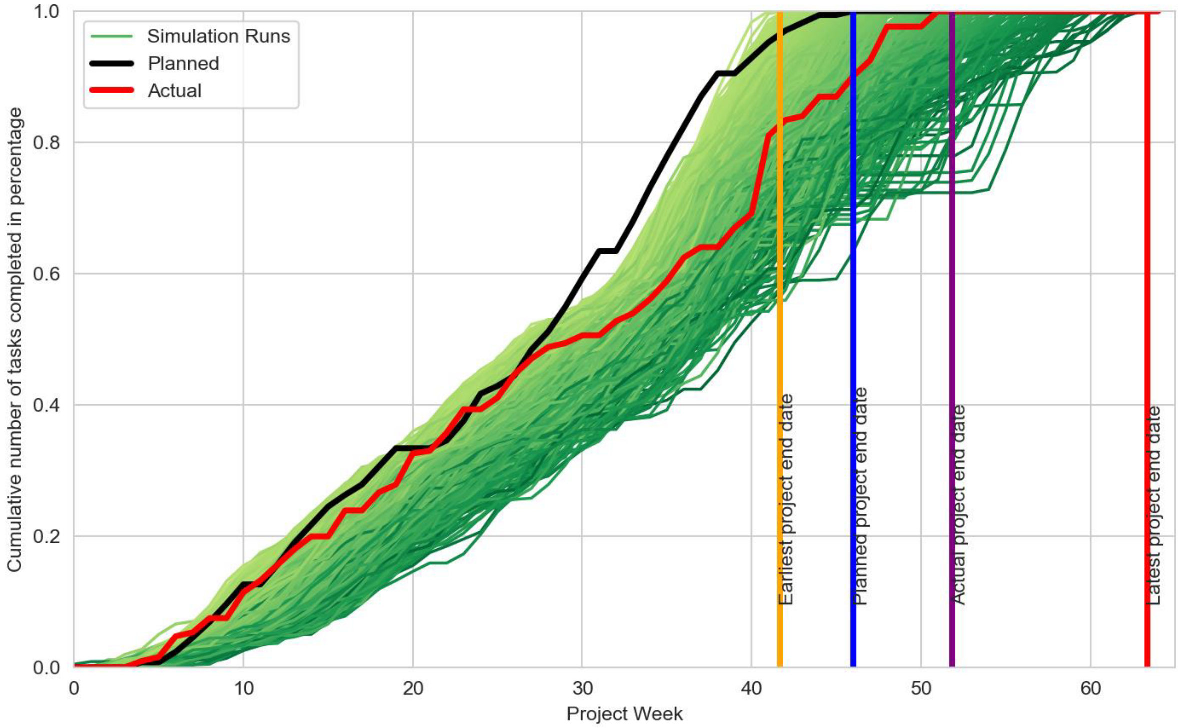

Figure 5: Progress trajectory of 500 simulation runs (green) plotted against the planned (black) and actual (red) progress.

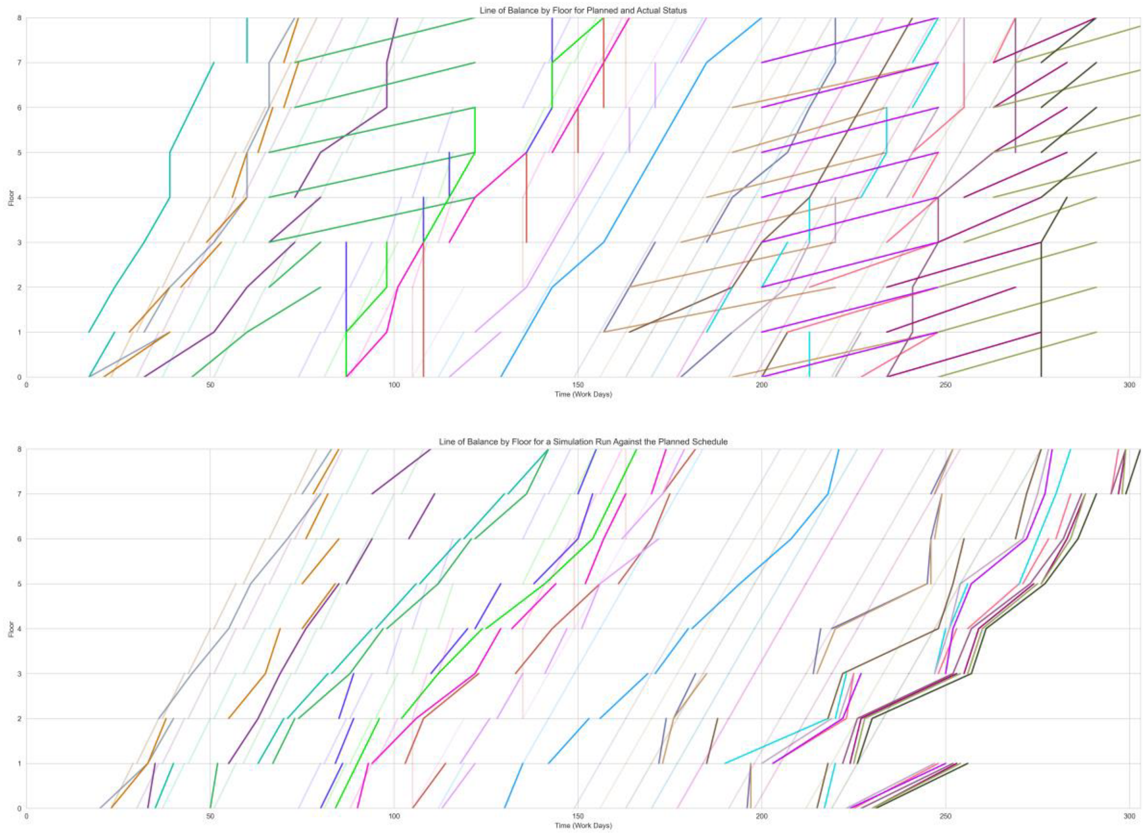

Figure 6: Line of Balance Charts. The top plot is the planned schedule versus the actual status. The bottom plot is the planned schedule versus a sample simulation run. In both plots, the as-planned schedule is plotted in semi-transparent colours.

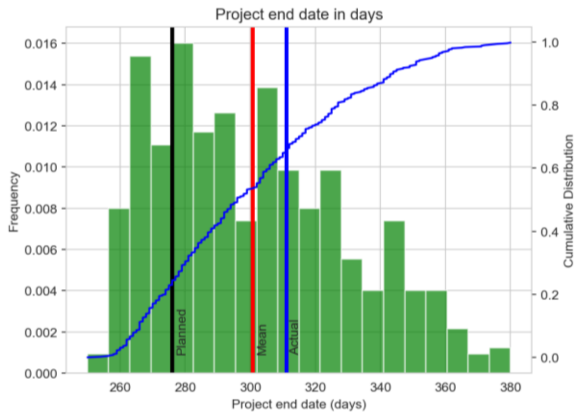

Figure 7: Histogram of project end date

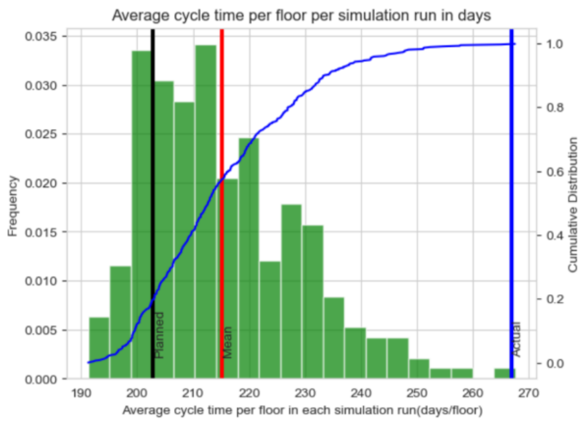

Figure 8: Histogram of average cycle time per floor

CONCLUSION AND FUTURE WORK

Automated Decision-Support Systems (ADSS) are essential components for adopting a broader view of production system design (PSD), extending PSD from a static, one-off design endeavour to a dynamic process of continuous improvement with optimisation. An automated ADSS can potentially help production planners explore the full feasible solution space to find optimal, evidence-based decisions in very short response times, making PSD a feasible exercise within the scope of lookahead production planning, and even weekly control, during the construction phase. The core function of such an ADSS is a predictive simulation engine that can project the probable future behaviour of a production system given its configuration, its current status, and the behaviours of its agents.

The paper detailed the input, output, and overall structure of a predictive simulation engine for an ADSS that is part of our ongoing effort to build such a system within the context of the BIM2TWIN project (BIM2TWIN 2021). Although the simulation can, at present, generate predictions of project duration that are a very good fit to the actual record of a validation project, a closer analysis of the results reveals that important discrepancies between the simulation results and the actual patterns of operation flow behaviours remain. This appears to be the result of discrepancies between the ways in which construction professionals at all levels understand and thus describe their behaviours and the ways in which they actually behave. This manifests in particular when crews complete the majority of the work in a given task or work package, but leave the final details unfinished, resulting in multiple instances of re-entrant flow in the actual record, and long cycle times for apartments, for example. Work remains to refine the behaviour of the agents to reflect this behaviour and to identify the production system parameters under which it occurs.

ACKNOWLEDGEMENT

This work was funded in part by the BIM2TWIN project of the European Union's Horizon 2020 research and innovation program under grant agreement no. 958398. The authors thank our BIM2TWIN colleagues from TUM, Orange, Fira Oy, SPADA, ACCIONA, and IDP for their support in the ongoing research on simulation and process prediction in the framework of DTC. Special thanks are due to Enni Laine, Kasperi Koivu, Oskari Kruth and Otto Alhava of Fira Oy for providing the project data and giving valuable feedback throughout the development process.

LOGISTICS PLANNING WITHIN THE LAST PLANNER SYSTEM FOR HIGHWAY CONSTRUCTION PROJECTS

Bruno G. Antonini[1], Fernanda M. Pimentel[2], Marcus C. T. Fireman[3], Bernardo M. B. S. Etges[4], Frederico R. Campos[5], João de Lima Junior[6], and Bárbara K. Kronbauer[7]

ABSTRACT

This study presents a new Logistics Planning methodology implemented in a highway construction project from May to December 2022. The objective was to analyze the feasibility of using a Logistics Planning method with the help of a Visual Board, in conjunction with the Last Planner System. The research method utilized was the Design Science Research. A 6-step method was developed to enhance the Lookahead Planning routine. After the implementation of the methodology, a decrease in the total and equipment-related impact hours in the productivity fronts was observed, as well as an improvement in the PPC indicator and labour productivity in each service front. It was concluded that the use of Visual Management, combined with Logistics Planning, stimulates the engagement of the operation's employees around the project schedule, increasing the accuracy of the Master Plan.

KEYWORDS

Lean construction Highways, Last Planner System, Visual Management, Lookahead Planning, Logistics Planning.

INTRODUCTION

Ever-shrinking margins and ever-increasing high-performance goals prompt construction companies to adopt the lean methodology in their construction sites (Tezel et al., 2018). Among all the tools within the Lean Construction methodology, the Last Planner System (LPS) stands out and aims to help in the implementation of Lean concepts in construction sites. Its goal is to create mechanisms to increase schedule reliability (Ballard & Tommelein, 2021). LPS seeks to transform long-term activities (what needs to be done) into medium-term activities (what can be done) by eliminating production restrictions and providing a bank of activities ready to be

executed in weekly work plans, thereby generating confidence in the outlined action plan (Ballard, 2000).

In the building construction sector, a wide range of papers aimed at the adoption of LPS can be identified. The same, however, does not occur in the context of Highway construction, as the study of the planning and control system applicability is still in early stages.

Given the above, the objective of this paper is to analyze the feasibility of using a logistics planning method with the aid of a Visual Board, aligned with LPS. The hypothesis that this study sets out to test concerns understanding that the possibility of using Visual Management, combined with logistics planning, would stimulate the engagement of field teams in the lookahead planning, thus increasing the ability to identify constraints and the resource planning. The methods used in a specific case study and the results found are explained below.

LITERATURE REVIEW

In order to better understand the application of the Logistics Planning within the Last Planner System in road construction projects, the state of the art was sought in the International Group for Lean Construction (IGLC) database. On January 3rd, 2022, the keyword "Highways" search resulted in 17 articles. The vast majority of the scientific articles published on the page refer to the development of a Lean Construction implementation project aimed at English highways, called Highways England.[8]

Highways England is a government initiative that aims to improve the overall performance of the supply chain and meet the performance goals and cost reduction targets established by the government of the United Kingdom (HE - Highways England, 2018). The Lean implementation pilot project was developed throughout 2006, culminating in the paper published by Ansell et al., in 2007. The authors analyzed production constraints, measured the number of weekly planned and completed activities, and analyzed the root causes of non-fulfillment with the scheduled tasks through routines and tools based on LPS. Furthermore, they noticed that only 3.6% of the short-term planned activities coincided with the activities set out in the long-term planning, demonstrating little assertiveness of the Master Plan.

Subsequent studies aimed at addressing the reasons for non-compliance and low accuracy of the long-term schedule, as inferred from Fullalove (2013), and the improvements perceived from a more collaborative planning, such as the Last Planner System (Drysdale, 2013). From the identification of these early works on the low engagement of collaborators around the implementation of Lean, subsequent projects aimed to bring new elements that could help with this problem, such as Visual Project Management (Tezel et al., 2016) and the implementation of continuous improvement cells in the highway sector (Tezel et al., 2018a).

Although the aforementioned studies address tools and routines based on Lean Construction, such as LPS, Continuous Improvement, and Collaborative Planning, several studies have found that there is a need for more visual management on the work fronts to increase engagement with field teams. Thus, it is necessary to conduct a preliminary study of the specific needs of each project to avoid the risk of implementing these tools without a clear purpose (Tezel et al., 2018b).

According to Dahlberg and Drevland (2021), the delay in the delivery of materials, equipment, and tools is the main cause of production delays. Dawood et al. (2010), analyzing earthworks operations, share a similar view, pointing out that poor resource planning (materials, equipment, and tools) and low productivity are among the main factors for increased costs and

[8] Of the 17 articles found, 13 were published by authors from the United Kingdom, 9 of which were the result of the Highways England project. The other articles found will not be extensively analyzed here, since they do not relate directly to this research topic.

schedule overruns. Thus, the logistics and dimensioning of resources within the construction site must be planned in order to assist in the flow of balanced production.

Visual information can be an excellent strategy to assist in resource planning and logistic planning, alleviating a gap in the Last Planner System (LPS) and facilitating the visualization of constraints, leading to higher engagement from teams in collaborative meetings. In recent years, there has been an increase in the number of Visual Management (VM) studies in civil construction. However, the visualization of these effects is still done in a conceptual way. Within the context of highways, the study of using Visual Boards is still incipient, with few empirical studies (Tezel et al., 2016b). From the best of the authors' knowledge, the connection between logistics planning and VM is barely explored in the literature.

It is noted that, in the context of highways, visual information is generally limited to health and safety indicators. Nonetheless, it is clear that field teams want to view information related to schedule, quality and planning processes. Tezel et al. (2016a) showed that implementing Visual Boards on highway construction sites helped in mapping and preventing problems, brought greater visibility to planning and improved the coordination and harmonization of work teams.

METHOD

The methodology adopted in this study was Design Science Research (DSR), a method in which the strategy helps in the search for solutions in the field of innovation and continuous improvement by using the research strategy (Carneiro et al., 2019). This research model seeks to develop valid artifacts and reliable knowledge for problem solving (Van Aken, 2004), reiterating that its use must be developed based on the usefulness it will have for the organization and literature, by developing and applying theoretical knowledge (Monteiro, 2015; Järvinen, 2007; Lukka, 2003). The artifact developed was the Collaborative Method of Logistics Planning for sizing the quantity of equipment needed over a period of 6 weeks, linked to a Visual Framework, for highway construction projects.

The method was applied in a pilot study of a highway construction project executed by Company A. Company A operates in the heavy construction sector, offering infrastructure solutions, and has over 1200 employees in its workforce. Company A did not have a specific structured planning method, at the long-term level there was a Gantt-based planning software due to the need established in the contract with the highway concessionaire, the lookahead planning didn´t exist and at the short-term level there was formal planning but without collaboration between team leaders. However, the isolated tools was not sufficient to meet the complexity presented in this project and did not allow the visualization of possible conflicts between different services in the same locations.

The company was starting a Lean transformation process, and this project was chosen as a pilot due to its size and complexity, as the project was already partially executed when Company A entered the project. The construction project, still under construction, is located in Brazil, in the state of Santa Catarina, and has 37 km of extension. The authors of this work were part of the Lean implementation nucleus, consisting of external consultants and collaborators from Company A. The implementation of Lean Construction within the pilot study started in May 2022 with the application of the Last Planner System (LPS).

The steps followed by the research were: (i) identification of the problem after the implementation of the LPS; (ii) mapping Company A's internal systems for adjusting resources; (iii) development and application of the method; (iv) review of the method based on data analysis; (v) assessment of the methodology developed through employee survey and result analysis. The survey was focused on understanding the evaluation of the employees regarding ease of use and usefulness.

The Logistics Planning method was developed iteratively, taking inspiration from the playful approach of some logistic simulation software such as AnyLogic. The parameters and resources sizing calculation were based on Mattos (2019). Table 1 summarizes the main sources of observation used to refine the artifact and collect data for analysis.

Table 1: Main sources of evidence.

Case Study	Highway Construction Project
Duration	6 months
Number of meetings	12 meetings (estimated total of 24 hours)
Participant observation in planning meeting	Bi-weekly Logistics Planning meetings and daily huddles
Role of the observer	Initially led meetings during routine implementation. Then transitioned to a spectator providing insights and improvement suggestions for meeting management
Direct observations	Informal conversations and observations during the daily huddles
Document Analysis	Schedule, daily huddles, weekly plans, and the materials factory, internal processes for hiring and mobilizing equipment and purchase of material
Employee Survey	10 Collaborators (field managers, engineers, project director, and contract manager)

The project involves a two-lane highway with flexible pavement and five layers. Excavation is done first, followed by rock fill and subgrade layers (25 cm each) locked with fine material. Sub-base layer (25 cm) follows with Macadam and fine material. Then the Single-Sized Gravel (SSG) base layer (15 cm) and the hot mix asphalt (HMA) pavement layer (3 parts) are added. Understanding each layer is important for specific equipment and cycle times, affecting logistics planning.

METHODOLOGY DEVELOPMENT AND INITIAL RESULTS

PROJECT DIAGNOSTIC ASSESSMENT

The project started with the introduction of the LPS and its management tools, as requested by Company A. A Master Plan was developed using the Time-Location planning technique and daily Check in-out meetings were established. Using these daily routines, relevant data and key performance indicators (KPIs) were collected to detect issues in the field. The analysis revealed that equipment-related interferences from field teams accounted for 43% of all interferences, with much of it stemming from inadequate supply to the service fronts. Further on-site inspections were carried out to determine the true nature of the problems reported by the field teams.

A notable aspect of the project undertaken with Company A is that two other companies had previously carried out separate sections of the highway. This added complexity to the planning process, as the activities were not performed in a linear manner and internal logistics were hampered by the extended travel required to cover the scattered activities throughout the construction site.

During the workflow analysis in the service fronts, a clear connection between value aggregation and equipment resources was identified. Figure 1 showcases one of these observations carried out in the Macadam work front in August 2022. During a 1 hour and 30 minute observation period, it was observed that the tractor remained idle for 52 minutes, accounting for 58% of the total time. This idle time is represented in red in Figure 1, while the green section represents the time when the equipment was active. This revealed that the equipment quickly returned to inactivity after a period of truck unloading. As a result, the number of dump trucks was adjusted to increase the delivery frequency of materials and meet the daily production target set in the Master Plan. The findings align with those in the literature. Haronian and Sacks (2020) carried out three studies to calculate value aggregation in earthwork fronts and found that the percentage ranged from 36% to 58% of the total work time.

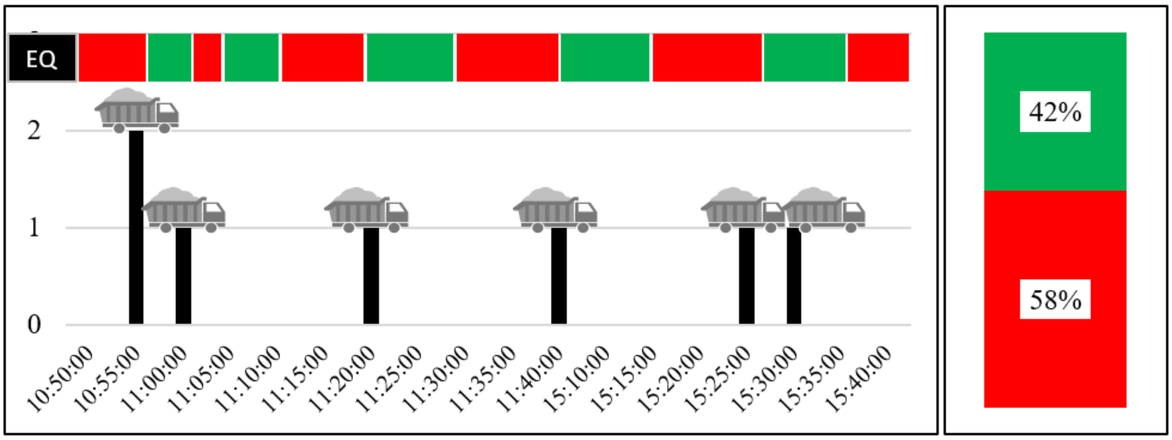

Figure 1: Field observation based on chronoanalysis carried out on the macadam front in August 2022.

Additionally, initial interviews were conducted and it was identified that field staff had difficulty visualizing medium-term constrains when presented with work plans outlined in the standard LPS models. This highlights the shortage of the medium-term model, as field employees struggled to map and size equipment for the sections that needed to be produced. Given this information and the imbalance of field resources, it became necessary to develop a routine that could dimension the necessary resources in advance for the project's execution, while also having the action plan for the coming weeks represented in visual charts alongside the project map.

Given the demand for the improvement of LPS routines for field teams, a complement to the classic framework by Ballard (1994) was proposed, as shown in Figure 2, combining the Look Ahead Planning routine with Logistics Planning. To this end, a method was created for sizing equipment needs according to what was planned in the Master Planning, using the expected productivity and cycle times of each equipment, in order to better visualize equipment-related restrictions.

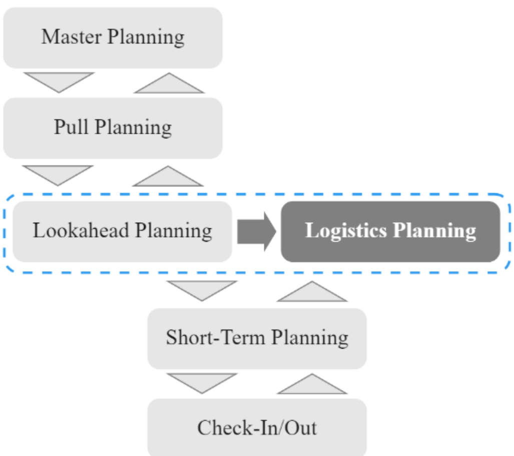

Figure 2: Proposed Logistics Planning and LPS Framework, adapted from Ballard (1994).

Logistics Planning is positioned alongside the Lookahead Planning step due to their similarities. Lookahead Planning seeks to visualize a production horizon, based on updates and adjustments to the Master Planning, and through the mapping and removal of constraints, allocate only activities that are cleared for execution in the upcoming weeks (Ballard, 1997).

To determine the study horizon in this routine, the average time for driver and equipment mobilization was checked with the human resources and equipment departments within the company. During the study, it was found that the average time between the request and the entry of employees with the equipment took, on average, 4 weeks. Hence, the method presented here takes place within a 2-week interval, with a planning horizon of 6 weeks, in order to have a reasonable hiring time when an eventual need is identified.

METHODOLOGY DEVELOPMENT

After conducting this diagnosis with the work teams, the need to hold a Logistics Planning meeting on the construction site to calculate the quantity of equipment was identified. A 6-step model was then developed for conducting Logistics Planning in highway construction projects.

Step 1: Scope Analysis

In this first step, it is necessary to have the Master Plan developed, with a clear action plan, as well as to have the productivity of the equipment of each service fronts, as shown in Figure 3a. In the Company A scenario, six main services are identified: Excavation, Rock Fill (or Land Fill), FEL (Final Earthwork Layer), Macadam, SSG (Single-Sized Gravel), and HMA (Hot Mix Asphalt). For each of them, there are productivity rates planned to meet the long-term planning, along with the equipment's own productivity. With this information, it is possible to analyze the production volumes for each of the lots and the deadlines for completing each activity in the location where it should be executed.

Step 2: Sequencing of Fronts

After completion of Step 1, the action plan is reviewed and defined with the field team, as well as the sequencing of the service fronts. This step aims to map out the ideal workflow for executing the work, considering the priority production batches and also the contractual milestones imposed by the client. As shown in Figure 3b, the fronts that will be worked on over the next 6 weeks are placed in the Visual Board. Different colors were used for each service in order to visualize the workflow over the weeks. It is also important to consider the interdependence between activities, so that all can be completed in an adequate manner.

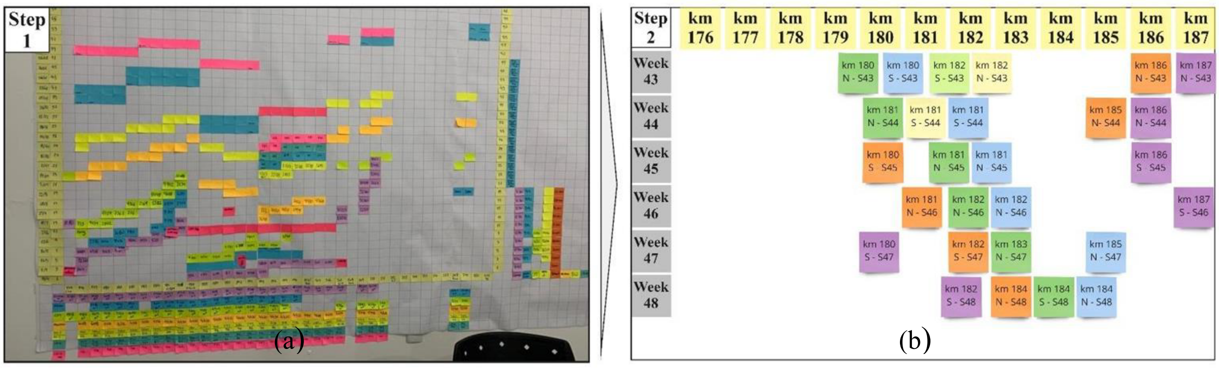

Figure 3: (a) Step 1: Master Plan defined; (b) Step 2: Visual Board with 6-week planned work fronts.

Step 3: Supply Logistics

In this step, the feasibility study and analysis of material extraction sites is carried out in order to attend the construction production and visualize the material supply routes and note the necessary distance for material transportation. The Visual Table indicates where the material pickup (Storage – ST) and deposit locations (Land Fills – LD) are, as shown in Figure 4a.

Step 4: Supply Cycles

With data already analyzed in the field, such as cycle time (Figure 4a), material loading and unloading, as well as the information on location, execution deadline, transportation distance, and heavy machinery productivity, a calculation is made of the number of dump trucks required, as well as the number of trips needed by each truck throughout the day, to meet the established goals. The information on the compliance with the plan is then collected in daily huddles, in order to have an agile response and schedule corrections within the same week.

Step 5: Resource Sizing

With the drawn plan, it is possible to balance the best workflow, respecting large mobilizations and demobilizations of trucks from week to week. Thus, the aim is to arrive at a plan that is more consistent with the reality of the work. The logistics planning is updated every 2 weeks, i.e., there is always a 4-week protection for the planned horizon, which, as mentioned earlier, is sufficient time to mobilize equipment and drivers within the company. With the work fronts and locations of material removal and deposit defined, as well as with the number of dump trucks established, it is possible to design the truck routes on the Visual Board, as shown in Figure 4a, thus starting Step 6.

Step 6: Constraint Analysis

As part of the Lookahead Planning routine, in this phase, employees are encouraged to map out any constraints that may hinder the execution of the proposed plan. With the Logistics Planning Visual Board positioned below the job site map, employees found it easier to map production risks and see attention points that could impact labour productivity in each service front. From the mapping of the restriction, proactive actions can be taken to mitigate or even eliminate it before it becomes an interference and, as a consequence, impacts the productivity of the work front. For each mapped constraint, actions and responsibilities are listed on another Visual Board, to eliminate them and thus release the activity for execution. To protect production, these actions are transferred to a spreadsheet by the Planning team and sent to each of the responsible service front parties. As the actions are completed, they feed the Constraint Removal Index (CRI), as shown in Figure 4b.

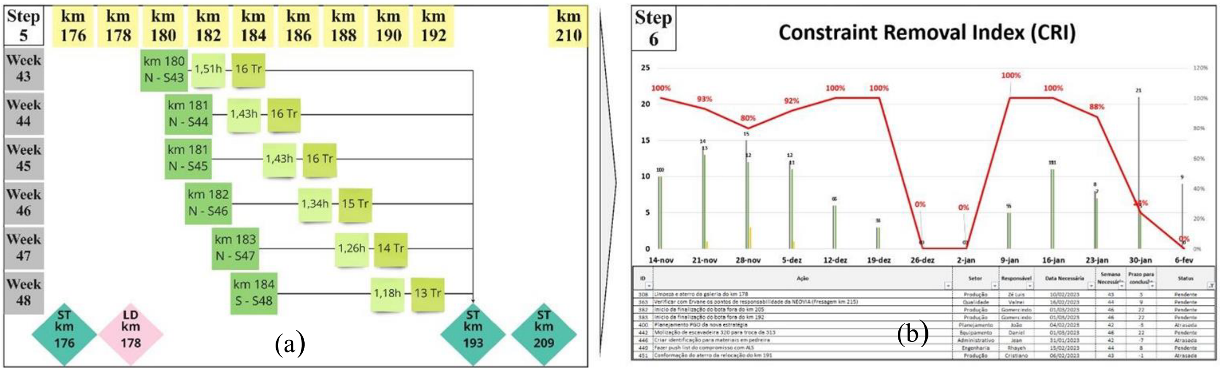

Figure 4: (a) Step 3 to 5: (3) Locations and routes of deposit and withdrawal of material mapped; (4) calculation of the cycle time; (5) Sizing and balancing resources; (b) Step 6: Control of removal of restrictions based on visualizing obstacles to productivity.

As these 6 steps were developed, it was possible to observe a greater level of worker and field team engagement in adhering to the long-term planning, considering the increase in PPC, as shown in Figure 7a, and the productivity in the field, Figure 7b. Furthermore, with the implementation of the Logistics Planning Visual Method, workers were observed to have developed a higher level of responsibility regarding the elimination of the mapped restrictions. Beyond participation in the meetings, workers would take photos of the visual board, presented in Figure 5 in order to meet established goals. This team engagement confirms what Ballard and Tommelein (2021) bring in their LPS benchmarking work. The Lookahead meetings should be collaborative, involve all the responsible parties from the service fronts, including the decision makers and on-site workers who can provide the necessary information for the meeting to proceed. Only in this way is it possible to create a functional activity sequencing plan with flows and transformations.

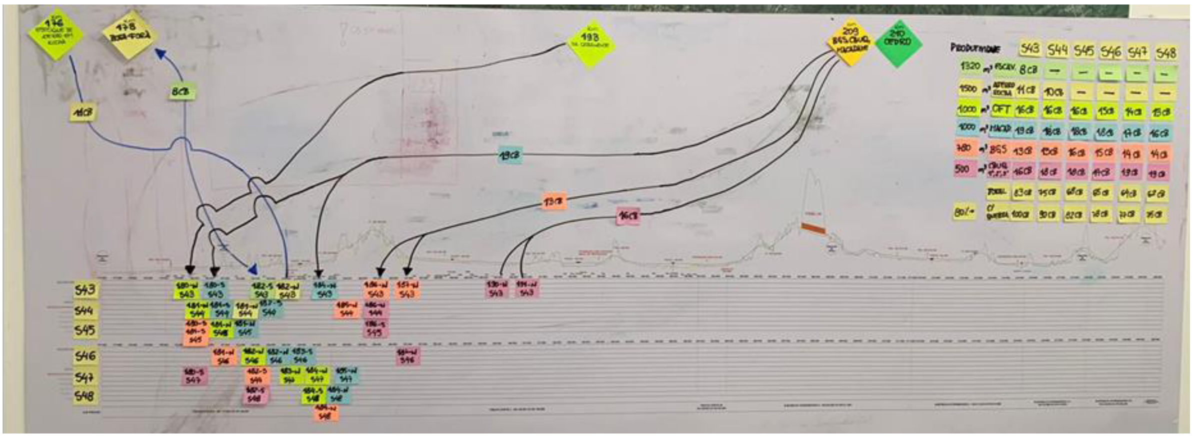

Figure 5: Routine of Logistics Planning and Visual Table of sizing trucks and routes

INITIAL RESULTS

After the implementation of the 6-step Logistics Planning method, an improvement could be noted in the primary indicators consulted, when compared to the months of June, before the beginning of the Logistics Planning meetings, and November, after the beginning of the Logistics Planning meetings. The total hours of impact correspond to the hours that services remained stopped, whether due to lack of material, equipment, project, or other factors. Hours related to equipment refer specifically to those hours that services remained stopped due to a lack of equipment. Figure 6 shows that the total number of hours of impact in productivity during the Check in-out meetings decreased from 881 hours in June to 278 hours in November, which represents a 68% decrease in total hours. Similarly, a decrease in the hours of impact related to equipment was observed, from 43% (374 h/881h) in June to 29% (81h/278h) in November.

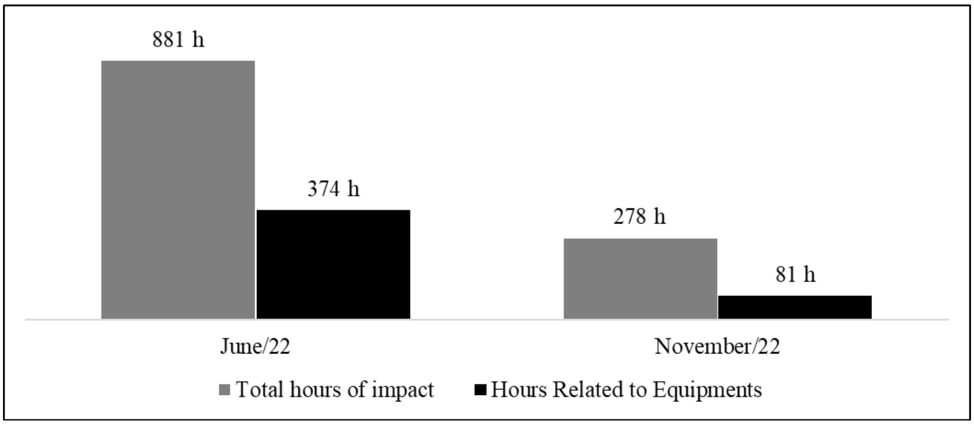

Figure 6: Hours of impact in productivity, total and equipment-related.

There was also an improvement in the PPC indicators, as shown in Figure 7a. The PPC indicator showed continuous growth since June, from 20% to 52% at the end of the collection in November. This percentage is due, among other factors, to the complexity of the section, as mentioned during the implementation of the LPS, and due to the recurrent rains in the region during that period consisting of rain on 41% of the days.

The data found is corroborated by Tezel et al. (2016a), who, in two road projects, identified an increase in PPC after the implementation of visual management on the construction site. In the first, PPC increased from 60% to 85%, while the second had an average PPC of 76%. Drysdale (2013) also achieved similar improvement values, rising from 59% to 85% in Percentage of Plans Concluded.

Figure 7b shows an improvement in the indicators of labour productivity. This indicator was used to identify whether the Logistics Method helped the team, resulting in an increase in production from the Sub-grade, Sub-base, and Pavement Base fronts. Thus, the calculation used to verify this increase was the ratio between the monthly volume produced and the number of hours worked. For the Sub-grade front, there was a 64% increase in productivity between June and November, while the Sub-base and Base front saw a 7-fold increase in productivity.

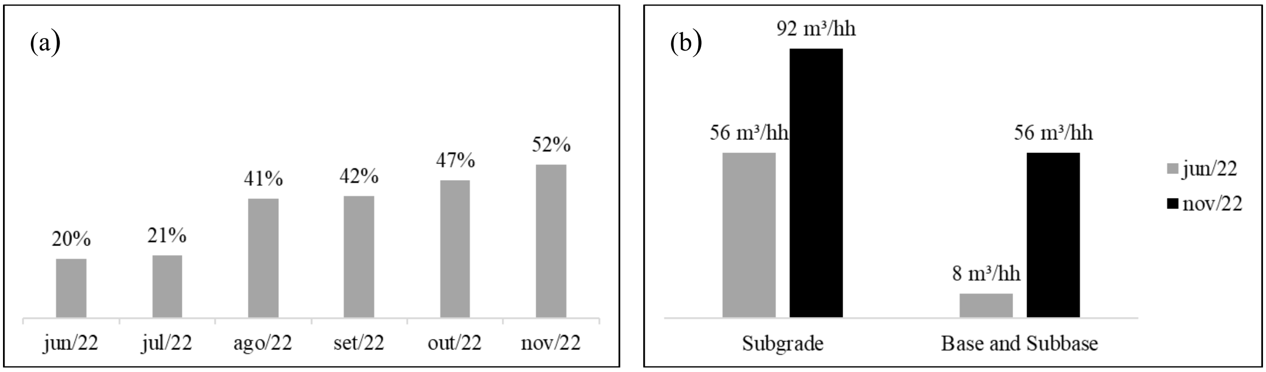

Figure 7: (a) Percentage of Plans Concluded (PPC) during the development of the Project: (b) Increase in Productivity of the service fronts before and after starting the Logistics Planning meetings.

In order to evaluate the usefulness and effectiveness of the proposed method in mapping constraints, and to separate the normal learning effect of teams, a survey with ten collaborators were done, including field managers, engineers, project director, and contract manager. Their responses, tabulated in Table 2, indicate a widespread approval of the method. While three out of the ten interviewees reported challenges in applying the method, all of them expressed the inclination to recommend it for future projects.

Table 2: Main sources of evidence.

N	Questions about the Logistics planning method	Strongly Agree	Agree	Disagree	Strongly Disagree
1.	Do you use the method for highway construction in your company?	9	1	-	-
2.	Is the method used by the company efficient?	8	2	-	-
3.	The method used by the company has improved the mapping and analysis of constraints?	9	1	-	-
4.	The method used by the company has improved the perception of resource sizing?	9	1	-	-

5.	The method used by the company has improved the visualization of where to deploy resources?	8	2	-	-
6.	Do you consider the logistic planning tool used by the company easy to apply?	7	3	-	-
7.	Considering usefulness and ease of use, do you approve of the method used by the company?	9	1	-	-
8.	Would you recommend the use of this method for future projects?	10	-	-	-

CONCLUSIONS

This study presents a new Logistics Planning methodology implemented in a Highway project between May and December 2022. The objective was to analyze the feasibility of using a logistic planning method with the aid of a Visual Board, combined with the Last Planner System.

The methodology employed is well-suited for LPS and is complementary to Lookahead Planning, given their similarities: (i) definition of the production batch sequencing; (ii) mapping and removal of production constraints; and (iii) the need to hold collaborative meetings. Six steps were developed to increase the lookahead planning, consisting of: 1. Scope Analysis; 2. Sequencing of Fronts; 3. Supply Logistics; 4. Supply Cycle; 5. Resource Sizing and 6. Constraint Analysis.

After the implementation of the methodology, a decrease in the number of impact hours (total and equipment-related), was observed. Additionally, there was an improvement in the PPC and productivity indicators of the service fronts. The results are corroborated by the literature (Tezel et al. 2016a; Drysdale 2013). Furthermore, the more visual and collaborative format of the meetings helped in the engagement of the field teams, who took photos of the developed visual board for on-site use.

Therefore, it can be concluded that the possibility of using Visual Management, combined with logistics planning, stimulates the engagement of the operation's employees around the construction schedule, increasing the accuracy of the Master Plan, confirming the hypothesis proposed.

An interview was conducted to perform a cross-analysis between the users' perception regarding the usefulness and effectiveness of the method. It was possible to perceive that the method was widely approved of, although some interviewees found it challenging to implement. Nonetheless, all interviewees expressed their willingness to recommend the method for future projects.

Despite finding improvements with qualitative and quantitative data, the implementation of Lean in highway construction projects must take into consideration the need to actively involve field collaborators in routines that facilitate the visualization of restrictions, in a simple manner that is easily understood. Companies need to go beyond simple implementation and actually incorporate supply chain and equipment routines into their projects, making strategic decisions aimed at increasing efficiency in the sector.

LEAN CONSTRUCTION THROUGH WASTE REGISTER METHOD: A CASE STUDIES PROJECT IN INDONESIA

Rina Asri Aisyah[1], Kevin Gunawan[2], and Abdhy Gazali[3]

ABSTRACT

Waste in construction projects is a significant research topic globally, including in Indonesia. The lean construction concept identifies any waste as a non-value added. Different waste management techniques categorize waste as either physical or non-physical. Based on literatures explain that most of project construction is bad on waste registration. The paper focuses on implementing lean construction for physical construction waste. Furthermore, this article presents Indonesian case studies to illustrate the impact of lean construction on building projects.

The study analyses waste management impacts across three periods of time. Lean waste management provides an early warning evaluation in the short term that are used as an indicator, so the project can evaluate and follow up as an effort to reduce waste, which in this study shows a reduction of waste from 2.1% to 1.7%. Addressing common waste in the medium-term increases project productivity by 50% and improves cost and duration efficiency. It reduces many possible wastages due to defects, overproduction, non-utilized talent, inventory, transportation, motion, waiting, and extra processing (DOWNTIME). Sustainable waste reduction practices can become a productivity standard in the long term by continuously improving the cycle of writing, categorizing, analysing, and writing for each job.

KEYWORDS

Lean construction, waste, productivity, value, continuous improvement

INTRODUCTION

The complexity of project construction has been considered based on production management, that must be designed, scheduled, produced, and presented in a timely manner. It is therefore characterised by delays and has often experienced cost and time overruns. (Vidhate, Tejas et al., 2018). A significant amount of construction waste has depleted the industry's total performance and production, and thoughtful action should be taken to address the undergoing state of affairs. According to the Lean Construction Institute (2004), the construction industry accounts for approximately 57 per cent of productive time lost (Ansah, Richard et al., 2016).

Waste in the construction industry not only a problem for the construction industry, it also has an impact on the economy of a country as a whole. The elimination of material and time wastage would improve the performance of the project, increase value for individual clients as well as providing a positive impact on the domestic economy (Polat & Ballard, 2004).

In recent years, many research studies around the world have focused on waste from the construction industry. Construction waste research suggests that a construction project produces large amounts of waste (Esin & Cosgun, 2007; Wanga et al., 2010). A variety of methods have been used over the past decades to reduce construction waste as well as its impacts. One of the most effective techniques is the adoption of a lean strategy in the construction industry. Lean construction is also the result of an innovative approach to production management to address the complexity of project construction. The fundamental idea of Lean Thinking is to cut waste in order to increase performance. Project managers generally take the view that "waste" is tangible construction waste. However, there is observable waste in the construction process, often referred to as "non-adding activities" in the lean construction method. (Hosseini, et al., 2012).

Construction management community efforts to understand waste are relatively low in comparison with other topics. Many research on waste has tended to focus on effects rather than avoidable root causes (Viana et al., 2012). Lack of integration of waste management into planning and control procedures and requirement not only to confirm but also to observe the efficiency of building processes (Formoso et al.,1999). In addition, it is necessary to enhance the model in order to obtain a precise understanding of the areas of lean construction principles and techniques where Indonesian contractors are deficient and require enhancement and promotion (Abduh et al, 2005).

Usually, project managers define waste as physical construction waste, which mostly includes material losses (Koskela, 1992). However, lean thinking focuses primarily on waste produced during a construction process, which can be separated into two main types: waste arising from the nature of the process and waste arising from work without added value (this group includes wait times, value-neutral activities and transportation of materials). It should be noted that not all waste related to the construction process can be attributed to the process itself or to non-value-added activities. But since only one class predominates, it will be assigned to each subdivision (Hosseini, et al., 2012).

Productivity and waste metrics can complement one another. There are similar fundamental reasons for waste and production research: to learn further information on the current situation in order to make improvements. Consequently, it can be useful to look at waste and productivity levels (Forsberg & Saukkoriipi, 2007). Based on literatures explain that most of project construction is bad on waste registration. This because of project complexity that effect the activity of collect and analysis waste never successful. So that, waste in the project already known large in the end of period time projects.

This research focus on the implementation of the lean construction principle in waste management, especially for physical construction wastes. We apply the Pareto item principle to the waste register method for materials such as concrete and steel works. An actual experiment is required for testing and assessing waste mitigation due to lean construction principles implementation in construction processes. The study therefore focused on strengthening operations in building projects in Indonesia.

WASTE MANAGEMENT

TYPE OF WASTE

The seven wastes of lean production that are often found are as follows: 1. Transport: unnecessary and ineffective flow of information; 2. Inventory: information waiting to be processed; 3. Motion: editing, verifying or creating inquiries; 4. Waiting: awaiting information; 5. Overprocessing: verifying, reprocessing, repeat applications, new procedural codes; 6. Overproduction: multiple bills, duplicate files, minor debt lawsuit; 7. Defects: complaints, corrupt or mis-coded data, recording and transcription errors, unauthorized procedures (Koskela et al, 2013). Several candidates were proposed for the eighth type of waste (Macomber & Howell, 2004) identify several of them, which can be categorized as: failing to use people's talents, skills and abilities; wasting information; wasting behaviours; and wasting good ideas. Waste comes in eight different forms in lean manufacturing. The seven well-known wastes focus on the production process, but the eighth has a direct impact on management's ability to employ staff (Brito et al., 2019). In this paper the eight wastes are defined by DOWNTIME (Defect, Overproduction, Waiting, Non-Utilizing Employee, Transportation, Inventory, Motion and Extra-Processing).

Waste identification will undoubtedly impact the results of the projects implemented and support sustainable development. The main pillars of the sustainable concept itself are people, planet, & profit (Crane & Matten, 2004), or the triple bottom line. Therefore, it is crucial to consider the needs of people or social aspects, the planet or environmental factors, and profit or economic aspects, especially in lean construction implementation. The waste will undoubtedly directly impact the environment, but not only that, because construction waste indeed involves collaboration on the lean principle of "respect for people," which supports the social aspects of sustainable development. In the end, the expected value in identifying this waste is to reduce costs due to waste that occurs and support profit or economic aspects to realize sustainable development.

WASTE IDENTIFICATION & REGISTRATION

As a result, we can anticipate the discovery of waste chains during the review of process waste. These are a range of causes and consequences in which one waste causes another. (Koskela, Bolviken, & Rooke, 2013). For example, one of the usual construction industry problems is the delivery process of the materials (Thomas et al., 2022). Equipment and workers are often held in abeyance because delays occur in the supply of materials and the finishing of preliminary work. This issue reduces productivity and prolongs the duration of the project (Tommelein, 1998).

However, responding to downstream demand too quickly results in a waste of inventory and may result in additional expenditures. Another fundamental lean manufacturing strategy known as "pulling" to ensures just-in-time synchronization between upstream and downstream processes. It is based on the notion that the upstream should not deliver a product or service until the downstream request it (Womack & Jones, 1996). Macomber & Howell (2004) identify other waste: failure to use people’s talents, skill and capabilities; information waste; behavioural waste; and wasting good ideas. This type of waste was categorized non utilize employee due to the practice of improvising to compensate for inappropriate upstream operations is particularly worrying as a major waste in construction (Koskela, Bolviken, & Rooke, 2013). If we compile this type of waste, there is eight waste taxonomy, defect (making defective products), overproduction, waiting (time on hand), non-utilize employe, transportation, inventory (stock on hand), motion (movement), and extra processing (over processing).

RESEARCH METHOD

This study uses trend and regression analysis to conduct studies related to the relationship between the parameters recorded in the waste register that occur in the project with other parameters in the production planning that is being carried out. The waste register in this study records two major elements: bodily waste and productivity. These two major elements are then recorded and analysed in a monthly basis according to the data realization and evaluation that can be carried out in production planning in the field, which in this case is carried out using the Last Planner System (LPS) method. Project records between the material that is recognized by the owner and the material that we bring in on a monthly basis, in order to get the trend from the pattern of waste that occur.

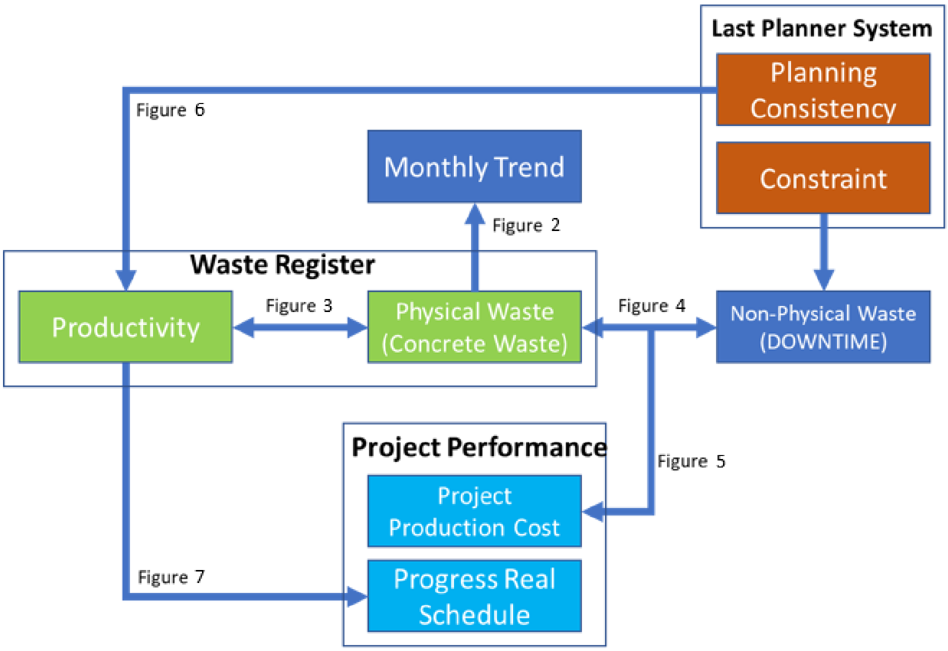

Figure 1: Research Method

The physical waste registration carried out in this study is done by examining the physical parameters that can be measured, namely concrete waste. This is done so that these parameters become a comparison with other performance parameters, which will be correlated because of using the waste register. The concrete material was chosen because it is one of the dominant (pareto) materials implemented in the work items on the project in this study.

Furthermore, an analysis is also carried out related to non-physical waste obtained from constraints that occur in the production planning stage using the Last Planner System (LPS). This constraint is then converted related to the impact of waste generated in the realm of DOWNTIME (defect, overproduction, waiting, non-utilize employee, transportation, inventory, motion, and extra-processing). In this study, the LPS result is used to see the effect of constraint analysis which then related to the concrete waste materials to be measured. This method applies so that the root cause analysis carried out in the LPS stage could become one of the tools that help to discuss the result of waste register that filled in.

WASTE REGISTER METHODOLOGY: IDENTIFY WASTE & PRODUCTIVITY

The waste register is a tool to identify patterns that occur in projects. This pattern is a collection of data that is recorded every month by the project team. The recorded data is a comparison of material that is recognized with what the project team has worked on. recording every month, allows us to see the pattern of productivity that occurs. Productivity is below standard, there must be a waste factor that needs to be evaluated. This is where we can find the direct impact of the waste that occurs with the productivity of a job. We record this waste (physical waste and other downtime waste) per month, the monthly data will be used as an evaluation for the next month as long as the work is still ongoing. The results of the evaluation serve as an early warning if the waste that occurs interferes with the target that has become a joint agreement, both concerning cost and time. The data per month can also be a trend which we can analyse to find the patterns, which makes it possible to find the characteristics of waste based on the type of building (high risk building, hospital, airport, building revitalization."

With respects to materials, equipment and labour, and productivity parameters, we used to determine waste register as a method to require that the objectives of this research suggest various goals in the waste register over time. In the short term, the waste register provides an early warning evaluation of budget costs according to budget waste, potential waste, actual waste, and productivity. In the middle term, mitigating common waste significantly increases productivity as well as project efficiency related to cost and project duration. It reduces many possible wastages due to defects, overproduction, non-utilized talent, inventory, transportation, motion, waiting, and extra processing (DOWNTIME). In the long term, sustainable conduct of waste mitigation can become a productivity standard by iterating the cycle of writing, classifying, analysing, and writing for each work. In this waste register, the parameters of the physical waste that are recorded are concrete waste materials. The unit used in this study is the unit that applies in Indonesia where concrete waste is defined as a percentage (%) and concrete work productivity is defined as m3/OH where this unit is equal to 1 m^3 of concrete produced by one person in one day (m3/man). -days)

CASE STUDY: BUILDING PROJECTS IN INDONESIA

This study is a case study from a building project that recorded waste and productivity on the waste register tools and implemented the Last Planner System method in controlling production on the project. The following is a project profile that is the focus of this research.

Table 1: Building Project Study Case in Indonesia

Project Name	Project Value (before tax)	Project Type	Location	Duration	Contract Types
A	11.862 €	Public	West Java	21 months	Regular; Unit Price
B	60.585 €	Private	Central Java	21 months	Regular; Unit Price
C	41.363 €	Private	Jakarta	24 months	Design Build; Lump-Sum
D	8.376 €	Public	Jakarta	10 months	Design Build; Lump-Sum
E	21.189 €	Public	Bali	17 months	Design Build; Lump-Sum

ANALYSIS

WASTE TRENDS

This waste trend is an output trend resulting from the monitoring of several projects in Indonesia carried out through the waste register method as a mention earlier in the waste registry methodology. This can be concluded through the time parameter that the more waste is recorded and monitored in a project, the quantity of waste decreases every month (confidence in a trend with an R-value or confidence level of 0.647).

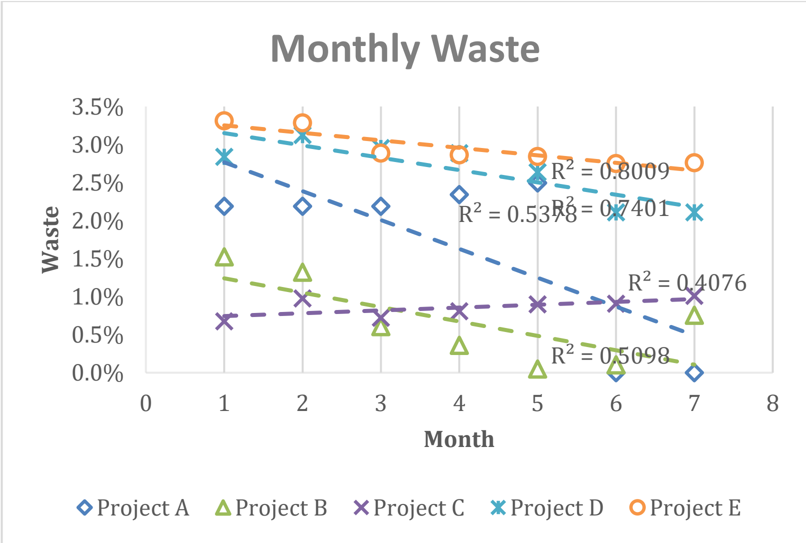

Figure 2: Comparison Between Waste & Time (Month)

The waste above is physical waste recorded in real terms from the Pareto elements in construction work, namely concrete waste. Based on the graphic in Figure 2, we can see that each project has the same linear pattern, then various trends refer to their activity according to waste monitoring in months. The high R-value means project has been considering doing waste monitoring each month; the highest order is from Project E 0.8009, Project D 0.741, Project A 0.5378, Project B 0.509, then Project C 0.4076.

The data show that Project C gets a positive gradient, meaning their waste is increasing every month. The first waste is already low; therefore, so the following record maintains the low trend baseline. Meanwhile, in the end, waste will increase. Therefore, even though the waste trend of Project C increases, the actual waste is still low. Based on the data in Figure 2, we can see that in the first month the average waste rate was 2.1%. This value shows the excess volume of concrete that occurs from the required initial volume. However, in the 7^{th} month, the measured waste decreased to 1.7%. This indicates that the recording of waste has affected.

Impact of Controlling Waste on Productivity

The waste register records the productivity of Pareto items production to the amount of workforce of each work. This productivity measured in this research is the amount of concrete volume compared to the amount of workforce. The purpose of this parameter is to see how controlling waste could impact productivity results.

The data in Figure 3 shows that the most controlled waste will be the lowest; refer to evidence obtained previously. Therefore, the productivity of concrete works in all projects also will be high. The graphic also shows the trends described by a negative gradient, although this is still a low regression value. Meanwhile, the trends may be explained by the fact that waste monitoring will prevent productivity improvements in the project. The result indicates that the projects have a confident correlation within the average value of regression is 0.350 (moderate). The graph shows an average increase of approximately 50% in the productivity of concrete work based on a decrease in waste from 2.1% to 1.7%. This means that the project could control its waste management and have an opportunity to increase productivity.

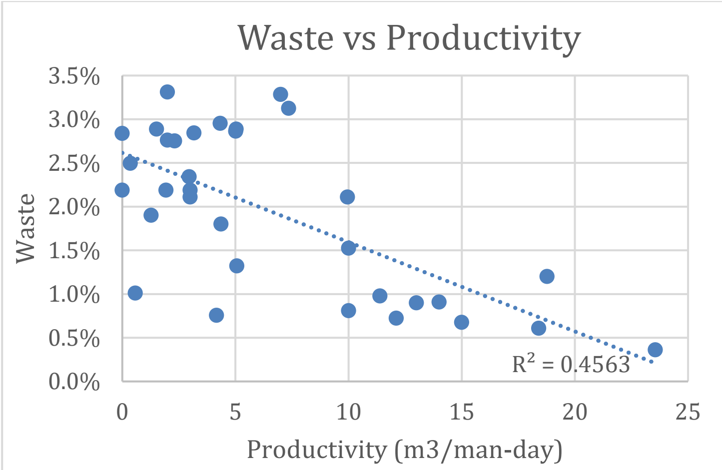

Figure 3: Comparison Between Waste & Productivity

In addition, the other tool of lean construction, the Last Planner System (LPS), already recorded the waste in terms of constraints that happen in the project. The constraint data which doesn't closed then analysed to determine a non-physical waste that we called DOWNTIME (defect, overproduction, waiting, non-utilizing people, transportation, inventory, motion, and extra-processing). This DOWNTIME score is obtained from the constraints that occur in the LPS implementation, as shown in table 2 below:

Table 2: DOWNTIME Score from LPS Constraint

CONSTRAINT / VARIANCE		D	O	W	N	T	I	M	E
1. Procurement of Materials & Equipment	INTERNAL FACTOR	1		1			1		
2. Subcontractor / Foreman (Contract)		1		1					
3. Procurement of Light Equipment / Auxiliary Equipment			1	1					
4. Payment to Vendors				1	1				
5. Design Decisions	OWNER FACTOR	1		1					1
6. Approval Shop Drawing / Method		1		1					
7. Material Approval				1			1		
8. Owner's Request		1	1						1
9. Land Handover / IMB				1		1			
10. Payment from Owner				1			1		
11. Limited Resource Subcontractor / Foreman	EXTERNAL FACTOR			1	1			1	
12. Limited Supply of Materials				1		1	1		
13. Time Limitation & Work Operations			1					1	1
14. Local Vendors Not Qualified		1			1				
15. Previous Work Not Completed		1		1					1
16. Weather / Natural Disasters				1					1

Figure 4 shows the correlation between the physical waste and non-physical waste. The graphic explains that if non-physical waste (DOWNTIME), there is a chance that physical waste will increase. One of the possible things that we can adjust is that this happens because the project cannot maintain physical waste, mostly defects and the overproduction type of waste.

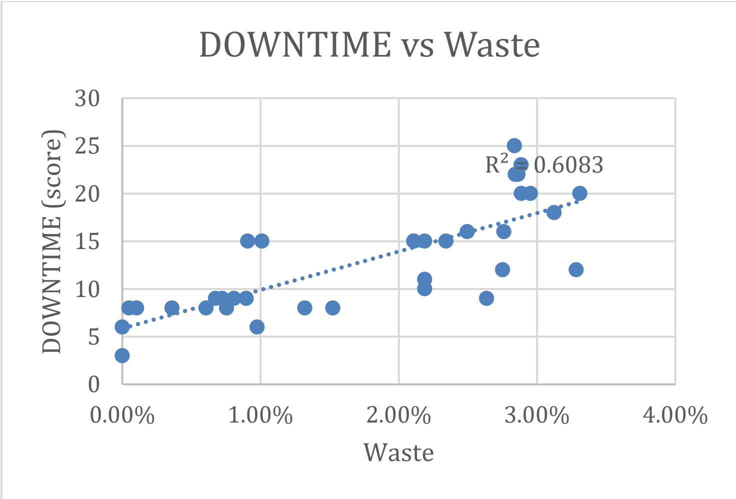

Figure 4: Correlation Between Waste & Waste DOWTIME

Waste & Project Production Cost

Ultimately, this waste monitoring will impact the project's performance. One of the indicators is cost parameters. Recording of waste which is done through the waste register form indirectly affects the cost performance parameters of the project under review. The cost parameters which are compared in the present study are monthly production costs which include direct costs and indirect costs which are reported in real terms every month along with the results of recording waste. It is shown by the percentage of the value, which is the amount of cost incurred compared to project cost, which the owner approves.

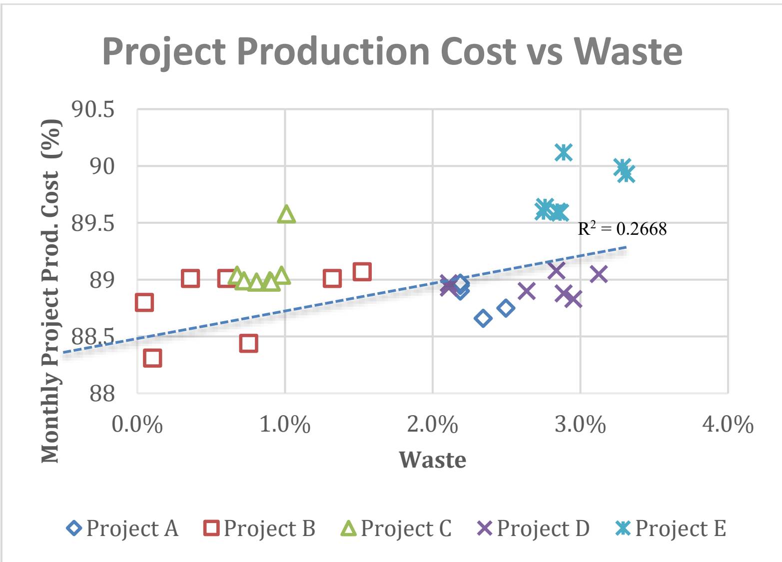

Figure 5: Correlation Project Production Cost vs Waste

The data above (Figure 5.) shows that all the projects have increased waste in the period and that increased production costs will impact on that period. This case, absolutely affected by costs incurred due to waste itself, is Pareto items, so it will impact all cost projects. In addition, if a project could control waste and reduce its value, it would decrease the monthly cost of production. We can see convincing data from the result that when the project can control waste, the cost will decrease with a correlation value of 0.2668.

Planning & Productivity

According to the waste registry method, the productivity value could be compared to the project's ability to plan better using The Last Planner System (LPS). In this case, the well-planned from the previous month will have a high consistency of planning (≥1). At the same time, the project that changes the planning to a lower target plan could be stated as not having good planning (<1). As shown in (Figure 6.), the average concrete productivity is 4.7m^3/person-day, which is considered on the basis of each of the consistent planning results for productivity.

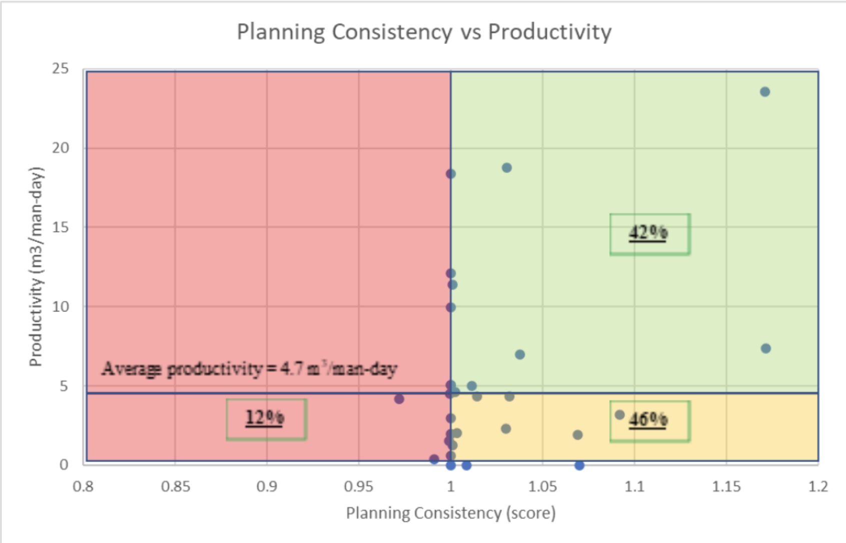

Figure 6: Impact on Planning Consistency and Productivity

The aforementioned data shows that when the consistency of planning when LPS is good (score ≥ 1), productivity is also improving. However, from the quadrant description above, there is still around 46% correlation value between planning consistency and productivity, which is below the average productivity value even though it already has good planning consistency. However, when planning consistency could be better (score <1), there is no doubt that the productivity value will be below average.

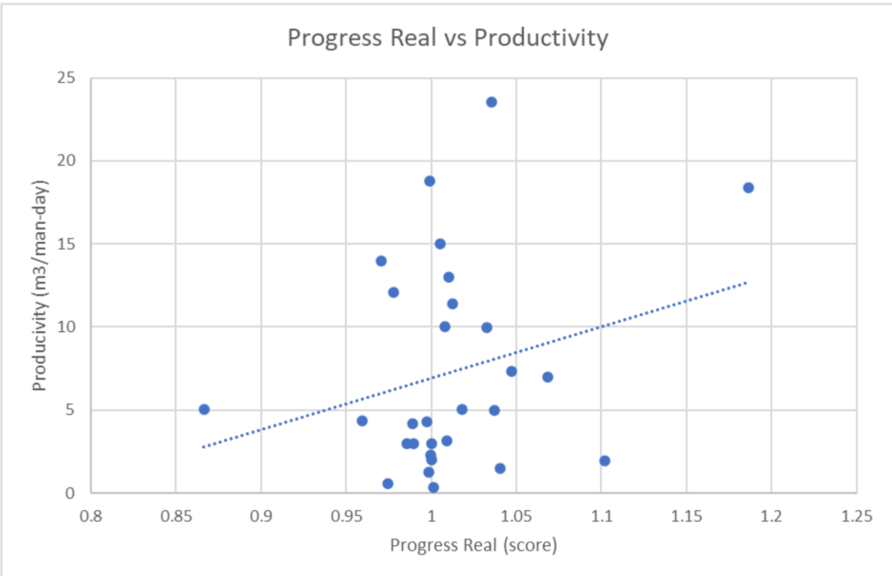

Figure 7: Correlation between Productivity with Progress Score

Ultimately, in line with the above conditions, that high productivity will benefit from a better performance in view of an excellent progress project result with improved productivity. Figure 7 explains that the correlation between productivity monitoring and progress results must be even higher. However, it also shows that the gradient value has a positive trend result. This is because physical waste and controlled productivity are just the dominant types of waste.

CONCLUSIONS AND PERSPECTIVE

The waste register method is a part of lean construction tools in the project for making a better improvement by controlling waste as a routine. Control and monitoring also do the same for the productivity from items of work. We can see from the resulting trend each month that projects with consistent waste recording will better impact the amount of waste in the project. The reason is that there is a control and monitoring process. In the final project, we will show the amount of low waste because we already have an early warning system from the internal team project to control waste. This is indeed affected by better productivity and project costs that can be reduced when controlling and monitoring waste as a routine.

In addition, recording waste project also benefits from seeing the impact of production plan control one of which is the Last Planner System (LPS) or other tools in the project that lead the lean construction concept. However, in the future, we still need to consider non-physical waste, which is being quantified and could be compared to the result based on the time and cost of the project.

INVESTIGATING EMERGENCE OF ‘NEW TASKS’ IN LAST PLANNER® SYSTEM: SOCIAL NETWORK PERSPECTIVE OF PLANNING BEHAVIOURS

Anukriti Gupta[1] and Ganesh Devkar[2]

ABSTRACT

The Last Planner System (LPS) is a collaborative planning process aimed at ensuring the efficient and timely completion of construction tasks and fostering trust among project participants. Despite its widespread adoption, it has been observed that ‘New Tasks’ that deviate from the original plan often arise in construction projects. This paper investigates the planning behaviours behind the emergence of these New Tasks by examining the social interaction patterns within a construction project.

Three different construction projects with varying degrees of LPS implementation were studied to identify the New Tasks that emerge during the execution process. To understand the planning behaviours related to the New Tasks, the interaction patterns of the individuals involved in the look-ahead planning and the weekly commitment planning were mapped using Social Network Analysis. The findings suggest that a tightly bound network exhibits more cohesiveness and can be associated with effective communication and streamlined information flow which leads to fewer New Tasks. While insufficient coordination and ineffective collaboration can be correlated to emergence of higher number of New Tasks. Look-ahead planning is key in this regard as it incorporates collaboration between all stakeholders into the pull-planning of the tasks.

INTRODUCTION

Construction projects involve the interaction between unfamiliar groups of people who come together for the project execution and do not always have complementary objectives. Construction planning is seen primarily as a decision-making and scheduling activity with a primary emphasis on identifying deviations from planned activities rather than refining plans for the upcoming week (Laufer & Tucker, 1987). Traditional construction management systems typically involve the creation of comprehensive schedules at the start of projects. However, the inherent uncertainties in construction projects make it difficult to rely solely on deterministic project scheduling methods (Ahuja & Thiruvengadam, 2004). The variability of the highly fragmented construction industry is captured by the Lean philosophy, based on the Toyota

Production System by Taiichi Ohno. It emphasizes customer value identification, elimination of non-value adding activities, creation of continuous production flow, and continuous improvement (Howell, 1999). Last Planner System (LPS) is one of the most developed lean tools adopted by the construction industry. With the growing complexity of construction projects, the use of LPS is growing in popularity to maintain project activities on schedule by reducing uncertainties in construction operations.

The implementation of the Last Planner System which was developed by Ballard and Howell in the 1990s, enhances work reliability and promotes better coordination among the project participants (Ghosh et al., 2019). LPS works through a series of steps that include the creation of a milestone schedule, a phase schedule, a look-ahead plan, and a weekly work plan involving commitment from the last planners at the site. This approach is based on a pull system as opposed to the traditional planning approach. Despite the systematic and well-planned collaborative efforts in LPS, the actual tasks performed on the job site may sometimes differ from the planned tasks. Tasks that were not previously included in the schedule or were incorrectly scheduled may need to be executed at the site. These are called **'New Tasks'** and arise during the week of the execution.

Hamzeh et al. (2008) first coined the term 'New Tasks' in their PhD dissertation describing them as the most under-reported tasks on a construction project site. These tasks, which do not make it through the look-ahead planning system but appear on the Weekly Work Plans (WWP), are within the project scope but their timelines change for various reasons. Similarly, certain tasks are neither included in the WWPs nor the Look Ahead Plans (LAP) but emerge during the execution week. The inclusion of these 'New Tasks' in the WWP, which were not addressed in the look-ahead planning, greatly impacts the overall workflow and adds additional burden to project planning (Rouhana & Hamzeh, 2016). The reasons for the emergence of these 'New Tasks' have caught the attention of various academicians and practitioners and have been extensively explored (Ballard, 1997; Hamzeh et al., 2012; Hamzeh & Aridi, 2013; Hamzeh et al., 2015; Wesz & Formoso, 2013; Da Alves & Britt, 2011). 'New Tasks' in the weekly work plans of LPS have been reported to arise due to planning behaviours, construction problems and uncertainties (Rouhana & Hamzeh, 2016).

This research paper aims to examine the social interaction patterns, using Social Network Analysis (SNA), in planning behaviours and their impact on the emergence of 'New Tasks' in the Weekly Work Plans of the Last Planner System (LPS). To achieve this, a deep understanding of the planning process, which is influenced by the social interactions and communication patterns among project participants, is necessary. SNA has been used as a prominent tool by researchers to analyse the interactions and relationships between project participants involved in the LPS implementation in a construction project (Herrera et al., 2018; Castillo et al., 2018; Priven & Sacks, 2015; Abbasian-Hosseini et al., 2015; Cisterna et al., 2018). The emergence patterns of 'New Tasks' are investigated in three construction projects located in India that adopted the Last Planner System as their planning method. SNA is conducted to examine the communication and interaction patterns among the project participants involved in the planning process.

The following sections present the literature review, the research methodology, case studies, social network analysis and the conclusion of the study.

LITERATURE REVIEW

LAST PLANNER SYSTEM

The complexities of the fragmented construction industry are addressed by the Lean philosophy, which is based on the principles of the Toyota Production System (TPS) established by Taiichi Ohno for Toyota in Japan (Howell, 1999). Lean construction aims to better meet customer needs by using fewer resources and is a departure from traditional mass production and push-based management practices. It decentralizes organizations, challenges the hierarchical nature of these organizations, and relies on pull-based planning as a fundamental principle.

The Last Planner System (LPS) is one of the most developed lean tools adopted by the construction industry. It incorporates pull planning, in which the Last Planners at the site (foremen/site engineers) are involved in the planning process and are responsible for giving commitments for the work that can be executed within the week after the identification and removal of constraints. The involvement of site personnel in the planning process fosters a culture of trust and commitment amongst the members of the construction project. LPS has five major components: Master scheduling, Phase scheduling, Look-Ahead Planning, Weekly Work Plans and Learning (Ballard & Tommelein, 2016). It is increasingly being used in the construction industry to increase project reliability which leads to better project performance (González et al., 2007).

LOOK-AHEAD PLANNING & NEW TASKS

Look-Ahead Planning is the most important, yet most overlooked aspect of the Last Planner System. Lookahead schedules in construction aim to focus management on future plans and promote present actions towards achieving those goals (Ballard, 1997). It involves the identification of activities to be carried out in the next four to six weeks in a collaborative manner involving all the speciality contractors and consultants. A poor implementation of look-ahead planning in construction projects reduces the reliability of the planning system by creating a large gap between long-term planning (master schedules) and short-term planning (weekly plans) (Da Alves & Britt, 2011). Look-Ahead Planning relies on anticipating the tasks by breaking down the tasks into sub-tasks at the operation level. These tasks are 'made ready' by the identification and removal of constraints six weeks before their actual execution. Hamzeh et al. (2008) conceptualized the phases in construction planning as 'boulders' which are broken down into 'rocks' that represent the processes. These rocks are further broken into 'pebbles' indicating the operations and finally, the steps are represented by 'dust'. Hamzeh, (2009) conducted a computer simulation study to understand the relationship between Tasks Anticipated (TA) in Look Ahead Planning and overall project duration. TA is a metric used to assess the ability to accurately predict tasks that will occur within the next two to three weeks. The simulation involved the addition of 'New Tasks' in the Weekly Work Plan of Look Ahead Planning. These new tasks were not a part of the Look-Ahead Planning and were not broken down or made ready systematically. Their appearance was believed to be caused by a lack of foresight and was presumed to add an extra burden to the planning process. The reasons behind the emergence of these 'New Tasks' were studied by (Rouhana & Hamzeh, 2016) and have been categorized as issues related to planning, issues related to ongoing construction, and uncertainties.

LPS PLANNING BEHAVIOURS

Gomez et al. (2019) explored the concept of Behaviour Based Quality, which suggests that the behaviours of individuals in an organization are influenced by the consequences they experience. This motivates project teams to behave in a way that produces the desired outcomes. Organizational behaviours are also affected by Respect for People and Psychological safety, a term coined by Amy Edmondson in 1999, which supports an individual's power of speaking the truth, making suggestions and asking for help knowing that the mistakes will be met with help rather than punishment. This concept supports the Lean principle of reliable promise-making in the Last Planner System (Ballard et al., 2009).

Fauchier et al. (2013) connected the behaviours arising from the implementation of the Last Planner System and found that LPS promotes the formation of a social network with improved coordination. Organizations that adopt LPS exhibit a higher level of trust among members and create a social system with an increased flow of information. Key behaviours observed in LPS-implementing organizations include collaboration, long-term planning, pull planning, look-ahead planning, commitment planning, constraint identification, making tasks ready, measuring performance, root-cause analysis and corrective actions (Aslesen & Tommelein, 2016; Laufer et al., 1992; Hamzeh & Aridi, 2013; Hunt & Gonzalez, 2018; Perez & Ghosh, 2018; Viana et al., 2010).

SOCIAL INTERACTIONS & SOCIAL NETWORK ANALYSIS

The decision-making process in an organization is directly affected by social interactions and communication between the different team members. The interactions between participants can be both task-based and relational. Task-based interactions involve the discussion of ideas, opinions, and suggestions related to a specific task, while relational interactions involve interactions for demonstrating support, establishing values, and resolving differences (Wang et al., 2018). Ghosh et al. (2019) analysed two healthcare construction projects, one implementing LPS and the other using traditional planning practices, and found that the former showed a higher level of trust among the members and created a social system with a better flow of information.

Social Network Analysis (SNA) is a widely adopted research tool that is used to analyse the interactions and relationships among project participants involved in the LPS implementation at a construction project site. The use of Social Network Analysis (SNA) enables the capturing of valuable information and communication that takes place informally in an organization. Alarcón et al. (2013) highlight the ability of SNA to analyse social relationships and interactions that are task-based or relational. It allows for mathematical and graphical analyses of otherwise essentially qualitative data in the form of nodes and edges. The nodes represent an individual or organization. The connections between these nodes, called edges, represent the transfer of material resources, associations or affiliations, behavioural interactions, information or knowledge transfer or conflict resolutions. By assuming that individuals in an organization are independent, SNA provides metrics to quantify the otherwise invisible flow of information (Pryke, 2012). Some of the metrics used in SNA are:

Network Density: This is the measure of the total number of connections between nodes in a given network to the total number of maximum possible connections. This value falls between 0 to 1. The network density can be used to define the fragmentation of a project team and the degree to which the project participants are connected.

Network Diameter: This defines the maximum number of links required to connect two diverse nodes in the network. It is the longest of all calculated path lengths and gives the measure of how far the information has to travel to reach all nodes.

Average Path Length: This averages the shortest possible path between all nodes and provides a measure of the communication efficiency in the network.

Network Degree: This represents the average number of links per node. A node that has a large number of connections may have significant influence and access to information.

Centrality: This is used to highlight the most important node and its strategic positions in the network. It can be defined by degree centrality, closeness centrality and betweenness centrality.

SNA can be used for different problems that the planners face related to coordination, cooperation and trust; power and influence; organizational levels; informal organizations; information flow; and dynamic network development (Dempwolf & Lyles, 2012). It addresses the relationship patterns over time, and in turn describes how these patterns affect behaviours (Wang et al., 2018). SNA has become a prominent tool for understanding the informal interactions between the project participants and their consequent information flows in construction projects implementing the Last Planner System. (Herrera et al., 2018; Castillo et al., 2018; Priven & Sacks, 2015; Abbasian-Hosseini et al., 2015; Cisterna et al., 2018)

RESEARCH METHODOLOGY

The research adopted a mixed-method approach combining interpretive (qualitative) and positivist (quantitative) methods to address the research questions. The data has been collected using both qualitative and quantitative approaches and includes case studies, questionnaire surveys and direct observation at the construction sites. Social Network Analysis is adopted as a research tool to study the formal and informal communication networks between the project participants with an intent of understanding the collaboration and coherence as organizational behaviours. Three case studies were selected to understand the behaviours and attitudes of project participants that eventually lead to the emergence of New Tasks. The use of multiple case studies, each supporting the phenomenon of the emergence of New Tasks and the subsequent social networks formed, help achieve triangulation in the research. The rationale has helped in ameliorating the internal and external validity of the research. Data was collected through primary sources, such as interviews and questionnaire surveys, and secondary sources, such as Look-Ahead plans and meeting records from the case studies.

As the research predominantly deals with informal networks built on social conventions rather than a formal binding contract, a *realist approach to boundary specification* in the Social Network Analysis has been applied. In this approach, the boundary networks are defined by the nodes (individuals) themselves. For example, a few individuals who are interviewed would identify other nodes with whom they would have to interact to achieve the project objectives (Pryke, 2012). The questionnaire survey for SNA was designed in a way that allowed the participants to list names of people with whom they interact regarding LPS. The questionnaire was further filled out by the people identified through the survey thus completing the interaction network.

The respondents chosen for the questionnaire were individuals involved in the look-ahead planning and the weekly planning of the Last Planner System in the projects selected for the case study. The links between the two nodes consisted of their formal and informal interactions. The data collection included the traditional approaches of surveys, interviews and direct observations and the use of big data of a passive nature including meeting minutes and timesheets. The collected data were edited, coded and translated into the SNA language. Data analysis was performed using Gephi, version 0.9.2, a multiplatform free software used for creating social network metric graphs. This software was used for both the graphical representation of the networks formed and the calculation of SNA metrics. The edges were defined using a source and a target, indicating the information flow between nodes.

The nature of interaction obtained from the survey was categorized into three LPS planning behaviours and the frequency of interaction was used to assign the weights to the edges. The paper investigated planning behaviours observed on the case study projects and those reported in the literature. Behaviours of similar nature were aggregated into one group; for example, all 'planning' behaviours such as updating the master plan, look-ahead planning and commitment planning were grouped into the 'Planning & Commitments' family. Similarly, two other groups, 'Constraint Analysis' and 'Continuous Improvement' were defined. The grouping was performed for convenience, was non-comprehensive and was solely based on the author's reasoning. Table indicates the planning behaviour categories and the weights decided for the analysis.

A cross-case analysis was performed to compare the number of New Tasks that emerged in each project. A scatter diagram was plotted to relate the percentage of New Tasks that emerged in each case study to the network cohesiveness represented by the network density. This gives a cause-and-effect relationship between the two parameters and is used to conclude the research.

Table 1: SNA Planning Behaviors & Edge Weights

Nature of Interaction	Planning Behaviour	Frequency of Interaction	Weight
Updating Master Plan	**Planning and Commitments**	Monthly	1
Look Ahead Planning		Fortnightly	2
Commitment Planning		Weekly	3
Constraint Analysis and Removal	**Constraint Analysis**	Daily	4
Problem-Solving		More than once daily	5
Corrective action of Non-completed Tasks	**Continuous Improvement**		
Decision Making			

CASE STUDIES

Three case studies were chosen for the exploratory part of the research and New Tasks were observed for six weeks during the study. The organizations chosen for the case studies had been implementing lean practices, specifically the Last Planner System for over a year ensuring a high level of lean maturity and the successful overcoming of initial cultural barriers in the implementation process. Each of the three selected projects had a planning system in place, with a designated planning engineer responsible for maintaining regular updates to the look-ahead and weekly plans. The case studies were selected to represent different sizes and scales, including one large-scale, one medium-scale, and one small-scale project, with the first two case studies being from the same organization and the third from a separate organization. Table 2 presents the location, type and size of the project, lean tools adopted, look-ahead planning duration and the total number of planned and New Tasks.

Table 2: Description of Case Study Projects

Case Study	1	2	3
Location	Mumbai, India	Khalapur, India	Ahmedabad. India
Built-up Area	93,000sqm	306,500sqm	56,000sqm
Project Type	Residential	Industrial Mega Park	Residential
Lean Tools Adopted	LPS, Work Sampling, Value Stream Mapping	LPS, Value Stream Mapping, Work Sampling	LPS
Look Ahead Planning	6 weeks	6 weeks	4 weeks
Planned Tasks	225	270	220
New Tasks	39	61	71

In all case studies, based on the secondary data collected from the site in the form of weekly plans and look-ahead schedules, a comprehensive list of 'New Tasks' that emerged within six weeks of site execution was prepared.

CASE STUDY 1

The project was chosen because the organization had been implementing lean since 2011 in facilitation with ILCE (Institute of Lean Construction Excellence), IIT Mumbai and IIT Madras. The data for the SNA questionnaire survey was gathered from individuals involved with the Last Planner System of the case study. The questionnaire for SNA was completed by 20 respondents involved with different stakeholder groups in the Big Room Meetings. In Case Study 1, 39 New Tasks emerged from a total of 225 tasks planned for each of the six weeks. Lack of communication between the project team was the cause of most New Tasks and delays at the site. A few other reasons were lack of coordination, improper task sequencing, clash detection at the site and unexpected arrival of information. The emergence of New Tasks had a direct impact on the Percentage Plan Complete (PPC), as tasks that were not constraint-free could not be completed in the execution week. Deploying resources on the New Tasks that emerged caused the incompletion of the already planned tasks in the Weekly Work Plan.

CASE STUDY 2

The implementation of the Last Planner System in the project began in 2018, with senior management leading the effort and with guidance from IIT Mumbai and IIT Madras. Each industrial plant within the project had its separate implementation of the LPS. The project made use of Big Room Meetings and Steering Committee Meetings to help with planning. The biggest challenge in the effective planning of this project was the involvement of multiple stakeholders in the form of customers and the complexities in their requirements. The data for the SNA questionnaire survey was completed by 15 participants involved in the Last Planner System. Case Study 2 accounted for a total of 61 New Tasks from 270 tasks planned for the six weeks of study. The New Tasks emerged mostly due to inefficiencies in the planning of the project. The scope of work was not clear from the client's end and there were multiple design revisions causing rework on the site leading to New Tasks. Similarly, when unplanned material was delivered to the site, additional tasks were added.

CASE STUDY 3

The organization had been practising lean construction, particularly the Last Planner System (LPS), since 2018. The project blended traditional practices, such as the Critical Path Method (CPM), with the lean practice of LPS. The planning software used for this project was Microsoft Project and an in-house software developed by the organization was used to update the weekly and daily reports. Unlike the first two case studies, the look-ahead plan was not prepared collaboratively by mapping out the constraints and taking inputs from all the vendors assigned for different work packages. The weekly work plans were prepared by the supervisors on-site, but since the work was based on a repetitive cycle, these plans did not change radically from one week to another. The supervisors added comments about some details and the constraints that might occur during the week. The data for the SNA questionnaire survey was completed by 12 participants involved in the Last Planner System. Case Study 3 had a total of 71 New Tasks from a total of 220 planned tasks over the six weeks of study. Some of the reasons for the emergence of these tasks were lack of coordination, unexpected completion of previous work and the addition of labours at the site.

SOCIAL NETWORK ANALYSIS

The behaviours related to the occurrence of New Tasks were analysed through Social Network Analysis (SNA) to understand the interaction patterns between individuals involved in the Last Planner System (LPS) approach. The SNA data was both qualitatively and quantitatively interpreted. The planning behaviours were compared qualitatively based on the SNA maps created for each case study, as shown in Figure .

It can be seen that the social network patterns for the 'Planning and Commitments' network of Case Study 1 form almost a geodesic structure implying strong connections among the members of the network. The network maps for Case Study 2 show some cohesiveness while Case Study 3 has a greater number of isolates. The 'Constraint and Problem-Solving' network corresponds to the process of constraint analysis and removal between different team members of an LPS organization. The network diagrams for Case Studies 1 and 2 show stronger cohesiveness than Case Study 3. This can be attributed to the daily constraint removal between the subcontractor groups in Case Studies 1 & 2 compared to Case Study 3 where constraints were only removed when the problems arose. In Case Study 1, all project actors had similar *network degrees* implying that all members participated in the process of constraint analysis. For the 'Continuous Improvement' network, all three case studies exhibited little cohesiveness and had a small number of nodes. Only the members at a higher level in the hierarchy participated in this process. The emergence of repetitive New Tasks across six weeks in all three cases can be attributed to poor involvement in the continuous improvement process.

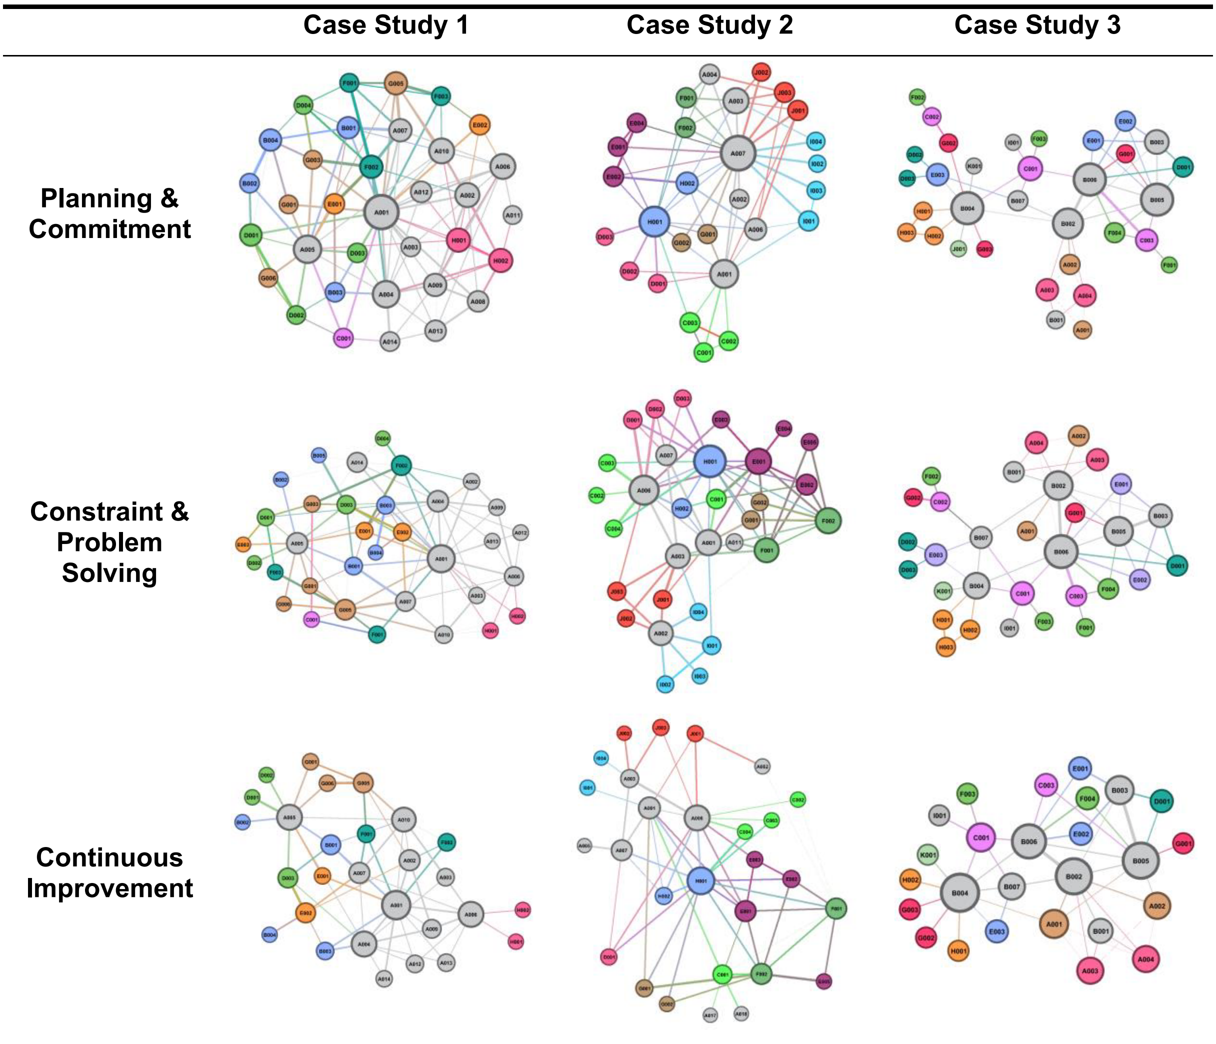

Figure 1: SNA Qualitative Comparison

The quantitative SNA used metrics like density, average degree, average path length and diameter. A single network map for each case study was prepared to perform this analysis to provide a comprehensive overview. Table presents a comparative analysis of all the network metrics. Network Density is the ratio of all the links present in the network to the total number of possible links. The unweighted density of Case Study 1 was 0.20 which signifies that 20% of the network was connected while for Case Studies 2 and 3 the values were 16% and 11% respectively. Since the number of nodes in all three networks was similar, higher network density could be correlated to higher cohesiveness and communication efficiency.

The Average Degree of all the nodes can be used to measure the structural cohesion of the network. The results for the same are in line with the average density as Case Study 1 had the highest average degree of 5.78 indicating a much more strongly connected network than the other two cases. Case Study 3 had the lowest average degree of 3.76. This can be understood by looking at the network map that has a higher number of isolates.

The Average Path Length is an indicator of communication efficiency. The path length was lowest for Case Study 2 and highest for Case Study 3. Since the members of Case Study 3 were connected only through the planning engineers and the project managers, any information would have to pass through them before it can be communicated to the entire network. The Diameter indicates the longest path for the information to reach all members. In Case Studies 1 and 2, any information had to pass through a maximum of 4 members to reach the entire network, while in Case Study 3, the diameter was 6.

Table 3: SNA Metrics Comparison across Case Studies

	CASE STUDY 1	CASE STUDY 2	CASE STUDY 3
Nodes	36	39	33
Edges	104	113	62
Density	0.20	0.16	0.11
Average Degree	5.78	4.36	3.76
Average Path Length	2.19	2.17	2.71
Diameter	4	4	6

The cross-case analysis helps establish the relationship between the New Tasks that emerged and the different planning behaviours observed at the site. To compare the New Tasks between the three case studies, a percentage measure was created. The percentages of New Tasks in the three case studies were 17.3%, 22.6% and 32.3% for Case Studies 1, 2 and 3 respectively.

A correlation between the percentage of New Tasks observed in each project with the density of the network helps to establish a cause-and-effect relationship between the communication efficiency in a network and the number of New Tasks that arise. Average Density was used for the correlation as it is independent of the number of members in each network. All other network metrics are absolute and depend upon the total number of project participants. As observed in Figure , the percentage of New Tasks was inversely proportional to the network density. The networks with higher density had fewer New Tasks and vice versa. This is related to the communication efficiency in the three networks. The emergence of New Tasks in each case was due to a lack of communication and collaboration between the project participants.

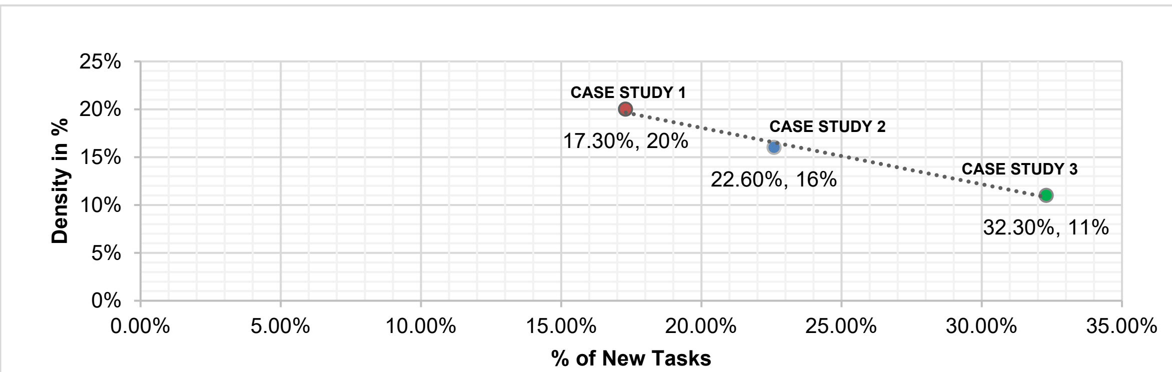

Figure 2: Correlation between Network Density and New Tasks

CONCLUSIONS

It was seen from the literature survey that the implementation of the Last Planner System in an organization engenders a social network among the members that enhances coordination. Three different organizations with varying degrees of LPS implementation were studied to evaluate the New Tasks that emerged during execution. SNA metrics like density, diameter, average path length and average degree were used to analyse the different case studies based on the planning behaviours they exhibit. The comparison of SNA results showed a relationship between the number of New Tasks that emerged during the six-week study period and the total number of planned tasks in each project. The following interpretations can be made from the research:

The inverse relationship between the percentage of New Tasks and the network density in the case studies highlights the importance of effective communication and collaboration among project participants. A higher network density, indicating better communication and efficient flow of information, is associated with fewer New Tasks.

The case studies presented highlight instances where unplanned and ad hoc tasks were added to existing tasks, leading to disruptions in the planned project schedule and impacting the project performance. It is important to acknowledge that the observed ad hoc reactionary behaviours were a result of the lack in systematic implementation of LPS, hence, there is a need for a robust LPS process to mitigate such issues.

Look-Ahead Planning is key in this regard as it enables collaboration between all the stakeholders in pull planning of the Tasks to be planned. The constraints are identified and resolved at this stage and the tasks are made ready for implementation. This reduces planning errors due to communication inefficiencies to a great extent.

This paper proposes a gradual increase in the authority and capability of subcontractors and foremen to participate in planning processes, with a focus on Look-Ahead Planning. The Last Planner, typically the foreman, has the ability to ensure a consistent and predictable flow of work downstream. However, cultural and language barrier can be a challenge in implementing LPS. Foremen and other workers who are not fluent in the language used in meetings may have difficulty understanding instructions and expressing their ideas. This can lead to misunderstandings, delays, and errors in the planning process. To overcome these barriers, it is important to provide training and education to all participants in LPS, including foremen and workers who may be less familiar with the planning process.

The findings from the case study research cannot be generalised for the entire construction industry as only specific planning behaviours are compared, not the overall projects. The research mentions the reasons for the New Tasks but does not provide insight into their impact on the time or cost of the project. Only the New Tasks that emerge due to deficiencies in the planning system have been included in the comprehensive list prepared. Those occurring due to uncertainties like weather changes or equipment breakdown have not been considered for the research. While performing Social Network Analysis, it has been assumed that the network graphs prepared at one point of time in the research are representative of the social interaction patterns for the six weeks of study. There is significant potential for future research to examine the impact of new tasks in weekly plans and their relationship with weekly PPC trends. Additionally, the application of Social Network Analysis could be expanded to the organizational level to investigate interaction patterns surrounding the emergence of New Tasks.

DEVELOPMENT OF A MACHINE LEARNING-BASED LABOUR PRODUCTIVITY PREDICTION TOOL TO PRACTICE LEAN CONSTRUCTION

Abhay Saini[1] and Albert Thomas[2]

ABSTRACT

The construction industry is a labour-intensive industry. This is one of the reasons why the industry has significant room to incorporate lean principles and reduce waste. Various lean tools can be implemented in construction projects, such as Kanban, JIT and 5S. However, these tools majorly focus on activities at an aggregate level and do not always incorporate sub-activities carried out within a small activity. The productivity of smaller activities (activities that typically span from minutes to hours) is essential to be assessed and controlled to increase the efficiency of overall activity. This paper aims to develop a labour productivity prediction tool based on machine learning principles and lean ideologies to improve the overall productivity of construction activities, considering the productivity of sub-activities. The developed framework is demonstrated by analyzing the productivity of reinforcement activity in a construction project. In the study, inventory wastes are minimized using the prediction from the developed quantitative labour productivity prediction model. An increase of 13.7% in overall productivity is achieved through the implementation of the developed framework.

KEYWORDS

Lean construction process, value stream mapping, machine learning, lean theory

INTRODUCTION

The construction industry is a labour-centric industry, and it may remain the same in the coming decades. The growth of the industry and the subsequent infrastructure growth depend heavily on completing projects on time and as per the planned cost (M. Hafez, 2014). 30%-50% of the total cost of construction projects is only spent on labour costs (Asadullah Tahir et al., 2015), and therefore achieving optimum labour productivity is crucial to prevent time and cost overruns. There are several approaches to predicting labour productivity in construction projects. These studies can be categorized into four, as given below.

1. The time-series analysis method involves historical data on productivity levels over time to identify trends and patterns that can be used to make predictions about future productivity. (Song and Abourizk, 2008)
2. Project benchmarking involves comparing the productivity of a particular project to those of similar projects and using this information to make predictions about future productivity. (Abdel-Razek et al., 2007)

[2] Assistant Professor, Department of Civil Engineering, Indian Institute of Technology Bombay, Powai, Mumbai, Maharashtra 400076, India, albert@iitb.ac.in, http://orcid.org/0000-0002-4924-6592

3. Surveys and expert opinions involve gathering information from experts in the field or from workers themselves to make predictions about future productivity. (Shehata and El-Gohary, 2011)
4. The machine learning and artificial intelligence approach involve using algorithms and computational methods to analyze large amounts of data and predict future productivity based on that analysis. (Heravi and Eslamdoost, 2015)

Even though four of these approaches are available to estimate productivity, it is also important to note that a combination of these methods is often used to make the most accurate predictions about labour productivity. The estimation of labour productivity for any given activity is typically achieved by calculating the ratio of total output to total input, where input can be measured as either the total number of hours worked or the total number of workers involved. Alternatively, multifactor productivity, which accounts for both labour and capital inputs, can also be used as a measure of labour productivity (Rojas and Aramvareekul, 2003).

While these methods provide accurate measures of productivity for tracking ongoing projects, they pose challenges when attempting to predict the productivity of an activity that is still in progress. For instance, the total output of such an activity may be zero, but the work remaining to complete the activity may not be equivalent to the initial work remaining. This discrepancy can occur in practice when certain steps of the activity have been completed but do not contribute value to the project, resulting in a calculated productivity of zero. Although this consideration may not impact the actual performance of the site, it can significantly affect the planning and management of the remaining activities. Thus, it is important to carefully account for such nuances in productivity calculations for accurate project planning and management. Once the prediction of productivity is achieved for an activity, we can use it to implement lean in that construction activity.

Lean-based techniques are also employed to improve labour productivity in the construction industry. The various tools and techniques to implement lean in construction projects include 5S, Just in Time (JIT) and Kanban, work sampling, value stream mapping, Poke-Yoke, Takt-Time, and Kaizen with waste minimization as the key objective (Leksic et al., 2020, Singh and Kumar, 2020, Cossio and Cossio, 2012.; Sundararajaan and Madhavi, 2018; Tommelein and En Yi Li, 1999). The first step in the implementation of these tools is to identify the wastes involved and perform various analyses such as Pareto chart, failure mode and effects analysis (FMEA), process improvement and variation reduction to improve the process (Banawi and Bilec, 2014). Understanding labour productivity plays a major role in implementing lean and reducing waste in the construction industry (Serpell et al. 1994). Therefore, it is essential to estimate the actual productivity by assessing the effects of various influencing factors.

Even though the traditional productivity estimation techniques mentioned earlier and lean-based solutions have provided approaches to quantify productivity, there is a need to accurately predict the productivity of construction activities while they are being performed by also considering the power of lean construction. This study, therefore, proposes a novel framework to predict the absolute productivity of any activity, regardless of its current stage of completion. To achieve this, the study employs breaking down the activity into smaller sub-activities, enabling precise prediction of absolute productivity by also incorporating non-value-adding yet essential steps in productivity prediction. This is a notable improvement over traditional approaches that often exclude such steps. Furthermore, the study discusses the potential use of the framework in implementing the lean principle, which aims to reduce waste and optimize efficiency in the activity under consideration. This novel framework presents a promising approach to accurately predict and optimize productivity, offering potential benefits for various industries and applications.

LITERATURE REVIEW

Studies on labour productivity in construction typically focus on factors that impact labour productivity and methods for improving it. Several studies have found that the construction industry has low labour productivity compared to other sectors (Dixit et al., 2018; Rojas and Aramvareekul, 2012.), and this is due to several factors, such as poor project planning and management, a lack of standardization and modularization, and the inherent complexity of construction processes (Agrawal and Halder, 2020). Further, the factors that have been shown to impact labour productivity in construction include worker skill levels, job site conditions, the use of equipment and technology, and the availability of materials.

Some studies have also highlighted the importance of worker motivation and job satisfaction and have found that these factors can have a significant impact on labour productivity. Mistry and Bhatt (2013) conducted a survey in Gujarat, India and categorized the factors into four categories and found that the most affecting factors influencing productivity are the outside weather and delay in payment. Similarly, Doloi et al. (2012) selected fourteen factors and tried to develop a predictive model for labour productivity using Artificial Neural Network (ANN), adaptive-network-based fuzzy inference system (ANFIS), ANFIS-Genetic Algorithm and Random Forest algorithms. In this study, a predefined rating between one to five was taken for the factors. Likewise, Thomas and Sudha Kumar (2015) conducted an Indian case study for the same and explored the effects of some external factors, such as political instability, on labour productivity. Similarly, Enshassi et al. (2007) conducted their study in the Gaza Strip and concluded that work front unavailability is the top most factor that affects labour productivity, followed by a lack of proper planning. Overall, it can be seen that the site layout, crew composition and management-related factors are primarily found to affect labour productivity (Alaghbari et al., 2019; Doloi et al., 2012; Enshassi et al., 2007; Hamza et al., 2022; Hiyassat et al., 2016; Makulsawatudom et al., 2004; Nyoni and Bonga, 2016; Thomas and Sudhakumar, 2015). However, all these factors are exclusive of on-site tangible factors that directly influence the productivity of an individual activity. For instance, the different shapes of formwork in the formwork activity and cutting and bending length in the reinforcement activity. Several approaches can be witnessed in the literature about measuring the labour productivity of construction projects, but there are very limited studies on finding out the absolute labour productivity of any activity by incorporating all sub-activities.

Various studies have also found that construction labour productivity can be improved through better project management practices, such as the use of building information modelling (BIM) technology and the implementation of lean construction methods (Poirier et al., 2015) by streamlining construction processes, reducing waste, and improve communication and collaboration among stakeholders. Waste in construction can manifest in various forms, including overproduction, waiting, unnecessary movement, carrying excess inventory, and rework (Abbasian, Nikakhtar et al., 2012). Time studies and different process analysis techniques have been utilized to systematically identify and quantify waste in the construction process (Suresh, 2013). After identifying waste and its underlying causes, the next stage is to identify cost-effective opportunities for improvement that can be applied to reduce waste and improve productivity. This analysis is typically carried out through collaborative teamwork and brainstorming among team members (Serpell et al., 1994).

Overall, there is a need for a quantitative model that can predict labour productivity by incorporating the sub-activities and help implement lean techniques at construction sites. Therefore, this study presents a framework to predict absolute labour productivity for an activity. The two objectives of this study are given below.

1. To develop a machine learning-based labour productivity prediction framework based on the productivity of sub-activities that can help in tracking and re-arranging the flow of the activity.

2. To utilize the result of the framework to implement lean principles in the activity to increase its efficiency.

RESEARCH METHOD

To achieve the above objectives, a three-stepped research methodology is adopted that includes construction activity selection and analysis, productivity predictivity model development and the model's output to implement the lean principle.

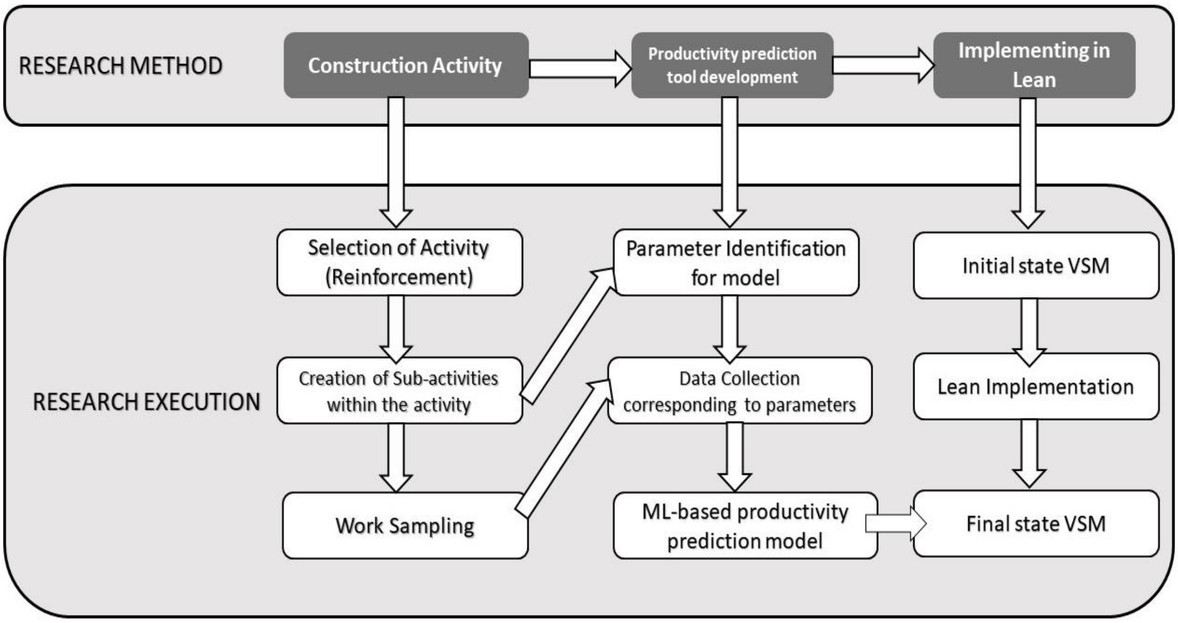

Figure 1: Research Methodology

The first step in research execution is analyzing a case study activity in detail and creating sub-activities. Activity is divided into sub-activities by capturing the actions that take significant time. By observing each sub-activity, the parameters that are affecting productivity are identified. Further, work sampling is performed for the entire cycle of the activity to collect relevant data for developing the machine learning-based multivariate linear regression method-driven predictive model for labour productivity using the parameters identified. A Value Stream Mapping (VSM) approach is then used to develop the detailed step-wise value stream map of the current state. Further, using the productivity values predicted by the productivity prediction tool earlier, a modified VSM is also developed. The detailed steps in identifying the sub-activities, work sampling, ML model development and performing VSM are explained below.

DIVIDING ACTIVITY INTO SUB-ACTIVITIES

The framework is applied at residential high-rise building construction sites in Mumbai. Reinforcement activity is analyzed, and it is then divided into sub-activities. This categorization is carried out based on the observation on site where the major time taking tasks are termed as sub-activities.

Table 1: Sub-activity categorization

Reinforcement Activity	
Sub-activity 1	Shifting and Cutting of Rebar
Sub-activity 2	Bending of Rebar
Sub-activity 3	Shifting to Workplace
Sub-activity 4	Laying and Fixing of Rebar
Sub-activity 5	Tying of Rebars

WORK SAMPLING

Once the sub-activities are formed, work-directed sampling is carried out to register the value of each activity in the sub-activities. This method involves observing employees performing specific tasks or activities. Observers record the activities being performed, and the data is later analyzed to determine the proportion of time spent on different tasks. The same is tabulated in the following table 2.

Table 2: Work Sampling for Reinforcement Activity

Sub-Activity	State
Cutting of Rebar	Shifting rebar to the cutting tool
	Measuring and cutting
	Shifting rebar to inventory 1
Bending of Rebar	Shifting rebar to bending Tool from inventory 1
	Measuring and bending
	Shifting rebar to inventory 2
Shifting to Workplace	Crane comes down from the 4^{th} floor
	Idle time
	Crane loading
	Idle time
	Crane going up to the 4^{th} floor
Laying and Fixing of Rebar	Shifting and laying of rebars
	Measuring and fixing rebar
	Idle time
Tying	Tying of rebars

PARAMETERS IDENTIFICATION

For the development of the absolute productivity prediction tool, input parameters are required. The parameters that are affecting productivity are shown below in Table 3. These parameters are tangible parameters collected from the construction site by visual inspection. Data is taken from a high-rise building construction site in Mumbai. Qualitative data are not considered here, so the productivity received is the absolute productivity for the considered activities.

Table 3: Identified Parameters table

Sub-Activity	Parameters
Cutting of Rebar	Number of rebars in one movement
	Diameter of the rebar
	Cutting the length of rebar
	The total length of the rebar cut
	Number of workers in the crew
	Weight of the rebar cut
	Percentage of skilled worker
	Time taken
Bending of Rebar	Number of rebars in one movement
	Diameter of the rebar
	The total length of the rebar cut
	Number of bends
	Number of workers in the crew
	Weight of the rebar bend
	Percentage of skilled worker
	Time taken
Shifting to Workplace	Height of the destination inventory
	Distance from crane placed to inventory
	The weight of the rebar shifted.
	Weight of the rebar bend
	Percentage of skilled worker
	Time taken
Laying and Fixing of Rebar	Diameter of the first type of bars
(Two different diameter rebars were used)	Diameter of the second type of bars
	Number of reinforcement bars of the first diameter
	Number of reinforcement bars of the second diameter
	Length of reinforcement bars of the first diameter
	Length of reinforcement bars of the second diameter
	The total length of reinforcement bars of the first diameter
	The total length of reinforcement bars of the second diameter
	Number of bends of reinforcement bars of the first diameter
	Number of bends of reinforcement bars of the second diameter
	Number of workers in the crew
	Weight of the rebar cut
	Percentage of skilled worker
	Time taken
Tying	Number of rebar joints tied
	Time taken

REGRESSION MODEL DEVELOPMENT

Regression models are developed using the above-mentioned parameters as input and the time required to carry out the sub-activity as an output. The first regression model for the cutting sub-activity is shown here. The input parameters shown as x1 to x5 are the diameter of the rebar, cutting length, rebar initial length, number of cuts and weight. The output parameter is the time required to carry out the sub-activity. A summary of the model is presented below in Figure 2.

Figure 2: Regression Model Result for Cutting Sub-activity

From Figure 2, we find the R-squared value as 0.949. That shows a good fit of the graph for the data entered. Eighty-five observations were used to develop this model.

IMPLEMENTATION AND RESULTS

The developed model is used to implement lean principles in the reinforcement activity. Value Stream Mapping (VSM) is used as a lean tool in this study. A current state VSM is developed from site observation which provides a snapshot of the current activity. Usually, in a VSM method, further, a future state would be developed based on assumed productivity values. Here in this study, the model developed above will be used to predict the productivities to be considered for developing the final state VSM.

CURRENT STATE VALUE STREAM MAPPING

For developing the current state VSM, a reinforcement activity is observed on the construction site. Data for developing the VSM is collected for each of the sub-activities, including idle time and wastage. The data collected is for 8.87 kg of rebar having a diameter of 10 mm and five bends. Figure 3 below shows the current state of the observed process.

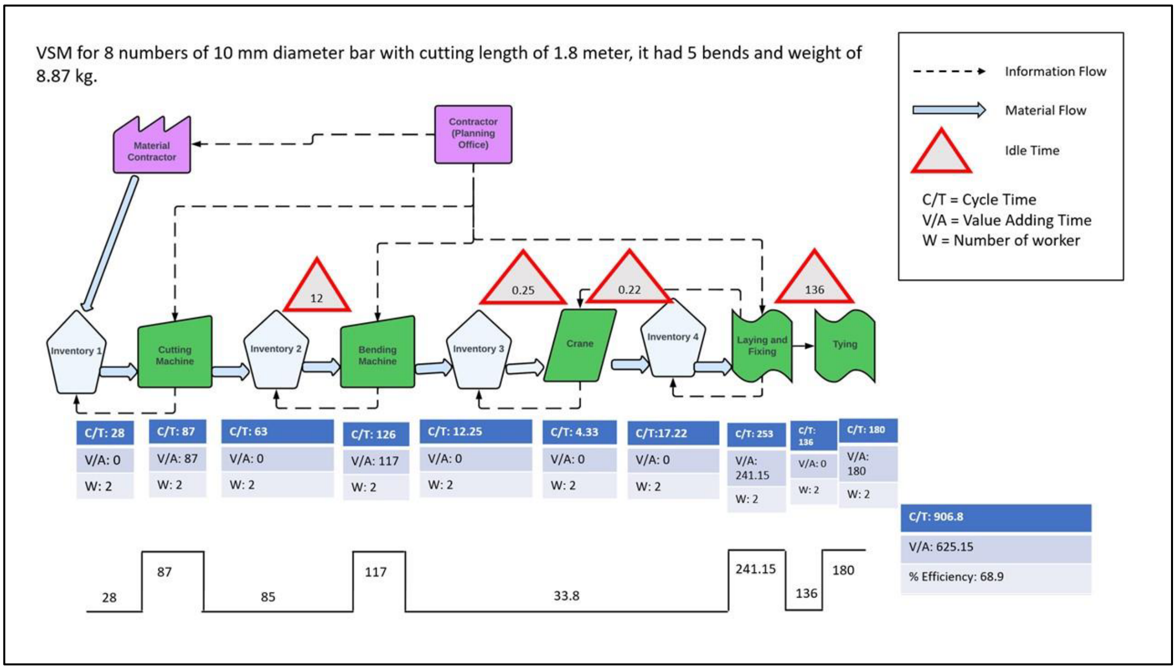

Figure 3: Current State VSM Diagram

PRODUCTIVITY OF EACH SUB ACTIVITY

For predicting the productivities of the sub-activities, multivariable linear regression is applied considering all the parameters shown above. The prediction was carried out for the same rebars in the current state VSM. Table 4 provides the details of predicted productivity values that are used to develop the future state VSM.

Table 4: Productivity prediction using regression analysis

Sub Activity	Workers in Crew	Productivity (kg/hr/crew)	R^2	Observations
Cutting	2	120.2	0.948	85
Bending	2	90.17	0.943	85
Shifting (Crane)	3	7673	-	17
Laying and fixing	2	51.43	0.915	85
Tying	2	147.8	-	35

As per the productivity obtained by the study, there are significant differences between the productivity of sub-activities. So, to remove some of the inventory from the current state of VSM, we need to match the productivity of sub-activities. That will make the activity more efficient as the material can be shifted to the sub-activity without going to inventory.

Here it can be seen that the productivity of cutting is 120 kg/hr and that for bending is 90 kg/hour, so if four crew for bending and three crew for cutting are assumed, the productivity of the process will be the same, and materials could be directly shifted to bending after cutting without using an inventory. In addition, after reducing the idle time, the final state VSM is proposed below, which is developed using the predicted productivity values.

PROPOSED FINAL STATE VALUE STREAM MAPPING

The final state VSM is developed using the predicted productivity values given below.

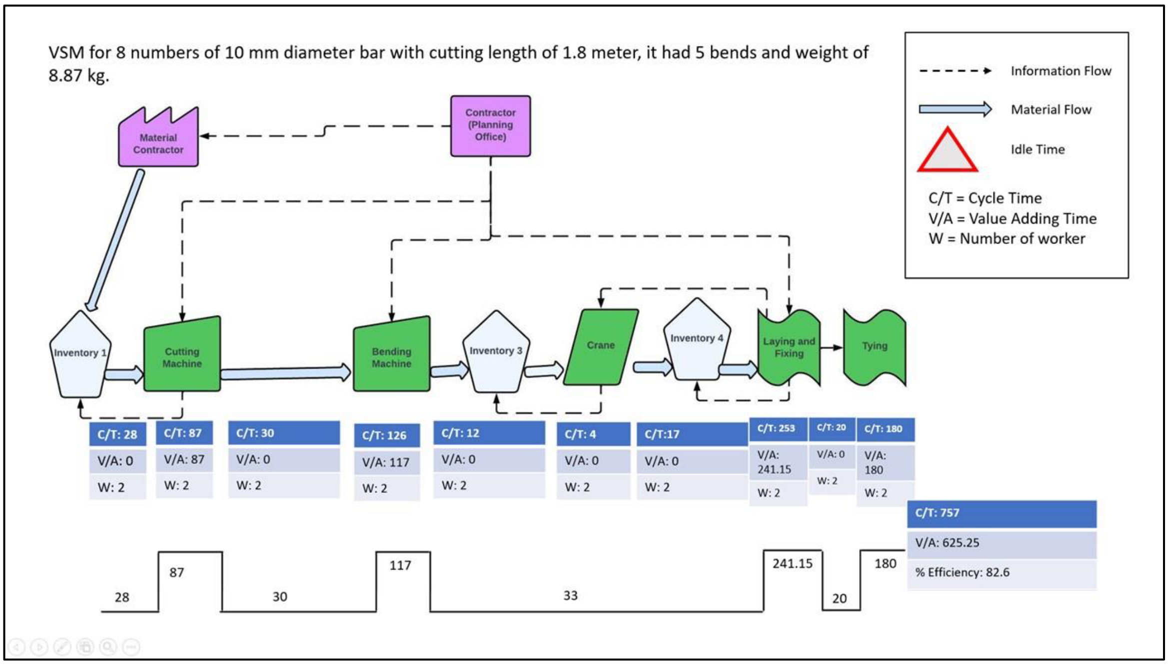

Figure 4: Final State VSM

As was discussed above, it is proposed to remove inventory 2, which is there between the cutting and bending sub-activity. It reduced the time between these sub-activities by 64%, and it also reduced one worker that was shifting the material to inventory. The overall efficiency of the activity, which was 68.9% in the current state VSM, is now 82.6% in the proposed state VSM after applying the lean principle and using the productivity prediction approach.

DISCUSSION

In this study, a labour productivity prediction model is developed using data from a construction site. The model is designed to accurately forecast the absolute labour productivity for upcoming reinforcement activity tasks. Subsequently, the model is utilized to implement lean practices in the activity. The predictions from the model indicate that there is room for improvement, and just-in-time techniques can be implemented by matching the productivity of workstations.

The current state Value Stream Map (VSM) for the activity resulted in a cycle time of 906 seconds. However, when the model's results are used to increase the number of bending workstations relative to cutting workstations, it is possible to reduce inventory and achieve a cycle time of 757 seconds. This demonstrates that utilizing the model can lead to a significant increase of 13.7% in activity productivity. This finding highlights the potential of the labour productivity prediction model in improving construction site efficiency and performance.

CONCLUSION

The construction industry is of labour-intensive nature, and there is a strong need for achieving improvements in the labour productivity aspect. However, the current practice of labour productivity calculation falls short of providing accurate productivity estimates for activity planning, especially when activities are partially completed. To address this gap, this study proposed a novel framework that utilizes the productivity of sub-activities within an activity to predict the absolute productivity of the entire activity.

The proposed framework offers an efficient approach to organizing resources and implementing lean principles, thereby enhancing the overall productivity of the construction project. Through the implementation of the framework, a notable improvement in productivity of 13.7% is demonstrated. It is worth noting that the framework has the potential to further enhance its predictive accuracy by incorporating deep learning algorithms. However, the implementation of such algorithms may require a substantial amount of data sets, making them more suitable for large-scale projects with ample data availability.

In conclusion, the framework presented in this paper addresses the limitations of current labour productivity calculation methods and provides a promising approach for predicting activity productivity in construction projects. The demonstrated improvement in activity productivity highlights the potential of the proposed framework in optimizing labour productivity and promoting the adoption of lean practices in the construction industry. Future research can further explore the integration of advanced algorithms to enhance the accuracy and applicability of the framework and investigate its effectiveness in different construction activities, contexts and project scales.

LIMITATIONS AND FUTURE WORK

The present study exhibits certain constraints which need to be addressed in future research endeavours. Firstly, the study's input parameters are limited in number, thereby failing to account for intangible inputs such as labour fatigue, management practices, and on-site safety factors. The exclusion of these inputs may hinder the accuracy of the prediction model. Thus, their inclusion could potentially enhance the efficacy of the prediction model.

Moreover, the study's prediction model only accounts for absolute productivity during reinforcement activities. However, to employ the model for project planning, it is imperative to consider labour efficiency. Therefore, the model's utility for project planning purposes needs further examination. It is noteworthy that the regression model employed in this study demonstrated satisfactory performance. Nevertheless, the applicability of other deep learning models must be explored for construction activities, especially if the results from the present model are suboptimal.

AN EVALUATION OF THE LOOKAHEAD PLANNING FUNCTION IN LAST PLANNER® SYSTEM

William Power[1], Derek Sinnott[2], Patrick Lynch[3], and Chris Solorz[4].

ABSTRACT

Last Planner® System (LPS) has been lauded as a critical improvement methodology for project execution. Best results accrue when all functions are utilised. However, in practice, due to lack of knowledge and appreciation of the LPS cycle and complementary interactions required, teams are not achieving optimal outcomes. Effective Lookahead planning that reduces variation and 'making-do' are primary concepts for facilitating better construction task execution.

This study goes 'back to basics' and explores how improved Lookahead planning can enhance project delivery. It utilised a mixed-methods approach with case study design, encompassing interviews, project documentation, and existing research data. The case project utilised Visual Management, Takt concepts, Scrum, and Flow Walks to engage site supervisors proactively and collaboratively in diligent Lookahead planning.

Findings demonstrate involvement of the trades persons in task breakdown and design of the operation ensured better activity and trade flow resulting in improved task execution. Proactive and diligent constraint screening and flow walks resulted in increased constraint identification and better on-time resolution, while also developing a workable backlog. Conducting a First-Run Study resulted in immediate productivity improvement.

The basics of production planning and control are an essential component of Lean Project Delivery. The research highlights the value in practitioners exploring original literature in more depth to gain better knowledge and skills of the Lookahead planning function.

KEYWORDS

Lean construction, Last Planner® System, Lookahead, takt, visual management.

INTRODUCTION & LITERATURE REVIEW

Progressing execution of construction activities is mostly dependent on the completion of other tasks in addition to the timely presence of critical inputs, referred to as the eight flows (Koskela, 2004; Pasquire, 2012). The challenge of coordinating and managing these inputs contribute to issues that frustrate the timely execution of construction projects. Last Planner® System (LPS) is a dedicated tool of Lean Construction (LC) and offers an integrated suite of techniques for

planning and monitoring task execution on construction projects (Hamzeh et al., 2016). Numerous case studies illustrate performance improvements but there are still implementations that are incomplete or fail to meet objectives, primarily due to difficulties with interpretation of LPS (Ebbs and Pasquire, 2018) allied to its ineffective implementation (Bellaver et al., 2022). Several studies (Daniel et al., 2017; Power and Taylor, 2019) argue LPS implementation varies, and its interpretation is inconsistent. Ballard and Tommelein (2021) sought to address such variation, emphasising the importance of using all functions to ensure planning and execution of tasks are linked to project milestones (Hamzeh *et al.* 2009; Ballard and Tommelein, 2016). A consistent and standard approach is essential as LPS is a series of interconnected functions and best results accrue when all functions are utilised. However, there is a paucity of literature that shows practitioners 'how to do' Lookahead planning and this served as a principal motivation for this research.

This study examines Lookahead planning and shows how the function was enhanced by introducing aspects of Takt planning, Scrum, and Visual Management. Literature and practice gaps suggest there is a need to improve trade involvement in assisting more rigorous and consistent Lookahead planning implementation. Two research questions are posed: 1) How consistent is Lookahead planning implemented in the case company's projects, and 2) What are the effects of the improvement measures implemented on the case company's projects?

The components of LPS include master / milestone schedule, phase / pull planning, Lookahead and make-ready process, commitment / weekly work planning, daily huddles / coordination, and learning and action (Ebbs and Pasquire, 2019). Lookahead planning has been highlighted as an essential step in shielding crews from undertaking tasks that are deficient in inputs, thereby ensuring crews only work on activities that are ready to be executed (Koskela, 2004). Lookahead planning is a first step in production control and links front-end planning with production by connecting the phase / pull planning function with weekly and daily planning by screening all committed tasks and effectively 'making work ready' to be completed (Hamzeh et al., 2012; Bellaver et al., 2022). Ballard (2003) posits Lookahead planning: (1) shapes the sequence and rate of workflow, (2) links master and phase schedules to weekly work plans, (3) shields downstream tasks from uncertainty in upstream tasks, (4) sizes workflow to match capacity and constraints, and (5) produces a backlog of workable activities by screening and pulling. Production is 'made ready' and is given the best opportunity of uninterrupted flow by removing constraints, sizing capacity to workflow, producing a backlog of workable activities, and designing how operations are performed (Ballard et al., 2007). These objectives are accomplished through three main steps (Hamzeh et al., 2008):

- Breaking down tasks into the level of processes then to the level of operations.
- Identifying and removing constraints to make tasks ready for execution.
- Designing operations through First Run Studies.

WORK STRUCTURING

A key element of Lookahead planning is the concept of work structuring, which concentrates on both designing and executing the construction production system. Work structuring can be defined as developing product design (the facility) in parallel with process design (schedules, delivery methodology), organising supply chains, allocating resources, and designing offsite preassemblies to produce reliable workflow and maximise value to both customer and site crews (Ballard et al., 2001; Tsao et al., 2004). This process should span across all project development phases, from definition through design, supply, and assembly (Ballard et al., 2009).

In a construction project, Bertelsen et al. (2007) asserted production flow is optimised when all flows required to complete a task are present at the right time and in the correct amounts for efficient task execution. In addition, Garcia-Lopez et al. (2019) suggest there are two work structuring methodologies: LPS, which has been advanced by other Lean construction researchers (Ballard et al., 2001; Hamzeh et al., 2008), and Takt planning (Frandson et al., 2013; Tommelein, 2017). According to Tsao et al. (2004), LPS work structuring methodology focuses on activity definition, sequencing, and assignment:

- breaking down work into units that can be assigned to specialists (activity definition).
- sequencing activities.
- understanding how work will be handed off between specialists.
- understanding whether work will be executed continuously between locations.
- placing and sizing decoupling buffers.
- scheduling activities (Tsao et al., 2004).

Activity breakdown occurs in conjunction with defining operations, optimising sequencing, coordination of tasks among project stakeholders, resource loading operations, sizing tasks to match available capacity, and analysing tasks for soundness so that all prerequisite inputs are in place (Hamzeh et al., 2008).

CONSTRAINTS

Identification and removal of constraints is the core process for producing dependable workplans and is conducted within a 4-to-12-week planning window (Hammerski, 2021). Constraints should be identified as early as possible in the project (Ebbs and Pasquire, 2018) and can be resolved as late as when tasks are being committed to the weekly work plan. As Hammerski et al. (2021) noted, constraint removal can become a prolonged process as removing a primary constraint can then expose other upstream constraints. Therefore, having a backlog of constraint-free activities is an essential element of Lookahead planning and provides work for crews which can restrict improvisation or 'making-do' (Koskela, 2004).

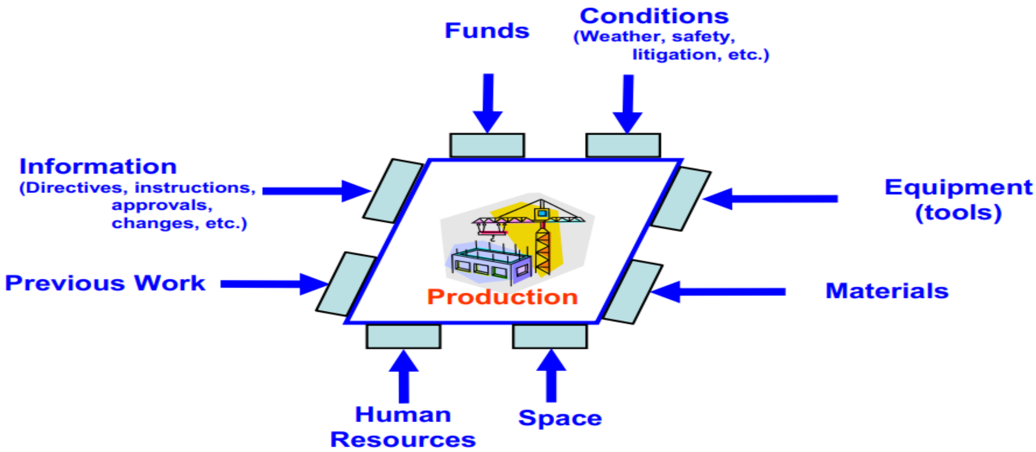

Figure 1: Shielding production from the effects of uncertainty in inputs (Hamzeh et al., 2008).

When an activity starts without having all its prerequisites ready (an incomplete kit), a 'making-do' waste is generated leading to reduced crew productivity (Ronen, 1992; Koskela, 2004). Therefore, a key role of Lookahead planning is to shield production from the adverse effects of uncertainty in inputs as illustrated in figure 1.

FIRST RUN STUDIES

Design and testing of operations should be advanced during Lookahead planning and at least three weeks ahead of execution, according to Hamzeh (2009). A first run study (FRS) is primarily a trial or test run of an operation to evaluate and improve the techniques and methodologies necessary to execute that operation. Potential processes requiring a FRS are those that are new, critical, or repetitive (Hamzeh et al., 2008). Ideally, a FRS should become a standardised element of planning, conducted three to six weeks in advance of a new set of tasks to be executed. A FRS requires the operation to be executed as it normally would by the crew; observations or recordings will seek to improve the process and ensure it interacts effectively with other processes (Howell et al., 1993). By agreeing an effective way to do the work and by setting an achievable standard, a measurement system is then in place on which to assess performance. Standards are an essential part of any process which allows learning and improvement as any movement from the agreed standard can be assessed and examined (Ballard et al., 2007).

PURPOSES OF VISUAL MANAGEMENT

Greif (1991) describes Visual Management (VM) as the use of visual information to enable those that are undertaking work to immediately transfer that information to assist execute the task. The principal objective of VM is to allow production systems learning and improvement while enhancing communication across teams and organisations by increasing process visibility and transparency (Tezel et al. 2016). VM also contributes to the reduction of variability and the elimination of non-value-adding activities (Koskela et al., 2018), as well as to continuous improvement, and incorporates foundational Lean principles. Koskela et al. (2018) suggest VM facilitates faster and more consistent and reliable communication; this contributes to shorter cycle time and less variability. Collaborative planning boards and pull planning exercises facilitate development of a common understanding of different trades inputs, helping to better structure the project planning process. When effectively implemented, VM practices break down complexity by sharing relevant information on-time and by removing information barriers in the work environment (Valente et al. 2019). Systematic and standardised implementation of VM establishes a visual workplace where different objectives of VM can be communicated (Tezel et al., 2016).

Grönvall et al. (2021) suggest the positive effects of takt control and continuous improvement can be enhanced with the adoption of VM tools. Continuous production flow, enabled by increased use and understanding of VM, results from benefits in transparency, discipline, management by facts, simplification and unification, and the creation of shared ownership (Tezel et al., 2016). VM tools are a critical aspect of takt production communication as takt production plans themselves are visually more understandable than traditional schedules.

TAKT PLANNING

In construction, Takt time is a design parameter for labour-paced flow of work (Frandson et al., 2013). A key aspect of takt time planning is to bring more stability to the production process by pro-actively designing continuous workflow for trade activities wherever possible. LPS then provides the control mechanism and stability of the production system. Construction can utilise Takt time as a work structuring methodology to align the production rates of trades by pacing work sequentially through planned zones creating continuous workflow, reliable handoffs, and an opportunity to continuously improve the production system (Frandson et al., 2013). Takt time regards 'space' as a resource to be considered when planning construction projects and designing production operations. Another critical consideration is, in construction workers move around the work as opposed to the work moving to the worker, for example, through an assembly line. Frandson et al. (2013) suggests the difference between Takt time planning and other location-based planning methods is the balance between 'work waiting on workers' and 'workers waiting on work.'

SCRUM

Scrum is a flexible, adaptable, empirical, productive, and iterative method that uses the ideas of industrial process control theory for the development of software systems (Sanchez and Nagi, 2001). Its theory is founded on empiricism and Lean thinking (Engineer-Manriquez, 2021) and is built on three pillars of transparency, inspection, and adaptation. A key characteristic is the autonomous team which is empowered to make relevant decisions to achieve its goals. Work is carried out in time-boxed 'sprints' that empower teams to examine progress and adjust if required, thus minimising risk of miscommunication or over-processing of tasks. In the context of design and construction, Scrum is a framework applicable to project work planning through to deliverable completion. The deliverable could be a calculation, a design, a drawing, an element of a physical task, or a component of a structure.

FLOW WALK

Ebbs and Pasquire (2018, p.736) proposed a 'Flow Walk' to '…firstly identify project constraints at milestone level planning and secondly, to provide the context for desirable action to remove constraints within the framework of the Last Planner® System at Milestone, Phase and Make Ready Planning'. The 'Flow Walk' was used as a structured approach to collaboratively identify constraints and incorporate them into the risk registers and Make Ready Planning. The 'Flow Walk' effectively validates the assignment screening process and replicates Pull Planning conversations at the point of work execution. A common and shared understanding of 'done' and required conditions of satisfaction are direct benefits of the approach (Ebbs and Pasquire, 2018).

RESEARCH DESIGN

The paper reports on an in-depth case study of an EPCMV consultancy implementing LPS and specifically examines the Lookahead planning function. The case project is in Ireland and involved the decommissioning of a pharmaceutical facility and the site's return to an environmentally protected zone to be used as the local community's public space. The critical phases of the project are Clean to Shell, Demolition, Site Remediation, and Groundwater treatment and monitoring. Power et al. (2021) presented an LPS Implementation Health Check (IHC) to highlight the critical components of the functions of LPS and allow project teams to check whether each is being utilised effectively. This study builds on the initial primary research from the IHC paper and then utilises 18 months of new IHC data to specifically examine inconsistencies in Lookahead planning implementation within the case company. This qualitative study utilises a mixed methods approach with case study design (Yin, 2009). Unique sources were purposely sought to increase validity and to provide a wider research perspective, as advocated by Yin (2009) and Stake (1995). The interviews were transcribed and then analysed using a thematic analysis approach, as suggested by Braun and Clarke (2006).

The data was organised into different themes (Braun and Clarke 2006); inferences drawn from the emerging themes were checked by triangulation against the literature review findings and against other sources to check their reliability and integrity. One of the authors was embedded as a Last Planner Facilitator / Lean Mentor on the case project. An action research approach (Eden and Huxham, 1996) was taken on the implementation so the effectiveness of any interventions could be clearly monitored and measured.

Primary data from Power et al. (2021) was examined which investigated 12 projects that utilised LPS to assess effectiveness of implementation of all LPS functions. The projects were measured for compliance with the five core functions of LPS: Milestone Scheduling, Phase Planning, Lookahead Planning, Commitment Planning, and Learning (Ballard and Tommelein, 2016). The implementations were scored on a range from 0 to 5 with: 0 = 'no existence of the function', 3 = 'Partial existence of the function', and 5 = 'Full existence of the function'. Table 1 presents the sources for this paper's research.

Table 1: Research Sequence and Source

Source	Project and Participants
Power et al. (2021) primary research.	12 case company LPS project data from 2017 – 2020. Assessed & analysed implementation of all LPS functions across 12 projects. (n=12)
IHC Data; Case project LPS data.	86 Implementation Health Checks from 6 projects; PPC, reasons for non-completion of tasks, & constraints data from the single case project.
Purposeful Interviews	Interviews with 1 X Client Project Manager, 2 X Construction Manager, 2 X Contractor Site Manager, & 1 X Last Planner Facilitator. All from different projects. (n=6)

For this study, 86 IHC from six projects from June 2021 to December 2022 were examined for alignment with the Lookahead planning function of LPS. LPS data from the single case project was also examined with specific focus on the constraints analysis and resolution data. Semi-structured purposeful interviews were conducted with six interviewees across six projects which implemented the IHC to elicit views on Lookahead Planning. Table 2 presents the interviewees profile.

Table 2: Interviewees profile.

Interviewee	Role	Experience in construction & with LPS
1	Client Project Manager	28 years; 2 years.
2	Construction Manager 'A'	16 years; 6 years.
3	Construction Manager 'B'	9 years; 2 years.
4	Civils Contractor Site Manager	22 years; 2 years.
5	Electrical Contractor Site Manager	11 years; 1 year.
6	Last Planner Facilitator	17 years; 11 years.

Findings were collated and countermeasures proposed which were then piloted on a single case project. Mason (2002) suggests a major challenge for interpretive approaches revolves around how researchers can be sure that they are not inventing data or misrepresenting perspectives. As with any research, this study has limitations pertaining to the small survey size within a single organisation, lack of generalisability, and minimisation and elimination of bias during data collection and analysis stages. Limitations exist due to the research being conducted within a single organisation. Generalisability is not the main concern of this study and Yin (1993) argued that the relative size of the sample "…whether 2, 10, or 100 cases are used, does not transform a multiple case into a macroscopic study", thus, asserting a single case is considered acceptable once it meets research objectives. Bias was mitigated by two researchers being distanced from the project and unconnected with the case company.

FINDINGS AND DISCUSSION

RESEARCH QUESTION 1: HOW CONSISTENT IS LOOKAHEAD PLANNING IMPLEMENTED IN THE CASE COMPANY'S PROJECTS?

Power et al. (2021, p.690) found haphazard and inconsistent LPS implementation across the case company's projects. That study was examining consistent use of all functions and by extension, this study seeks consistency of approach towards implementing Lookahead planning. The summarised findings from 12 selected projects that implemented LPS from 2017 to 2020 were evaluated by Power et al. (2021) and results are presented in table 3.

Table 3 indicates difficulties with understanding the importance of consistent implementation of all functions of LPS. While the Learning and Phase planning functions were poorest used functions, Milestone and Commitment planning were most used. Lookahead planning, considered so critical in the literature, scored 55%; this pointed to inconsistent use of the complementary functions of LPS. Following from this Power et al. (2021) finding, the next step was to examine how the Lookahead planning function implementation could be improved.

Table 3: Status of LPS implementation on twelve projects (Power et al. 2021).

Survey Findings Score from 0-5 (0=no, 5=full)	Milestone Planning	Phase Planning	Lookahead Planning	Commitment Planning	Learning
Mean Values	3.7	2.1	2.8	3.7	2.2
Median Values	3.5	2	2.5	4	2
Lowest Values	2	0	2	3	0
% Implementation	73%	42%	55%	73%	43%

The IHC was introduced on projects using LPS in June 2021. By December 2022, 86 IHC are available for examination from six different projects. As the IHC is a system compliance and process improvement tool, its purpose is to reduce non-compliance with the agreed LPS implementation standard. An audit of 86 IHC showed high levels of non-compliance with the Work Structuring and Constraint Management requirements of the Lookahead planning function of LPS. At the time, First Run Studies (FRS) was not incorporated into the IHC. The next step was to conduct interviews with persons knowledgeable on LPS to seek further detail on the Lookahead planning process. Table 4 presents interviewees collated opinions on the Lookahead planning process.

Table 4: Interviewees opinion on Lookahead planning process.

Opinions on Lookahead planning process
"Looking 4 to 6 weeks ahead is too far and is unnecessary as there are more urgent issues to address."
"LPS is taking too much time and Constraint Walks take supervisors away from direct supervision."
"Design should be completed, and it isn't our job to screen their deliverable."
"It shouldn't be the contractor's job to identify what inputs are missing."
"Constraints identification is not taken seriously enough."
"It is difficult to plan off PDFs of Master Schedules."
"Being pushed to start new tasks on a specific date when ongoing tasks are incomplete leads to frustration, especially when the ongoing task has extra scope added."
"Let us finish what we are at before we move onto a different location."
"Being able to 'see' what needs to be done where, and who is doing it would be helpful."
"Incumbent client contractors need to understand that external contractors have work priced through competitive tenders and therefore the incumbents should get their own tasks complete when they say they will."
"Constraints removal process needs accountability and management."
"Several contractors working in the work area can sometimes slow each other down and lead to safety issues."

Analysis of the comments confirms a distinct lack of awareness and understanding of the LC and LPS ways of working and how that differs from traditional push methodologies. LPS implementation needs to be more than just a tool-focused approach and must bring cultural, and mindset change along the journey as well. Some comments in table 4 point to frustration with the constraints process and indicate any next steps should be holistic in approach and include all stakeholders' interests.

RESEARCH QUESTION 2: WHAT ARE THE EFFECTS OF THE IMPROVEMENT MEASURES IMPLEMENTED ON THE CASE COMPANY'S PROJECTS?

Literature asserts the importance of the Lookahead planning function and the IHC examination findings indicated poor focus and application of the constraints process across the six surveyed projects. Table 4 confirmed this and added further detail. In addition to the constraints process, improved work structuring was required and there was an absence of FRS. The case company has a 'Lean Team' that supports project teams implement process improvements. The Project Director was favourable towards experimentation to improve the Lookahead planning function. This leadership support was a critical first step in implementing changes to the existing processes. Firstly, the team needed to agree on what constituted 'good' Lookahead planning. From the literature it was agreed to focus on Work Structuring, Constraints Management, and First Run Studies. These were further broken down into actionable activities as shown in table 5.

Table 5: Actionable activities to implement Lookahead Planning

Work Structuring	Constraints Management	First Run Studies (FRS)
Break work into defined activities that can be assigned to specialists. Sequence activities by logic and flow. Make explicit how work will be handed off between specialists by involving the 'next-customer.' Visualise the Pull / Phase Plan to understand continuous workflow. Position, size, and make visible decoupling buffers. Schedule activities to prioritise release of value-adding work to progress the project. Introduce Takt concepts to structure task, trade, & inputs flow.	Seek to identify constraints at every opportunity. Ensure primary constraints are broken down to permit recursive examination of sub-constraints. Establish clear ownership and accountability. Make the 8-flows visible to all. Keep building a constraint-free backlog that is available for all crews. Visualise location-based constraints. Introduce Scrum framework to ensure daily focus on constraints removal.	Introduce the concept of FRS to encourage studying an activity with the objective of standardising the work and removing any non-value adding steps. Video record where possible to review several cycles of an activity to seek improvements. Create an environment where new ideas can easily surface and be tested. Focus on enhancing persons jobs, welfare, and working conditions through improving safety, quality, and logistics. Adopt a quality focus on handoffs to ensure no defects are passed on.

Work Structuring - The primary change implemented with work structuring was the involvement of the trades persons in breaking down the tasks into finer detail and then building the operation to ensure activity and trade flow through the buildings. A sticky-note example of a work structuring exercise was conducted with the work crew supervisors. Firstly, all tasks required to 'clean' a building were written on sticky notes (dedicated colour per trade) and put on the board. Next, each task was ordered in sequence to generate an Overall Process Analysis

(OPA). Durations were assigned to the OPA for a specific building, and this was then tested in the field. Once durations were validated the OPA could be extended into a visual that incorporated all areas in the selected Lookahead window. In addition to the OPA sticky note visual, a 6-week Lookahead was applied onto the site layout plan (figure 2); crew supervisors could then view which locations were coming into the near-term planning horizon.

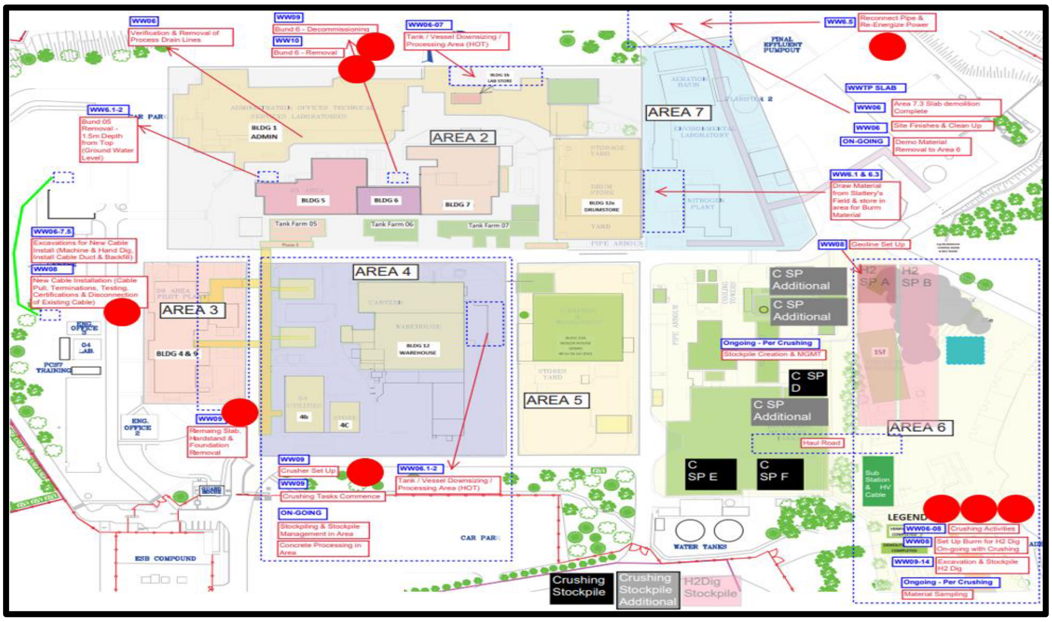

Figure 2: 6-week Lookahead / site layout plan.

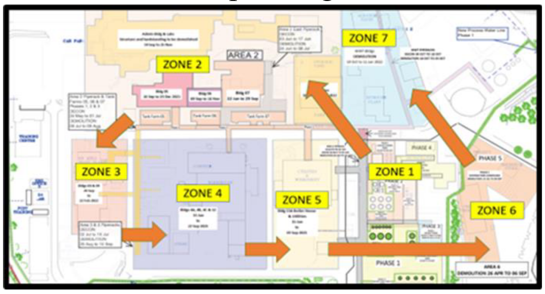
Takt concepts of moving through zones in sequence, balancing work package sizing, and matching crew and plant capacity with planned work durations were implemented in the earthwork remediation phase. Visualisation of the planned progression through the zones (figure 3) and its positioning on the site information board shared the high-level plan with the entire team. Incorporating both Takt and VM concepts assisted planning work structuring.



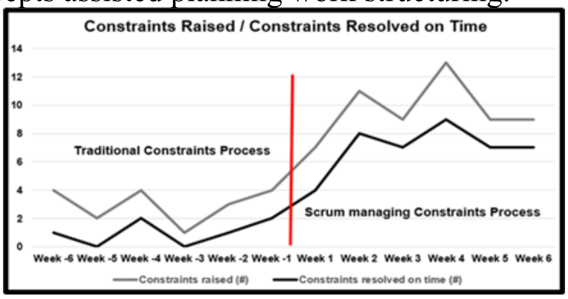


Figure 3: High-level work-flow visualization. Figure 4: Improved constraints process.

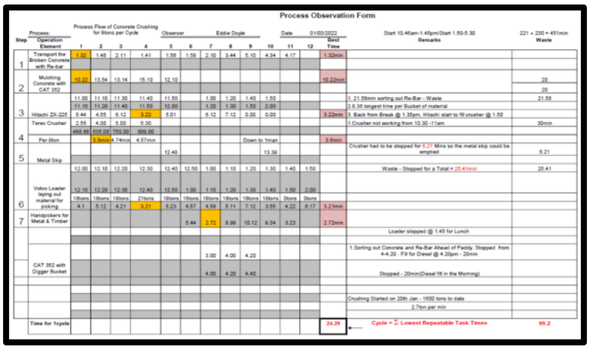
Constraints Management - Constraint screening occurred at every opportunity and red dots as suggested by Ebbs and Pasquire (2018) were positioned at each location where an unresolved constraint existed (figure 2). Constraints were managed on a virtual board (Trello) using the Scrum framework. A key point was the presence of a dedicated Scrum Master who was managing the constraints resolution process with a committed 'Development Team'. The Construction Manager was the Product Owner, and the entire constraints process was proactively driven. Twice-weekly constraint / flow walks were mandatory on Tuesdays and Thursdays with the distinct objective of identifying any possible risk or concern that might cause delay to a task, a safety issue, or a quality defect. A critical finding was the increase in both constraints raised and constraints resolved on-time as indicated on figure 4. This was a direct result of the constraint / flow walks and the commitment to the Scrum process for resolving the constraints. A relentless focus was placed on creating a backlog of constraint-free tasks. These were available on each week's weekly work plan should any adverse event impact the planned tasks. A new area of focus was the concept of testing the resolved constraint for quality. Past experienced had shown that incomplete closure of the constraint only led to further delay and frustration as supervisors resorted to improvisation to allow the activity to proceed. It is important for the overall implementation that a quality focus is maintained at all steps in the design, construction, and close-out phases.

First Run Studies – A large stockpile of demolition material was ready to be crushed with the concrete and reinforcement steel to be separated and recycled. It was agreed the specialist contractor would commence the first run of the activity and allow video recording and observation to facilitate process examination and improvement. The activity involved excavator #1 sorting broken concrete from earth and creating a spoil heap for excavator #2 to feed the crusher. Crusher output from 1100hrs to 1400hrs was averaging 100 tonnes per hour. The activity was recorded and logged as per figure 5. The Process Observation noted excavator #2 was constantly waiting for material and often had to move around and commence segregating its own clean stockpile. Excavator #1 was on a separate location on the heap and was not communicating with excavator #2. This was discussed with the crew leader and the key point identified was the excavators were not working together as a team and coordinating their movements. The supervisor spoke with both drivers, and they then began to work together in more coordinated action as shown in figure 6. This change increased crusher output from previous average of 100 tonne per hour to 146.4 tonne per hour from 1500hrs to 1600hrs on that day. On subsequent days production was consistently more than 135 tonne per hour.



Process Observation Form

Process: Process Flow of Concrete Crushing for 9tons per Cycle — Observer: Eddie Doyle — Date: 01/03/2022 — Start 10.45am-1.45pm/Start 1.50-5.30 — 221 + 230 = 451min

CONCLUSION AND RECOMMENDATIONS

The research shows that the basics of production planning and control are an essential component of construction delivery and posit practitioners revisit original literature to gain better knowledge and skills of the Lookahead planning function. Improving input flows to reduce variation and 'making-do' are primary concepts for improving construction task execution. Consideration of the three primary aspects of Lookahead planning, namely Work Structuring, Constraints, and First Run Studies should be fundamental to LPS implementation.

Involving the wider management team and trades in the work structuring exercise creates a common and shared understanding of the challenges and peculiarities of the project. Diligence around screening of tasks, constraints identification, their prioritisation, and effective resolution contributes to smooth workflow as well as enhancing enthusiasm and engagement amongst the team. Creating an environment where First Run Studies are encouraged and financially supported leads to less disruption and increased productivity during the project.

Previous studies have shown how the Lookahead planning function can be advanced with metrics and digitisation. However, to ensure we do not digitise a poor process we must make certain Lookahead planning is structured in accordance with the basics of production planning and control. The effective use of Visual Management, Takt concepts, and the Scrum framework can complement Lookahead planning, task make ready, and ensure better project execution.

A STUDY OF THE BENEFITS OF LEAN CONSTRUCTION DURING THE PANDEMIC: THE CASE OF PERU

Andrews A. Erazo-Rondinel[1], Isaac M. Ccoyllar[2], Anabela Huaccha[3], and Godofredo Barrantes[4]

ABSTRACT

Lean Construction (LC) has been implemented worldwide in different construction projects, and the Covid-19 pandemic has been no exception. However, more research needs to be compiled on the benefits of LC during this period, considering the high variability and uncertainty generated. Therefore, this article evaluates the benefits of implementing LC during the pandemic stage. In the first stage, a literature review was conducted using PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses), where the main benefits of implementing Lean Construction during the pandemic are identified. In the second stage, the benefits were validated through interviews with professionals in different Peruvian construction projects. The main benefits were: improved planning, easier identification of constraints, and improved project communication. The following study will help construction industry professionals consider LC implementation's benefits in future scenarios with high variability.

KEYWORDS

Lean Construction, Covid, pandemic, benefits, Peru

INTRODUCTION

The construction sector is one of the sectors that promote higher economic growth worldwide. However, it faces several problems, such as low productivity (Barbosa et al., 2017) and; a fragmented chain (Hossain & Nadeem, 2019); it is also a dangerous industry, where personnel are exposed to numerous safety risks, resulting in deaths or serious injuries (Lee et al., 2014). These problems have been heightened in the wake of the COVID-19 pandemic, where the construction sector faced various impacts such as reduced productivity, delayed project delivery, cost overruns (Ahmed et al., 2022), labor shortages (Husein et al., 2021), among others.

Many of the problems described above have been solved through the application of LC; several authors have recorded benefits such as reduced variability (Alarcón et al., 2008), mitigation of cost overruns and delay in project delivery (Gómez-Cabrera et al., 2020). So also during the pandemic, LC has been implemented, achieving benefits such as improved planning

(De la Torre et al., 2021), improved workplace safety, reduction in the number of contagions (Verán & Brioso,2021), maintaining social distance between workers (Santos et al., 2022).

Despite the benefits shown during the pandemic, little research has compiled the benefits obtained from LC. Therefore, the main objective of this study is to identify the main benefits of implementing LC in the Peruvian construction industry during Covid-19. The construction sector in developing countries was hardest hit by Covid-19 (Al-Mhdawi et al., 2023). In Peru, the construction sector was one of the sectors most affected by the onset of the Covid-19 pandemic since the Peruvian government declared a state of emergency in the country, paralyzing all activities in the construction sector (Instituto Peruano de Economía, 2020), which caused the construction sector to suffer a reduction in GDP of -30% per year (Madera et al., 2022). In addition, the Peruvian government proposed a series of guidelines for the spread of Covid-19, such as evaluating the outbreak (control of body temperature and pulse oximetry, and identification of symptoms), installing information panels, maintaining a distance of 1.5 meters, providing hygiene products, ensuring the use of masks, using personal protective equipment, and daily cleaning and disinfection of the entire construction site and equipment (MINSA, 2020), which affected the construction work (Verán-Leigh & Brioso, 2021).

The article begins with a literature review identifying the main benefits associated with LC during the pandemic. After that, six Peruvian professionals were interviewed to compile the benefits they obtained with the implementation of LC and validate them with respect to the benefits obtained from the literature review.

BACKGROUND

COVID IMPACTS IN CONSTRUCTION PROJECTS

The Covid 19 pandemic has affected the whole world, especially in the construction sector (Rani et al., 2022), so several studies have been conducted to understand the impact in different parts of the world. For example, Al-Mhdawi et al. (2021) studied the impacts in Iraq, where the significant impacts were supply chain disruptions, labor restrictions, and legislative changes. In South Asia, research was conducted in India, where, according to Rani et al., 2022, the three main impacts were labor shortages, supply chain disruptions, and decreased productivity in Construction. In Latin America, studies have also been recorded; for example, according to Araya and Sierra, 2021, based on data from 40 interviewees, in Chile, impacts on productivity, technical performance of workers, and present and future financial solvency were obtained, such impacts were the ones that caused the most effects on the stakeholders who addressed the construction project. These impacts are mentioned following the impacts found in the United States; according to Alsharef et al. (2021), among the impacts found are reductions in efficiency and productivity rates, material delivery delays and material shortages, and the suspension or slowdown of construction projects. Finally, in the case of Peru, according to Fernandez et al. (2021), the impact was evidenced by a significant increase in labor costs.

LEAN CONSTRUCTION BENEFITS

Lean Construction has been implemented in different countries, such as, for example, Egypt, where Shaqour (2022) mentioned that the main benefits are improved process control, improved planning, reduced project execution time, and improved safety. Similarly, Sarhan et al. (2017) evaluate the benefits in Saudi Arabia. He identifies similar benefits to Shaqour's (2022) study, such as reduction of construction time and process improvement, and mentions that quality improvement is the main benefit of the Saudi Arabian industry. Finally, in the case of Peru, Erazo-Rondinel and Huamán-Orosco (2021); identified the main benefits of improving on-site planning; identifying waste and minimizing it; and reducing construction time.

RESEARCH METHOD

The following research follows two stages; in the first stage, a literature review is conducted using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) methodology. In the second stage, a qualitative study is conducted through 06 interviews with professionals about their experience implementing Lean Construction during the pandemic. Each of the stages is described below (Figure 1).

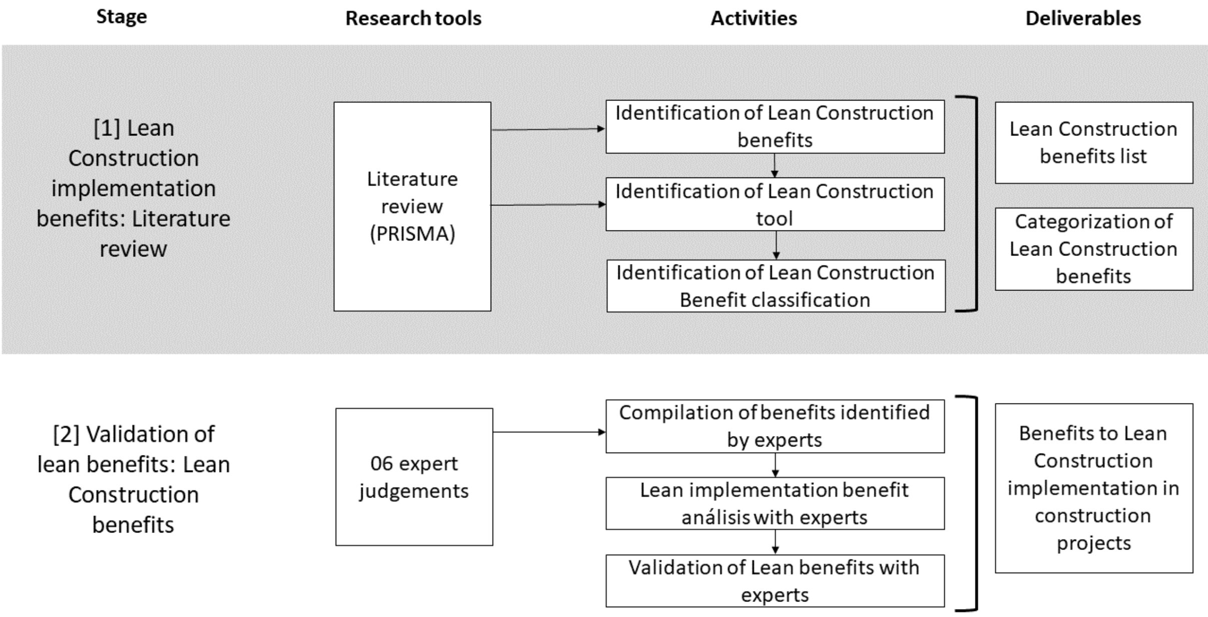

Figure 1: Diagram with the main stages of the investigation.

FIRST STAGE: PRISMA REVIEW

A systematic literature review was performed to identify, select, and include the articles to be evaluated in this study, following each step of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) methodology (Mamani et al., 2022). PRISMA has been used in studies associated with Lean (Besser et al.,2017; Souza et al.,2021).

For the literature review, a search of publications related to Lean Construction and Covid was conducted using Scopus and the IGLC database. Scopus is one of the databases with a vast domain in construction research compared to other databases (Galaz-Delgado et al., 2021). In addition, the IGLC database was used, which hosts most publications on the application of Lean Construction worldwide (Daniel et al., 2015). In the first stage, the search was performed using keywords, as shown below. For the SCOPUS database, they were I ("lean construction" AND "covid"), II ("lean construction" AND "pandemic"), and III ("lean construction" AND "coronavirus") and for the IGLC database, they were a) coronavirus, b) covid and c) pandemic.

A filter of publications ranging from 2020 to 2023 was applied, which had 85 articles and included four by collecting snowballs that could contribute to the study/evaluation of the benefits of Lean Construction, having a total of 89 articles. For the next eligibility phase, 48 duplicate publications were eliminated from the reviewed articles after having combinations I, II, and III. Next, relevant articles were filtered for evaluation, considering that they refer to the benefits, impact, or applications of lean tools during the Covid-19 pandemic. In total, 22 articles were excluded through a title and abstract review, leaving a total of 19 articles, which were filtered again through a complete review, thus excluding six articles that did not meet the criteria to be considered in this study, leaving a total of 13 articles that were considered for this research. The above steps are described in Figure 2.

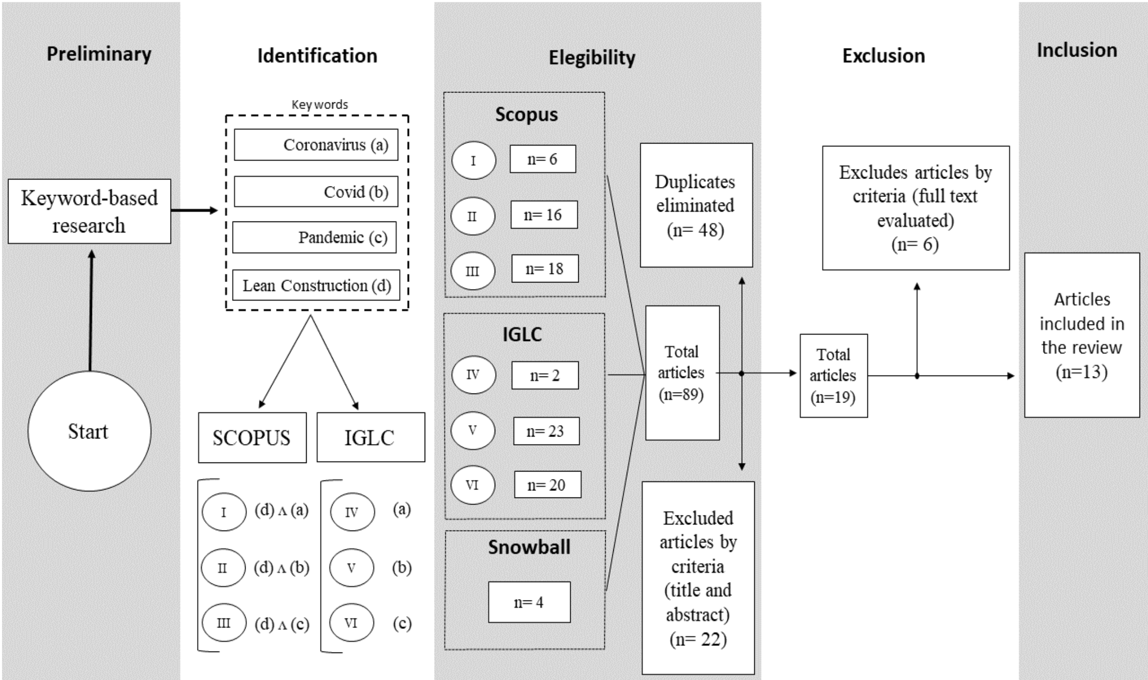

Figure 2: PRISMA flow diagram for the systematic review.

After the literature review, we will continue with the second stage corresponding to the research's qualitative approach.

SECOND STAGE: QUALITATIVE STUDY

The qualitative approach has been previously used with topics related to Lean Construction, for example, to identify the significant impacts and difficulties of LPS in Brazilian companies (Viana et al., 2010), to identify tools and facilitators for lean adoption (Bashir et al. 2013 and Marhani et al. 2018). That is why the following study, like those mentioned, is based on a qualitative analysis of the benefits of Lean Construction during the pandemic context.

For this stage, 6 participants were selected from various construction projects in Peru who applied Lean during the pandemic; below is a description of the profile of the interviewees and the type of project in which they participated (Table 1). The interviewees were asked to have at least five years of experience implementing the Lean philosophy. The interviews were conducted by telephone and video calls and lasted 20 to 30 minutes with each interviewee. The interview was divided into two stages: a first stage where the interviewee's information was collected, such as years of experience, experience in implementing Lean Construction, and types of projects in which he/she has participated. In the second stage, the benefits obtained in the literature were validated. The experts were asked if they had observed the benefit, and they were asked to give examples. Concerning the limitations, the study includes using a convenience sample and a small sample size because six professionals were interviewed. In addition, the benefits obtained will vary according to the region where they were applied since government measures about COVID vary.

Table 1: Profile of interviewees

Number	Years of experience	Years of exp. With LC	Current role	Projects participated in
Interviewee 1	7 years	7 years	Risk leader	Infrastructure, Urban development, mining, plants, the aviation sector
Interviewee 2	12 years	12 years	Manager	High-rise buildings and retail projects
Interviewee 3	15 years	7 years	Operations Manager	High-rise buildings
Interviewee 4	7 years	7 years	Technical Office Engineer	High-rise buildings and sports infrastructure
Interviewee 5	17 years	12 years	Superintendent	High-rise buildings
Interviewee 6	5 years	5 years	Fire Water Subcontractor	High-rise buildings

RESULTS AND DISCUSSION

RESULTS OF LITERATURE REVIEW

Main Lean Benefits

Another result of the literature review was the identification of benefits. Thus, 11 main benefits were identified from the 13 articles mentioned. The benefits are arranged in Table N°2. Among the benefits, the following were identified: Improved planning ("B1"), Facilitation of constraint identification ("B2"), Improved productivity in the COVID stage ("B3"), Alternatives for activity sequencing ("B4"), Improved decision making in the project ("B5"), Maintaining social distancing ("B6"), Improving safety at the work site ("B7"), Reducing the number of contagions ("B8"), Transparency with project information ("B9"), Improving communication in the project ("B10"), Continuous improvement of the project ("B11").

From Table N°2, we can notice that the main benefit obtained by the authors is the improvement of planning through the reduction of variability (9 results) because most authors have implemented LPS. The second benefit identified is the timely identification of constraints (6 results) because the Covid-19 context is a context of high uncertainty, and the team, using lean tools, can better protect its planning. Another benefit obtained is the improvement of productivity (with five results). In this case, the authors have mentioned that the use of LC helps mitigate the effects of the pandemic on the project's productivity. In addition, other results obtained have reduced the number of contagions and improved safety at the work site because they are mainly related to better project planning and adequate distribution of the crews.

Table 2: Lean benefits in relation to the selected articles.

RESULTS OF INTERVIEWS IN PERUVIAN CONSTRUCTION PROJECTS

Likewise, the benefits obtained by the interviewees are related to the list of benefits obtained in the literature review, which we can evidence in Table N°3 that the most frequent benefit by the interviewees at the time of using Lean Construction was benefit B1(Improvement of planning) taking into account that each of the interviewees applied in the six construction projects the LPS tool for example, interviewee 01 mentioned ["*Level 4 schedules were developed to support the master schedule and it was beneficial to consider the restrictions we had with the Covid problem*"]. Regarding the relation of items obtained from the literature review, benefit B1 has a frequency of 9 answers, a similar frequency also happens with B2 (Facilitation of constraint identification) being the second most demanded, with a total of 6 answers.

In contrast to the literature review, benefit B3 (Improved productivity) and benefit B6 (Maintaining social distance) was not very common among the interviewees, as they indicated ["*Due to social distance some activities saw their productivity reduced"]* and *["They only followed legal norms*"], and in comparison with the items obtained from the literature review, they had a total of 5 and 3 mentions in favor, respectively.

We highlight benefit B4 (Alternatives for the sequencing of activities) by the six mentions by the interviewees. With B4, the time has been optimized by flexibly changing schedules, having an objective as a goal, and concerning B5 (Improvement of decision making in the project), had a total of 4 according to the answers of the interviewees, for example, according to interviewee 01 ["*It helped in the integrated meetings that were made with the field people*"]. Likewise, in the literature review, both benefits B4, and B5 obtained a total of 4 mentions, which evidences a small variation in the frequency given in B4.

Table 3: Benefits identified by interviewees.

Code	E1	E2	E3	E4	E5	E6
B1	X	X	X	X	X	X
B2	X	X	X	X	X	X
B3						
B4	X	X	X		X	X
B5	X	X			X	
B6		X		X		
B7		X	X		X	
B8		X				
B9	X	X	X	X		X
B10	X	X	X	X		X
B11	X	X		X		X

Of the benefits related to workers' safety, benefit B7 (Improvement of safety in the workplace) and B8 (Reduction in the number of contagions), B7 has a higher frequency than the literary review, also according to interviewees 02, 03, and 05, they mention that ["*The companies implemented order and cleanliness, through the 5S tool*"]. On the other hand, benefit B8 has a better frequency in the literature review and interviews since it is complicated to establish a relationship between lean tools and reducing the number of contagions. However, one of the respondents mentions that ["*Thanks to planning and proper distribution of subcontractors, in 8 months only one member of his team was infected by Covid-19*"]. Therefore, both benefits compared to the article got two mentions.

We see that also the benefits B9 (Transparency with the project information), B10 (Improvement of the communication in the project), and B11 (Continuous improvement of the project) have a high degree of percentage accepted by the interviewees, taking into account that in B9, the Spaghetti diagram was used, for the subject of the approaches, optimizing displacements and that they are the correct ones, in B10, the communication channels were improved to make them more effective. Finally, in B11, the PPC (Percentage of Plan Completed) and CNC (Causes of Non-Compliance) metrics together with a historical database, according to the interviewees mentioned that the above ["*serves to make decisions and corrective options, since it allows you to have more practical and dynamic visual tools*"]. Therefore, in this opportunity, B9, B10, and B11 obtained two mentions of each benefit compared to the article.

CONCLUSIONS

The following research seeks to identify the main benefits of implementing Lean Construction through a literature review and interviews with Peruvian construction professionals. The main benefit obtained was the improvement of planning, associated with identifying constraints and generating alternative plans, all related to the Last Planner System. The second benefit identified was the improvement in the identification of constraints, improved communication, and improved transparency, mainly because the interviewees have been implementing the Last Planner System and promoting weekly meetings. The least observed benefit is the reduction in the number of contagions. The interviewees mentioned that this could not be determined and could be an effect of good lean planning.

Another important conclusion is that the interviewees quickly identified the benefits associated with Lean Construction because they have been implementing LC for over five years, which generates an understanding of the tools and principles. These results could change if professionals with little experience with LC are interviewed.

The authors recommend conducting qualitative studies in other countries since each country implemented different measures concerning Covid-19 and to determine if there could be any relationship between the measures and the benefits of LC.

INTEGRATING STANDARDIZED WORK AND PRODUCTION STATUS CONTROL TO SUPPORT LOCATION-BASED PLANNING AND CONTROL

Fabrício Berger Vargas[1], Fabiana Bonesi[2], Carlos Torres Formoso[3], and Iamara Rossi Bulhões[4]

ABSTRACT

Standardized Work (SW) is an approach to standardize and improve the efficiency of operations cycles. SW can support the implementation of Location-Based Planning and Control (LBPC) by balancing workload between workers, synchronizing different processes and allowing early identification of deviations. Digital technologies can support the implementation of SW by providing real-time feedback to support project monitoring, communication, and information management. The aim of this research work is to propose a model that integrates SW and production status control by using existing digital technologies to support LBPC. Design Science Research (DSR) is the methodological approach adopted in this investigation. The study initially focused on the collaborative identification of critical interrelated activities to implement SW. Then the integrated control model of SW and production status was proposed with the support of visual management devices and digital technologies. As a result, it was possible to effectively synchronize and balance the resources of a set of interrelated activities, increasing the stability of those activities. Therefore, the model can be used as a mechanism to manage variability in LBPC and increase the degree of process standardization while having short cycles of feedback to promote continuous improvement.

KEYWORDS

Location-Based Management (LBM), Takt planning (TP), standardization, production status control, digital technologies.

INTRODUCTION

Standardization is a key managerial mechanism to reduce process variability. In construction, standardization is often focused on achieving compliance with standard procedures, based on the traditional idea of finding the best way of performing an activity, with little emphasis on continuous improvement (Saffaro et al., 2008). By contrast, in the Lean Production Philosophy, standardization is focused on the operations performed by workers (Martin & Bell, 2017) and is known as Standardized Work (SW) (LIB, 2003). SW is an action-oriented procedure in which detailed instructions are established for each operator's work in operations cycles (Ohno, 1997).

These procedures lead to the standardization of operations (Mariz, 2012) and are the basis for continuous improvement (Liker, 2004). Ohno (1997) suggests that there are three necessary elements for SW: (a) takt time – time available for production, based on customer demand (Alvarez & Antunes Jr., 2005); (b) standard sequence of operations – sequence of steps performed by each worker within a cycle time[5] (Monden, 2011); and (c) standard inventory – minimum amount of items needed in the process that allows the operator to work efficiently (Ohno, 1997). In addition, Fireman et al. (2018) pointed out that slack must be defined when designing SW for any activity and that the existing variability of construction operations must be considered.

Takt time has been strongly related to Location-Based Planning and Control (LBPC), which can be defined as a planning and control approach that makes explicit the workflow and the relationship between construction activities, time and work zones (Olivieri et al., 2019). LBPC involves a set of techniques, including the line of balance (LOB), which represents the master plan (Ballard & Tommelein, 2021). The major benefits of the LOB are that several concepts related to the Lean Production Philosophy are explicitly used, such as batch size, work-in-progress, cycle time and rhythm of processes (Schramm et al., 2006).

SW is a collaborative effort aiming to standardize operations cycles to reduce variability, which plays a critical role in the synchronization of processes. Therefore, different crews can achieve similar cycle times by balancing the workload between different workers or teams and aligning them with an established takt time (Mariz, 2012). Although SW is one of the most important aspects of the Lean Production Philosophy, it is still underutilized in the Construction industry (De Bortoli Saggin et al., 2017). In fact, previous works on LBPC have not emphasized the opportunity of using SW to support the synchronization of processes by using collaborative planning meetings (Binninger et al., 2017).

Moreover, the growing complexity of construction projects has demanded the adoption of digital technologies to support project monitoring, communication, and information management (Bryde et al., 2013). Current data collection and monitoring systems depend on on-field personnel, which is time-consuming and error-prone (Golparvar-Fard et al., 2011; Son & Kim, 2010), while people should spend time analysing progress and metrics, detecting deviations and problems early (Fullerton & Wempe, 2009). Therefore, there are opportunities for using digital technologies to improve progress monitoring, by providing real-time feedback on the status of the production system (Kropp et al., 2018) to improve the capacity to respond and adapt to expected and unexpected changes (Hollnagel et al., 2006).

Therefore, alternative and complementary controls to support existing planning and control approaches are needed to deal with the dynamic nature of construction (Hajdasz, 2014). Controlling production status can potentially increase transparency and promote better communication between trades, which, according to Lehtovaara et al. (2021), must be considered in LBPC approaches. Additionally, technology can be used to monitor construction progress and production status, e.g., 360º cameras attached to hard hats connected to data management cloud platforms (Kropp et al., 2018).

Accordingly to Koskela and Howell (2008), job dispatching consists of assigning a task ready for execution to a crew and communicating this assignment as authorization to start work. However, this procedure is generally done by oral communication (Koskela & Howell, 2008). So, there is an opportunity to develop planning and control models that adopt digital technologies to formally assign workers to tasks and workstations, enhance understanding of planned work and increase commitment.

Studies that address SW in construction (De Bortoli Saggin et al., 2017; Mariz, 2012; Tommelein & Emdanat, 2022) have not explored a broader perspective of the SW basic

[5] Cycle time depends on the production capacity and corresponds to the time elapsed between the beginning and end of a cycle to complete all operations (Alvarez & Antunes Jr., 2005).

elements (e.g., sequence of steps, location flows, slack), and neither explored its integration with production status control with the support of digital technologies. This integration can potentially increase the degree of standardization of production cycles, increase the efficiency of operations, and contribute to the synchronization of processes. So, this research aims to propose a model that integrates SW and production status control by using digital technologies to support LBPC.

RESEARCH METHOD

Design Science Research (DSR) is the methodological approach adopted in this investigation. DSR seeks to produce scientific knowledge (Holmström et al., 2009) while solving problems faced in the real world (March & Smith, 1995) and contributing to theoretical developments (Kasanen et al., 1993). The artifact proposed in this investigation is the production management model, which results from the combination of LBPC, SW and production status control with the support of digital technologies. This research work was based on an empirical study carried out in a Brazilian company involved in the development and construction of residential and commercial building projects, named Company A. This company is well-known in the market for the successful implementation of Lean Production practices and had implemented the Last Planner System for more than 15 years. The main company's motivation to take part in this study was to increase the degree of standardization of critical processes. This study occurred between January and September 2022.

The empirical study was divided into four phases: (1) assessment of the existing planning and control system; (2) analysis of data and proposition of the model; (3) implementation and refinement of the model; (4) evaluation and final discussion. The first phase consisted of understanding the existing situation in one of the company's construction sites. The planning and control system was assessed, and several Quality Management System (QMS) documents were analyzed. Moreover, some workers and site logistics operations were monitored, and critical processes and improvement opportunities were identified. The research team proposed the model in close collaboration with the company's managers. The development and test phase occurred through iterative learning cycles of data collection, analysis and reflection, in which the solution was implemented and collaboratively improved. During the implementation phase, the artifact was evaluated, and at the end of the study, the proposed model's practical and theoretical contributions were identified.

PROJECT DESCRIPTION

The project comprised a residential tower and a commercial area of 15.341,13m², which started in September 2020 and was expected to finish by March 2023. This study focused on the 15-floor residential tower built on structural masonry and internal drywall partitions. Thirteen floors had the same layout, containing 12 apartments. The apartments had between 56m² and 67m² of private area and were divided into three typologies. The apartments had similar work densities, which provided an ideal base to devise and implement the planning and control model proposed in this investigation. The study was performed during the finishing phase when the interior drywall partitions were almost finished.

EMPIRICAL STUDY STEPS AND SOURCES OF EVIDENCE

The assessment of the existing planning and control system included site visits, participation in planning meetings and interviews. Consequently, important aspects were analyzed: building systems adopted, the Location Breakdown Structure (LBS), production batch sizes, the volume of WIP, visual devices to support planning and control, direct observation of vertical and horizontal material transportation operations, layout and stocks. Moreover, the master plan was translated from a Gantt Chart into a LOB using a LBPC software. As an outcome of this stage, some improvement opportunities were identified: the need to plan, standardize and synchronize critical activities based on the SW concept, and introduce the production status control with the support of digital technologies. The **analysis of data and proposition of the model** were focused on a set of critical processes, which were selected according to the following criteria: (a) a high degree of variability; (b) a large number of interdependent activities; (c) about to start activities. A protocol for direct observation of the 3rd, 4th and 5th floors' ongoing activities was applied, and semi-structured interviews with workers were carried out to map the work content of those critical activities (cycle time, sequence of operations and requirements to perform an operations cycle). Data collected included the floor location flow followed by workers, the number of workers and their distribution within the floor, the actual cycle time for each worker to execute each apartment, the trade's floor cycle time and existing procedures. Based on that data, a qualitative and quantitative analysis was conducted to compare work-as-imagined and work-as-done. The improvement propositions included a standard sequence of operations, a detailed division of work zones, a new cycle time for operations, and a production pace for the processes. The digital solutions adopted were: (a) 360° camera mounted on a hardhat and connected to a mobile app to perform offline captures and upload to a cloud-based platform to monitor actual construction progress on the web browser or app; (b) tablets to update production status, collect activity progress data, which trigger quality inspections; and (c) andons to monitor workers' check-in and check-out at different locations and to control the amount of WIP. The andon device was not used as a tool to stop the line when problems occurred and manage production alerts.

The **implementation and refinement** stage started by training managerial and production teams on key lean topics (e.g., LBPC, takt time, batch size, SW and production status control). This training also enabled managers and workers to operate digital technologies and visual devices. The implementation process focused on committing the workers to standard production cycles. Managers, researchers, and team members involved in the critical activities discussed the SW proposal in a collaborative meeting. The conversation focused on discussing the proposed standard production cycles and showing possible earnings they would have if they committed to the plan. Site visits were then made to observe the work performed, monitor production status, and discuss and refine the proposed standard. Finally, in the **evaluation and final discussion** phase, performance metrics were analyzed: the amount of WIP, apartment and floor cycle time variation, production pace deviation and batch adherence. Workers' and management team feedback was collected, and the artifact was then evaluated based on utility and easiness of use criteria, as suggested by March & Smith (1995).

Table 1: Summary of sources of evidence

Phases	Time Spent	Sources of Evidence
1- Planning System assessment 2- Improvement propositions	17 hours 30 min	Direct and participant observations; Semi-structured and open interviews; Document analysis; Photos.
3- Implementation and refinement	46 hours	
4- Evaluation and final discussion	6 hours	Participant observations; Semi-structured interviews

RESULTS

ASSESSMENT OF THE EXISTING SITUATION

The transcription of the existing master plan into a LOB (Figure 1) pointed out some problems: (i) not enough time gaps (buffers) between processes; (ii) limited process synchronization as cycle times varied from three to ten days; (iii) the continuous product flow was emphasized, focusing on executing tasks as soon as possible, and causing workflow interruptions.

A set of five critical interrelated activities was chosen for the implementation of SW: ceiling plaster lining, waterproofing, mechanical protection, and wall and floor ceramic tile (Figure 1). The site manager pointed out that keeping this set of activities on time was challenging. A major cause of this problem was the high amount of WIP: work was spread over several floors, and there were site congestions of different teams working in the same location.

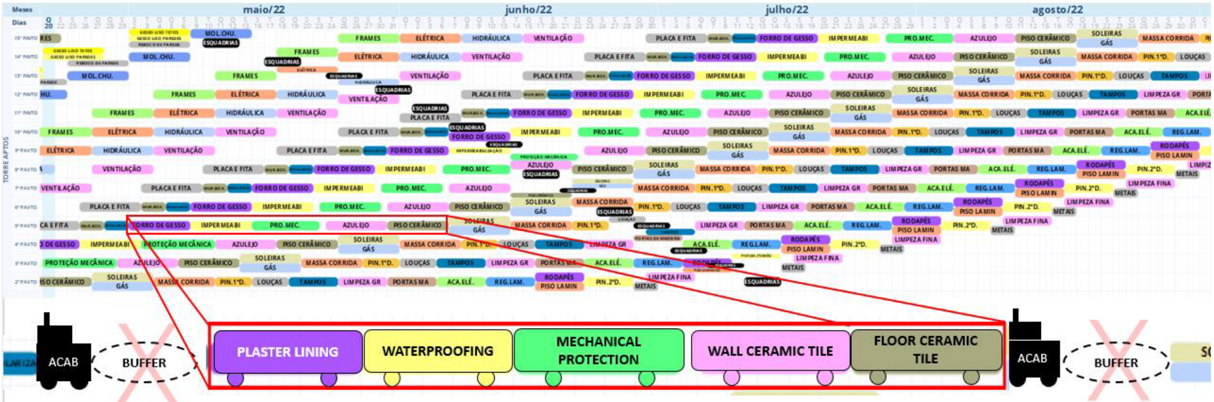

Figure 1: Master Plan and the set of critical interrelated activities selected

Figure 2a and 2b compare the initial plan and the projection of the production pace, based on existing performance, for the set of critical activities. The following problems were detected: (a) the actual production paces were different from the master plan; (b) there was a 24-day delay in the starting day of the set of critical activities; (c) waterproofing and plaster lining were being executed in parallel which caused some interferences between crews; (d) wall and floor ceramic tile actual cycle time was 16 days, i.e., longer than the 10-day planned duration; (e) wall and floor ceramic tile were planned to be executed in sequence while executed in parallel, and based on the projected production pace tendency it was not going to finish within the established deadline (September 1st 2022).

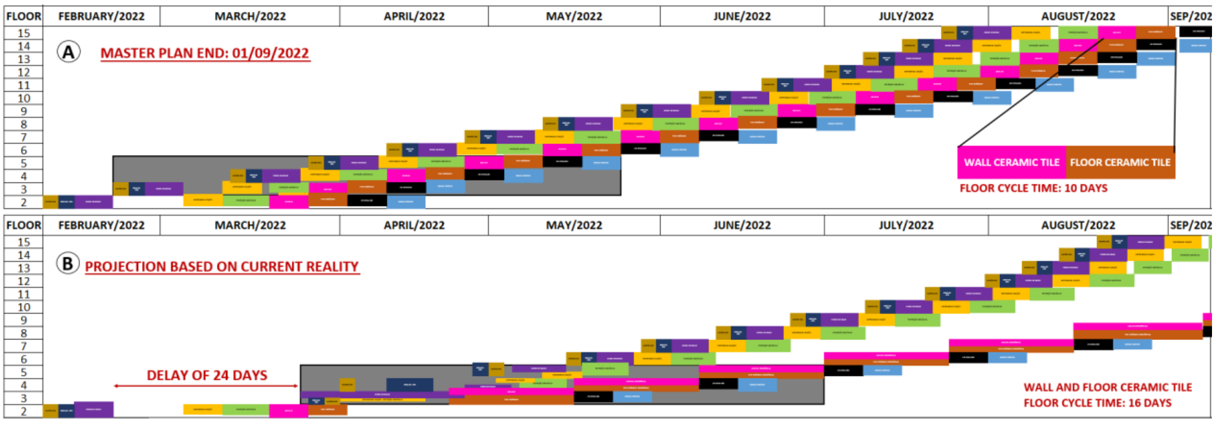

Figure 2: (A) Master plan and (B) Projection based on current reality

STANDARDIZED WORK PROPOSAL

Based on the identified delay trend, mostly related to the execution of the wall and floor ceramic tile, a future state plan was proposed considering ideal cycle times (Figure 3). The five critical interrelated activities were merged into three activities: (1) ceiling plaster lining; (2) waterproofing and mechanical protection (3) wall and floor ceramic tile. For these three critical interrelated activities, a 5-day floor cycle time was considered as well as a new crew size definition. This research paper focused on the wall and floor ceramic tile activity, as this was the one that had the highest impact on the existing delay. By implementing these improvements the new projected conclusion of the set of activities was August 19th 2022, which represented a reduction of two weeks' duration compared to the master plan.

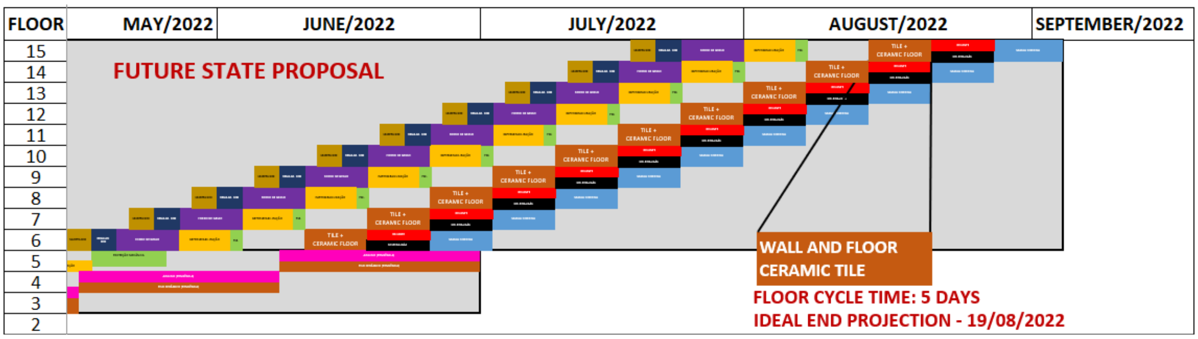

Figure 3: Future State Proposal

In order to implement SW, the future state proposal needed to be detailed, observing actual cycle times, necessary production and setup times, execution alternatives and good practices informed by workers. The aim of this stage was to balance the amount of work among crews to reach the takt time of five days per floor and synchronize the processes. Figure 4 shows the current state of the wall and floor ceramic tile, which makes the number and distribution of workers into work zones (Y-axis), durations (X-axis) and location flows explicit. It highlights that the actual floor cycle time is sixteen days, while it was planned for ten days.

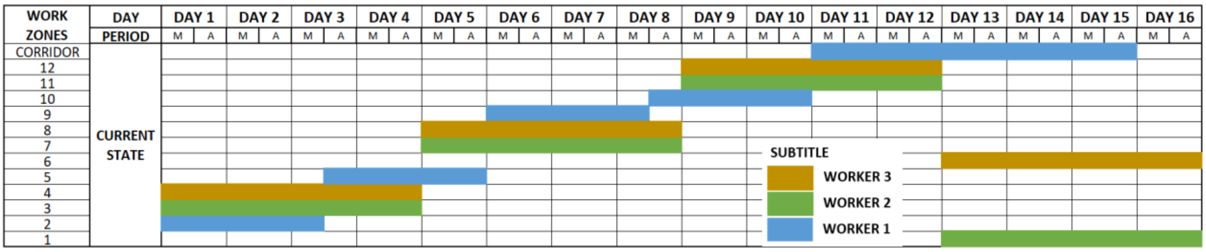

Figure 4: Current State – Wall and floor ceramic tile

The current state of each critical activity was initially discussed with the site manager and the subcontractor. Based on that, a new crew size was established. After that, the distribution of work was discussed with the workers involved in the task, resulting in the proposal of the first version of the SW. This proposal comprised the elements: takt time, worker cycle time, standard floor location flow, followed by workers and standard sequence of operations in each apartment. In the second version of the SW proposal, some types of slack were included. Figure 5 presents the SW sheet for wall and floor ceramic tile.

In order to commit workers to the implementation of SW, managers and researchers promoted a meeting with all of them to discuss the plan and explain the benefits to all parts. It was emphasized to workers that they would benefit from better working conditions, increase in the learning effect and production predictability, and consequently, raise their earnings.

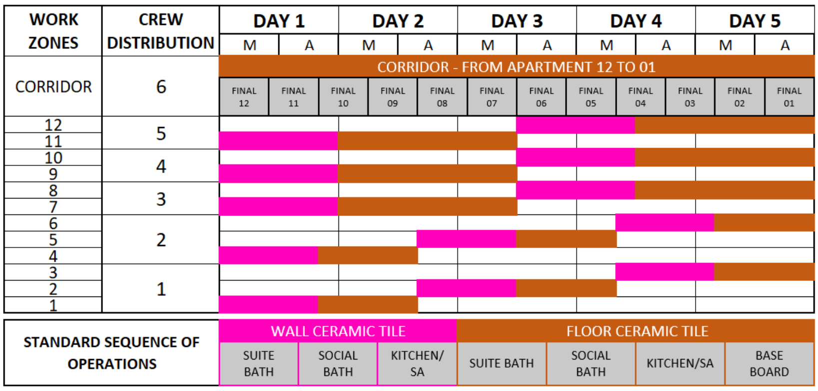

Figure 5: First Standardized Work Proposal – Wall and floor ceramic tile

INTEGRATION OF STANDARDIZED WORK AND PRODUCTION STATUS CONTROL

After defining the SW, control routines were proposed to achieve takt time and synchronize interrelated activities. The LBS played an important role in defining production control cycles. The company was used to allocate crews to floors. However, it was decided to reduce the production batch size to one apartment to make it easy to control each operation flow of each apartment (12 apartments per floor) and perform quality inspections. Nonetheless, the production pace control was still being controlled per floor (13 floors total) so that it could be compared to floor takt time. Reducing the batch size was important to improve the commitment of crews to the location flow and to encourage them to take proactive measures to achieve the proposed apartment cycle time. This was named hierarchical work zone control, as different work zone levels enabled different location-based controls.

The inclusion of different types of slack was due to the need to cope with the variability in workers' productivity, as teams used to work in a fragmented way. The main types of slack adopted were: multifunctionality of some subcontracted crews, time buffers, and space buffers, e.g., apartment and corridor areas to be produced which had no worker assigned by the one that finished their assigned apartments before the floor takt time.

With all these decisions, visual devices, digital technologies and control routines were implemented to promote transparency and increase understanding and commitment to plans and standard working routines. Figure 6 shows a visual device used on each floor to make production goals explicit for each worker of ongoing activity (apartment takt time, time and buffer, location flow and standard sequence of operations). Other visual solutions were also adopted: workers' names were written close to the entrance door of the assigned apartment, and spray was used to mark the best sequencing of ceramic installation to encourage repetition in operations.

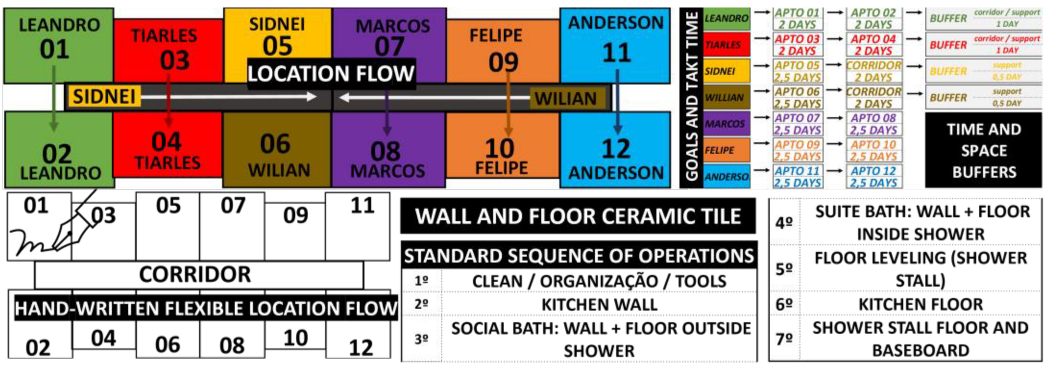

Figure 6: (1) Visual device that displays batch sizes, workers allocation and location flow, apartment takt time, time and space buffers and standard activity sequence; (2) Example of flexible allocation visual device.

An LBPC software was used to produce the plan, support control routines and allocate workers. A key step in allocating workers to work packages was following the planned floor location flow and prioritizing the execution of the same apartment typology to promote the learning effect in order to increase productivity. After some production cycles, the need for flexibility in assigning workers to their activities in work zones was observed due to workforce turnover, variation in production pace and work absence. This was done by using a visual device that allowed some degree of flexibility in the allocation of labour, as shown in Figure 6.

SUPPORT OF DIGITAL TECHNOLOGIES TO CONTROL THE PRODUCTION STATUS

The production status control matrix was devised to control the amount of WIP while assigning activities and work zones to workers. It can be considered as an application of the pull production concept proposed by Hopp & Spearman (1996): activities are triggered by the status of the system. The aim of this visual device was to improve communication between trades, and enhance data accuracy and traceability of process status. The source of data was the check-in and check-out control process, which allowed the start and finish times of different operations to be obtained. Three different mechanisms were used (Figure 7). Initially, paper tables were already adopted by the company, producing a daily manual report on activities status – besides the lack of automation, that solution resulted in inaccuracy for start and finish times, as data collection was performed generally once a day and sometimes not in all work zones. Then, two other mechanisms replaced it: a cloud-based electronic spreadsheet with mobile data collection, which produced a reduction of data collection and processing times, increased data accuracy and provided an overview of the production status in each work zone (Figure 7a); and a semi-automated status registration using an andon system (Figure 7b).

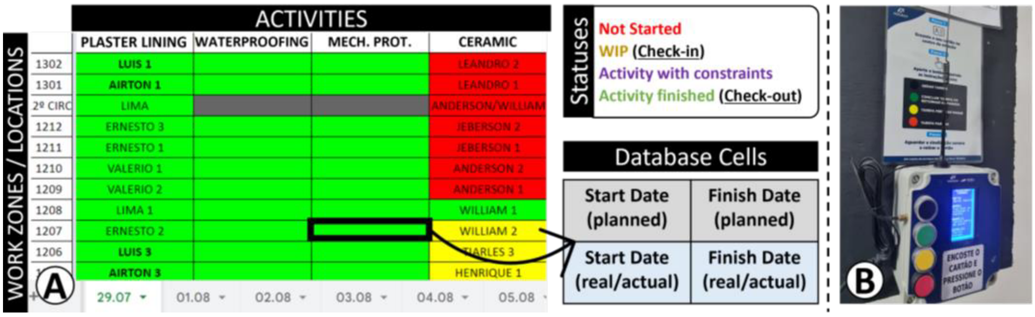

Figure 7: (a) Production Status Control Matrix and database that originates the statuses, and (b) electronic device to self-register actual start and finish (e.g., Andon).

Workers allocation was done in a mobile app which automatically updated the LBPC software, and workers received a message about the updated assigned activity and work zone. This information was also updated to the andon system, enabling workers to use their tags to obtain their assigned activity and update its status. This app was used to improve WIP control, as workers should follow the assigned location flow. The managerial team started anticipating allocations 1-2 weeks before activity should start accordingly to the production status. To some extent, this system lacked the flexibility to allocate workers and change locations flow. But the check-in and check-out mechanism automatically updated a database that stored planned and actual start and finish dates. This information allowed the production status matrix to be updated in real-time and provided an overview of the status of each location, represented by different colours (Figure 7a). Also, this database was the source of information for all production performance graphs (see the following topic). The 360-photo database, located on a cloud-based platform, was useful to support tracing WIP, work completeness and production cycles by location. It was also used to assess start conditions, site organization and stocks. Some constraints and the need for additional logistics work were identified, resulting in the assignment of new tasks for managers and crews. All the analyses made through this platform were triggered by the production status control.

DISCUSSION

Several different production metrics resulting from LBPC were used in this project: cycle time (per apartment and floor), batch adherence (per floor) and production pace deviation (per process). Figure 8 presents graphs generated for wall and floor ceramic tile. Figure 8a shows that, even though this process had not started at the initially planned start date, it finished on time. In fact, balancing the amount of work among employees allowed the floor delivery pace to be lower than it was initially planned. Figure 8b indicates that this was achieved, i.e., actual cycle times ranged from six to seven days per floor. On the 12th and 13th floors, there was an increase in cycle time due to sharing the resources with the 2nd floor. Hierarchical work-zone control was fundamental to this process, as it enabled different location-based controls: even though apartment cycle times (a lower control level) varied inside the floor production cycle, floor takt time could be accomplished (a higher level of control).

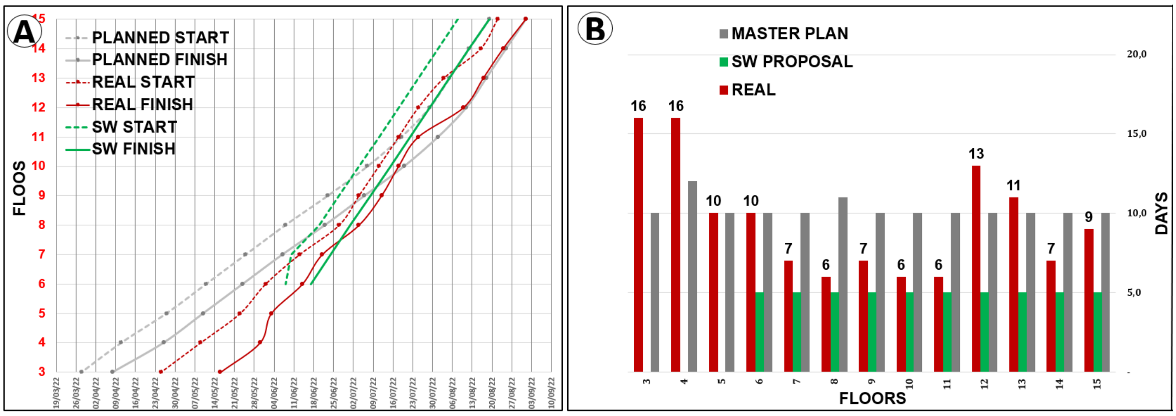

Figure 8: (A) Batch Adherence and (B) Cycle Time – Wall and floor ceramic tile

Two graphs were created to analyze the impact of SW on the set of interrelated activities (Figure 9). Figure 9a plots the production pace deviation by process, showing a trend of process synchronization. Figure 9b shows the evolution of cycle time, indicating a trend of reducing both duration and variation. This confirmed that the combination of SW and production status control was successful in terms of implementing production improvements towards process synchronization.

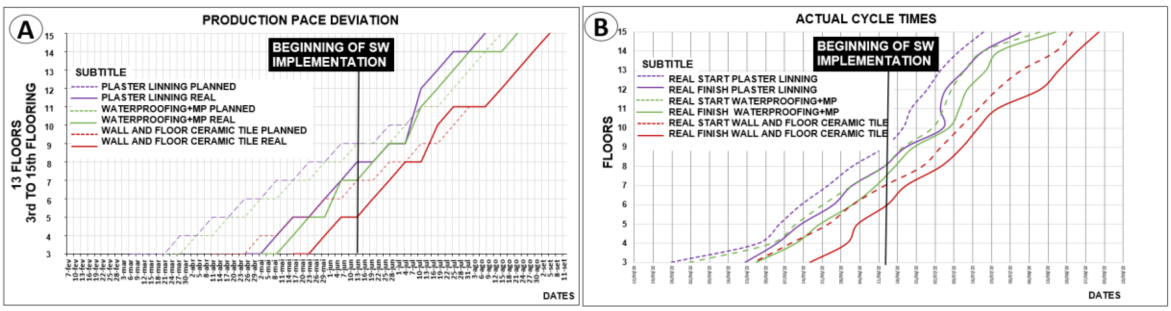

Figure 9: (A) Production Pace Deviation and (B) Actual Cycle Times-Interrelated Processes

Implementing SW enabled stabilizing processes' cycle time, reducing work zones congestion and displacements. The focus on the execution of the same apartment typology generated learning and increased the crew's productivity. The effects of the SW and production status control combination enhanced subcontractor trust and the prediction of the amount of work ahead and monthly incomes. These reduced workforce turnover, a problem identified during the first production cycles. Monitoring production status successfully supported work allocation, based on the pull production principle, which increased WIP control and helped crews to anticipate initial conditions and problems and report them to managers, so they could solve them before starting their activity in that location. Digital technologies also provided a key support in quickly obtaining accurate, traceable and transparent construction progress data, which was used to make production adjustments when needed. Visual devices, such as the production status matrix and metrics report, supported weekly meetings with subcontractors to have a production overview, detect rhythm deviations, align goals to follow the proposed plan and make the necessary adjustments. The need to adopt slack was endorsed during production cycles to cope with productivity variability. However, this mechanism was not enough. Anticipating the requirements to perform an activity beforehand was also important to eliminate constraints, but this was not fully explored in this investigation. This was made evident by some problems identified, such as the unavailability of crews to execute the 2nd floor, which increased the cycle time of the wall and floor ceramic tile on the 12th and 13th floors, as the same crews had to execute these in parallel. Also, problems with pipe leveling on the slab surface were not identified in advance and did not allow the installation of the kitchen floor on time and generated additional activities. Therefore, using digital technologies to analyse ideal conditions to perform activities and controlling task completeness while considering quality standards play a key role in the successful implementation of SW and process synchronization.

INTEGRATED CONTROL MODEL AND EVALUATION

The proposed model for integrating SW and Production Status Control is presented in Figure 10, being divided into five main steps. The model was evaluated accordingly to its utility and easiness of use. Regarding the utility construct, the model contributed to the implementation of collaborative processes in LBPC and the level of standardization, promoting team engagement and increasing the reliability of the production system. By encouraging participation and work autonomy, SW provides a suitable balance of standardization, flexibility and continuous improvement. In fact, workers provided feedback on their learning, and productivity increased along standard production cycles. The model also increased workers' autonomy by providing a clear scope of flexibility bounded by the standardization of operations: location flows and apartment cycle time were part of the standards, while workers could change operation sequencing during execution. Consequently, the model provided mechanisms to increase the stability of processes' synchronization and production cycles. Regarding the ease of use construct, it was observed that the model enabled the understanding of LBPC practices and concepts, as well as made information available to support decision-making effectively and transparently.

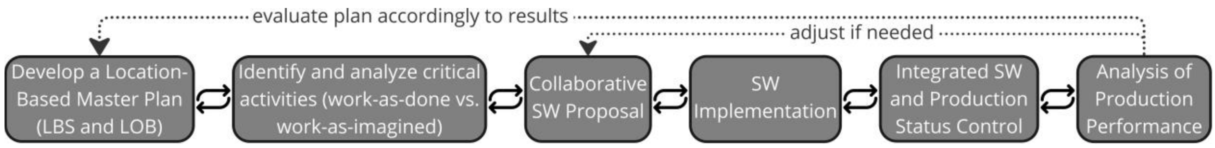

Figure 10: Integrated Control Model of SW and Production Status to support LBPC

CONCLUSIONS

The main contribution of this investigation is extending the use of LBPC to the very operational level, by adapting the SW approach, developed in manufacturing, into the construction industry. This study has also explored the use of production status control by using digital technologies. This model is based on the assumption that the implementation of the Lean Production Philosophy in construction must emphasize the management of variability, rather than simply trying to eliminate it. Collaborative processes involving the workforce, and the use of visual management supported by digital technologies play a key role in the model. This results in a set of lean metrics and concepts that are effectively used in production management: takt time, cycle time, slack, standard floor location flow, standard sequence of operations, production status, and work-in-progress control. Therefore, the model can be understood as a mechanism to systematically manage variability and uncertainty in LBPC (workforce and processes) and increase the degree of standardization of processes while having short feedback cycles to promote adjustments while monitoring the construction progress. The control model must seek an equilibrium between standardization, flexibility and autonomy in production processes. The proposed model still needs to be refined to provide a robust decentralized management system. Further studies should consider: (a) implementing the model in projects with lower levels of repetitiveness; (b) investigating other digital technologies for monitoring production; and (c) further investigating requirements (standard kits) and slack to avoid the negative impact of variability.

A LOGISTIC FRAMEWORK TO ENABLE TAKT TIME PLANNING

Raquel H. Reck[1] and Marcus C. T. Fireman[2]

ABSTRACT

Takt Time Planning (TTP) methodology has gained growing popularity in lean construction, with the aim of improving workflow and increasing production stability. Despite the numerous research efforts surrounding TTP, there is a gap in understanding how logistics planning should support TTP in a construction project. This study presents a framework for developing logistics in a construction project that uses TTP as its planning method. The framework consists of four drivers: (a) equipment sizing, (b) layout risk study and analysis, (c) material management, and (d) structuring of daily routes and routines. The results show that the integration of TTP into the logistics framework allowed for the design of the production system to ensure Takt, and to structure a rapid response to the variations found during the LPS control cycles. Hence, the project deadline was reduce by 16.4%, or 4 months.

KEYWORDS

Takt Planning, WorkFlow, Last Planner System, Logistic

INTRODUCTION

In the last decade, it is possible to observe a growing application of the Takt planning method in the lean construction. Among the main benefits achieved with the methodology, we have better team organization, better transparency, reduction of handoffs between sequential teams, reduction of cycle time, increased productivity, reduction of project duration in construction, among others (Yaw et al., 2020; Dlouhy et al., 2019; Binninger et al., 2018; Frandson et al., 2014).

Takt Planning is a structured planning method that brings a perspective of workflow and rhythm to civil construction, since it organizes the sequence of locations that should receive tasks in a construction site and, at the same time, synchronizes the execution of these tasks around a Takt time (Frandson, 2019). Takt time is a unit of time that represents the rate at which a product must be completed to meet customer demand in a specific period of time (Hopp; Spearman, 2004). According to Binninger et al (2018), one of the differentials of Takt Planning, when compared to traditional methods of construction planning, is the fact that services are produced at a constant rate, allowing a reliable pre-planning of activities. Gardarson et al (2019) points out that Takt Planning can be represented as a train with several wagons that move through the areas of a project. In this format, the wagons are different groups of workers who complete a set of tasks before moving to the next area, being followed by another wagon of workers who will complete their respective tasks (Gardarson et al, 2019).

Vatne and Drevland (2016) signal the important role of logistics for the successful application of Takt. According to Lehtovaara et al. (2019), one of the main barriers to Takt Planning is precisely logistics planning and material control. Tommelein and Emdanat (2022) corroborate this thinking, and suggest a correlation between Takt and logistics planning. If, on the one hand, Takt analysis is an input to logistics planning, on the other hand, logistics can become a bottleneck for the application of Takt, since the dimensioning of transport equipment, the space for storage and movement interference of equipment can make a Takt unfeasible to be applied in a project (Tommelein; Emdanat, 2022).

Recently, Al Barazi et al (2021) demonstrated the potential of simulation methods, such as Agent Based Modeling, for logistics simulation in vertical construction sites, with the goal of fulfilling a hypothetical Takt planning. In this study, it was possible to identify the best number of equipment according to variables such as elevator capacity and speed, storage capacity on site, lunch and snack time, etc. Tetik et al. (2019) set out to analyze the benefits of using appropriate logistics solutions for Takt application in construction. The research focused on the logistics solution of material picking and kitting in Assembly and Logistics Unit (ALU), identifying that the main benefits were related to the reduction of material waste, ability to follow the predetermined Takt sequence, and a better quality of acquisition (Tetik et al., 2019).

While recognizing the significance of logistics in realizing the expected advantages of Takt planning, there is a lack of practical research that illustrates how to establish logistics in a project to fulfil predetermined Takt time. Hence, it is crucial to devise a Takt planning while simultaneously designing and executing logistics strategies for the construction site. The purpose of this article, therefore, is to demonstrate the utilization of a logistics framework to fulfil Takt planning through a case study.

METHOD

The research is positioned as Design Science Research, in which innovative constructions (or artifacts) are developed, designed to solve classes of problems encountered in the real world and, at the same time, make theoretical contributions (Lukka, 2003). The artifact proposed in the present study is a logistics framework motivated by the systematics of Takt time planning. In this type of study, the starting point for conducting the research is the knowledge of a set of practical problems (Van Aken, 2004), in this case, the design and execution of logistics strategies that guarantee the transformation of the construction site to comply with the Takt time requirements.

The framework was developed during a case study about a housing project with 23 residential towers in 5-storey structural bricklaying, totaling 1180 apartments, divided into 3 distinct contracts (Figure 1).

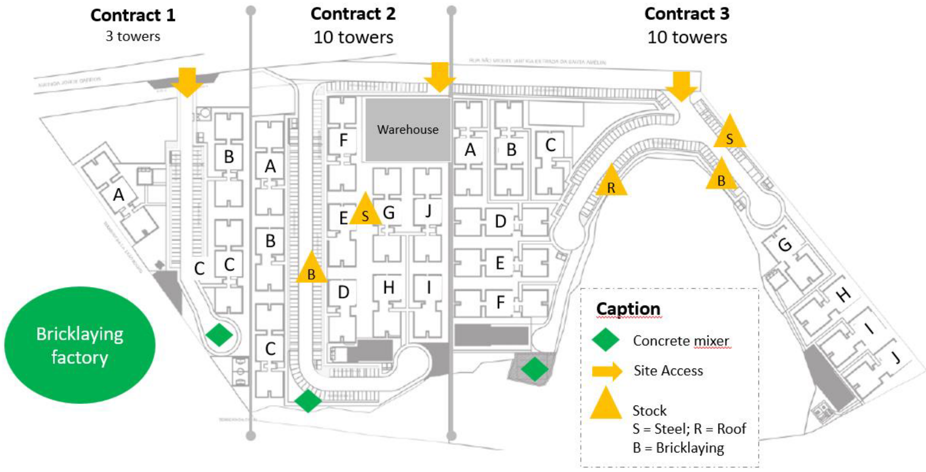

Figure 1: Location of the towers and construction site facilities

The contractor of this project was interested in implementing Lean practices, hiring a consulting company for this purpose (implementation period from September 2021 to February 2022, total of 6 months). At the time of the diagnosis carried out by the consulting company in September 2021, only masonry structural walls and structured concrete slab activities had started, and the project still had 15 months left until its completion (September 2021 to October 2022). Due to the project being divided into 3 contracts with the same due date, during the diagnosis phase there was a scenario of a large amount of work in progress, since all 23 towers had initiated structural activities, but none of them had advanced to the 5th floor. In this regard, the deadline, inicially October 2022, pointed to a 5-month delay trend, going until March 2023.

Thus, in addition to Last Planner System routines, we proposed the deployment of a TTP and a logistics system that would allow the project to be delivered on time. The biggest challenge in this project was to scale the logistics system, as well as to be able to maintain the Takt of the productive activities, since the construction site had approximately 75,000 m², 800 employees during its peak of execution and a complex system of material and transport centers, as shown in Figure .

This research presents three distinct steps: (a) definition of Takt and structuring of the logistics system; (b) development of logistics strategies; and (c) evaluation of the logistic system implemented. The development of these steps is described in detail below. As sources of evidence it is possible to highlight: (i) participant observation of the authors of this paper at the construction site and at LPS meetings, acting as project consultants; (ii) reports on the status of the consulting project, periodically developed during the consulting; (iii) result and process indicators applied during the consulting period until the end of the construction project; and (iv) logistics checklist (Fireman et al, 2023).

DEFINITION OF TAKT AND LOGISTICS FRAMEWORK

Takt definition was carried out according to Equation 1 , in which we used 80% of practicability, because the construction site presents horizontal characteristics and external activities, which were very affected by climatic conditions. The available time, number of repetitions and number of activities vary according to activity groups, called "trains" in the case study, and assumptions of initial projects. It is important to point out that although the practicability factor is sometimes implicit in the calculation of available time in the literature, here we prefer to use it explicitly.

$$Takt = \frac{available\ time\ *\ 80\%\ practicability}{(repetitions + number\ of\ activities - 1)}$$ Equation 1

To define the Takt, a mapping of the construction sequence was designed, and we identified the existence of 17 internal and 9 external activities for each Takt area. However, at that time, there were still restrictions with long lead time that had not been hired, for example the ceramics tiles, which would take 180 days, and the materials for gas system installation that had a lead time of 90 days. Due to these factors and prerequisites, such as safety buffer and executive sequence restrictions between internal and external activities, the Takt application strategy for the entire construction site was divided into groups of activities, creating 5 trains, as described below and outlined in Figure 3:

a) masonry structural walls and structured concrete slab activities had already started and had no initial prerequisite, thus, their Takt was calculated separately;
b) train 1 corresponds to electrical and plumbing installation activities, waterproofing and cementitious floor underlayment, without time restrictions, but not yet started;
c) train 2 corresponds to gas system installation and gypsum coating activities (due to gas lead time this activity train would have less time available than train 1);
d) train 3 corresponds from ceramic tiles activities until the end of internal activities (it would also have less available time than train 2 due to ceramic tiles lead time);
e) train 4 corresponds to façade activities, which can only start when the first roof top structure of the towers is completed;
f) train 5 corresponds to façade activities after the first window installation (internal activity), and must be completed one month before the end of the work.

<table>

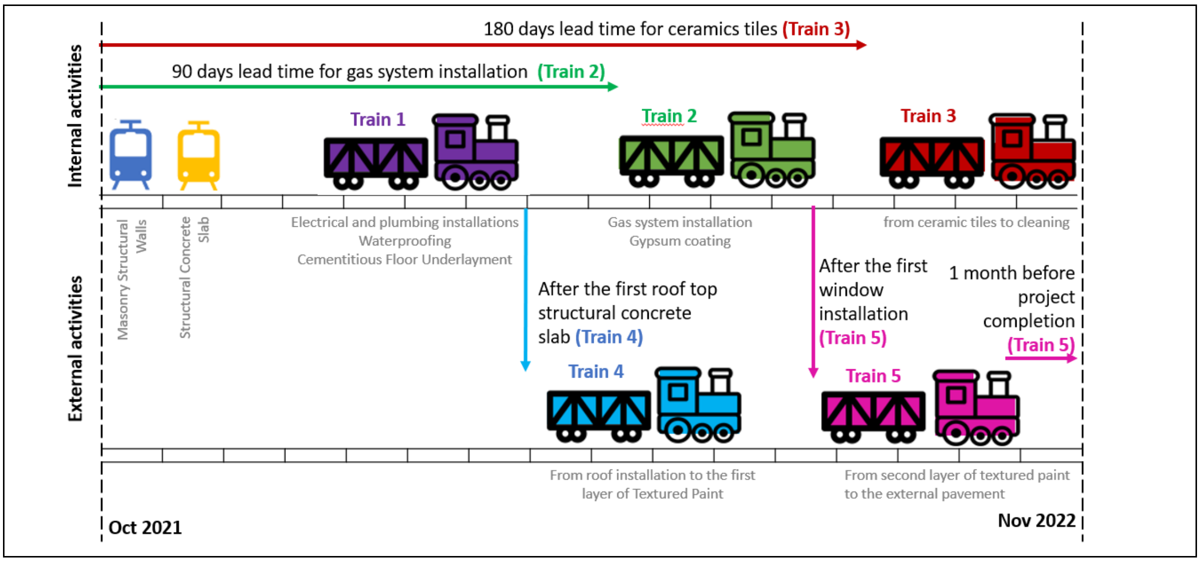

Figure 2: Takt Calculation table

Soon after the definition of the planned Takt, it was necessary to establish logistical planning and control that would allow to meet the TTP. Thus, the framework presented in Figure 3 was proposed, containing four drivers: (a) equipment sizing; (b) layout potential risk study and analysis; (c) material management; and (d) structuring of daily routes and routines. Evaluation of these drives is presented in Fireman et al (2023). In this article, we will present the use of this framework as a logistic strategies structurer carried out in the analyzed case.

Figure 3: Logistic Framework

EQUIPMENT DRIVER

Since demand sizing is done by input, a total of 48 inputs were studied. This was carried out through the Takt area, considering the storage of input in batches and the number of batches that can be transported by equipment (Figure 4). Thus, as an example, for each apartment unit, 73 sqm of ceramic tiles is required. These are transported in boxes, which can store 2,12 sqm of ceramic tiles each. Each pallet can carry 32 boxes and only 5 pallets can be transported by each truck, due to volume and weight restrictions. At the end, as shown in Figure 4, 197 ceramic tiles travels are required to supply the 1,180 apartments (Takt areas).

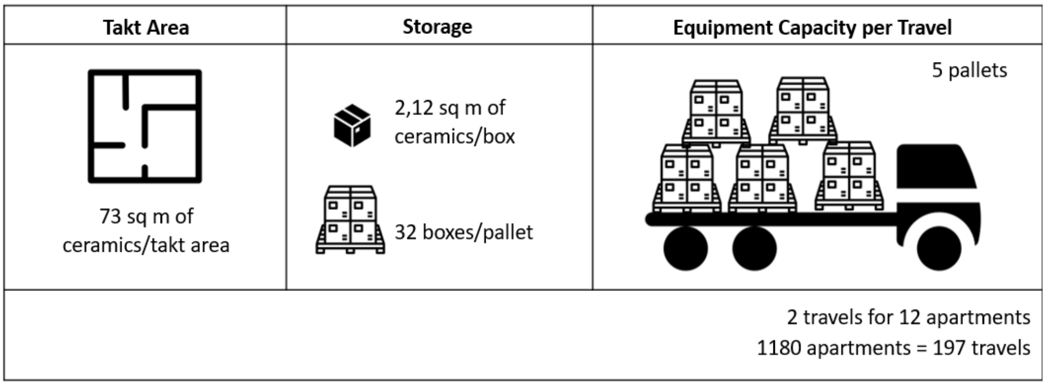

Figure 4: Example of quantification of materials by input and Takt area

For the equipment to meet the TTP, it was necessary to size the number of travels per type of equipment per input, characterizing the necessary demand. Soon after, this demand was compared with the current capacity of the equipment on site (data collected daily during the project). Table 1 presents the comparison between demand and capacity of critical equipment. Since demand is bigger than capacity, it was necessary to exchange supply equipment for input, and a fuel supply pump was allocated on site to reduce the set-up time of such equipment.

Table 1: demand versus capacity of critical equipment

Equipment	Demand (peak)	Capacity (peak)
Munk	73 trips per day	73 trips per day
Backhoe loader	62 trips per day	57 trips per day

LAYOUT DRIVER

To evaluate potential logistics risks, a layout study was carried out in an analogical manner, where in which each frame represented a period of time and a specific train. Thus, every 3 months it was highlighted in the frame where each of the 5 trains plus the masonry structural walls and structured concrete slab activities would be located. In this way, it was possible to evaluate risks of crossing different workflows, storage locations closest to the towers in construction and pre-assembly locations, such as cutting and folding steel rebars and concrete mixer. Figure 6 shows this layout analyses. Vertically, we have the different trains in different colors, and horizontally each column corresponds to 3 months of the project.

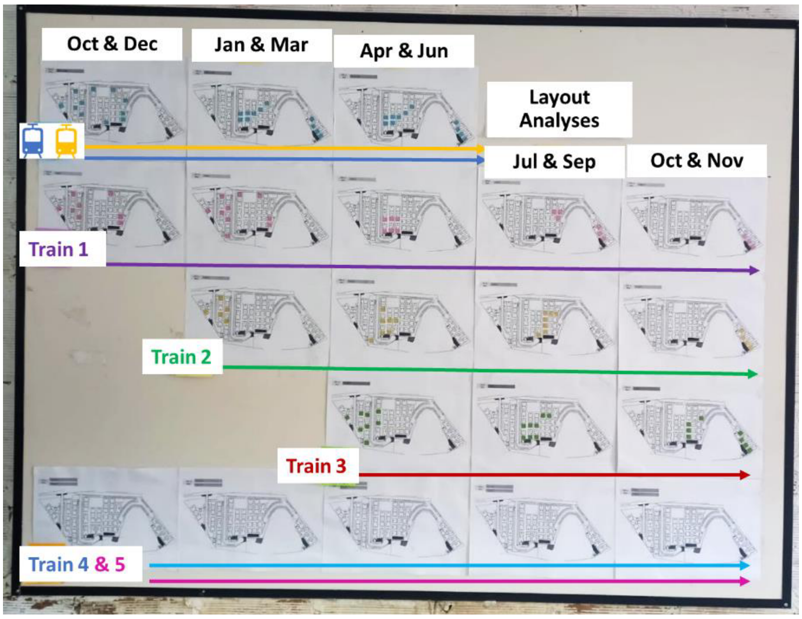

Figure 5: quarterly Layout Study

Then, Figure 6 presents a detailed study for the site's peak working week. It presents, the routes between pre-assemble location (such as cutting and folding steel rebars and concrete mixer) and storage (such as material stocks and warehouses) to workstations. Thus, it was possible to assess the density of workflow and identify the main transportation risks.

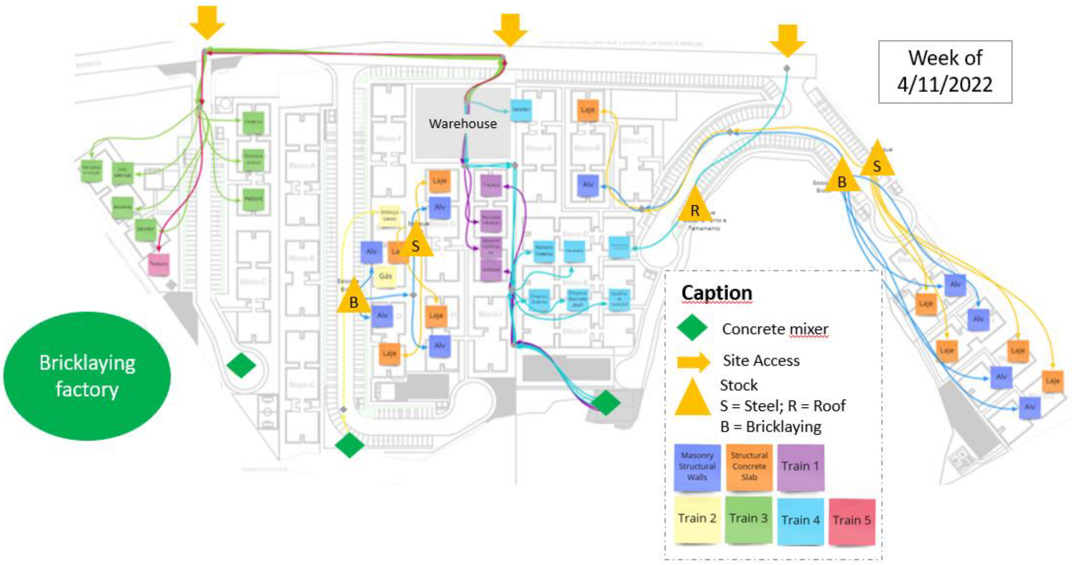

Figure 6: study of routes between production/storage locations and workstations

MATERIAL MANAGEMENT DRIVER

From the tools developed in the layout driver, it was possible to identify different potential risks for material management. The main ones were:

a) assess whether the flow of sand (number of travels per day) would impact the movement of materials at the site, since all concrete was produced at the site in only 3 concrete mixers;

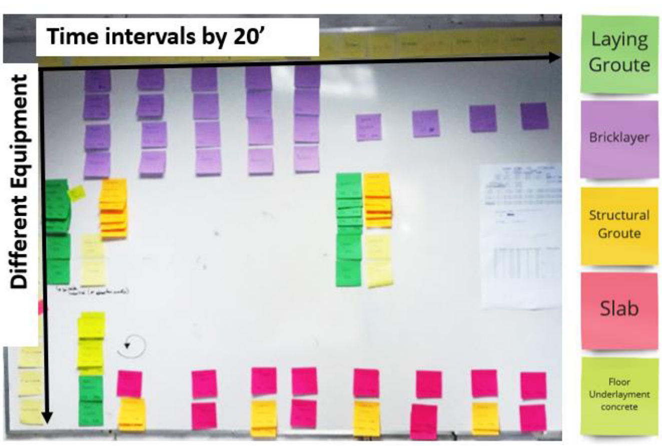
b) define the supply flow of the cementitious floor underlayment, mainly identifying the equipment to be used to avoid possible obstructions to pumps due to density and gravel incorporated into the mixture;
c) definition of evening supplies to avoid route jamming during the teams' working hours;
d) definition of ceramic tiles storage locations at the manufacturer and in front of the towers, since 983 pallets of this input would be needed to build the 1,180 apartments (as discussed in the equipment lever);
e) considering the ceramic tiles to be supply to the floors via a small crane by boxes, since each floor would need 10 pallets, or 320 boxes;
f) considering the installation of the crane in the elevator shaft of the towers in order to vertically supply the apartments;
g) definition of roof tile storage and supply, since it would be necessary to store 5,784 roof tiles for each tower module (the construction project has 59 modules, totaling 341,256 roof tiles for all towers);
h) definition of wood storage and supply for the roof structure, since it would be necessary to receive 4 trucks every 2 weeks (supplier restriction), which could supply the demand of 9 modules.

Thus, during LPS meetings, together with the warehouse manager and the logistics manager, the logistics strategies for these materials were discussed and applied on site.

ROUTE & ROUTINES DRIVER

After defining the three previous levers, it was necessary to implement the equipment Kanban and Check in/out tools for structuring of routes and routines. These tools had as input the sizing of daily goals from TTP and the demand for materials, dealt with in previous stages of the framework.

The equipment Kanban had 5 inputs: laying grout, bricklayer, structural grout, input of slab and cementitious floor underlayment. Kanban was partially implemented - it was not used for hands-off management between workstations and pre-assemble location and storages. But, according to Figure 8(a) the demand for each input was analyzed for each supply equipment (vertical) per hour (horizontal). Initially, the construction team had a certain resistance to the implementation of this tool, but eventually it was used for critical analysis of supply, involving the production engineer, the logistic manager and the foreman.

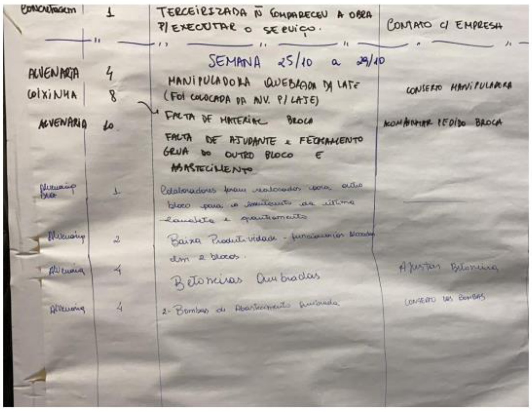


(a) Kanban by equipment (vertical) and time interval (horizontal);

(b) check in/out routine per work front

Figure 7: tools developed for leveraging routes and routine

Check in/out was defined for 13 services (see Figure 7 - b) and played an important role in solving logistical problems at the site. There were a significant number of Reasons for Non-Compliance regarding equipment breakdown and supplies delay. These were reported daily during the Check in/out routine by team leaders. These observations were acted out in daily action plans (see Figure 8a) and helped structuring a fast-problem-solving flow for equipment (see Figure 8b). Because of that, we established more frequent preventive maintenance for certain equipments, such as the external plaster projection pump, shown in Figure 8(b).



(a) notes from check in/out;

(b) evidence of breakage in the external plaster projection pump.

DISCUSSION

The benefits, as indicated in the literature (Yaw et al., 2020; Dlouhy et al., 2019; Binninger et al., 2018; Frandson et al., 2014), that have been observed with the implementation of the logistics framework are:

a) improved team organization, achieved through the use of layout, material, routes and routines drivers, risk analysis of layout, defining strategies for managing storage and supply of materials, as well as structuring daily production routes and routines.
b) enhanced transparency, facilitated by the visual board implemented in this case study, as in the quarterly layout study (Figure 6), route study (Figure 7), Kanban (Figure 8), and check in/out (Figure 8);
c) increased productivity through the check in/out routine, which facilitated the structuring of a fast-problem-solving action plan for any issues that arose daily.

It was also possible to make progress in sizing the equipment and material to meet the production demand defined by the Takt planning through the equipment and material drivers, which was a barrier described by Lehtovaara et al. (2019). However, logistics strategies such as material picking and kitting in the Assembly and Logistics Unit (ALU), as described by Tetik et al. (2019), could represent an even greater advancement in this driver. Tommelein and Emdanat (2022) have pointed out this synergy between Takt and logistics for the dimensioning of transport equipment, storage space, and interference of equipment movement, which are reflected in the equipment, layout, and materials drivers described in this paper. However, the proposed framework also advances the structuring of routes and routines on the construction site. Therefore, the structured use of these four drivers allowed for the design of the production system to ensure Takt, as pointed out by Tommelein and Emdanat (2022), and a rapid and structured response to the variations found during the LPS control cycles.

Figure 9 presents a comparative analysis of the projected duration. At the time of diagnosis, while there was no prospect of starting any activity other than masonry structural walls and structured concrete slab activities, and without Lean practices implemented, the project duration was 5 months after the contract, totaling 390 days. The actual duration of the project was 326 days, a 16.4% reduction in relation to the projected deadline. In Figure 9, it is possible to identify that if the proposed deadline reduction suggested by TTP was achieved in its entirety, the project end date would be October 2022, according to the contract, representing a potential time reduction of 27.9%. The main roots causes of problems that prevented from the reduction propose by the potential reduction are related to the above-average weather conditions and delays in the supply chain due to lasting COVID-19 effects.

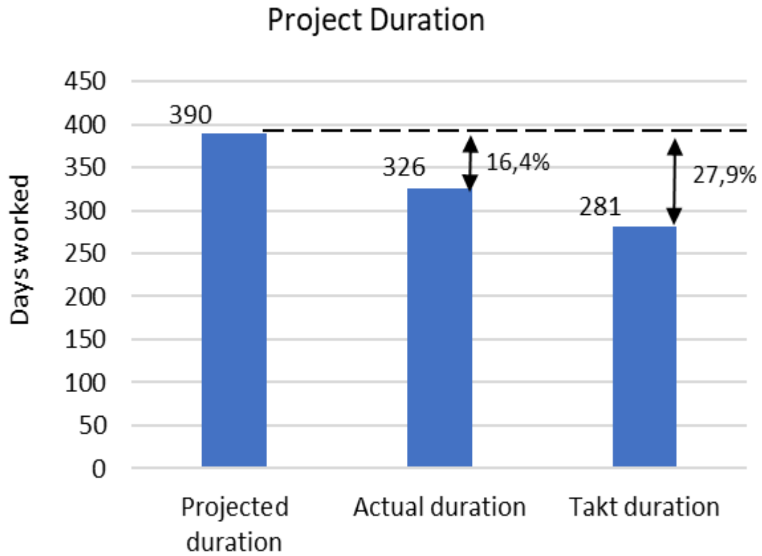

Figure 9: evaluation of the framework drivers

Even with these two roots causes, we understand that the joint application of a logistics framework and TTP contributed to achieve a good performance on the project. But, a limitation of this study is that there is no data to confirm that the 16.4% of reduction was only motivated by the joint application of them.

CONCLUSION

This article fulfills its goal, since it presents the development of logistics strategies considering the drivers of the proposed framework and the TTP. The drivers are: (a) equipment sizing, (b) layout risk study and analysis, (c) material management, and (d) structuring of daily routes and routines. These drivers allow a multivariate analysis with different sources of evidence to identify problems and logistics potential risks, allowing more efficient action plans and acting directly on the root causes. The proposal of this framework can structure both the development and the evaluation of logistics systems to support TTP. In this paper, only the development was explored, but publications focusing on evaluation, such as Fireman et al (2023), can assess the logistics strategies in different contexts, fostering good practices that guarantee Takt enforcement.

Another important paper output was to bring light to some difficulties faced when applying Takt planning. For example, the artifice of creating 5 trains was applied to circumvent some obstacles identified during method application, such as the long lead time restrictions of ceramics tiles and gas system installation or the interference between some internal and external activities, differently from Gardarson et al (2019) approach which these problems did not exist. These obstacles demonstrate that the best time for applying TTP with a focus on the project's macro strategy is before the project begins. If the method it is applied during the project, some services may not act synchronized to a single Takt, and it would be necessary to use more than one train, as present in this paper.

DO FAILURES IN A TAKT PLAN FIT THE FMEA FRAMEWORK?

Becca Apgar[1] and James P. Smith[2]

ABSTRACT

Few studies have explored takt planning failures and how they might be better prevented. Recently Failure Modes and Effects Analysis (FMEA) has been proposed as a framework for actively preventing failure in takt planning projects. This project tests case study failures against the proposed FMEA framework as a first step to determine whether a FMEA-takt plan framework can help identify and respond to takt plan failures. In this case study, takt planning was implemented halfway through the construction of five large data centers in Utah, USA. The project was repetitive, enabling a takt of one day despite the large size of the project. Any variance from the schedule (a takt plan failure) was associated with a specific task and marked in their weekly work plans (WWPs). A reason for the variance was identified. These variances were compiled for all available WWPs and are compared to the failure categories proposed in the FMEA-takt plan framework. This study shows that the FMEA-takt plan framework is feasible with minor adjustments to account for failures in takt plans that are due to variables that are beyond the scope of a takt plan, such as unforeseen conditions or extreme weather.

KEYWORDS

FMEA, process, takt planning (TP), variability, work flow.

INTRODUCTION

Over the last ten years, takt planning has been developed and applied in the construction community. Starting with Frandson et al. (2013) detailing takt planning, research has been conducted with the goal of understanding its impact and value in reducing variability and improving efficiency.

As research continues to explore takt planning, the question becomes why does it continue to be an area of focus for academia, and why does it work well? Takt planning is especially effective because it emphasizes eliminating bottlenecks, resulting in a decrease of compounding delays (Tommelein et al., 2022). Takt gives immediate feedback which allows for early recognition of whether the project is running according to schedule or behind schedule. Takt increases transparency but it also structures work which allows for an easy understanding of next steps (Frandson & Tommelein, 2014; Kujansuu et al., 2020). Takt time reduces throughput time and enables projects to finish in shorter amounts of time (Binninger et al., 2017). Takt has great benefits, however it requires significant effort at the start of the project and dedication to maintain it throughout the project (Frandson et al., 2013). Due to this effort, when takt plan

[2] Assistant Professor, Civil and Construction Engineering Department, Brigham Young University, Provo, USA, james_smith@byu.edu, orcid.org/0000-0001-8925-5680

failures occur it can be harder to keep the takt plan through to the end of the project (Alhava et al., 2019).

Takt plans have been compared with other scheduling methods, and recently combined with a Failure Modes Effects and Analysis (FMEA) framework to better combat failures that occur within a takt plan. FMEA is a method for identifying possible errors in a system or process with the goal of better avoiding the errors in the future (Carbone & Tippett, 2004). FMEA has been used in other industries, such as medicine and manufacturing to improve complex processes and has the potential to greatly benefit production control methods in construction. Lehtovaara et al. (2022) outlined how to apply FMEA to takt plans.

This paper specifically focuses on testing the categorization of takt plan failures within the FMEA framework outlined by Lehtovaara et al. (2022). In their paper, they defined three failure categories for a FMEA-takt plan framework: wagon content failures, wagon handoff failures, and takt train failures. Wagon content failures occur within a wagon or one trade. Wagon content failures result from overburdened workers, a lack of materials, or missing equipment. Wagon content failures are limited to the trade and task that they affect. Wagon handoff failures are failures that impact the turnover of a takt area from one trade to another; these may include quality defects or the prior trade being late to handoff the area. Wagon handoff failures impact the shift between trades or tasks, but do not impact the project and takt plan success as a whole. The last type of failure defined by Lehtovaara et al. (2022) is a takt train failure. Takt train failures impact the whole project; this may include significant scheduling and coordination errors or compounding delays in wagon handoffs. Each failure may lead to a further failure, thus the FMEA framework aims to resolve takt planning failures before they cause a takt plan to fail. If the FMEA framework proves effective in categorizing takt plan failures, the rest of the steps outlined by Lehtovaara et al. (2022) can be applied to a takt plan. The FMEA framework has the potential to greatly decrease takt plan failures and therefore increase takt plan success.

The research was guided by the hypothesis that the FMEA-takt plan network will cover all identified types of failures within a takt plan. This paper applies the FMEA framework for identifying types of failures in a takt plan outlined by Lehtovaara et al. (2022) to a large scale, repetitive project, with the goal of determining the effectiveness of the framework in classifying failures within a takted project. The FMEA-takt plan framework has not been tested empirically. This paper seeks to begin the process of testing the FMEA framework by determining whether failures in a takt plan case study project fit the failure categories proposed by the FMEA framework.

LITERATURE REVIEW

TAKT TIME PLANNING

Takt time is often associated with the manufacturing industry, however its use in the construction industry dates back to the construction of the Empire State Building (Frandson et al., 2013). Its goal is to produce based on customer demand or the desired time frame of the customer (Haghsheno et al., 2016; Hopp & Spearman, 2008). It has proven more difficult to apply takt to construction than manufacturing for a variety of reasons. Most notably, construction happens on a much larger scale. For takt, construction may be considered a form of low-volume high-variety manufacturing so the takt time is typically a few days or one week as opposed to one minute (Ricondo Iriondo et al., 2016; Tommelein et al., 2022). Takt can be revolutionary since it increases both flow and transparency. Increasing flow and transparency levels the playing field on site or prioritizes all the contractors and trades equally and gives them equal opportunity to complete their work effectively (Koskela, 1992). Although similar to other methods that increase flow (LPS, LBMS), takt differs because it focuses on creating capacity buffers and decreases variability by providing consistency in turnover rates (Ballard, 2000; Seppanen & Kankainen, 2004; Tommelein et al., 2020). Frandson et al. (2013) proposed a method for planning and production control, takt planning. Takt planning allows takt to be applied to construction systematically.

Case studies have supported the value of takt planning as a method for construction production planning and control. Apgar et al. (2022) found that takt planning reduced planned and actual construction durations up to ~70% of the total workdays. A similar case study with a large, repetitive style project concluded that takt planning reduced project duration by 50% (Yassine et al., 2014). Binninger et al. (2018) conducted a case study and came to the same conclusion: takt planning significantly decreases construction duration. Even in cases where the takt was lost by the end of the project, takt planning decreased project cost, increased quality, and decreased throughput times (Alhava et al., 2019). In addition, takt aids in creating flow in the construction process, specifically within the trades (Kujansuu et al., 2020). However, despite these studies demonstrating the effectiveness of takt planning, further research is needed. Takt planning applies to the construction process with the goal of continuous improvements. More research should be conducted with a focus on how continuous improvements can be made to takt plans during the construction process (Lehtovaara et al., 2020).

FAILURES IN TAKT PLANS

Variability has always been at the forefront of research in lean construction since it is the enemy of reliability and productivity. For example, Tommelein et al. (1999) presented the Parade Game to teach students (and others) about the impact variability within and between trades has on the timeline of a project. The Parade Game effects teaches about variability in construction since it shows how having an inconsistent turnover rate frequently results in delays or other problems (Tommelein et al., 1999). Flow systems, such as takt plans, seek to create consistent turnover rates. However, this does not mean there is no variability in flow systems. Variability leads to failures; research into takt plan failures is research into variability. There is a lack of research regarding failures in flow systems, but other literature discusses reasons behind failures in scheduling. Some of these reasons include ignorance, weather, unique project nature, and lack of belief in scheduling methods among workers and management (Iyer et al., 2006; Muhammad et al., 2020). Weather is a common cause for scheduling failures in projects in the United States (Liu et al., 2021).

Research on takt planning investigates methods for preventing failures or reacting to failures but few apply these theories to case studies. Dlouhy et al. (2016) explored project management through a related method for production control, takt planning takt control (TPTC), that follows the project past the production stage. Application of TPTC resulted in a case study project reducing their construction time from eleven months to five months (Dlouhy et al., 2016). A recent case study described how unreliable workflow leads to greater waste by preventing the greatest possible production capacity and that increased transparency prevents delays (Dahlberg et al., 2021). Although takt plans result in greater construction efficiency, due to takt plan failures, the takt plans often take longer than planned. Real construction rates are approximately 20% slower than what is planned (Binninger et al., 2019). Dahlberg et al. (2021) proposed that weekly meetings and daily huddles are proactive steps to decreasing failures in takt planning. Binninger et al. (2017) identified 31 adjustment measures to increase flexibility in takt planning and decrease the impact of failure on the project. Most recently, Lehtovaara et al. (2022) applied FMEA methods to takt planning to better classify and proactively counter failures. Further understanding of failures in takt planning in practice is necessary for better scheduling and for improvements in project control systems such as takt planning, LBMS, and LPS (Ballard, 2000; Lehtovaara et al., 2022; Seppanen & Kankainen, 2004).

As presented by Lehtovaara et al. (2022), the FMEA method can be applied to takt planning to follow the takt plan through its lifespan and help with continuous production control and decreasing failure frequency. This is not the first time that FMEA has been applied to construction planning methods; FMEA was explored in construction in relation to the Last Planner System (Wehbe & Hamzeh, 2013). However, a detailed understanding of FMEA's utility in construction has yet to be realized. FMEA's usefulness has been demonstrated in other industries such as medicine and manufacturing (Bahrami et al., 2012). FMEA works well with takt planning since FMEA aims to result in action before any failures occur and takt planning increases transparency to enable improvement in the takt plan throughout construction (Bahrami et al., 2012; Lehtovaara et al., 2022).

METHODOLOGY

CASE STUDY

A case study was conducted to assess the applicability of the takt planning FMEA framework as outlined by Lehtovaara et al. (2022). Applying the FMEA-takt plan network to a case study project, bridges the gap between the theoretical and practical value of FMEA in takt planning. Not only is a case study a valid method for determining the validity of the FMEA takt planning framework, but in general case studies are valuable because they allow theories to be studied in their natural environment, possibly revealing new information that would remain undiscovered otherwise (Crowe et al., 2011). This case study was conducted using data from one project; Hartmann et al. (2008) demonstrate how a single case study has been used as an effective research methodology. Additionally, Lehtovaara et al. (2022) specifically call for validation of their theories via case studies and more in-depth research about failures within takt plans via case studies. This paper seeks to fill both research gaps.

The case study for this project followed a large data center project in Utah, USA, where five large data centers have been constructed, three of them being planned and scheduled using a takt planning system (Apgar et al., 2022). The case study project implemented a takt time of one day to enable a quicker throughput and a higher level of detail in the planning stage of the project (Apgar et al., 2022). Figure 1 shows a takt plan used in the case study project. Each row on the schedule corresponds to a workday and each row to a project work area. It is important to note that although a takt of one day was chosen, depending on the task, some trades worked in the same area for more than one day. The takt time was maintained by highly detailed schedules working to maintain a consistent beat despite this fact. In addition, the case study implemented pieces of the Last Planner System, such as Weekly Work Plans (WWPs), to guide the focus on pull planning during schedule creation (Ballard, 2000).

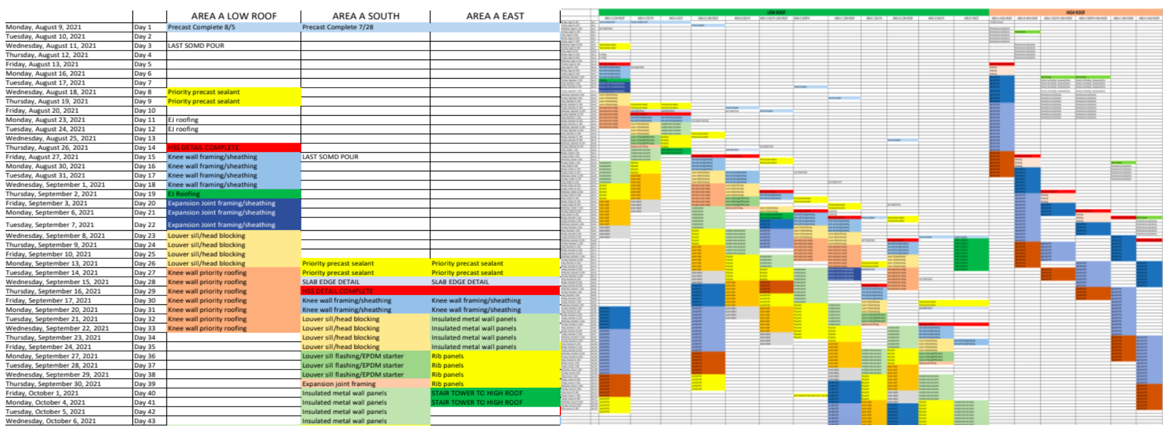

Figure 1: Takt Plan (with takt of one day)

APPROACH TO DATA COLLECTION AND ANALYSIS

Data was pulled from Weekly Work Plans (WWPs) for three of the five buildings in the case study. Since takt planning was implemented halfway through the construction process, data only exists for part of the project, however due to the size of the project, extensive data was collected on takt plan failures. Using the WWPs, they applied continuous production control by marking every failure in the takt plan and assigning a reason for the failure. Through observation of common causes of takt plan failure, the flow managers identified sixteen causes for failures within the takt plan and each failure was placed in one of those categories. The WWPs were available for data collection and analysis for half of Building 3, and all of Building 5 and Building 6. Six months of WWPs were available for data collection and analysis for Building 3 whereas Building 5 and Building 6 both had over one year's worth of WWPs to pull from. Each failure in the takt plan was gathered from the WWPs and then compared with the FMEA framework outlined by Lehtovaara et al. (2022) with the goal of determining whether the proposed FMEA framework describes all documented causes for failure in the case study takt plan. Despite unequal data for each building, sufficient data was collected to determine the trends of the data. The number of takt plan failures for each failure identified in the case study was summed based on the failure category as well as the total number of failures for the building. Trends in the data are identified and possible explanations for the trends are discussed, such as the impact of a learning period after the implementation of a takt plan (on both planning and production sides).

FINDINGS AND DISCUSSION

DATA AND ANALYSIS

For each week in the WWPs, failures in the takt plan were identified by the superintendents, along with their associated reason for failure. Takt plan failures were only identified when the task would not finish on time. Therefore, the number of failures in the takt plan was not heavily impacted by the project having a takt time of one day. During data analysis both the task that didn't follow the takt plan and their reason for failure was pulled from the WWPs. Then the failures (called variances in the case study WWPs) were organized into the failure categories outlined in the FMEA-takt plan framework proposed by Lehtovaara et al. (2022). In the case study project, the flow managers identified sixteen types of failures that occurred in the takt plan. Notably, the failures include both administrative failures that impact construction tasks such as submittals, trade failures such as failed inspections, and logistical failures such as missing materials and equipment. The identified failures and number of each failure for Building 3 are shown in Table 1. Table 1 also correlates each failure identified in the case study to a FMEA takt plan failure.

An additional FMEA takt plan failure was added, titled 'other', that contains failures identified in the case study that don't correlate to any of the three FMEA takt plan failures. This category includes takt plan failures due to weather, unforeseen conditions, COVID, and unknown reasons (i.e., failures that are outside the control of a takt plan or uncontrollable in nature). This last type of failure was added by the researcher to describe the failures marked in the WWPs for which no distinction of reason for takt plan failure was given. Any number with an asterisk next to it (*) indicates that failure in the case study could fall into more than one FMEA takt plan failure category. Four of the case study failures fit this description: client change (it is assigned to wagon handoff but could be in the 'other' category because it is not directly part of the scheduled takt plan), submittals (same as client change), contracts (same as client change), and finished late (could result in a takt train failure). It was debated where the administrative tasks fit in the FMEA framework (client change, submittals, and contracts), however they were ultimately placed under wagon handoff because the takt plan methodology can be applied to all project aspects, not just physical construction. Further investigation into how a takt plan may be applied to all aspects of a project would be worthwhile in order to better understand all the factors that make a takt plan successful.

Table 1: Building 3 FMEA and Failure Classification

	Types of Failures			
Variances	**Wagon Content**	**Wagon Handoff**	**Takt Train**	**Other**
Client Change	-	0*	-	-
Submittals	-	0*	-	-
Arch/Eng/Design	-	-	4	-
Contracts	-	0*	-	-
Materials Not Available	42	-	-	-
Equipment/Lift Not Available	2	-	-	-
Labor Not Available	125	-	-	-
Prior Work Not Complete - Others	-	125	-	-
Prior Work Not Complete - Self	23	-	-	-
Schedule/Coordination	-	-	70	-
Weather	-	-	-	37
Unforeseen Conditions	-	-	-	16
Finished Early	-	26	-	-
Finished Late	-	9*	-	-
COVID	-	-	-	0
Unknown	-	-	-	2
Failed Inspection	-	1	-	-
Totals for Each Failure Type	**192**	**161**	**74**	**55**

For Building 3, wagon content failures account for the largest reason for takt plan failure, with *Labor Not Available* being the largest addition to the wagon content failures. The case study had construction spanning over large portions of COVID-impacted time, and therefore during a time of labor shortage in the United States. A case study conducted in a different time or place likely would not have *Labor Not Available* as the largest wagon content failure. *Prior Work Not Complete – Others* ties with *Labor Not Available*, accounting for 125 takt plan failures; this type of failure falls under wagon handoff and demonstrates how unreliability is still prevalent in takt plans as well as the importance of continuous improvement in takt planning.

Building 5 (shown in Table 2) was analyzed in the same way, however, results were very different. Takt planning was applied to construction midway through the construction of Building 3, and only six months of data was collected for Building 3. Building 5 was the first building that used takt planning for its entire construction, resulting in a much high number of variances or failures marked in the WWPs. Building 5 had approximately 2400 takt plan failures with 1/3 of them lacking a reason for failure (*Unknown*). This can be due to a variety of reasons, such as a lack of awareness of how to use the WWPs and the takt planning system and/or a lack of dedication on part of the superintendents to the takt plan. Therefore, the 'other' FMEA failure category is responsible for the greatest number of failures in the takt plan for Building 5. However, the second and third most common reasons for takt plan failure are *Labor Not*

Available and *Prior Work Not Complete – Others*, respectively. Building 3 was not unique in having a high percentage of takt plan failures due to *Labor Not Available* and *Prior Work Not Complete – Others.*

Table 2: Building 5 FMEA and Failure Classification

Analysis of data from Building 6 (Table 3) shows similar results with *Prior Work Not Complete - Others* as the top reason for takt plan failure and *Labor Not Available* as the second most prevalent reason for failure. For Building 6, the FMEA category that accounts for the highest number of takt plan failures is ‘other’ due to the large amounts of *Unknown* failures. However, the number of failures identified as *Unknown* decreased dramatically between Building 5 and Building 6. This shows the learning associated with the implementation of takt plan and reflects their efforts to use production control (Seppanen et al., 2004). Another difference from Building 5 is that the second highest FMEA failure category was wagon handoff as opposed to wagon content. This also shows learning on the part of the flow managers since they were able to better supply the materials necessary for construction. This is possibly due to outside factors, however for Building 6, failures due to wagon content errors is significantly less that failures due to wagon handoff.

DISCUSSION

The FMEA framework proved mostly effective in separating takt plan failures into correct categories. However, an additional 'other' category was necessary to account for conditions that cannot be controlled by takt planning, and to note the human error that occurred in documenting takt plan failures. This reflects what Binninger et al. (2019) found, that outside forces are major components in whether the takt plan follows the proposed schedule or not. Therefore, the FMEA framework for takt should be altered to account for these 'other' failures to improve effective application to takt projects in general.

The *Unknown* failures are important to note since they show that accurate documentation and reporting of variances from the schedule can influence an understanding of which failures are most prevalent. In addition, they show that without complete dedication on part of the superintendents to document failure information on the takt plan, FMEA may be harder to apply. Lehtovaara et al. (2020) list "social integration" as a key step to better takt planning implementation. To effectively use FMEA in conjunction with takt planning, the system must be socially integrated. In the case study, there were multiple superintendents and flow managers that worked to enable takt planning to be carried out on such a large project, yet, despite their best efforts, there was still significant human error that led to inadequate data collection. Therefore, it must be noted that successful takt plan application reflects whether the management teams and contractors are willing to put in the additional administrative work.

The amount of data and specifically the amount of clearly labeled takt plan failures across the three buildings shows learning on part of the project team. As they better learned to use the takt planning system and WWPs, more failures were identified, and more were recorded with an associated reason for failure. Building 3 has an artificially low number of failures as compared to the other buildings since the takt plan was not applied until halfway through construction. The project team also likely did not record all the variances that occurred in the takt plan because they were still learning how to work the new scheduling system. However, the volume of data enables some trends to be identified. The number of recorded failures jumped up dramatically with Building 5 due to the fact that they were more diligent in marking the variances from the schedule and that data was recorded for the entirety of the building's construction. A high number of *Unknown* failures was present reflecting the learning of the superintendents. Building 6 saw a decrease in both the number of *Unknown* takt plan failures and the total number of failures. The decrease in takt plan failures show continuous improvement, reflecting the goal of flow and lean construction (Koskela, 1992). Takt plans work but take production control to be effective. Between Buildings 5 and 6, the number of wagon content failures dropped significantly. The team worked to prevent wagon content failures as the project progressed. This resulted in a significant decrease in construction duration between the two buildings (Apgar et al., 2022). In fact, Apgar et al. (2022) found that there was approximately a 70% decrease in the total number of workdays required for roofing construction. However, the number of wagon handoff failures increased. An assumption may be made that if the project were to continue and more buildings were constructed and their failures analyzed, improvements would be made in wagon handoffs and the total number of takt plan failures would continue to drop.

Limitations to the study include the fact that the project was done on a case study, the study was done on a project not using the FMEA framework, and limited communication was available between the researchers and the project team. Although case studies are valuable to understand theory as it exists in practice, it is important to note that the results from the study are specific to the project. This project was a large scale, repetitive project that implemented takt planning halfway through. Other projects may have very different results due to size, project nature, and method for takt plan implementation. The case study project did not use the FMEA framework, so failures in the takt plan were classified according to the project flow team. It is important to note that since the FMEA framework wasn't used, the researchers were unable to analyze the full impacts of FMEA on a project. In a project where FMEA has been fully applied, continuous improvements are made as failures are identified to improve project performance over time. However, the purpose of the study was to determine whether the FMEA-takt plan framework addressed all the failures that exist in a takt plan. The project goal was achieved but the project must be understood in context. Limited communication prevented the researchers from understanding more about some of the failure categories designated by the lean innovation team on the job site. Using intuition and available resources on the WWPs, the researchers fit the project failures into the FMEA-takt plan failure categories as best as possible. Many of the failure categories given in the project, however, were self-explanatory or easy to infer context for due to notes in the WWPs. Therefore, despite limitations, the case study effectively increased an understanding of how failures exist in takt plans and how they might fit into a FMEA framework.

CONCLUSIONS

The purpose of this paper was to serve as a case study to test the validity of the failure types identified by Lehtovaara et al. (2022) in their proposed FMEA-takt plan framework. Collected data and analysis demonstrate that although the framework works for most failures in a takt plan, another category should be added to account for the failures that are beyond the scope of the takt plan or outside of normal causes for failure within a takt plan. These include failures such as *COVID*, *Unforeseen Conditions*, and *Unknown* failures. Although possibly not true for every project, *Unknown* failures should be expected since not all failure may be documented correctly nor fit into a specific failure category. This is not to say the rest of the FMEA-takt plan framework is not applicable or that it could not be altered slightly to fit all types of failures that occur in a project with a takt plan. The purpose of the study was to determine whether the proposed failure categories might work for a real project. The study demonstrated the learning that is associated with takt plan implementation on a large scale, repetitive project. As the project team learns the takt plan production control method, takt plan failures decrease.

An additional insight the researchers gathered while conducting the study was that some takt plan failures result from administrative decisions. The researchers chose to sort those failures into wagon handoff failures. However, since administrative decisions exist above the scope of a takt plan, they could also fit into 'other' failures. This allowed for the insight that it may be valuable to apply takt planning to all processes that exist within a project, not just the construction process.

Further research should be done to follow the proposed FMEA-takt plan framework through the lifecycle of a project (Lehtovaara et al., 2022). Research should also be done on other projects to discover whether certain failures are more prevalent takt plans than others or if they are completely project dependent. Additionally, further research should be completed to understand the relationships between failures and whether seasons, trades, or areas in the world are more predisposed to a certain failure than another.

ABSTRACT

This report aims to present the possible relationships between the prerequisites, categories, and impacts of *making-do* wastes from the non-conformity data provided by the Quizquality of six companies participating in INOVACON. From the analysis of the missing prerequisites related to the city of Fortaleza, it was possible to see that labor (52.75%), materials and components (26.69%), and interdependent tasks (5.90%) presented the most associated wastes. The main categories related to wastes are component adjustments (53.84%), sequencing (21.01%), and storage (9.76%). The highlighted prerequisite information for the Goiania cases was motivated by the absence of projects, blueprints, studies, or procedures that should provide necessary information to execute work packages which were unavailable, unclear, and/or incomplete. Based on these results, the determined actions are the need to improve information management to cooperate so that there are no errors arising from incomplete projects or difficulty in passing on necessary information to the employees responsible for performing the service/work.

KEYWORDS

Making-do, prerequisites, categories, impacts and work packages.

INTRODUCTION

It is a common goal among the academic and technical communities to make the construction industry more competitive. To this end, it becomes necessary to increase controls at all project stages and to increase the performance of processes and products, as well as to reduce

production, material wastes, and impacts on the environment (ADEWUYI, IDORO and IKPO, 2014; ANSAH, SOROOSHIAN and MUSTAFA, 2016).

Thus, companies have developed actions that provide improvements in construction processes to avoid the occurrence of failures, losses, accidents, and/or rework, thereby ensuring improvements at the organizational level, cost reduction, meeting deadlines, minimizing errors, as well as in quality and productivity. Studies conducted in different countries indicate that losses in construction represent a relatively high percentage of production costs (FORMOSO et al., 2002; FORMOSO et al. 2017; HWANG et al., 2009; KOUSHKI, KARTAM, 2004; LOVE, LI, 2000; LEÃO, 2014; LEÃO et al., 2016). High production costs are related to losses throughout the construction processes and should be understood as any inefficiency in the use of equipment, materials, labor, and capital (VIANA; FORMOSO; KALSAAS, 2012).

Moreover, productivity is a constant concern for any construction company in the current landscape of the construction industry to establish itself in the market competitively. Companies face great competition due to increasing demands from customers who want products with adequate quality and satisfactory performance. Nevertheless, management strategies have been adopted by construction companies to improve organizational and construction performance. In this sense, the implementation of lean construction based on the Toyota Production System (TPS) and Total Quality becomes an answer to the culture of improvisation in construction sites and can be proven by several implementations around the world.

Toyota created a loss classification aimed at making wastes visible and facilitating identification of their causes to foster a "zero waste" culture among its employees called the "Seven Wastes" (Shingo, 1989). According to Ohno (1988), waste or loss refers to all production resources which only increase costs and do not add value to the product, explained through the seven major categories of wastes adopted by the STP.

Soilbelman (1993) states that the reduction of wastes must consider that there is an acceptable level of wastes, which can only be reduced through significant changes in the level of technological and managerial development of the company. Accordingly, the referred author classifies wastes as unavoidable (or natural waste) and avoidable, in which the occurrence costs are substantially higher than the prevention costs. Thus, several theories arise or evolve in this context. However, it is known that an important increment for lean construction was the designation by Koskela (2004) of a new category of wastes called making-do, added to the widely known and applied list of Ohno (1988) and Shingo (1989).

THEORETICAL REFERENCE

The terms unfinished work, work in progress, buffer, rework, work completion, and work stoppage have been reconceptualized in a trajectory of lean history to be associated with making-do. Nevertheless, it is important to note that these terms already existed before the evolution of lean construction theory. Likewise, Ronen (1992) and Koskela (2000) already presented the theoretical basis for the making-do in their works, highlighting that the latter was based on the former to establish the complete kit (prerequisites to perform a certain task). Koskela, Bolviken, and Rooke (2013) point out making-do as a central waste in construction for being the possible main cause of other wastes.

Since then, studies related to ways to use the concept of making-do loss to minimize or eliminate activities which do not add value to the process have been developed, either in various stages of the life cycle (from project conception to maintenance), such as in: project preparation (Koskela et al., 1996; Grosskopf; Menezes; Santos, 2004; Neve; Wandahl, 2018); construction site logistics (Ghanem et al., 2018, Perez et al., 2015); the supply chain (Taggart, Koskela, and Rooke, 2014); production slack (Fireman, Saurin, and Formoso, 2018); developing or augmenting methods or tools, virtual or otherwise, to facilitate the identification of these wastes (Sommer, 2010, Fireman, 2012, Leão; Formoso; Isatto, 2016); or by identifying other wastes in a cause and consequence discussion concerning making-do waste (Koskela et al., 2019; Formoso et al., 2011; Fireman; Formoso; Isatto, 2013; Santos; Santos, 2017; Pérez, Costa, and Gonçalves, 2016; Pérez; Costa, 2018).

Several studies have been conducted seeking to identify the causes and effects of making-do waste in construction, notably those by Sommer (2010) and Fireman (2012). However, few works are dedicated to identifying specific cause-effect relationships associated with this type of waste. In one such study, Spohr and Isatto (2018) argue that the associations between causes and effects of making-do are quite diverse, with some being very close and central, while others are quite diverse and peripheral, suggesting that managerial attention aimed at reducing making-do wastes should focus on a more central set of effects. However, due to the small number of cases studied, the results obtained in that study do not enable a broader generalization to identify the associations between each of the causes and effects individually considered, or specific mechanisms which govern such relationships, pointing out a gap to be explored.

According to Koskela (2004), making-do waste occurs when a job site activity is started without having all the necessary prerequisites, or when its execution continues even if one or more prerequisites are no longer available. Ronen (1992) called this set of prerequisites a complete kit and states that there are two consequences, technical and behavioral. In addition to these consequences, Koskela (2004) added the safety waste caused by making-do; this safety waste is the result of abnormal manufacturing conditions.

The waste identification method proposed by Sommer (2010), and then complemented by Fireman et al. (2013) and Santos and Santos (2017), presents three groups. The first is used to identify missing prerequisites in work packages, the second is to identify the most affected waste categories, and the last assesses the impacts of waste.

Next, the work packages to be executed are defined in planning, and making-do wastes are identified when there are no working conditions, and therefore alternatives or improvisations are used so that the work is not interrupted. The method application must consider that these wastes may or may not generate some impact on production, not jeopardizing the execution of the packages. Therefore, it is necessary to first identify which activities can lead to these or other wastes in the production process (SOMMER, 2010).

It is noteworthy that wastes by making-do can occur in different ways, and there are numerous possible combinations of prerequisites, categories, and impacts in the construction environment. Some authors have highlighted that improvisations are present in all of the construction site stages, thereby making it difficult to identify and avoid them, and requiring strict control of construction processes, investments in cultural change conducive to improvisation and standardization (AMARAL et al., 2019; SANTOS et al., 2020, FORMOSO et al., 2002; JOSEPHSON; HAMMARLUND, 1999; HORMAN; KENLEY, 2005; FORMOSO et al., 2017; OHNO, 1997). Moreover, some authors reported difficulties in identifying and classifying making-do wastes, pointing to the need to improve the methods used. In addition, the need to develop more quantitative analyses and the acceptable limits of making-do wastes is also highlighted in the literature by several authors (SAURIN; SANCHES, 2014; AMARAL et al., 2019; SANTOS et al., 2020, JOSEPHSON; HAMMARLUND, 1999; HORMAN; KENLEY, 2005; FORMOSO et al., 2002; FORMOSO et al., 2011; FORMOSO et al., 2015; FORMOSO et al., 2017; FORMOSO et al., 2019; LEÃO, 2014; FIREMAN & FORMOSO, 2013; and KALSAAS, 2012).

On the other hand, it is noteworthy that only surveying making-do wastes does not provide enough information for the manager to completely prevent these wastes from occurring in their next undertaking or task. The targeted analysis of impacts is also important to facilitate feedback to the manager, as it allows the manager to prioritize the necessary corrections toward the most efficient work possible.

Leão et al. (2014), Formoso et al. (2015), Fireman et al. (2013), Saurin and Sanches (2014), and Kalsaas (2012) reported difficulties in identifying and classifying making-do wastes, pointing out the need to improve the methods used and develop more quantitative analyses and the acceptable limits of making-do wastes, as well as highlighting the need to prioritize decision-making by the manager; this means instead of the manager concentrating their efforts to correct all the intercurrences identified on-site, they may concentrate energy, resources, and management on the stages that contribute greater impact to achieve better results in the most critical points of the work concerning making-do.

OBJECTIVE

This report aims to present the possible relationships between the prerequisites, categories, and impacts of making-do wastes from the non-conformity data provided by the Quizquality of six companies participating in Civil Construction Industry Innovation Program (INOVACON).

METHOD

Table 01 characterizes the companies participating in these analyses. The group of companies defined in the sample are part of the INOVACON and subsidized this survey stage.

Table 1: Characterization of the construction companies.

Company Code	Code Work	Description	Current Phase Execution	Total Employment Area (m²)	Nr. of Floors
M	M-E1	Medium standard residential building - 3 towers	Concluded	9,444.6	23
N	N-E1	High Standard Vertical Residential Condominium - 2 towers	Running	2,860.0	15
	N-E2	High-end Vertical Residential Building	Running	2,390.0	19
	N-E3	High-end Vertical Residential Building	Running	2,480.0	30
O	O-E1	Low-rise residential building - 11 towers	Running	18,700.0	4
	O-E2	Medium standard residential building - 3 towers	Running	12,200.0	7
P	P-E1	Low-rise residential building - 11 towers	Running	26,145.0	5
Q	Q-E1	High-end Vertical Residential Building	Running	2,420.0	23
R	R-E1	High-end Vertical Residential Building	Running	2,350.0	20

IMPLEMENTATION STEPS

The research steps are detailed below.

Step 1: Definition of protocol for identifying making-do wastes.

Protocols for data collection were proposed based on previous studies. The causes, categories and impacts for making-do wastes were defined. The wastes were classified according to the steps and sub-steps following the NBR 12721 presets (ABNT, 2005). The impacts were classified according to the adopted parameters of reduced productivity, lack of motivation, loss of material, rework, reduced safety, reduced quality, and lack of finishing (RONEN, 1992; KOSKELA, 2004; FIREMAN et al., 2013).

Step 2: Diagnosis performed in Fortaleza/CE/Brazil based on the export of QuizQuality.

Preliminary analyzes of a database with 156,762 compliance and non-compliance data from the companies were conducted. From the 8,842 non-conformities analyzed, 6,339 instances of data were classified. The analysis period covered the years 2020 to 2022. The data refer to seven construction companies from Ceará, using data stored in the QuizQuality management platform, developed by the company Aval Engenharia.

Step 3: Dashboard enhancement for analysis of interactions between parameters.

The data were integrated into Microsoft Power BI® and the analyzed parameters were chosen based on the information classification on wastes, being divided into eight items related to prerequisites, eight to categories and seven to impacts (Table 2). Then, the parameters from this group (presented in Table 02) which highlighted the information were chosen to obtain a more specific and detailed analysis of the database.

Table 2: Parameters analyzed for making-do wastes.

Prerequisite	**Categories**	**Impacts**
Information	Access/mobility	Decreased productivity
Materials and component	Component adjustments	Demotivation
Labor	Workspace	Loss of material
Equipment or Tools	Storage	Rework
Space	Equipment/Tools	Security reduction
Interdependent tasks	Temporary installations	Quality reduction
External conditions	Protection (security)	Lack of finishing
Temporary installations	Sequencing	

Source: The authors.

The distribution of wastes by making-do could be interpreted by the hierarchical tree diagram graphs with the analysis carried out in Microsoft Power BI® (Figure 1), and the counting of wastes from this analysis can be sequentially analyzed from the prerequisites, categories and impacts of these, thus enabling to identify which prerequisites have the greatest influence on the occurrence of wastes.

The graphic representations chosen for data analysis were: hierarchical tree (to obtain a Diagram with the relations between the wastes by prerequisites, categories, and impacts), funnel (to analyze the construction stages and their relationships with the teams of works with the highest occurrence of wastes) and ranges (to identify the relationships between the chosen parameters, and how the prerequisites, categories and impacts interacted with the database), as they better present the analyzed results.

The 156,762 compliance and non-compliance data from the companies were analyzed according to the distribution shown in Table 3. From the 8,842 non-conformities analyzed, 6,339 instances of data were classified. The reduction of the database for the classified data is justified by the absence of response or inconclusive answers for the Quizquality fields: "characteristic description", "problem response" and "correction action response", making it impossible to classify the data according to the spreadsheet used by the research group. Table 4 shows three cases that make it impossible to tabulate the data.

Table 3: Database extracted from QuizQuality.

Company	**Database**	**Analyzed Data**		**Classified Data**	
M	63,618	6,367	10.01%	4,770	7.50%
N	63,601	1,887	2.97%	1,077	1.69%
O	26,923	512	1.90%	460	1.71%
P	41	41	100%	15	36.59%
Q	34	34	100%	17	50%
R	2,545	1	0.04%	0	0%
	156,762	**8,842**	**5.64%**	**6,339**	**4.04%**

Table 4: Examples from the analyzed database that were not classified.

Item	Feature Description	Problem Answer	Response Action Containment
1	*Shafts* Compartmentalization with drains	Locked Hydraulic *Shafts*	Not defined
2	Painting Walls and Frames - Stains	Room 01 - Stains on the wall	Repaint wall
3	Operation	Does not turn on	Repair

It was necessary to individually analyze each non-compliance provided by the companies to classify the data, which were subsequently tabulated in Microsoft Excel®. Then, a Microsoft Power BI® dashboard was developed from this data to provide an interactive data analysis and the parameters to be analyzed were chosen. These in turn were divided into eight items related to prerequisites, eight to categories, and seven to impacts for making-do wastes.

Step 05: Alignment meetings between partners.

Alignment meetings were held with all the companies participating in the study to present and discuss the results and analyzes, and to establish new theoretical frameworks aimed at reducing wastes in the production process, including new concepts and classifications about wastes.

TEAMS AND STEPS INVOLVED

The non-conformities found had a concentration of 54.33% of the data related to the coating and finishing stage, and 19.03% for installations and appliances, as shown in Table 05. It is believed that this percentage (54.33%) is related to the more complete recording of non-conformities in the final inspection stages, with repair needs for receiving the housing unit by the client since all the identified problems must be solved, thereby resulting in a greater recurrence of non-conformities described/detailed by the team involved in filling in this data.

Table 5: Wastes by classified stages.

Step	N.º	%
Coating and finishing	3,444	54.33%
Fixtures and fittings	1,206	19.03%
Structure	723	11.41%
Walls and panels	538	8.49%
Completion of the work	404	6.37%
Initial Services	22	0.35%
Covers and protections	2	0.03%
Total	**6,339**	**-**

Problems in the main stage of cladding and finishing were identified in the wooden doors, such as damage and malfunctions in the stops and jambs, requiring adjustments and/or replacement. Additional problems were identified in floor trims, malfunctions and/or changes in tone and/or the presence of stains on the ceramic tiles.

Regarding the teams involved, we conclude that the carpenter, bricklayer, tiler, janitor, plumber, and painting teams presented the most non-conformities, with 22.68%, 16.26%, 14.45%, 13.87%, 9.69%, and 8.69% respectively.

These teams were mainly related to the coating and finishing stages and to installations and appliances, suggesting a need for monitoring and training of these teams so that there is a reduction in these non-compliance occurrences.

ANALYSES OF THE PREREQUISITES, THE CATEGORIES, AND THE

IMPACTS OF MAKING-DO

From the analyses of non-conformities in the database, it was found that labor (52.75%) and materials and components (26.69%) were the prerequisites that showed the most associated wastes. The labor wastes were related to execution problems in the coating and finishing stages (57.12%), involving the mason (27.06%), carpenter (21.02%), and tiling (15.40%) teams, directly impacting the execution and completion of the services.

The wastes related to materials and components were linked to problems in the supply and use of the material, being associated with the "covering and finishing" (51.06%) and "installations and appliances" (16.84%) stages from applying non-compliant materials (e.g., damaged window frames; ceramic coating with stains or changes in tone), materials in insufficient quantities (i.e. electrical material), or materials with higher performance than those specified or requested in the project (i.e. steel).

The prerequisites of labor and materials and components were related to the highest impacts of rework (41.63%) and lack of completeness (33.27%), which are intrinsically related to the characteristics of the most recurrent stages (Figure 01).

The analysis of the non-conformities shows that labour, materials, and components are the main prerequisites related to the associated wastes, with 52.49% and 26.6%, respectively (Figure 01). The adjustment of components category can be understood as adjustments made on-site to speed up the service or simply adapt it to what should be done, justifying its relationship with the stages of "coverings and finishing" and "structure", corresponding to 42.31% and 19.87% of the cases identified, respectively, as well as "installations and appliances" and "panels", corresponding to 19.13% and 13.18% of the cases identified, respectively. The impact of this category on the structure, wall and panel stages occurs more frequently since the laborers end up making decisions on-site without consulting those responsible for their work.

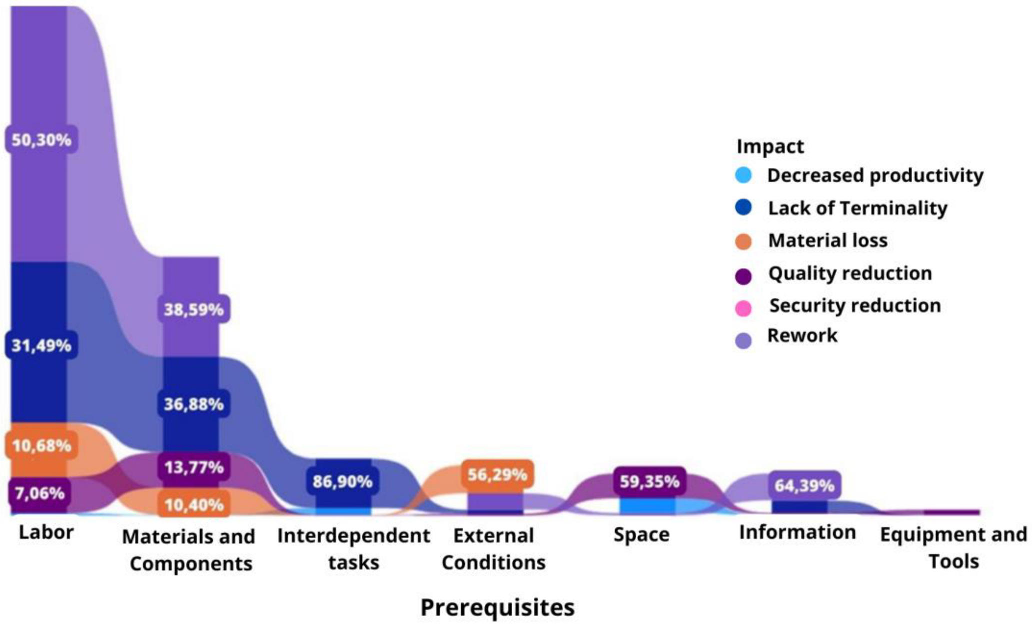

Figure 1: Correlation of wastes between prerequisites and impacts.

Next, the "sequencing" category has "coatings and finishing" (47.52%) as its main associated stage, and "lack of completeness" (70.12%), "rework" (19.07%), and "reduction in quality" (8.11%) as its main impacts. The main prerequisite regarding company "M" was labor (47.34%), followed by materials and components (31.97%) and external conditions (6.96%). The categories of greatest influence were component adjustments (44.03%), sequencing (23.94%), and storage (12.91%). The main impacts were in rework (39.12%), lack of completeness (33.48%), and material loss (12.52%).

The main prerequisite found when analyzing company "N" was labor (69.55%), followed by materials and components (11.42%) and interdependent tasks (9.66%). In addition, the categories of greatest influence were component adjustments (84.77%), sequencing (10.31%), and access/mobility (3.25%). The main impacts were rework (46.80%), lack of completeness (33.61%), and material waste (10.96%).

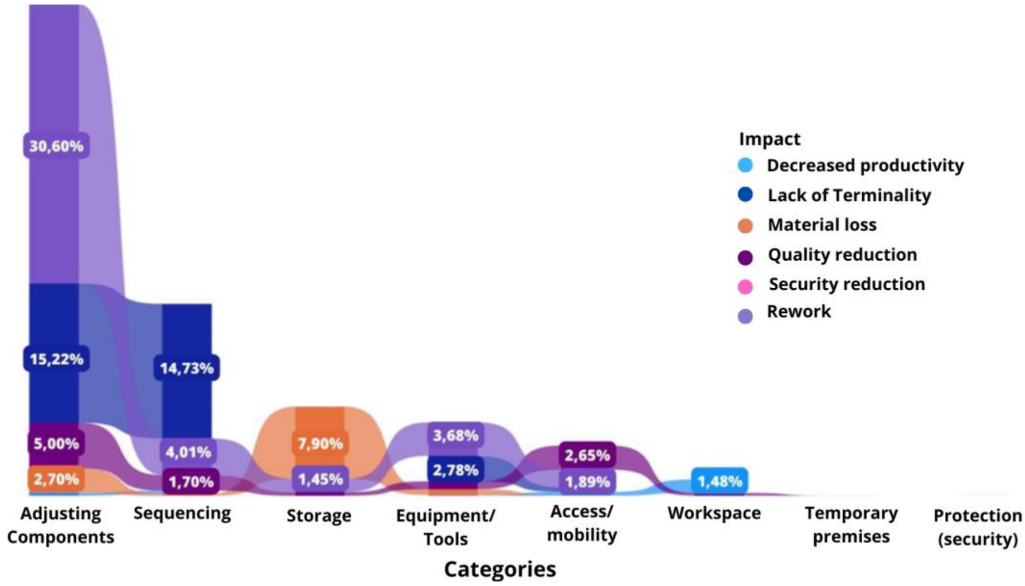

Figure 2: Correlation of wastes between categories and impacts.

The main prerequisite found for company "O" was labor (71.09%), followed by information (10.43%) and interdependent tasks (9.35%). In addition, the categories of greatest influence were component adjustments (81.96%), sequencing (15.65%), and work area (1.09%). The main impacts were rework (56.74%), lack of completeness (31.52%), and reduction in quality (8.04%). Next, the main prerequisite found by analyzing the data from company "P" was labor (33.33%), followed by materials and components (26.67%) and information (20.00%). Moreover, the categories of greatest influence were component adjustment (53.33%) and sequencing (46.67%). The main impacts were presented by rework (4.00%), lack of completeness (33.33%), and material waste (20.00%).

Next, the main prerequisite for company "Q" was equipment and tools (58.82%), followed by labor (29.41%) and materials and components (11.76%). The most influential categories were component adjustments (88.24%) and equipment/tools (11.76%), while the main impacts were presented by quality reduction (82.35%), rework (11.76%), and productivity decrease (5.88%).

From an overall perspective, it is concluded that the prerequisites of greatest influence among the companies are labor (52.75%), followed by materials and components (26.69%) and interdependent tasks (5.90%). Furthermore, the categories with the highest occurrence are related to component adjustments (53.84%), sequencing (21.01%), and storage (9.76%). The main impacts were rework (41.63%), lack of completeness (33.27%), and loss of material (11.50%).

DISCUSSION

The hierarchy diagram graph shows the relationships between the prerequisites, categories, and impacts. The center represents the total number of impacts recorded in the database, while the total value is highlighted in blue, and the quantities and lines under analysis are different from each other on both sides (Figure 3). In Figure 3, two diagrams are shown, split between the left and right-side diagrams, of the relationship between the prerequisites, categories, and impacts. The center represents the total number of impacts recorded in the database, while from the total value (center) the quantities and lines are highlighted in blue, which are different from each other for both sides.

From the analysis of the missing prerequisites related to the city of Fortaleza, it is possible to see that labor (52.75%), materials and components (26.69%), and interdependent tasks (5.90%) presented the most associated wastes. The main categories related to wastes are component adjustments (53.84%), sequencing (21.01%), and storage (9.76%). In addition, rework (41.63%), lack of finishing (33.27%), and material waste (11.50%) represent the main impacts related to wastes (Figure 3).

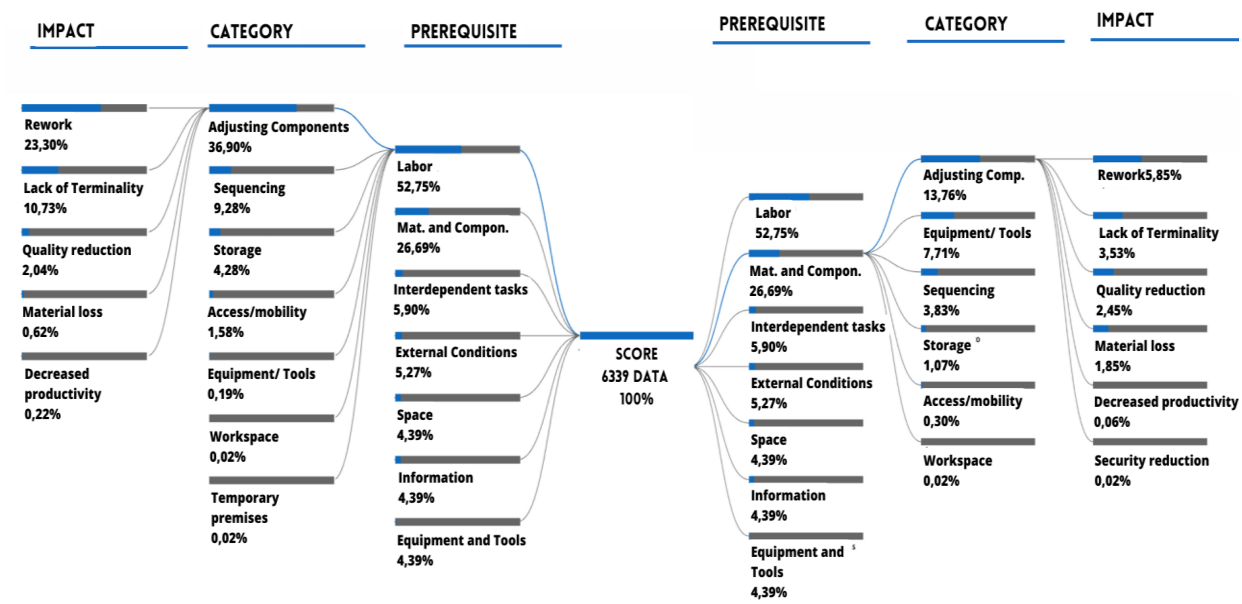

Figure 3: Diagram of the relations between wastes per prerequisite, category, and impacts - Fortaleza Results.

The teams involved in the analyses were: carpenter (22.68%), bricklayer (16.26%), tiler (14.45%), laborer (13.87%), plumber (9.69%), and painter (8.69%); while the percentages show the team that presented the highest non-conformities. Through these data, the labor prerequisite can be justified by its unavailability in terms of quantity and/or skills needed by the work teams, specifically the carpentry (22.68%), bricklayer (16.26%), and tiling (14.45%) teams, who contributed to the impact of wastes mainly related to rework. With this in mind, we suggest actions aimed at identifying the need for requalification, monitoring the services performed, the need for adequate dimensioning of the construction management, and better selection and supervision of the companies outsourced for the execution of the services.

CONCLUSION

The aim of this work was to identify associations between each of the causes and effects considered individually, or the mechanisms which direct such relationships; as a result, it is concluded that making-do wastes can occur in different ways, and there are numerous possible combinations between prerequisites, categories, and impacts on the construction environment. Different enterprises, regions and cultures have different prerequisites. Uniformly using average results and implications is not applicable.

Improvisations are present at all the construction site stages, making it difficult to identify and avoid them, requiring strict control of construction processes, investments in cultural change conducive to improvisation and standardization. Only surveying wastes by making-do does not provide enough information for the manager to prevent them from occurring in their next undertaking or task, but it does provide a more robust and interactive analysis of information to minimize them.

With the study it is concluded that instead of the manager concentrating their efforts on correcting all the intercurrences identified in the construction site, they will be able to concentrate resources and management in the stages, teams, and processes which most contribute to greater impacts, or those which are more significant in terms of costs or delays in the works in order to achieve better results. From this particular study, these efforts should be directed towards requalifying the workforce, investments in materials and components which are compatible with the dimensions established in projects, and investments in medium-term planning in order to eliminate interdependent tasks; and lastly, it is still extremely important to analyze the risks linked to the impacts of rework that are directly associated with the decrease in productivity, the waste of material and the lack of terminality and quality reduction.

WHAT DOES A COMMITMENT TO A PLAN MEAN?

John Skaar[1], Trond Bølviken[2], Bo Terje Kalsaas[3], and Lauri Koskela[4]

ABSTRACT

A plan in the making should pull from what creates customer value and from the performers' knowledge and understanding of the context. A plan for commitment should represent the customer's intent in a way that calls for action on the intent's behalf. A promise to commit to a plan happens at many levels and in many forms toward execution, and every promise made becomes a push mechanism to keep that promise. Since a plan represents both push and pull around a commitment, knowledge about these mechanisms can help to understand a plan's function. The main contribution is a reflection on how a plan's push for commitment interacts with emergent situations and an analysis of what part of the commitment is within or outside the scope of the promise and the promiser's influence and control. The promise made committing to a workplan as input to a Percent Plan Complete measurement is used as a practical example. The paper's conclusion arguably strengthens many of the existing parts and principles of the Last Planner System but also gives suggestions for improvement.

KEYWORDS

Complexity, Commitment, Promise, Construction, Project-Based Production.

INTRODUCTION

Any plan or drawing, 3D model, contract, etc. is merely an abstraction and simplification of what it wants to achieve. It is impossible to give a "true" replica of a complex thing or phenomenon. Therefore, any plan simplifies the expected process of making an output. A plan has the function of pushing its intent into action but should also consider how the situation is here and now and how this will affect the plan. Before the execution of a task, a promise to commit to the plan and/or the plan's intent is often made by the performer. A worker on a construction site might say: "I will try to do the task according to the plan", a response from the manager can then be, "No, I want to hear that you say you are going to do the task according to the plan." The divergence in the use of language has a logical connection to the pull and push mechanism at play that is under scrutiny in this paper. The paper is based on reflection initiated by the first author after measuring workflow reliability with Percent Plan Complete and using the 5 Why methodology on tasks that were not done according to the weekly plan. Deviations from the plan happened even though the activities had been marked as sound. In a sound activity, all prerequisites are evaluated as made ready when the task starts. The 5 Whys often pointed

toward events outside the worker's influence, responsibility, and scope of work. This raised the fundamental question of what the promisers promised when committing to the plan.

THE METHOD AND APPLIED THEORY

The paper presents a conceptual discussion based on a combination of theoretical reasoning and practical and empirical observations in construction projects. This is done through a pragmatic and critical realistic perspective (Ackroyd & Fleetwood, 2005; Sayer, 2004). We use planning approaches such as the Critical Path Method (CPM), the Last Planner System (LPS), Takt planning, Line of Balance, Scrum and Kanban to exemplify and understand the functions of a plan and how different issues can be handled. We apply the principles underpinning the above-mentioned planning approaches in our reasoning about what a plan is, in which the distinction between pull and push plays a significant role. Complexity is conceived as an attribute of planning and production; in this context, we first discuss what a plan and planning is before we address the issue of making promises in planning. To establish the context of complexity the Cynefin framework (Snowden & Boone, 2007) is central, differentiating between complicated and ordered vs. complex and unordered. In addition, we address uncertainty (Hillson, 2016) and unpredictability (emergent factors) in project execution when analyzing the making of promises in a complex setting (Brady & Davies, 2014). Moreover, we use the principal-agent theory when addressing asymmetric information in the relationship between the parties making and using a plan (Martimort & Laffont, 2009). We place the paper as a contribution to Speech Act Theory and Promise-Based Management (Sull and Spinosa 2007; Cleary et al. 2008)

CONTEXT

A construction project consists of several phases, from the front end with project idea and design to the execution phase with production as the main activity. The front end has more positive iterations (Ballard, 2000) and reciprocal interdependencies (Coyote & Thompson, 1967), and has been characterized as the solution of wicked problems (Churchman, 1967; Spitler & Talbot, 2017). It has been suggested to take different metaphysical views in different phases, a process-view in the front end and a thing-view in the execution phase (Ika & Bredillet, 2016). The main context for this paper is production planning. We do however to some degree also look towards design since this in most projects has a close link to the production phase.

COMPLEXITY AS A POINT OF DEPARTURE

We use the definition and differentiation of complexity vs complicated from The Cynefin Framework (Snowden & Boone, 2007). In short, in the complex domain, we cannot forecast cause and effects, and they can only truly be perceived in hindsight. In the complex domain deviations from a plan should be expected to occur, so dynamic and proactive preparations and an agile and flexible way of planning should be used. In the complicated domain, we can identify causes and effects and predictions can be made. If we treat a project as a fundamentally complicated matter, deviations from the plan need not happen. If a deviation still happens, it is an abnormality caused by a fault, lack of planning or underperformance. The Cynefin framework is a sense-making framework, to be used to constantly sense and reflect on the situation you are in. Although a project will contain situations or elements of all domains (simple, complicated, complex and chaotic), we in this paper focus only on the complex (where cause and effect only can be deduced in retrospect) and complicated (where expertise and analysis are needed to find and understand cause and effect.).

THE PRODUCT AND THE PRODUCTION IN CONSTRUCTION

If we use the possibility of prediction as the main distinction between something complex and something only complicated, we position the phenomenon of design as something unpredictable and therefore complex. A design process can result in infinite solutions to the design problem. The final design is often an artifact comprising a complicated network of tasks and interdependencies. When the design has been decided the sequence and way of production can be decided before the actual production starts. A plan can then be made, and if everything is predefined in a logical sequence, the plan is often in its structure on the ordered side of the Cynefin Framework (Snowden & Boone, 2007). The process of putting the artifact together is a social endeavour in a complex context. It also depends on many prerequisites that are not defined to be within the project members' control. The production process then becomes a complex undertaking, but with many elements that are only complicated. The fact that many projects overlap the design process with the production process adds to the complexity of the production process, but we want to stress that this choice does not make the actual product more complex.

THE ACTIVITY

Many plans are made with only a deterministic view of the duration of the activities. This is a simplification of reality with a more stochastic variability since the activity is a process in a complex context. It is difficult to make a promise on ambitious deadline when dealing with an activity with large inherent stochastic variation on its duration, in theory, any promise to be shorter than the worst case cannot be guaranteed. Reduction of internal variability is hence an important task that must be dealt with before a certain duration can be forecasted with accuracy (Spear & Bowen, 1999), but shifting context, a unique product, and a fragmented building sector (Ballard & Howell, 1998) become issues adding complexity. A traditional view of a finished plan before execution can be claimed to be the best way to produce the product. Using Cynefin analogy again, best ways only exist in the clear (simple/obvious) domain (Snowden & Rancati, n.d.). In the complicated domain, you can identify good practices, but they can always be challenged to be better. A point here is that not only the design details but also the production methods used within the activities might be challenged and be under development; this adds to the complexity of reducing variability. If you improve more than one independent variable, the effect of improvement initiatives is hard to single out with small amounts of data. An ambitious promise on duration is difficult to make, even if all prerequisites for the activity are considered sound.

THE PLAN AND THE PLANNING

Using a push/pull analogy, we argue that there are two main functions of a plan; the first is to convey and represent the project's intention to be achieved (pushed from the plan), the second is to learn from the context and adapt accordingly (pulled to the plan). This is described by (Howell, 1999) through the terms planning and control. Howell sees planning as defining criteria for success and producing strategies for achieving objectives, while control is seen as causing events to conform to plan and triggering learning and replanning. Plans are tools made and used by people to plan and control production, that is to both pull and push. Also, a plan made by pull-based planning will when used have a push function. This push is expressed through demand to follow the plan and requests to make reliable promises. The aim of this paper is to zoom in on this push and pull functions, mainly seeing it from the perspective of the people making and using the plan, both pushing and pulling others.

A plan can be seen as an attempt to predict the possible outcome of multiple events. A project is divided into smaller manageable pieces, that is the tasks (activities) we must do to carry out the project. We search for probable causes and effects, recognize patterns, map interdependencies, and try to forecast how the interactions between tasks will play out in the future. However, "*all plans are forecasts, and all forecasts are wrong. Forecast error varies with forecast length and level of detail*"(Ballard & Tommelein, 2021). A plan is normally set up to be ambitious (a stretch goal), a probable outcome or a minimum acceptable outcome. Using principal-agent theory we can see those making the plan as principals and those using it as agents. There will always be some sort of information asymmetry between the principal and the agent. The principal's intentions with the plan might (consciously or unconsciously) not be communicated to the agent. Any plan will be based on presumptions, assumptions, and simplifications that can be interpreted differently by the principal and the agent. How the principal and the agent see and use the plan affects how they relate to and execute the push-and-pull functionality of the plan. As an example, an opportunistic principal might make a plan with stretch goals but communicate it as a probable outcome.

A Takt plan (Dlouhy et al., 2018) pushes a parallelism in the flow of trades or set of activities. The Takt planning method constraints the plan actively by "shaping"(Binninger et al., 2017) the work into equal timeboxes (Birkeland, 2010). Takt can be seen as a cooperative approach with the Last Planner System (Binninger et al., 2017), so Takt can be used within the Last Planner System. A Takt plan pushes towards a demand to stay within timeboxes, and a commitment to the timebox must be done early in the project. The reasoning behind allowing this hard commitment to a timebox, is its ability to align the flow of trades and hence reduce waste and prioritize the production's overall process flow. Critical Path Method also pushes commitment early, but without a demand for parallelism in the trades flow as Takt Planning does. Line of Balance also seeks parallelism but does not push it the same way as takt planning and does it with more involvement and hence also choice of the participants. Parallelism of flowlines is the goal but not always the result from Line of Balance planning, this might be an indication of the power of pushing coherence in Takt planning.

A plan in a construction project is not only an explicit and written plan but also contains elements of tacit knowledge (Nonaka et al., 2000) that project members hold. In the limitations of collecting tacit knowledge also lies the notion that explicit plans are not comprehensive. A plan is a simplification of both the intent of the project but also the context. With simplification, the amount of data needed is reduced, but it also reduces the possibility to grasp the situation.

THE PROCESS OF MAKING READY

The Last Planner System has a systemized approach not to let an initially planned activity be equal to a made-ready activity, it goes through a SHOULD-CAN-WILL process that enables an alignment to the context. An underlying principle of the Last Planner System is both about the quality of assignments and a principle that you only do activities that should and can be done. Pulling the tasks from the context makes the push from the plan much more linked to the maturity and readiness of the task. An assignment of good quality should also be specific and clear in the language of the performer; this means that the assignment must contain what's to be done, where, when, who, and with what. Many projects still have a lot of improvement to make in just following the preparation of the activities. The Last Planner system waits with the final promise for a commitment from the performers until the (weekly) workplan. When a promise is made according to and on elements within the trade's control, the commitment is higher. When the performers finally commit to the workplan, a push also happens here, and this is where we want to reflect on its implication using the Last Planner System as a reference. However, first, we look into some other plan and control systems and methods. Our claim is that none of the planning systems mentioned below has the same level of built-in proactive mechanism towards systematically making tasks ready, though the Takt plan creates an even higher need for this proactive thinking and can therefore have benefits to using the Last Planner Systems logic.

A Takt plans early and high demand for making tasks ready is pushing a proactive attitude and sets a high focus on reducing variability in the tasks; this might force a high need for standardization both on product and process in order to try to push the process of production into the complicated domain. The downside of this can be that value in the product is lost or that the design process is pushed into an even more complex situation to cope with the constraints of standardization.

In the Scrum system, a prioritization and check of readiness is done from the product backlog and into a sprint backlog, but Scrum is positioned for doing this in a shorter timeframe and is for this and other reasons, positioned for an even more complex situation than The Last Planner System. In the Last Planner System, the selection, sequencing, and sizing of activities starts after the phase scheduling, normally at least 6 weeks prior to execution of any task, and continues all the way down to the weekly work plans. The work plan is often at a weekly timespan, but this might differ from the planning context. When put on the work plan the activities should be classified as sound, so the making ready process does in a systematic way stop here, and a promise to commit to the plan is done. Scrum makes a similar commitment to the content and goal of a sprint, and by having sprints in the original length of 2-4 weeks (Sutherland, 2014) this system places a promise on the content entering the sprint.

Some key initiators of agile in the software business created The Agile Manifesto (Fowler & Highsmith, 2001) where one of the principles is “Deliver working software, from a couple of weeks to a couple of months, with a preference to the shorter timescale”. The preference for a shorter time has later been challenged down to a 5-day length of a sprint (Knapp et al., 2016), and even hours depending on the definition. A sprint is a defined time with a defined goal and testable output; there is often an explicit zero tolerance for not meeting these goals within the timebox, when made explicit, this functions as a hard push from the plan to the team in the sprint. The Last Planner System lacks Scrum's defined roles of “The Product Owner” and “The Scrum Master”. The Scrum Master is accountable for the Team's performance, removing impediments, and a facilitator for the team to meet their commitment. The Product Owner is the role of one person that is accountable for backlog management and is the only one with authority to cancel an ongoing sprint if it is found to be obsolete (Schwaber & Sutherland, 2021).

The Agile software community calls a system for “Kanban” which is an alternative to Scrum. The Kanban system is less defined as a common system and has many different versions, more or less based on the principle of Kanban signals or logic related to that (Lage Junior & Godinho Filho, 2010). Kanban systems do not have clearly defined roles and sprints as in Scrum, but there the activities from the backlog are pulled into a Todo board to create a constant flow of activities in the pipeline. The Kanban system is normally more flexible, with longer and shorter pipeline activities pulled from the backlog than Scrum. In defence of Scrum and Kanban, long making-ready processes might hinder the wanted agility of the system.

The Critical Path Method (CPM) is often developed with great detail over a long time span and knowingly or unknowingly then oversimplifies the plan. It is often made static and communicated with a strong signal that this is the “optimal” way of conducting the project. If we go back to the claimed push and pull function of a plan, the strong signal and rigidness of the plan create a strong push to the whole organization.

DISCUSSION

We claim the plan references the project's complicated building blocks, leaving out the complex project creation process. A strong push is sometimes maintained even though it meets a context that, for practical reasons, should be learned and give input for a rescheduling. Practitioners should commit to the plan and the context, but if the gap creates a paradox, the plan might lose commitment, and the risk of total failure of the plan might be the consequence. In many projects, the planning that does not consider the production process can be aligned with driving by looking in the rear-view mirror (Ballard & Tommelein, 2021). If a plan is not aligned with the current state of production, a large amount of the planning capacity might be needed to update the plan. The function of pushing any new signal out to production might be futile. If this happens, the plan has no actual push/pull function toward production, and the functions only work as a benchmark function upward toward project goals. A strong push for an early detailed plan meets challenges when met with emergent situations.

EMERGENCY VS UNCERTANTY

"Only what has already happened may be used for forward-looking decision-making" (Schwaber & Sutherland, 2021).

By only starting tasks that should and can be done, there is an expectation in The Last Planner System that the task is sound before it is put into the (weekly) workplan. But even though a task is qualified as sound, many uncertainties and their potential consequences might have been identified to matter (Hillson & Murray-Webster, 2007). By matter we mean "that, if it occurs, will affect the achievement of objectives" (Hillson, 2016). The identified potential consequences are recommended to become a part of the clarification and negotiation process suggested in the Last Planner System (Ballard & Tommelein, 2021) they can be dealt with beforehand and increase the reliability of conducting the task. But identified uncertainties will for practical reasons only be treated superficially and a promise that is made must have some presumptions and remaining assumptions that the promise cannot have the time to be explicit about. If the uncertainty for getting materials is considered low, there is still some possibility that they will not arrive or be destroyed at the site. There is always a possibility that you for practical reasons leave them out because you consider them low even if they are identified, so even the identified uncertainties can turn into an emergent situation because it happens even with a low probability. The challenge with a complex context is that the unidentified variables can come from a lot of "sleeping" mechanisms and past experience provides only limited assurance for future events. When the event happens, we can go into a retrospect determinism and go into the fallacy of believing that if we only do something to that emerging event nothing more will happen. Since production is often sensed in or close to a complex problem new events will emerge but maybe from a different uncertainty and variables. This might force a promise to be broken or make a re-promise (Macomber et al., 2005).

The Last Planner System follows the principle of learning from breakdowns (Ballard et al., 2009; Ballard & Tommelein, 2021), do we then mean that this is a futile principle since we get emerging events? No, but because we acknowledge emergent situations, we mean that how we learn might differ from believing that the cause is something we can find direct countermeasures to. We need to lift the countermeasures we suggest to be more adaptable and general because we do not know where the next event will emerge, ex. good processes rather than specific tasks. What kind of event is classified as uncertain will be a dynamic definition based on multiple factors.

In this principle lies the measurement of Percent Plan Complete (PPC) which measures the percentage of tasks committed at the start of the week that is being done at the end of the week. This is referred to as a measurement of workflow reliability and activities that have not been done at the end of the week should be analyzed in order to learn from it. The method of "5 Whys" can be used to find the root causes for why it was not conducted as planned and search for "root causes". We claim that in a complex world, a true root cause cannot be found, but the method of using 5Whys often helps the user to go beyond the level of more obvious symptoms and closer to systemic causes. The first writer's experience from testing the "5 whys" is that it quite often is situations outside the trade workers' immediate responsibility that are analyzed as the root cause. So it is in a sense beyond the scope of what they made a promise on earlier. Originally the PPC measure worked on a weekly basis, but the possibility to trace PPC on shorter time intervals has been acknowledged (Ballard & Tommelein, 2021).

A COMMITMENT TO A PLAN

“Projects are a network of commitments” (Ballard & Tommelein, 2021).

A plan contains an element of trust and/or power to be executed. A static plan may need a larger element of power to be effective, especially if the plan deviates from the present and it becomes harder to gain the wanted trust. If the plan is not reached any negative deviations from the plan will often have economic consequences. To avoid this deviation resources are adjusted during the execution of the task to regain any lost time. If the plan is delayed because of something that the trade cannot be blamed for, the demand for compensation for forcing the plan back on time is often presented by the trade in advance. When the trades are involved in the planning the trades not only commit to the plan towards the project management but also to the other trades that are part of the planning process. As an example the Last Planner System facilitates a reversed-phase scheduling process where all trades are often gathered and everyone expresses a common commitment toward each other that they will manage to follow the plan. In our experience, this commitment from one trade to another is an important part when involving the trades in the planning process and the commitment to another trade seems to be just as strong if not even stronger than the commitment to the project management. Our experience is mainly based on a Norwegian culture that has been labelled as a “high trust society” (Covey, 2022) with a flat structure, this might influence the level of commitment among the trades.

A RELIABLE PROMISE TO COMMIT

A promise is a statement of intention made in certain specifiable conditions (Árdal, 1968). Statements may include all kinds of stated confirmation and signs of commitment to follow up a plan, including contracts, handshakes, subtle signals, and spoken utterances. A statement may include both explicit statements like “I promise I will do x” and also “I will do x” due to its implicit obligation in the latter statement (Árdal, 1968). In construction, a contract is a document of a promise between two firms where one firm promises to follow the terms to deliver the contract's content by a negotiated payment. A promise to a plan relates to reliability and how seriously the promise giver takes their promise (Ballard & Tommelein, 2021) and building and rebuilding trust with promises and apologies (Schniter et al., 2013). A promise is, therefore, related to a personal or cultural commitment to the task. An often-important part of people's integrity is to keep their promises. When a promise is not kept and the commitment is not delivered, the blame might be put on the person that promised to deliver, and explanations for not delivering are often noted to be bad excuses and apologies. We want to challenge how a commitment is pushed to give a more nuanced picture of the actual promise.

FROM A PROMISE IS GIVEN TO A PROMISE IS KEPT

One of the five original Last Planner Systems principles is “Make and secure reliable promises” (Ballard et al., 2009), but is a promise something you can do in advance and secure? The principle was in the 2020 benchmark for Last Planner System modified. It has become: “Make and secure reliable promises, and speak up immediately should you lose confidence that you can keep your promises (as opposed to waiting as long as possible and hoping someone else speaks up first).“ (Ballard & Tommelein, 2021). The new version acknowledges that the situation might change after making the promise, but it still signifies that the promise is yours to keep. We want to challenge how a promise is treated in both theory and practice, because of the emergent events that can take several forms. We do this to increase “reliable promising” (Ballard & Tommelein, 2021) by creating a better contract to the promise that a performer can make but also creating a better framework for improvement measures on the tasks that are outside the performer's control. We are not trying to underestimate the importance of respect for each other's concern on the contrary we want to increase the respect by letting the performer and the requestor understand the scope and limitations of the promise and also let the requestor see when the performer goes beyond expectancy to deliver the task that is planned for and reduce the amount of work that no one is accountable for. We use the promise made by the performer as input to a PPC measurement as an example. For simplification, we assume there is perfect communication between the performer and the requestor for the scope of the promise and task that is planned, even though this might be an issue in practical application. The performer makes the promise to do the task after clarification and negotiation according to the Last Planner System (Ballard & Tommelein, 2021) and the task is considered defined, sound, sized and sequenced. The task is put into the workplan and the (weekly) period for the plan starts. Then something emerges that was not accounted for in the initial preparations. We believe that at the moment something emerges having a system that respects what really happens is important to the situation. We currently suggest two questions should be asked about the emerging matter;

- Is the emergent matter within the scope of the promise put into the plan?
- Is the emergent matter within the expertise of the performer/promiser?

If we put those two questions in a matrix (Figure 1) we get 4 quadrants where the emergent matter can be categorized;

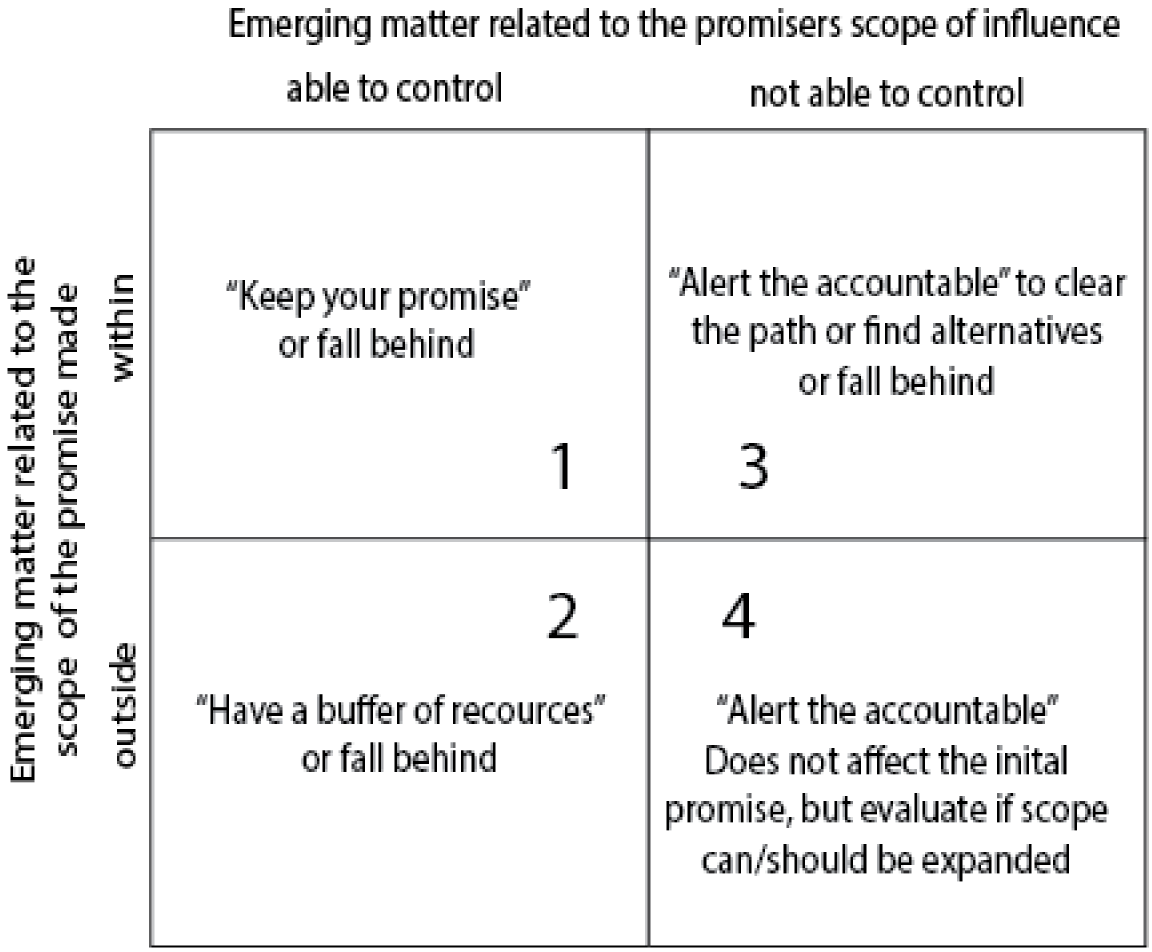

Figure 1: Emerging matter related to scope and expertise.

In quadrants 1 and 2, the performer has expertise within the emergent matter. This means that the performer can have the attitude to deal with those issues, if is not done, it will be because of prioritization or capacity issues. In quadrants 3 and 4 it is outside of the performer, control but in quadrant 3 the matter will still affect the performer's promise, while in quadrant 4 the emergent matter will not be within the promised scope. All the emergent matters can stop the progress of the planned work, but having a language to categorize and communicate and discuss how to deal with them can be useful. It will depend on the consequences of the emergent situation if it becomes a delay or not and the ability to making-do (Koskela, 2004):

- In quadrant 1: The emergent matter will be within both the scope and expertise of the performer. Example: Prerequisites that the performer is accountable in the make-ready process are missing.
- In quadrant 2: The emergent matter will be outside the scope but within the expertise of the performer. Example: An increased amount of work.
- In quadrant 3: The emergent matter will be within the scope but outside the performer's expertise. Example: The previous work is late and occupies the location for the work.
- In quadrant 4: The emergent matter will be both outside the scope and outside the performer's expertise. Example: A change in the content of the work that needs a third party to be solved.

Identifying what quadrant situations emerge might increase motivation for the performer to fix things that are within the control of the performer, but also show the performer's attitude toward fixing obstacles outside influence. It can provide a clearer language to make sure that interfaces between roles are accounted for.

An already identified reduction of PPC measures on work plans down to days and half days will reduce the consequences of emergent matters and will in practice probably need to put the promise part into a daily stand-up meeting setting. This can also give the skilled worker the possibility to promise when the prerequisites are cleared for the whole period, on a weekly plan often not the material, and never the people are prerequisites that can truly be guaranteed.

CONCLUSION

A plan is always a simplification, and when made and committed to a push on behalf of the intent is created. Trades and other project members commit to the plan at different levels and times. When committing and making the promise, they do not account for emerging matters that might affect the plan. Emergent matters are things that you had not anticipated and that will affect the work and the promise to commit to the plan. A higher understanding of the types of consequences the emergent matter can have both on the scope of the promise but also that it can affect outside of the performers space of influence or expertise. The boundaries of the promise and expertise should be recognised to manage the interface between them. Due to the emergent nature of the consequences, it must be a systematic and flexible way of dealing with these interfaces, not case specific. A better understanding of these boundaries might also motivate the performers and get more respect for each other's processes, this can again improve the total workflow reliability.

We suggest that the Last Planner System account for emergent matters when a workplan is made and separates the performer's promise from what cannot be promised by the performer. A shorter timespan on PPC should be considered to give a more reliable promise.

INTEGRATING A STRATEGIC MILESTONE AND PHASE PLAN (SMPP) AS A NEW LEVEL OF THE LAST PLANNER SYSTEM (LPS): AN INVESTIGATION ON MEGAPROJECTS

Annett Schöttle[1] and Andreas Böker[2]

ABSTRACT

Megaprojects often struggle with their production planning. One of the reasons is a lack of common understanding of the project scope and goals within the project teams and stakeholders as the basis for reliable project delivery. The Last Planner System (LPS) is a well-known method for production planning and control. Nevertheless, the LPS has its limitations in megaprojects as the gap between the master schedule and the phase plan is vast. On the one hand, the master plan consists of the milestones, the phase durations, and overlaps only. On the other hand, the phase plan (also named milestone and phase plan [MPP]) already consists of specified handoffs and conditions between processes within a phase duration. Thus, the master schedule is too vague, and the phase plan is too detailed. To overcome this limitation, the authors propose integrating another level, on a monthly basis, between the master schedule and MPP in the LPS.

Based on two case studies, this paper describes and analyzes how a Strategic Milestone and Phase Plan (SMPP) can be integrated as a new level into the LPS and demonstrates the benefits based on the findings of the two cases. The authors finally conclude that the SMPP should be integrated into the LPS at a new and additional level.

KEYWORDS

Last planner system, strategic milestone and phase plan, megaprojects.

INTRODUCTION

Flyvbjerg (2017) defines megaprojects as "large scale, complex ventures that typically cost $1 billion or more, take many years to develop and build, involve multiple public and private stakeholders, are transformational, and impact millions of people" (p. 2). Challenges often come with this: The development of a huge organization that contains constantly high employer fluctuation, unclear roles and responsibilities, a hierarchical decision-making process, long duration times when it comes to decision-making, lots of stakeholders with different expectations and interests, strong power relations, a lack of clearly defined goals and scope as well as unclear and undefined interfaces, a changing scope over time, technological innovation, a lack of common understanding within the project team, asymmetric information among the different stakeholders, a lack of transparency, a lack of seeing the overall project, working in silos, political interests, political decisions impacting the project (power games), and different financial funding (Flyvbjerg, 2017; Flyvbjerg et al., 2003; Merrow, 1988; Priemus et al., 2013).

[1] Dr.-Ing., Partner, refine Project AG, annett.schoettle@refine.team, Founder and Co-Director, CollabDecisions, orcid.org/0000-0001-6001-7320.

[2] Independent Project Management and Lean Expert, andreas.boeker@gmx.de, orcid.org/0009-0009-4535-7381.

Furthermore, Greiman (2013) points out that "[l]engthy projects create multiple unknowns, ambiguity, uncertainty, and risk that do not exist in projects of much shorter duration" (p. 186). This aligns with the description of Floricel and Miller (2001) that megaprojects contain "anticipated risk and unexpected events" (p. 446). Such risks can be design risks related to the planning phase of the megaproject, construction risks with the project schedule and coordination problems as well as financial and/or economic risks (e.g., Irimia-Diéguez et al., 2014; Little, 2011). With the named challenges, risks, unknown events, and the importance of success to the sponsors, megaprojects can easily fail (Merrow, 1988). Thus, in sum, a megaproject is impacted by a variety of factors that are not clear from the beginning. Hence, the teams must understand the project goals, constraints, risks, and the dynamic of the organizational environment and use a production planning and control method to help them navigate through the project.

In IGLC community, many papers have been published supporting the implementation of the LPS as a production planning and control system. The LPS consists of five steps (1) Master Scheduling, (2) Phase Schedule, (3) Lookahead Planning, (4) Weekly Work Plan, and (5) Learning (Ballard & Tommelein, 2021). Regarding megaprojects and LPS, almost no papers have yet been published (Ibrahim et al., 2017 – hospital project in San Francisco; Leth et al., 2019 – redevelopment of an offshore oil and gas field in the North Sea).

When it comes to a megaproject LPS, we see a gap between the master schedule and the phase plan. On the one hand, the master plan consists of the milestones, the phase durations, and overlaps only. On the other hand, the phase plan already consists of specified handoffs and conditions between processes within a phase duration. Thus, the master schedule is too vague, and the phase plan is too detailed. Therefore, an additional level between both levels is missing when it comes to large or mega projects. Implementing the LPS on two megaprojects allowed the authors to integrate another level into the LPS and research the value of the outcome. Consequently, based on the two cases' findings, we propose to integrate the SMPP as another level into the LPS.

RESEARCH METHOD

The objectives of this research are to introduce the SMPP to the IGLC community and to demonstrate the value of the SMPP as a further level of the LPS based on the two case studies: (1) Stuttgart Main Station Building (Bonatzbau), and (2) Munich Main Station. Therefore, a combination of action research and case study research was used to achieve the research objective as the first author was involved as a consultant/researcher in the second case and the second author was involved as a consultant/researcher in the first case (Dickens & Watkins, 1999; Yin, 2014).

During LPS workshop execution, the authors observed the teams and had small feedback sessions to improve the workshops as well as to define the content/next steps of the following workshops. To better understand the difference between the master schedule and the newly introduced SMPP, worldwide experts were questioned regarding their understanding of the master schedule in January 2023. Furthermore, in January 2023 a survey was carried out to collect data regarding the user experience of the SMPP during the workshops and how the outcome is used. In total, 19 responded to the survey: 42% (response rate 53%, 8 out of 15) from the project team of the first case and 58% from the project team of the second case (response rate 35%, 11 out of 31).

UNDERSTANDING THE MASTER SCHEDULE

To get a better understanding of the master schedule, worldwide experts were asked via mail and call for their definitions of the master schedule (see Table 1). In sum, the master plan can be defined as a general plan based on important milestones and depicts the different phases of the project by considering previous experiences. This is in alignment with the theory where Ballard and Tommelein (2021) defined the master schedule as "set milestones and phase durations and overlaps" (p. 12).

Table 1: Definitions of the master schedule from worldwide experts

Expert	Definition
Ballard, Glenn (USA)	The master schedule consists of the start and end dates of the project phases. The master schedule is produced within a project execution plan that treats risks and opportunities and is examined to see if the risk that remains after developing mitigations is acceptable. Revision may occur in an indefinite number of cycles until a go/no-go decision is made.
Christensen, Randi (DK & UK)	Includes contractual deadlines/milestones and, depending on the duration of the project, 1–4 milestones per year. Besides contractual milestones, potential additional milestones are either fixed based on delivery time (e.g., precast elements, governance processes by official bodies or the like) or some could be set based on a process plan made by the team.
Etges, Bernado (BR)	A plan that splits the project into general work packages (phases) to help define labor and equipment histograms and the flow through the project.
Hackler, Cory (USA)	General outline with milestones and phases based on previous data.
McConaughy, Tammy (USA)	Aligning Project Phases and Key Milestones that also help outline phase pull plans. This includes: (1) Utilizing any milestone information from the owner or other stakeholders, and (2) any baseline schedules that have been created.
Mossmann, Alan (UK)	A Milestone plan is the first level of decomposition of a project. It defines the overall design or construction and logistics strategy; key dates both for the customer and for the delivery team; the conditions of satisfaction for key milestones; the phases of the project for subsequent phase scheduling; and it details the 'last responsible moments' for ordering long-lead items.
Tsao, Cynthia (USA)	Initially, it was meant for milestones for one project, not for multiple projects.

INTEGRATING A NEW LEVEL TO THE LPS

Tsao et al. (2006) suggested that the IGLC community consider broadening the scope of the LPS so that it scales up to assist with portfolio management. Specifically, they recommended that owners start tracking a project-level Planned Precent Complete that measures how well their projects are meeting initial project goals (e.g., budget, schedule, quality, etc.) and start tracking a project-level variances chart that identifies the root causes of not meeting initial project goals (e.g., labor, long-lead item procurement, etc.). With this trending information, the owner could work on improving portfolio management by addressing those root causes when setting up the initial contractual terms and conditions for new projects. While Tsao et al. (2006) focus on portfolio management that would be integrated into the LPS above the level of the master plan, we suggest integrating an SMPP underneath the master schedule regarding the project itself.

Greiman (2013) reported that on The Central Artery/Tunnel Project in Boston, a Milestone Manager Group was successfully installed "to help manage and overcome project delays that resulted from the unpredictable nature of several aspects of the work" (p. 188). Therefore, the project was divided into four major milestones to track the project's progress and develop countermeasures based on the outcome. As this task force focused on the milestones, the SMPP focuses on milestones as well as the phases of the project.

Figure 1 shows the integration of the SMPP as a new level into the LPS and considers the level of portfolio management proposed by Tsao et al. (2006). The SMPP covers the entire project from start to finish including major milestones and their fulfillment criteria, all phases of the project/subprojects, specific handoffs as well as conditions of satisfaction between processes, strategic conditions, and defined premises with possible alternatives.

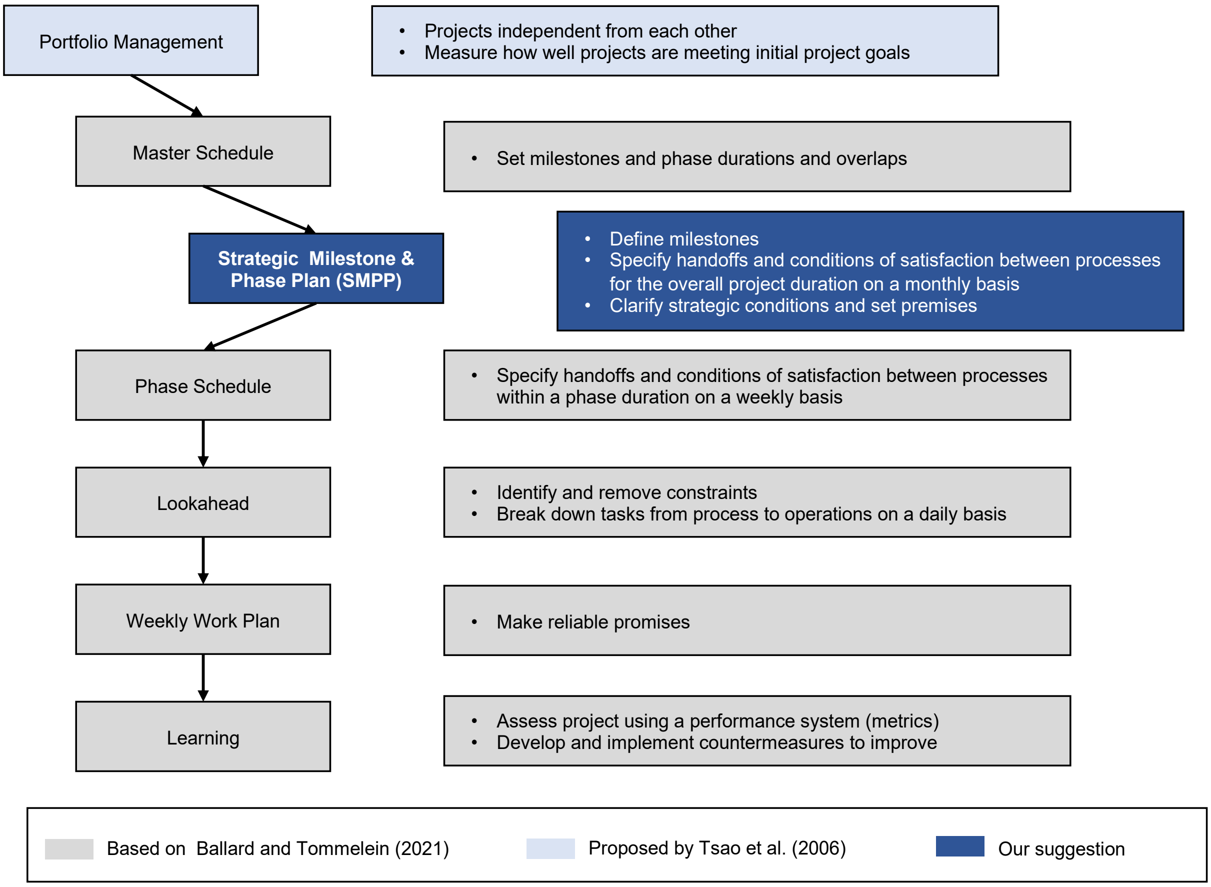

Figure 1: Integration of the SMPP into the LPS

CASE STUDIES

The case studies presented are both main stations in the south of Germany (Stuttgart and Munich) that are part of the infrastructure expansion from the German national railroad company (Deutsche Bahn, DB). Thus, both are capital projects in which the owner initiated the implementation of the LPS. In both projects, the SMPP was integrated as part of the LPS.

CASE 1: STUTTGART MAIN STATION BUILDING (BONATZBAU)

As part of the infrastructure project, Stuttgart 21 (reorganization of the railroad hub), the historic main station building (Bonatzbau) will be completely modernized. The renovated building, in addition to a new stabilizing structure, will contain two floors of a shopping mall as well as a hotel including a lounge and meeting areas. The exterior walls of the almost 100-year-old building are under preservation. The future main entrance allows easy access to the tracks of the new platform hall, which too, is currently under construction. Overall, the investment cost of the whole Stuttgart 21 project is currently indicated at €9.8 billion, of which €200 million is attributed to the historic main station building.

When the new project manager took over in 2020, he found that the team didn't have a common understanding of the project's goals and scope. Searching for an approach that would help the team achieve the milestones brought up the idea of implementing the LPS. Thus, a workshop series was rolled out to implement the LPS. By that time the project was in the phase of demolition and schematic design. After a project status check, a lean competence workshop, and an Overall Process Analysis (OPA) the SMPP was set up in two workshops for a period of five years (see Figure 2). Based on the SMPP, a weekly MPP was defined in May 2021 to set up a complete LPS for demolition and renovation works. In parallel, the basic design for the new building was further developed which led to an adaptation of the SMPP in four additional sessions from December 2021 to February 2022. To assure a flow from the demolition and renovation works to ground works as well as core and shell works, the schematic and detailed design development was included in the LPS.

Figure 2: SMPP Bonatzbau, 2021

CASE 2: MUNICH MAIN STATION

The core system of the city train (1.SBSS) needs a second core line (2.SBSS) as the first is overloaded. Accordingly, the main station needs to be extended and modernized—this includes overground and underground work. Besides the existing operations, all other buildings will be demolished, and new buildings will be built including services areas, areas for restaurants, shops, and office spaces. The project also incorporates a precautionary tunnel for another subway line as well as the complete renovation of the track hall roof and a new cross-platform roof. Thus, they are building under and overground while the fast trains, city trains, and underground lines are still operating, and services need to be provided for the customers. The anticipated cost for the main station (overground) is estimated at €1.2 billion and the expected cost for the 2.SBSS is approximately €7.2 billion.

In mid-2021 the development of the project organization started with the assignment of a project lead. The project lead was involved in the project team from the first case study. Drawing on his experience of the effect of the workshop series from the first case and understanding of how important it is to tear down silos and enhance communication between participants across different areas of responsibility, a workshop series was rolled out while the project was in different design stages. The project lead intended to reorganize the project organization based on the outcome of the SMPP:

"We intended to develop an SMPP based on lean principles [pull from the last process step of the commissioning process] to achieve a shared and deep understanding of the project program and scope as well as the necessary structure of the subprojects to define the overall project structure and develop a project organization that aligns with the project [...] and we did. Based on the SMPP outcome we structured, developed, and formed our project organization from scratch. [...] Because our organizational structure reflects this new project structure it is part of the project DNA and therefore will continue to grow naturally. This also ensures that lean and the strategic direction of the project no longer have to be carried into the project [...] [and they] will remain as part of the project from the inside out." (André Haubrich, DB Netz AG, April 2023)

In total, seven full days of SMPP workshops were necessary to produce an overall picture—the first four workshops were executed in April and May 2022, and the last three workshops were executed in September and October. The break between the workshops became necessary for the team to work off defined actions and to reflect on and adjust the defined premises outlined in the SMPP. It needs to be said that the workshops consist of a core owner team of 10–12 people and additional people that were brought in to work on specific topics. The SMPP was developed for a period of 15 years, aiming for completion at the end of 2035. Figure 3 shows an extract of eight years of the SMPP and Figure 4 the digitalization of the whole SMPP. In between the SMPP workshops, in June 2022, a strategic meeting with the project managers regarding the roles and responsibilities occurred. In addition, in May and June, four workshops were held to analyze the personnel requirements, not only for the main station but also for the whole project. The journey then continued with further workshops regarding the reorganization. Additionally, the team decided to continue learning by developing the MPP on a weekly basis to achieve the first major milestone of the project in January 2026 (duration of MPP 34 months).

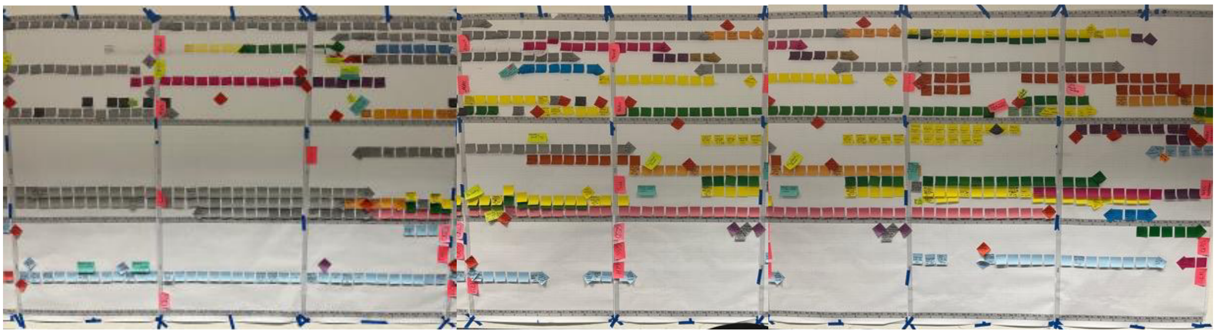

Figure 3: Extract of SMPP Munich Main Station, 2022

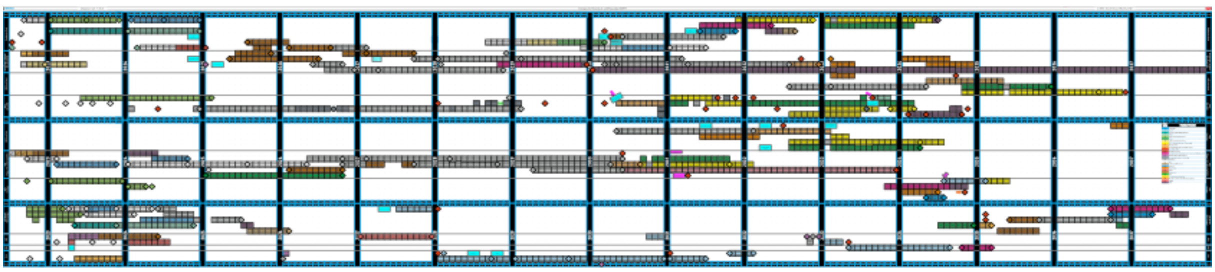

Figure 4: Digitalisation of the SMPP Munich Main Station, 2022

IMPLEMENTATION OVERVIEW

In the Stuttgart main station building project the SMPP was used as the basis to set up a complete LPS followed by an MPP, a six-week lookahead, and weekly work plans to steer and control the overall project delivery. In addition, it was transferred into the overall schedule of the project of the whole reorganization of the railroad junction. In the Munich project, the SMPP was used to better understand the project to restructure its organization. Afterward, the SMPP was transferred into an MS project timetable which is currently supposed to be the control schedule. In March 2023, the team started with workshops to develop an MPP.

Table 2: Overview of the workshop series and execution time for both cases

Workshops	Description	Bonatzbau	Munich Main Station
Project status check	Common collection and assessment of risks, obstacles, opportunities, and drivers of the project.	One workshop, March 2021.	One workshop, February 2022.
LPS competence workshop	Villego simulation to learn about the LPS.	One workshop, March 2021.	Two workshops, February and March 2022.
Condition of Satisfaction	Development of a common goal understanding for the project with a definition of what "success" means for the project team.	Not part of the tendering.	One workshop, February 2022.
Definition of the milestones	Definition of the important project milestones and specification of the compilation criteria of the most important milestones (20% of the project milestones).	Included in the OPA.	One workshop, February 2022.
OPA	Time-independent process analysis to determine and record the project-relevant interfaces.	Two workshops, April 2021.	Three workshops, March 2021.
SMPP	Pull planning from the last project milestone on a monthly basis for the whole project timeline.	Two workshops, April 2021.	Seven workshops: First four workshops, April and May 2022. Last three workshops, September and October 2022.

DISCUSSION OF CROSS CASE FINDINGS

FINDINGS COMPARING IMPLEMENTATION

In both projects, the SMPP was implemented successfully following the different requirements of the project leads. When comparing the implementation of both projects, there are six differences:

1. **Duration of SMPP:** In Case 1 the schedule duration is five years, while in Case 2 the SMPP covers a period of 15 years.
2. **SMPP scope:** Case 1 is a large project that is an integral part of a megaproject, while Case 2 is a megaproject including subprojects.

3. **Project phase when SMPP was developed:** In Case 1 the project was already under deconstruction and in the design phase of construction documents, while in Case 2 the project was mainly in the design development stage.
4. **Intention of the owner regarding SMPP:** In Case 1 the owner's intention was to get a project overview including the main dependencies between design, deconstruction, construction, and the different building parts. While in Case 2, the intention was to restructure the project organization based on the project's needs.
5. **Action of the owner:** In Case 1 the project was already in progress when the implementation started (reactively), while in Case 2 the implementation was used to set up the project (proactively).
6. **Availability of project participants:** In Case 1 the contractors for demolition and structural works were partly involved in developing the SMPP, while in Case 2 just the owner's team participated in the workshops as the tendering process did not start yet.

The differences show that the SMPP is flexible in its application and focus. Thus, there are no constraints on the time the SMPP should be developed; however, the criteria can be set that the earlier the SMPP is developed, the better.

SURVEY FINDINGS

Before being asked about their SMPP experience, participants were first asked about their pain points regarding the traditional scheduling process of megaprojects to obtain a reference point. Overall, the answers can be clustered into seven major points: (1) political deadlines; (2) missing identification and a lack of understanding of interfaces, dependencies, risks, and responsibilities; (3) lack of communication and information regarding goals and tasks; (4) missing integration of relevant stakeholders and their knowledge; (5) missing focus of the overall project; (6) lack of common understanding among the project team; (7) lack of moderation during development. The pain points result in an unreliable schedule that contains unrealistic durations and impossible sequences.

Participants were then asked how helpful the SMPP workshops were and how helpful the outcome was for furthering the procedure of the project. For most of the participants, 79%, the workshops, as well as the outcome, were extremely or very helpful. Furthermore, 11% answered that the SMPP workshops were somewhat helpful (see Figure 5). Only one person (5%) answered that the SMPP was not helpful, and one person (5%) checked the box of no answers. Overall, it can be stated that the SMPP was very helpful for both project teams. In further questions, the survey participants were asked to give more insights based on open-ended questions. Participants mentioned that simplification and visualization helped to get a better overall view of the relevant processes and dependencies without getting lost in detail. In addition, the information and knowledge exchange and solution-finding collaborations supported by neutral moderation helped to gain a common understanding of the project and critical aspects. It also helped to identify missing dependencies, gaps, prerequisites, and related challenges. They finally stated that the SMPP should be set up as early as possible.

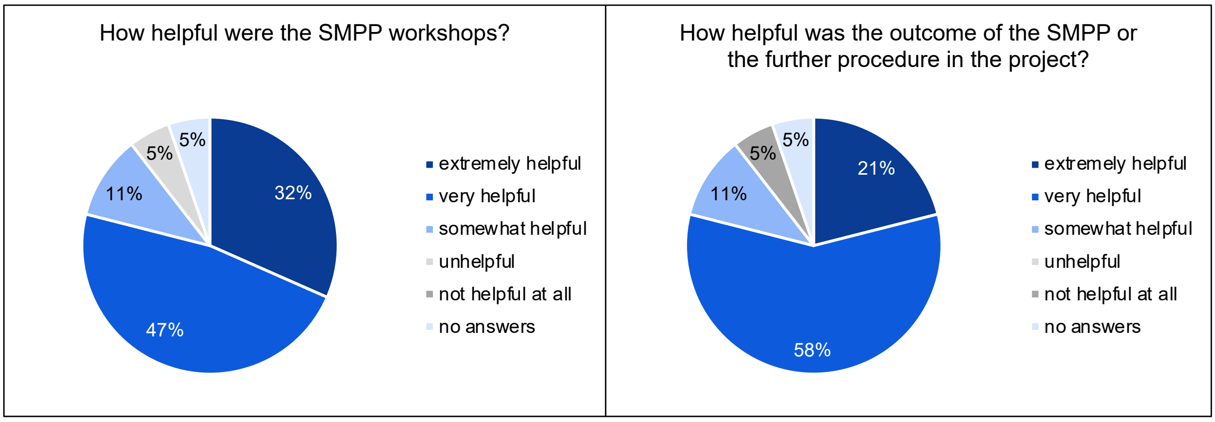

Figure 5: Response of the survey participants regarding the SMPP workshops and outcome

Overall, the survey participants highlighted the following advantages of the SMPP:

- Overview of the entire project on an intermediate and manageable level (measurable).
- Increased focus on relevant steps and long-term scope sequencing/milestones.
- Plausibility check of the total construction time and handoffs.
- Simplification of complicated issues using a common (simple) language.
- Creation of a common understanding of the goals and subsequent steps.
- Exchange of valuable information.
- Involvement of all project participants.
- Joint development process.
- Increased focus on relevant steps and results through pull-planning.
- Transparent and structured presentation of the project.
- It allows the development of a different perspective.
- The holistic approach.
- A better understanding of the current project status.

With the last question of the survey, participants were asked how often the SMPP should be updated (see figure 6). Most participants stated that a smaller time duration (every three or six months) would be better because of the dynamic and resulting changes. A smaller period would also help new project members get a better understanding and check on the intermediate milestones to maintain awareness regarding the overall project milestones.

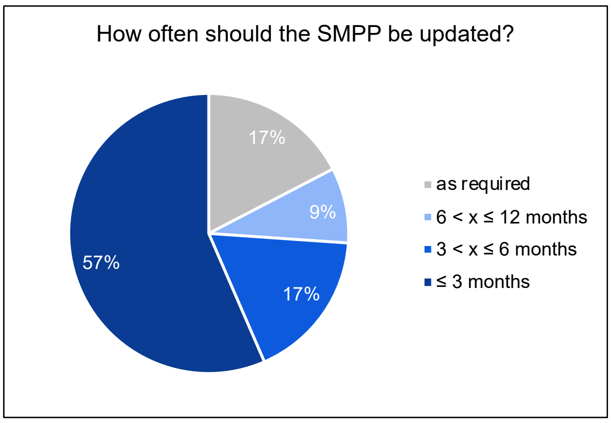

Figure 6: Response on the sequence of updating the SMPP through workshops

CONCLUSION AND RECOMMENDATION

The case studies presented in this paper show the research and findings of the implementation of the SMPP into the LPS of two megaprojects. In the presented cases, the SMPP was developed for a mid (five years in Case 1) and long time period (15 years in Case 2). In both cases, the implementation of the SMPP was a significant benefit for the project teams. It helped to achieve a common understanding of the overall project schedule, related interfaces, and process dependencies. It also helped to close the gap between the master schedule and the MPP. Thus, our recommendation is to implement the SMPP as early as possible in a project. Furthermore, we recommend adding the SMPP to every LPS implementation for projects if it is necessary to generate a full project overview with the project team, the time frame is a minimum of 18 months, and the project is highly complex. If otherwise, the phase plan could be extended.

As both cases are still ongoing projects, the value of the SMPP cannot be evaluated with finality. Also, as in both cases the SMPP was developed for five and 15 years, the value of adding this level to a smaller project with a three-year duration might be beneficial, but this cannot be verified yet. Furthermore, what would happen if the project duration and thus, the SMPP, were more than 15 years? We assume that the SMPP would then be revised at different, wider intervals for the entire period. For example, instead of monthly, it would be quarterly, with the first years being on a weekly basis. The switch from monthly to quarterly depends on the project stage, the available information, and the independence of the project - the shift from weeks to quarters might be between five to eight years.

ACKNOWLEDGMENTS

We would like to thank both project teams for their support, collaboration, and open mindset, as well as for answering the survey from DB Netz AG and DB PSU GmbH.

ABSTRACT

The registered levels of failure in construction projects encouraged searching for new concepts and methods to improve the performance of these projects. Lean construction and Advanced Work Packaging (AWP) are examples of these concepts. While lean construction has been practiced for three decades, AWP is still newer. Despite the growing interest in Advanced Work Packaging (AWP) and Lean Construction, there is currently no published research that explores the feasibility and effectiveness of applying AWP and Lean Construction in construction projects. The current study aims to provide a comparison between the two concepts based on the results from reviewing the literature. This study, which covered 29 studies, summarizes similarities and differences between lean and AWP based on four categories; context and principles, project specification, roles in the project, and work approach. Based on the results, the study recommends investing in ways to integrate the two concepts aiming at achieving better performance on all levels and decreasing the impact of uncertainty and complexity in construction projects.

KEYWORDS

Lean construction, Advanced Work Packaging (AWP), construction projects, Last Planner System (LPS), comparison, literature review.

INTRODUCTION

During the last few decades, the increased levels of complexity and rates of failure to deliver construction projects on time, with the planned cost, and with good quality have encouraged the movement toward the adoption of new concepts that are more related to thinking about construction as a production system (Farghaly & Soman, 2021). Unlike the traditional project management theory, understanding construction as a production system means that construction systems should be designed, controlled, and improved based on three goals improving the intended produced product, improving the production process and its characteristics (e.g. cost minimization), and meeting the needs and requirements of the customer (e.g. quality) (Koskela et al., 2002; Koskela & Howell, 2002).

Lean Construction and its related applications and tools such as the Last Planner System (LPS) and Integrated Project Delivery (IPD) and more recently, Advanced Work Packaging (AWP) are examples of the concepts to support the management and control of construction production systems (Farghaly & Soman, 2021). In many locations around the world, the implementation of lean construction has shown improvements on various levels including cost saving, project duration reduction, higher safety awareness and fewer accidents rates, sustainability, errors and rework reduction, wastes reduction, better inventory management, higher predictability of work, higher labor productivity and increasing customer satisfaction (Albalkhy & Sweis, 2021). The concept of AWP is still new compared to lean construction but shows positive signs about its ability to improve performance in construction projects. For instance, a study that included 20 construction projects in the United States and Canada showed that implementing AWP helped achieve better predictability and improved productivity, cost, safety, and quality (Hamdi & Lafhaj, 2021; O'Brien et al., 2016). Some estimates showed that AWP can help achieve around 25% gain in productivity and 10% installation cost savings in construction projects (CII & COAA, 2013; Rebai et al., 2022). Accordingly, research and interest in AWP are increasing.

Although Advanced Work Packaging (AWP) and Lean Construction have been shown to have significant benefits in enhancing construction productivity and efficiency, their feasibility and efficacy have yet to be examined in the scientific community via a research article. Although both concepts aim to improve performance and productivity in construction projects, the link between them to provide more chances for project success remains inadequately explored. An essential question to be asked is how the two concepts can complement each other. The present study investigates the similarities and differences between AWP and Lean Construction by reviewing the existing literature to address this inquiry.

DEFINITIONS

Lean Construction

Lean originated following the development of the Toyota Production System (TPS) in Japan. Since then, there have been many works that aimed to describe TPS and the principles and theory of lean (Liker, 2004; Ohno, 1988; Womack et al., 1990; Womack & Jones, 1996). In these works, lean principles were defined based on the identification of value based on the client's needs and requirements, value stream mapping, creating a flow of information and materials and waste elimination, establishing pull and producing only what is needed, achieving continuous improvement, and respect for partners and people.

The success of lean in Toyota encouraged its implementation in other fields; including the construction field. The first work about lean construction was the presentation of the "new production philosophy to construction" by Lauri Koskela (1992), which was then followed by the Transformation-Flow-Value theory (TFV) in 2000 (Koskela, 2000). Another important work was the presentation of the most famous lean tool, the Last Planner System (LPS) (Ballard, 2000). LPS can be understood as a planning and production control tool that integrates collaborative planning with all possible stakeholders especially the last planner (people who do the work), incorporates the pull concept and plan based on what "CAN" be done instead of the push mechanism that is based only on what "SHOULD" be done, identifies constraints to be removed, develops performance measures such as Planned-Percent-Completed (PPC), and integrates learning process based on the principles of continuous improvement and non-compliance to plan analysis (Porwal et al., 2010).

LPS and TFV together helped to construct a base for the theoretical and practical streams of the theory of lean in the construction sector (Albalkhy & Sweis, 2021). Over the years, there has been no agreement on a specific definition for lean construction, but one of the definitions that were raised following studying a list of existing literature about lean construction was *"a philosophy that aims to improve the collaboration between all project stakeholders to maximize value for all of them in general and the customer in particular, in addition to eliminating all kind of wastes, achieving continuous improvement, improving flow, reducing cost and enhancing safety and quality"* (Albalkhy & Sweis, 2021).

AWP

AWP roots go back to the development of Workface Planning (WFP), which was one of the best practices to face the challenges facing the construction of oil and gas projects in Alberta according to the Construction Owners Association of Alberta (COAA) (Hamdi, 2013). WFP is "*the process of organizing and delivering all the elements necessary, before the work is started, to enable craft persons to perform quality work in a safe, effective, and efficient manner. This is accomplished by breaking down (planning) construction work by trade into discrete work packages that completely describe/cover the scope of work for a given project to efficiently use available resources and track progress"* (Hamdi, 2013). In 2011, a joint research work between COAA and the Construction Industry Institute (CII) started aiming at reviewing different methods (including WFP and LPS) and developing a project planning and execution model. The research was based on studying industry cases, literature review, interviews with experts, and team experience resulted in the development of the AWP approach (Halala & Fayek, 2019). According to the CII (CII - RR272-11, 2013), AWP is *"a planned, executable process that encompasses the work on an engineering, procurement, and construction, beginning with initial planning and continuing through detailed design and construction execution"*.

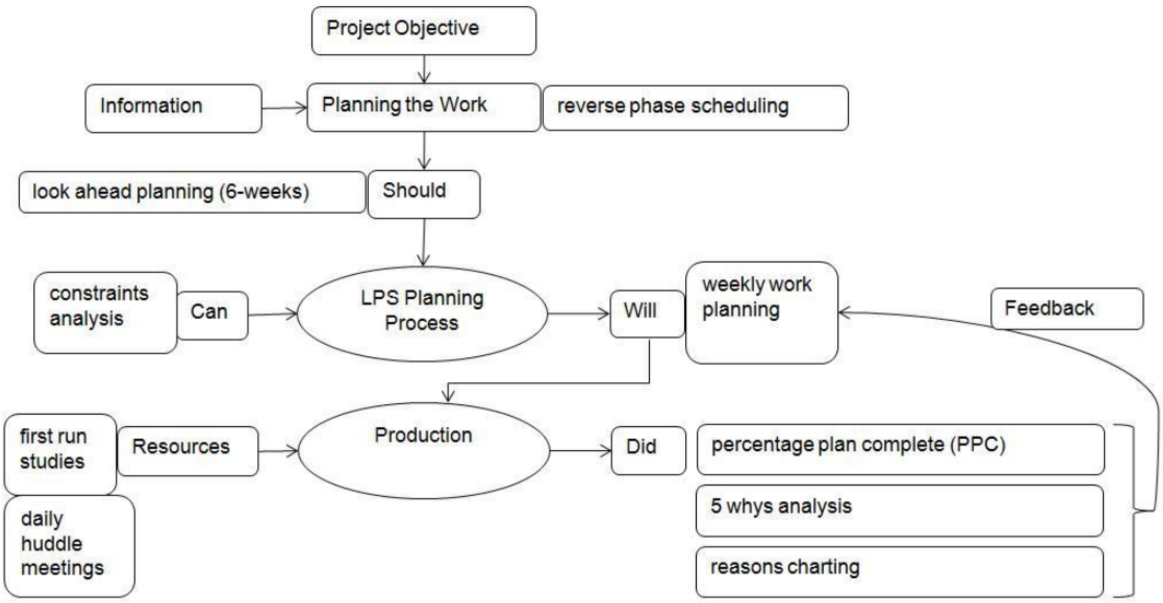

Figure 1: LPS planning process (Porwal et al., 2010).

AWP is a construction-driven project delivery process that begins with the end in mind, in which construction and engineering must collaborate during planning to create a constraint-free field environment (Wu et al., 2021). This collaboration ensures that the project is designed with a construction-friendly sequence and that the supply chain is sequenced accordingly by breaking down the project scope into Construction and Engineering Work Packages (Ponticelli et al., 2015). AWP was also designed to facilitate the planning process and reduce the burden while creating work packaging by removing any possible constraints as early as possible (Halala, 2018). Unlike traditional work packaging where planning is done only in the early phases of the project, AWP tries to provide a holistic approach to planning and execution of work packaging along the whole project life cycle as follows (Olfa et al., 2013; Ponticelli et al., 2015):

- The first stage of a project involves identifying critical planning elements to define work packaging deliverables. The project is divided into Construction Work Packages (CWPs) which align with the execution plan and Engineering Work Packages (EWPs).
- The second stage is Detailed Engineering which refines the work from the first stage. Output includes detailed specifications for EWPs, a discipline-based schedule, and aligning plans to ensure consistency.
- The third stage is Construction, with detailed planning and execution of Installation Work Packages (IWPs). IWPs are issued 3 weeks before the start and are approved by frontline personnel. After execution, IWPs are controlled by owner representatives for quality checks and updates.

Despite receiving some criticism from the Lean community due to the expected impact on inventory growth, push orientation, and variability increase (Arbulu & Shenoy, 2021; Tommelein & Ballard, 2016), there have been several calls to integrate AWP and lean construction, especially by the CII and the Lean Construction Institute (LCI) (CII & LCI, 2022a, 2022b; CIIBuilds, 2022b, 2022a). Nevertheless, a scientific paper still has not addressed the possibility of applying AWP and LCI.

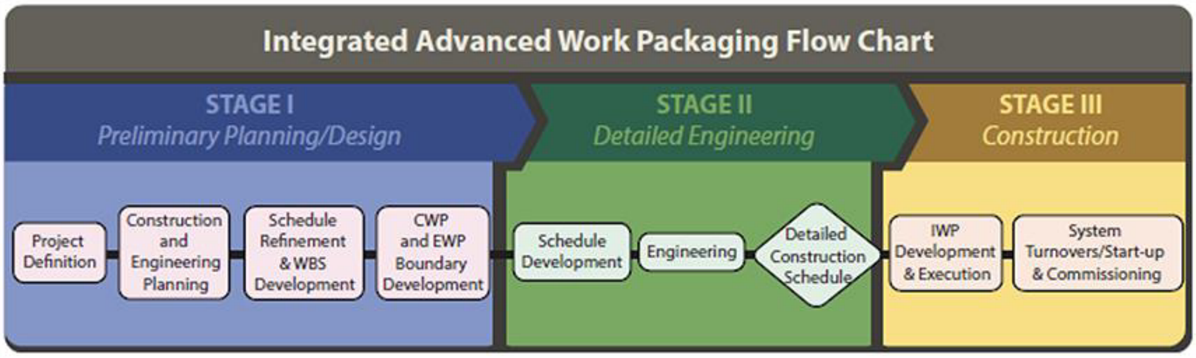

Figure 2: AWP flowchart (CII - RR272-11, 2013).

RESEARCH METHODOLOGY

This study aims to conduct a comparison between lean construction and AWP to identify similarities, differences, and possible opportunities. To do so, a literature review was conducted using a search for the keywords: ((“advanced work packaging” OR AWP) OR (“workface planning” OR WFP)) AND (construction or building). The focus on AWP is because of the low number of publications about it in comparison to lean. The search was done firstly on Google Scholar, Web of Science, and Scopus to cover the scientific articles about the studied topic. Then, it includes other resources; especially those published by CII.

The total number of studies included in the literature was 29. The charactersitcs of the studies are shown in Table 1. Following the analysis of these studies, four main categories were studied, which are context and culture, project specification, roles in the project, and work approach. The selection of these four main categories in this study was based on their relevance to the implementation of Advanced Work Packaging (AWP) and Lean Construction in construction projects. These categories were chosen to explore the factors that could affect the implementation and success of AWP and Lean Construction in various project contexts and organizational cultures.

Table 1: Literature characteristics.

Characteristics		Number of publications
Type of publication	Journal Article	11
	Conference	4
	Book	2
	Thesis	3
	Report	7
	White paper	2
Year of Publication	2013	3
	2014	-
	2015	2
	2016	2
	2017	1
	2018	2
	2019	2
	2020	6
	2021	4
	2022	8
	2023	1

The category of context and culture was included due to its broader organizational and cultural factors that can impact the implementation of AWP and Lean Construction. Project specification was identified as a category due to its critical role in determining the scope and objectives of the project, which could influence the selection of the appropriate work approach, roles, and responsibilities required for AWP and Lean Construction implementation. Roles in the project were selected as a category due to the need for clearly defined roles and responsibilities for the successful implementation of AWP and Lean Construction. Finally, the work approach was chosen as a category to analyze the implementation of AWP and Lean Construction in the context of the project management approach used, as well as the availability of technology and resources necessary for successful implementation. Due to the presence of different lean tools, the fourth part, which is about the work approach provides a comparison between AWP and LPS as LPS is the most known planning and control tool in lean thinking.

RESULTS

Context and principles

Context includes the type of each concept, origin, orientation, and purpose as explained in the literature. The comparison based on the context is shown in Table 2. Concerning the type, it is agreed that lean is not based on a specific tool or methodology; rather, it resulted from a set of principles that were first coined in the automotive industry and constitute what is called lean thinking. Accordingly, lean can be seen as a philosophy based on which different tools and methodologies were developed (Albalkhy & Sweis, 2021; CII & LCI, 2022a). On another hand, AWP is an approach or a methodology that was considered a best practice in work packaging to solve the problems facing construction in the oil and gas sector as explained by the (CII - RR272-11, 2013). In terms of orientation and purpose, AWP can be considered a task-oriented approach that aims to improve task management to increase predictability and productivity in projects (Halala, 2018). While lean has evolved to be more of a human-centric approach that values workers' engagement and is based on collaboration to create value, flow, and continuous improvement (Santos et al., 2021). Orientation toward "respect for people" and collaboration made it possible for lean to go beyond time, cost, and quality improvement to cover other aspects such as innovation and integration of workers' ideas, sustainability, and safety (CII & LCI, 2022a). This does not mean that AWP neglects the human factor. For instance, Path of Construction (POC), which is an essential practice in AWP should be jointly developed and aligned with respect to all stakeholders (CII & LCI, 2022b). Additionally, according to CII and LCI, a key value for AWP and lean construction is integrating the safety, health, and well-being of workers in the process design (CII & LCI, 2022a).

Table 2: AWP vs Lean- context

Context		
Criteria	**AWP**	**Lean Construction**
Type	Methodology	Philosophy
Origin	Oil & Gas Industry	Automotive Industry
Orientation	Task-oriented	People-oriented
Main Purpose	Increase productivity, predictability, and efficiency	Value creation, flow, and continuous improvement

Project Specification

AWP method was developed to respond to the increased complexity of capital construction projects (Halala, 2018). According to Hamdi (Hamdi, 2022), the implementation of AWP in small projects is possible but not attractive as it fits more megaprojects. In contrast, lean can be implemented in all types of projects (Albalkhy & Sweis, 2022). Concerning the contractual relationships and project delivery types, AWP considers early contracting a priority, in which the requirements for AWP and AWP language (plans, procedures, strategies, and responsibilities) should be clearly stated and included in the contract (Halala & Fayek, 2019). For lean, lean can be used with different types of contracting and project delivery methods. However, the lean community has had a big role in the development and adoption of collaborative delivery methods such as lean project delivery system (LPDS), integrated project delivery (IPD), target value delivery (TVD), and others (CII & LCI, 2022a; Koskela et al., 2002). Referring to the costing strategy, the AWP requires defining the initial conceptual model and estimate based on the work packages and then conducting formal cost-saving ideas, which results in the locking of the estimate (CIIBuilds, 2022b). For lean, one of the most encouraged practices is the Target Value Design (TVD), which is based on keeping the design and costs aligned with the client's target cost defined in the early design phase (Ng & Hall, 2019). Regarding the project planning methods, AWP conducts interactive planning sessions, which include all key stakeholders and are driven by the construction, until the preparation of the CWP (Construction work packages) with a push aspect in the CWP release matrix, but once on the site, the workforce planner changed the concept dealing with the IWP (Installation work packages) release plan in a pull concept. The pull could also be promoted when a supplier needs to provide relevant information to Procurement Work Package(CII, 2020). All that is always conforming to the main plan and with the alignment to the POC (path of construction) and (CIIBuilds, 2022b). On another hand, lean construction strictly focuses on pull planning and builds its plans using a collaborative planning method in presence of all stakeholders and participants (CII & LCI, 2022a). The comparison based on project specification is shown in Table 3.

Table 3: AWP vs Lean- Project specifications.

Project Specifications		
Criteria	**AWP**	**Lean Construction**
Suitability	Capital Projects	All types of Projects
Contracting and project delivery	Contracting strategy is a priority and needs to be defined	Different types of delivery but encouraging IPD
Costing/value	Initial conceptual model and estimate Conducting formal cost-saving ideas	Target value design (TVD)
Planning Principle	Push and interactive planning Pull for supplier and PWP, and in the site	Pull and collaborative planning

Roles in the project

As AWP is a structured approach, it has clear definitions for various roles, which is not the case in lean. For instance, while in lean, clients are the main focus and their presence and participation is a key to success in all project phases (Albalkhy & Sweis, 2021), there is no strict definition of their representatives like that in AWP. AWP champions, who act as the voice of the client are responsible for the implementation of AWP procedures and standards throughout the project (Hamdi, 2022). Additionally, while the collaborative planning sessions require the attendance of all possible stakeholders in LPS, there is no strict requirement to make someone a facilitator. In contrast, AWP interactive sessions are usually led by the Construction Manager (1^{st} to 3^{rd} levels of planning) and then workface planners (4^{th} and 5^{th} levels of planning) (Hamdi, 2022). The workface planners are responsible for IWPs definition and management on site to ensure the removal of constraints and the proper execution of the work (CII & LCI, 2022a). A clear definition of lean roles can be found in the last planner which refers to the foreman or the frontline supervisor who has to engage in constraints management and removal (Porwal et al., 2010).

Work approach

AWP is a structured approach that has three main phases of work that are resulting in the CWPs, EWPs, and IWPs. The work in AWP usually starts with area-based decomposition by developing the construction work areas (CWAs) and then over the disciplines-based planning and control. As an approach with origins from the oil and gas sector, during the planning process, AWP focuses on aspects such as constructability, operability, maintainability, and constraint removal (CIIBuilds, 2022b). In turn, lean practices in LPS adopt the short-range production planning levels (i.e. master schedule, phase or pull planning, look-ahead planning, weekly work planning, and daily huddle meetings and learning). Aligned with some practices such as takt planning, short-range planning in LPS aims to ensure the avoidance of overlapping between trades and remove variability sources that may hinder the flow of the work (CII & LCI, 2022a).

Concerning performance measurement, AWP relies on productivity measures for the CWP, and EWP, in addition to safety and delay indicators. It also uses the installation cost of IWPs and their conformity with the planned budget (Halala & Fayek, 2019; Hamdi, 2013; Rebai et al., 2022). In lean, as stated earlier, the focus is on trying to achieve continuous improvement in all possible aspects (e.g. client satisfaction, safety, sustainability, time, cost, and quality). Specifically, in LPS, different measures are considered to cover different aspects including for instance the percent plan complete (PPC), which helps to identify the deviation between what was planned and what was executed (Ballard, 2000). In addition to other measures such as cost reporting (CR), schedule variation (SV), quality reporting (QA/QC), Root-cause Analysis (RA), and Reason Summary for non-competition (RS) (España et al., 2012).

Regarding the learning process, AWP refers to knowledge management related to the IWP process and value chain (Hamdi, 2022). In lean, the learning process is a fundamental concept that supports the continuous improvement goal. Therefore, many tools can be used to support the learning process in LPS such as the analysis of the frequency of plan failures, 5 Whys, Plan–Do–Check–Act (PDCA), Detect–Correct–Analyze–Prevent, variance analysis and the reason for variance (Hannis Ansah et al., 2016). Table 4 summarizes the comparison between AWP and LPS in relation to the work approach.

Table 4: AWP vs Lean- Work approach.

Work approach		
Criteria	**AWP**	**Lean Construction (LPS)**
Planning Structure	Milestone Planning L1 Planning (Areas) L2 Planning (Disciplines) L3 Planning (Work for a crew) CWA, CWP, EWP, IWP	Master Schedule Phase Scheduling Look-Ahead Planning Weekly Planning Daily huddle meetings and learning
Risk	Systemized risk analysis and constraints removal	Constraints removal throughout the whole project Error-proofing
Performance measurement	Productivity Safety Installation cost Delay	PPC, CR, SV, QA/QC, RA, RS, and others
Planning classification (colored stickers)	By areas and discipline	By trades
Learning	Knowledge management (IWP)	Analysis of Frequency of plan failures 5 Whys, Plan–Do–Check–Act, detect–Correct–Analyze–Prevent Variance analysis Reason for variance

The literature was used in this study to compare two concepts that aim to improve the performance of construction production systems, which are AWP and Lean Construction. The analysis of the found studies showed that despite the differences in the approach, context and principles, type of projects, and structure and roles, the two concepts have many things in common. Which shows room for mutual interaction and integration between the AWP and Lean Construction. Figure 3 shows the possible integration chart between AWP and lean construction.

More specifically, AWP and lean construction share the goals of creating improvements in productivity, quality, and efficiency in construction projects. Both focus as well on the removal of all constraints that may hinder the flow of work and affect efficiency. The safety of workers and stakeholder participation in the planning and control are also among the shared points between AWP and lean construction.

Concerning how AWP can benefit from lean construction, one of the primary focuses can be more oriented toward the human factor. In lean construction, respect for people is an essential principle that is reflected in most lean tools; especially in the LPS. This principle requires respecting the inputs of workers, building trust, creating effective communication strategies, and strengthening the team working environment. Additionally, AWP can benefit from other lean principles such as the focus on flow and waste elimination and pull planning. Moreover, while AWP has its tools to improve the learning process, there is still room to benefit from the continuous improvement experience in lean thinking. Concerning performance measuring and control, focusing on the value of the client may help to produce more key performance indicators (KPIs) that can help achieve better performance on different levels while implementing AWP. Finally, AWP can benefit from the integration with other concepts related to lean such as TVD, IPD, and LPDS.

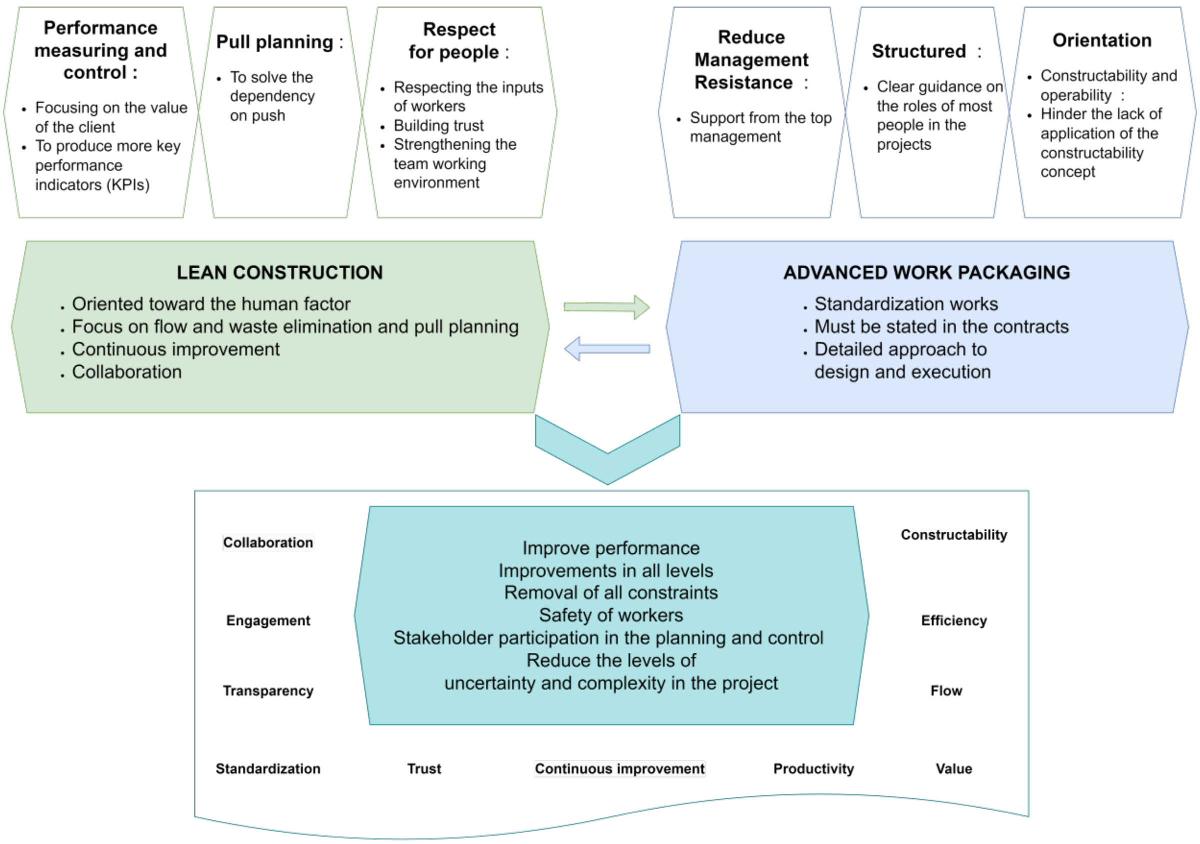

Figure 3: Possible integration chart between AWP and lean construction.

In turn, AWP can support the standardization works in lean. With its structured way, AWP offers opportunities for ease of implementation. This is supported by its clear guidance on the roles of most people in the projects. As a result, this might be helpful to face the challenges of the reluctance of people to adopt lean (Albalkhy et al., 2021; Albalkhy & Sweis, 2021). Additionally, as AWP has to be clearly stated in the contracts, its adoption with lean construction may help to reduce the management resistance to change and the lack of support from the top management, which was considered in many studies among the most serious barriers facing the adoption of lean (Albalkhy et al., 2021; Albalkhy & Sweis, 2021). Moreover, with its detailed approach to design and execution and its orientation toward constructability and operability, AWP adoption may hinder the lack of application of the constructability concept, which is another cited barrier that faces the adoption of lean (Albalkhy et al., 2021). Finally, as a method that was specifically developed for a large-scale project, the integration of AWP and lean construction can help to reduce the levels of uncertainty and complexity in the project.

DISCUSSION AND CONCLUSIONS

The integration of AWP and Lean Construction has the potential to create a more collaborative and efficient environment in construction projects, leading to improved project outcomes, reduced project delays, and cost overruns. The synergistic effect of integrating AWP and Lean Construction can promote standardization, constructability, and the adoption of best practices, leading to improved project outcomes. The integration can also promote the flow of work and value in the project and achieve continuous improvement through the use of lean tools and techniques.

However, the study has some limitations. The low number of publications about AWP in comparison to Lean Construction resulted in relying on non-peer-reviewed industry reports as a primary source of information on AWP. Further investigations based on case studies analysis, content analysis of the reports and standards of AWP compared to lean literature, or collecting perspectives via interviews, surveys, or any other data collection method may be required to investigate the possibilities, impacts, or challenges facing this integration between AWP and Lean Construction. The study does not focus on the detailed approach in AWP and a specific Lean tool such as LPS, rather, it covers the main themes of the work. Future studies can provide a comparison on the base of details in each phase of the project.

In summary, the study helps practitioners and researchers to understand the links and differences between AWP and Lean Construction concepts and how to integrate them to make improvements in the construction environment. The integration of AWP and Lean Construction represents a promising avenue for improving construction project outcomes, but further research is required to validate the impact of the integration on these measures.

MEASURING TIME SPENT IN VALUE-ADDING WORKSPACES USING SMARTWATCHES

Cristina T. Pérez[1], Stephanie T. Salling[2], and Søren Wandahl[3]

ABSTRACT

This study addresses the lack of procedures for automatically measuring the share of time that construction workers spend on value-adding activities as a way to automate the work sampling technique. While previous studies aimed to automate this technique by focusing on activity recognition using sensors or video-based technologies, this research is concerned with identifying workers' locations on job sites using location-based sensors embedded in smartwatches. For this, the authors conducted a case study, which aims to measure the share of time workers spent in different outdoor workspaces. The study was carried out on a renovation project and involved five steps: (1) clarifying the workspace categories (production, preparation, and transportation); (2) data collection of carpenters' locations using geographic data points collected by smartwatches during 7 days; (3) data extraction and data aggregation; (4) data cleaning; and (5) data analysis using a Python script to automatize the classification of the data points into workspaces. The main contribution is a visual tool to visualize workers' positions on the job site in 2D. This information can be useful to indicate how many hours per day they spend in different workspaces and to understand the nature of a given construction activity.

Work flow, workspaces, smartwatches, digitization, visual management.

INTRODUCTION

Tracking of resources can be useful on construction sites for different purposes, and the topic has gained increased attention in research in recent years. Several studies have adopted sensor technologies for location tracking of workers and construction equipment to monitor health and safety (e.g. Awolusi et al., 2018), and others have focused on on-site logistics (Nasr et al., 2013). Resource tracking has also been applied with the intention of analyzing on-site productivity (Zhao et al., 2019).

Despite these recent efforts on tracking resources, data on progress and productivity are still mainly being collected manually on construction sites, either verbally in meetings, through weekly routines such as job site walking rounds, or by performing activity analysis or Work Sampling (WS) studies (Teizer et al., 2020; Zhao et al., 2019). The WS technique quantifies shares of time using a set of activity categories, classified into the Lean activity categorization of Value-Adding (VA) and Non-Value-Adding (NVA) activities. Though the WS technique is widely applied and acknowledged, it has been criticized for its snapshot-based approach and

workflow interruptions of participants due to the presence of the observer on-site (Dozzi & AbouRizk, 1993; Wandahl et al., 2022).

Several studies have applied sensor-based and video-based technologies as alternative approaches for overcoming WS shortcomings. Vision-based activity analysis requires single or multiple cameras for detecting and tracking resources as well as procedures for activity recognition (Liu & Golparvar-Fard, 2015). Sensor-based technologies enable the identification of measurement of workers' posture, motions, and location (Cheng et al., 2017). But, only a few studies demonstrate how a real-time tracking system can be applied to determine the share of VA activities of construction workers (Görsch et al., 2022).

Another study applied an indoor positioning system based on Bluetooth Low Energy (BLE) technology, estimating presence indexes, representing uninterrupted presence time of workers in work locations considered production workspaces (Zhao et al., 2019). The presence index applied provides limited information on whether workers engage in VA activities when being present in productive workspaces and do not provide accurate information on the share of VA time spent during workers' daily activities. Nevertheless, this study suggests that uninterrupted presence is strongly correlated with VA time and can, thus, be used as a metric for measuring productivity on the project level based on two basic assumptions: (1) if work gets interrupted, these interruptions are mostly NVA activities; and (2) if work is uninterrupted in the productive workspace, VA activities are likely taking place (although NVA can also happen in productive workspaces).

Continuing the approach from Zhao et al. (2019), Görsch et al. (2022) combined video data from head-mounted cameras and location data from indoor positioning via BLE technology to understand the time spent in VA when uninterrupted presence is detected by indoor positioning. The study contributes to knowledge that the share of VA time that takes place during workers' uninterrupted presence can be numerically quantified, bridging a more explicit connection between VA time assessment and presence time analysis in construction. Therefore, the research by Görsch et al. (2022) suggests that uninterrupted presence with higher thresholds can be used to predict the VA level of workers more accurately without relying on manual efforts to scan through video recordings.

Based on this brief introduction, there is an identified need to conduct further studies that associate workers' presence in different workspaces with VA time to overcome the aforementioned WS shortcomings. For this purpose, job sites can be divided into direct and indirect workspaces similar to the Lean activity categorization into VA and NVA activities. It is reasonable to assume that if a worker spends most of their time in indirect workspaces, e.g., an unloading area, they are conducting NVA activities. On the other hand, if a worker spends most of their time in a production workspace, e.g., a floor under construction, they are most likely to conduct VA work.

Newer types of wearable devices, such as smartwatches, can be equipped with a wide range of sensors and technologies; accelerometers, electrodermal activity sensors, and location-tracking, to mention a few. Most smartwatches use a Global Navigation Satellite System (GNSS), for instance, the Global Positioning System (GPS), to capture information about the location of the watch, which then can be used to calculate current and average travel speed and distance or presence time in work zones (Pérez et al., 2022).

This paper continues the approach by the present research team, initiated by (Pérez et al., 2022) to use the geographical location data of workers collected by smartwatches as means of activity tracking. This new approach complements the current body of knowledge by providing a source of evidence that can potentially increase the accuracy of activity tracking studies to understand the time spent on VA activities. The ongoing research project seeks to answer the following research question:

- *Research Question (RQ):* How can the share of time spent on VA activities be estimated based on geographical location-based data?

To address this question, the authors conducted a case study on a renovation project. To the authors' knowledge, no study has been made on the accuracy of the GPS data from smartwatches used on a job site. Still, previous studies have obtained confident results when using the watches in outdoor environments (Pobiruchin et al., 2017; van Diggelen & Enge, 2015). Therefore, the data is only obtained from outdoor locations in this study.

RESEARCH METHODOLOGY

The authors of this paper adopted Case Study (Yin, 2003) as the primary research strategy, as case studies offer flexibility for explorative and theory-building research in real-life contexts. The phenomenon of the study comprised construction workers' locations using smartwatches as a digital tool for collecting data. The real-life context is represented by the building project studied.

CASE STUDY DESCRIPTION

The Case Study was conducted on a building renovation project in Roskilde, Denmark. The construction project consists of renovating 24 five-story buildings, totalizing 597 housing units (Figure 1). Four buildings were under renovation during the period of this case study, and these were named Building A1, B1, C1, and B2 (Figure 1a).

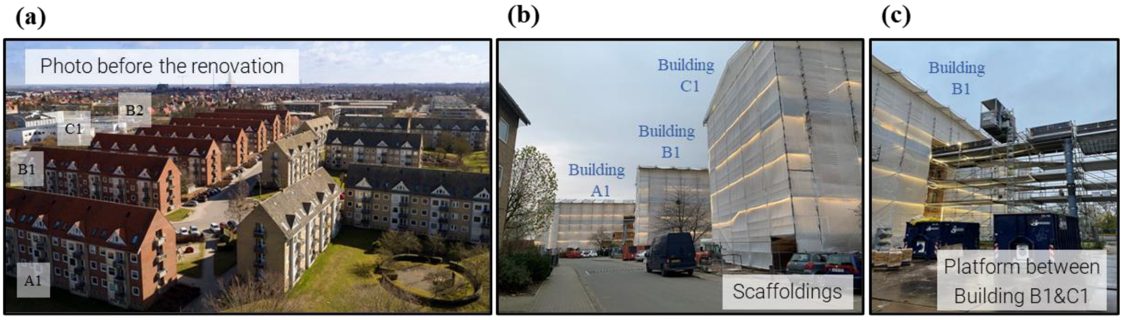

Figure 1: Job site of the case study: (a) before the renovation; (b) scaffolding used for covering the buildings; and (c) platform used to connect scaffoldings.

The main renovation tasks were related to external carpentry work, such as replacing windows and roofs. Installation of new ventilation, installing new electrical systems, and painting of the hallways represent the only three internal renovation activities. During the execution of the renovation project, most of the renovation activities were conducted from a façade scaffolding outside the buildings (Figure 1b). Besides carpentry tasks, this included masonry and painting work.

The main contractor placed modular containers within the job site for storage, administration, and changing rooms. The main material storage area, destined for inventory deliveries, was located next to the administrative containers. The contractor rented a façade scaffolding with plastic covering the entire temporary structure for each building under renovation. The scaffolding of Buildings B1, B2, and C1 were connected to facilitate workers' movement between the buildings (Figure 1c). Moreover, a mobile crane was used for lifting windows in place.

RESEARCH DESIGN

The authors adopted smartwatches to collect the distribution of GNSS data points in different workspaces. The research design consisted of the following five steps (Figure 2): (1) clarifying the workspace categories; (2) data collection; (3) data extraction and data aggregation; (4) data cleaning; and (5) data analysis.

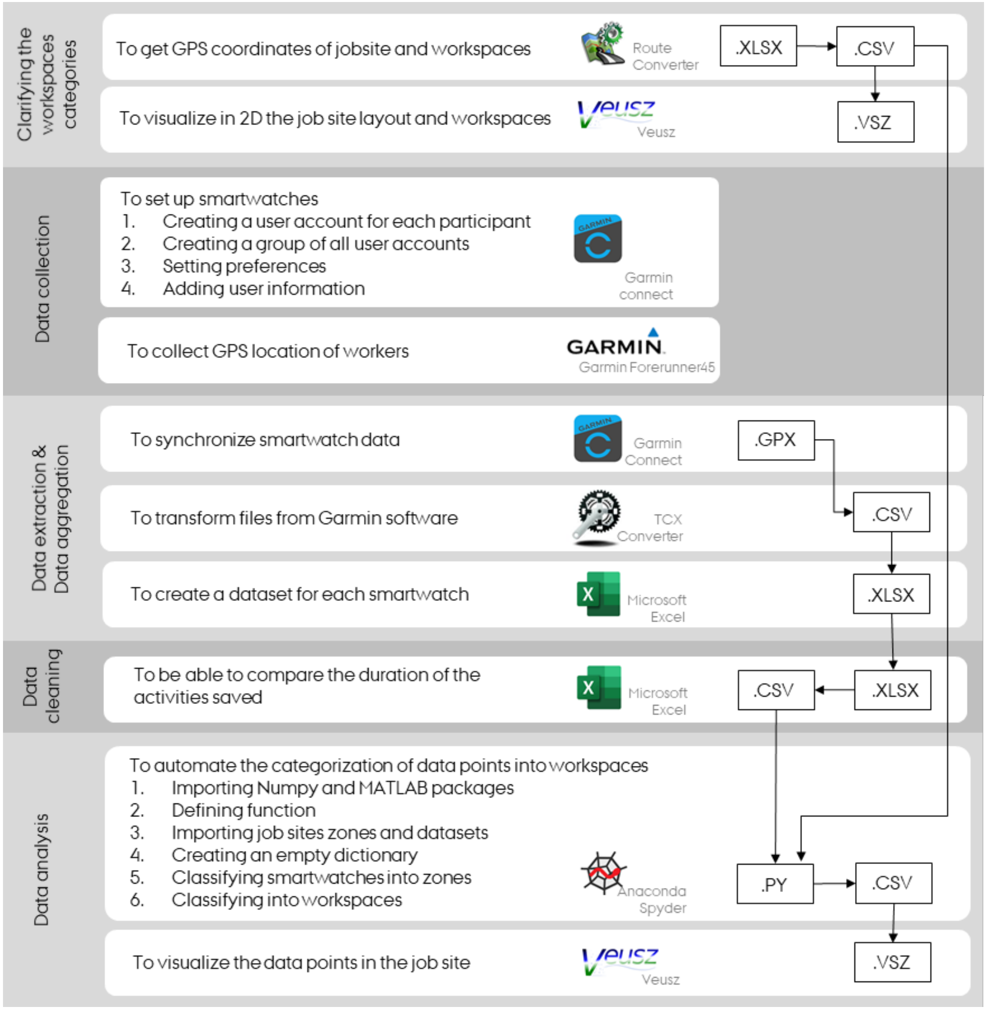

Figure 2: Research design.

Step 1: Clarifying the workspace categories

This study adopted the following workspace classification: (1) production workspace; (2) preparation workspace; and (3) transportation workspace. The production workspaces comprise the buildings under renovation and the scaffolding area. The preparation workspaces are represented by the area around all the buildings undergoing renovation at the time of data collection (Zone 1A and 1B in see Figure 3a), and the material storage area, where a dedicated preparation workshop was set up. The remaining parts of the job site are considered transportation workspaces (Zone 2A and 2B in Figure 3b).

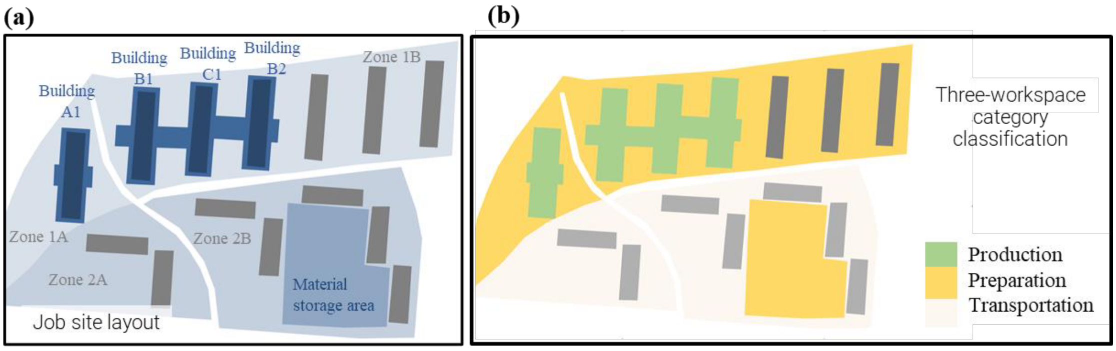

Figure 3: Job site: (a) description; and (b) divided into workspace categories

The authors collected the coordinates of the job site and workspaces using the RouteConverter program. RouteConverter is a GNSS tool used to display, edit, and convert routes from several different file formats (RouteConverter, n.d.). The list of data coordinates obtained from the RouteConverter was exported into a Microsoft Excel Worksheet (XLSX) file, converted into a Comma-separated Values (CSV) format, and then imported to Veusz. Veusz is a scientific plotting and graphing program (Veusz, n.d.). Veusz allowed the researchers to plot the data using a graphical 2D user interface for visualizing the job site layout divided into workspaces, cf. figure 3.

Step 2: Data collection

The data collection period lasted seven days (8.5 hours/each day) from 07:00 to 15:30, excluding breaks, totalizing 7.5 effective working hours per day. The seven days of job site visits were conducted in November of 2021. The research team adopted a stratified sampling approach for selecting the workers involved according to their tasks. Ten workers from the carpenter trade participated in the study. Each worker was associated with the serial number identification of each smartwatch.

The carpenters were equipped with a Garmin Forerunner45 smartwatch, which could collect the geographical location of the carpenters during their workday. This device provided the geographic coordinates using a combination of two GNSSs: The GPS and the GLONASS. The frequency of data point collection depended on whether a movement of the watch was detected and thus varied between one and 30 seconds. The preparation of the smartwatches involved four steps: (1) creating a user account for each smartwatch on the web version of the Garmin Connect app; (2) creating a group of all user accounts; (3) setting up preferences on the watches (e.g., notification settings, units of measure, GPS activation); and (4) adding user information (height, weight, age). Personal data policies hindered the collection of personal user information in this study. Consequently, general average data for a Danish male (Worlddata.info, 2019) was used as a substitute for the specific numbers. Lastly, to prevent data loss, the smartwatches were charged every night and synchronized after each day of data collection.

Step 3: Data extraction and data aggregation

The smartwatch data was synchronized to the Garmin web application (named Garmin Connect) using a USB cable. Since the devices have limited memory for storage, this functionality allows users to access historical activity data that can be used with other Garmin applications. The activity saved during the 8.5-hour workday was exported in a GPS Exchange Format (GPX) and then transformed into a CSV using TCX Converter program. TCX Converter program is a GPS data management solution for transforming files from different mapping software (TCXConverter, n.d.). For the purpose of the study, the authors exclusively used the following three features of each data point: (1) time; (2) latitude; and (3) longitude.

The data aggregation aimed to organize the three features of the raw data in a XLSX file to create a dataset over each smartwatch (named SW01 to SW10) for each day of collection (named Day 1 to Day 7). Due to various technical issues, not all activities were successfully recorded. The database contained 56 datasets, totalizing 188,180 data points.

Step 4: Data cleaning

For the data cleaning process, the main assumption considered was that to be able to compare the collected data, it must be uniform. The requirement established for this study was concerning the duration of the activity. In the same way as some activities were not recorded at all due to technical issues (e.g., the activity was stopped accidentally by the worker wearing the watch trying to look at the time), some were cut short in length or had large time gaps between the collected data points along the day. Activities with more than one hour of data missing were excluded. As only a low number of activities met the duration requirement on SW01, SW02, SW04, and SW09, the datasets from these smartwatches were excluded, leaving six smartwatches and 36 datasets for the analysis.

The remaining datasets were cleaned by excluding data from break times along the day. Moreover, only data within the official working hours (07:00 to 15:30) was included in the analysis. The data cleaning process reduced the size of the stored data from 188,180 to 115,072 data points, which is a reduction of 73,108 data points or 38.8% of the data.

Step 5: Data analysis

During the data analysis, the research team adopted Individual Participant Data (IPD) for a more appropriate analysis according to each participant's role. The main role and tasks of each carpenter of the six remaining datasets are: (a) Installing plastic frames for windows (SW03); (b) Installing windows from scaffolding (SW05); (c) Installation of windows and membrane on roof (SW06); (d) Installing wood boxes for ventilation pipes on the roof (SW07); (e) Grouting around windows and installing wood on roof after membrane installation (SW08); and (f) Foreman. Supervision activities and transporting materials from the storage workspace to their destination (SW10). The data analysis aimed to classify workers' positions into workspaces (Table 1).

Table 3: Summary of the collected data used for analysis.

Participants	Data sets	Total duration (h)	Data points SW03	Data points SW05	Data points SW06	Data points SW07	Data points SW08	Data points SW10	Total data points
6	36	270	26,983	26,199	16,607	17,014	13,063	15,206	115,072

To automate the categorization of each of the 115,072 GNSS data points from the 36 datasets into workspaces, the authors developed a script using Python scripting language. Python is a general-purpose scripting language (Python, n.d.). The authors used the Spyder IDE (Integrated Development Environment) version 5.1.1 bundled with the Anaconda package (64-bit version). The script includes six steps as illustrated in Figure 4: (1) Importing Numpy and MATLAB packages; (2) Defining zone function and smartwatches data points function; (3) Importing coordinates of the job sites zones and datasets; (4) Creating an empty dictionary; (5) Classifying smartwatch datapoints into zones; and (6) Classifying into workspaces.

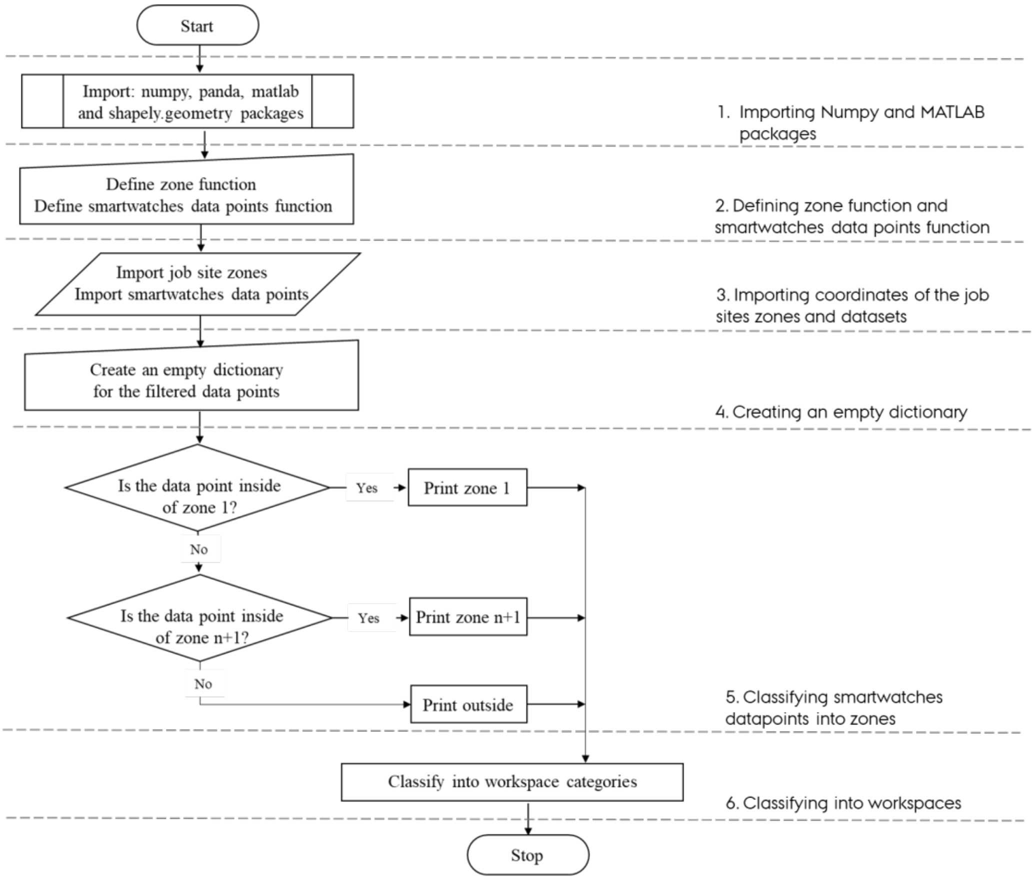

Figure 4: Flowchart of the process of classifying workers' positions into workspaces.

The authors also examined the distribution of data points within the job site using the Veusz program. Since the data points collected by the smartwatches are evenly distributed along the day, the number of data points in each workspace can be understood as the share of time spent in each workspace.

RESULTS AND DISCUSSION

VISUALIZATION OF THE WORKERS' LOCATIONS ON THE JOB SITE

The distribution of locations of the six participants in the smartwatch study from Day 5 to Day 7 of the data collection are illustrated in Figure 5. Each smartwatch is assigned a color of dots on the construction site maps, and each dot represents a data point. With more than 10,000 data points each day it is not possible to distinguish the points from each other or to analyze the watches individually, but the maps provide an overview of the places where the workers spent most time (i.e., the areas with the largest concentration of data points) and the paths they used when changing location. As expected, most of the time was spent in the area of the four buildings under renovation.

The overlapping of points from all the smartwatches in Figure 5 impedes an analysis of each worker individually based on these charts. For that reason, Figure 6 illustrates some examples of the distribution of data points on the job site when looking at only one worker at a time, in this case, the worker wearing SW06. It can be seen that the worker wearing SW06 spent most of their time in the production space of Building A1, walked between Building A1 and the material storage space using two different paths, and spent some time in the storage workspace.

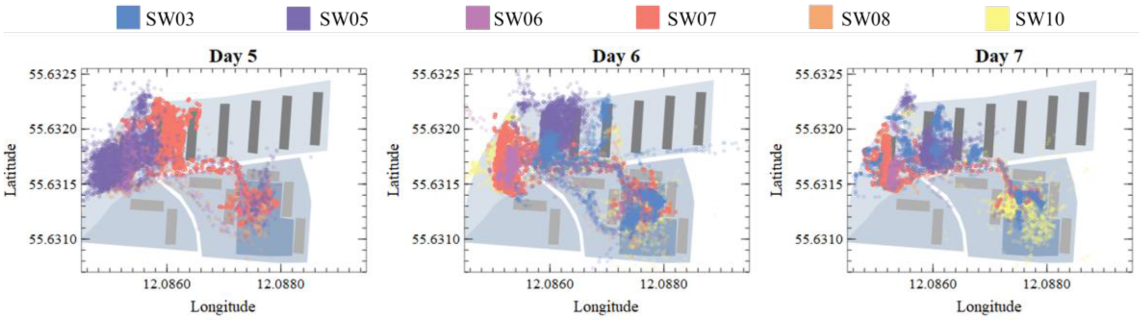

Figure 5: Workers' positions on the job site in Day 5, 6 and 7.

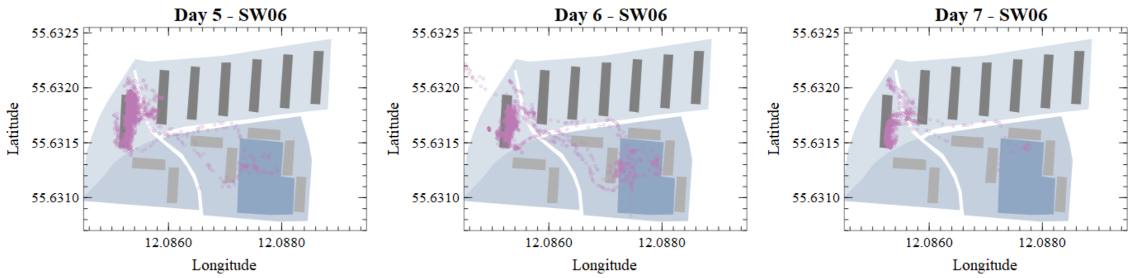

Figure 6: Positions of the worker wearing SW06 on the job site on Days 5, 6 and 7.

The visualization of workers' locations on 2D site maps can be used during planning meetings. These images are an objective way to visualize where workers spent their time during the week. Moreover, the visualization of the location of each worker helps to understand the places where each worker conducted activities. The 2D images can be combined with the location-based schedules to understand if each worker spent their time according to the planned location. So, the illustrations can allow trade supervisors and managers to solve problems and coordinate their work schedules, thus preventing minor issues from growing bigger.

WORKSPACE ANALYSES

Using the Python script, the authors classified the data points into a three-workspace categorization (Figure 7): (1) production workspace; (2) transportation workspace, and (3) preparation workspace.

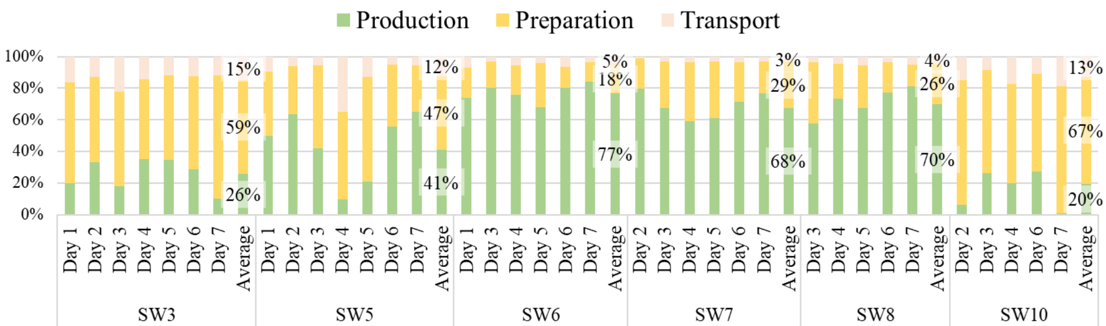

Figure 7: Distribution of data points in workspaces.

Thus, the Share of Time spent in Production workspaces (ST-Prod) represents the number of data points in the production workspaces divided by the total number of data points from that dataset, and likewise for the other two workspace categories. The distribution of data points in the different workspace categories as well as the standard deviation for each watch in each category, are summarized in Table 2.

Table 2: Classification of the GPS data points into workspaces for each smartwatch.

Workspaces	SW03	SW05	SW06	SW07	SW08	SW10

Production	6,995	10,674	12,726	11,486	9,126	2,983
Preparation	15,944	12,316	3,014	4,995	3,370	10,244
Transportation	4,044	3,209	867	533	567	1,979
Avg. ST-Prod (%)	26% ± 10	41%± 21	77%± 6	68%± 8	70%± 9	20%± 12
Avg. ST-Prep (%)	59%± 9	47%± 14	18%± 6	29%± 8	26%± 9	67%± 9
Avg. ST-Trans (%)	15%± 4	12%± 11	5%± 2	3%± 1	4%± 1	13%± 4

This study's main managerial contribution is identifying workers' locations recorded by smartwatches and grouped in predetermined workspaces (production, preparation, and transportation) representing different VA and NVA categories using scripting language. Although presence in production workspaces is not equivalent to time spent on VA activities, it is a prerequisite (Zhao et al., 2019). Hence, the information gathered about the share of time carpenters spend in different workspaces can be useful for several purposes. Two examples are presented as follows:

First, to indicate how many hours per day the workers spend on different tasks. For instance, considering the carpenter who was in charge of installing membrane on the roofs (carpenter wearing SW06); spent on average 5.78 hours in production workspaces (77% of 7.5 hours, see Tabæe 2), 1.35 hours in preparation workspaces (18% of 7.5 hours), and 0.37 hours in transportation workspaces (5% of 7.5 hours). According to these percentages, the authors can assume that the carpenter of SW06 spent almost three-quarters of his time doing VA activities, although being in a productive workspace does not exclude conducting other NVA activities. Another interesting example can be discussed by looking at the foreman (worker wearing the SW10). The foreman did not spend much time in the production workspaces, rather he walked around in the preparation workspaces around the buildings and spent most of his time in the storage and office area, which is defined as a preparation workspace. He spent, on average, 1.50 hours in production workspaces (20% of 7.5 hours, see Table 2), 5.03 hours in preparation workspaces (67%), and 0.97 hours in transportation workspaces (13%).

Second, to understand the nature of the different tasks conducted by each worker in a given construction process. It is well known that construction processes using prefabricated and off-site methods present a smaller share of time on VA activities on the job site and demand more time on NVA activities, such as preparation and transportation activities. An example of this can be seen observing the worker wearing SW05 in charge of installing prefabricated components, such as the windows (Figure 8a).

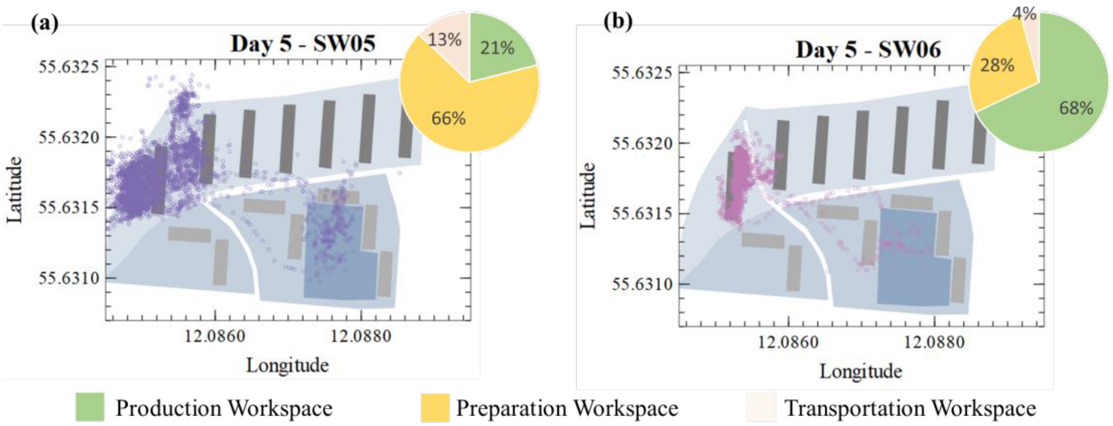

Figure 8: Distribution of points for the workers wearing: (a) SW05; and (b) SW06.

On Day 5, this worker spent 66% and 13% of his time in preparation and transportation workspaces, respectively. In contrast, the worker wearing SW06 was in charge of a highly on site-dependent activity, namely installing the membrane in the roof (Figure 8b). This activity involved measuring the membrane with a ruler, cutting the membrane with a knife according to the appropriate length and stapling the membrane, among other activities. Hence, on Day 5, the worker wearing SW06 spent 68% of his time in production workspaces, significantly more than the worker wearing SW05. So, the implementation of prefabricated components on the job site increased, among other factors, the time spent in NVA workspaces. This should be taken into consideration when conducting WS studies on job sites to align expectations with the applied construction processes.

CONCLUSION

This study addressed the lack of procedures for measuring the share of time that workers spend on VA activities automatically as a way to automate the WS technique. While previous studies have aimed to automate this technique by focusing on activity recognition using sensor-based or video-based technologies, this research is concerned with identifying workers' locations on the job site using smartwatches.

The research question formulated to serve as the guidance of this research was: How can the share of time spent on VA be estimated based on geographical location-based data? To address this question, this research conducted a case study. The results of the case study allowed the authors the identification of workers' time spent in VA workspaces (production workspaces) based on the GNSS data points collected by smartwatches worn by the carpenter trade on a construction site. Using scripting language, the workers' locations recorded by smartwatches were grouped into predetermined workspaces (production, preparation, and transportation) representing different VA and NVA categories. In this way, the information gathered about the share of time workers spent in VA workspaces, along with other information from additional sources, can indicate how many hours per day they spend on VA activities. Thus, the main contribution of this study consists of a novel approach using smartwatches to measure workers' distribution of time in workspaces. Smartwatches present a low-cost and scalable way of measuring presence in outdoor locations on construction sites.

This main limitation of this study is related to the workspace categorization employed for classifying data points. The authors adopted a three-workspace classification. The categorization of some places into one category or another may have impacted the distribution of time analysis. An example of this is the categorization of the scaffolding platform connecting some of the buildings as preparation workspaces. This workspace could have been categorized as a transportation workspace from another point of view. Future studies should adopt regression testing to verify which kind of category fits better for each workspace. Moreover, other zones can be used for the classification of the job site, such as the Location Breakdown Structure which uses location-based schedules.

Lastly, this study raised topics to be examined in greater depth in future research efforts, e.g., analyzing the utility of acceleration of watches to detect VA and NVA work. In this study, workers' locations were collected using smartwatches as the only source of evidence. To improve validity, future studies should collect data about the share of time spent in different workspaces from additional methods, such as the WS technique, questionnaire application or video analysis. Moreover, future studies could compare the locations collected using a GPS tracker or mobile phone with the locations collected by the smartwatches.

ACKNOWLEDGMENTS

A KAIZEN EVENT ENABLED BY SYSTEM ENGINEERING IN AN INFRASTRUCTURE PROJECT

Matt Stevens[1], Ali Eghbaljoo[2], and Frans Thevissen[3]

ABSTRACT

A Kaizen Event is a well-defined and accepted approach to construction outcome improvement. However, rising project complexity is making this a very involved process if it is to be successful. System Engineering (SE) is an emerging practice that can address project complication. This paper will share a journey of a SE team on how to streamline sophisticated internal processes that manifest in better safety, quality and productivity when improved. SE is a recent innovation emerging as an essential discipline considered state-of-the-art. It crystallises the integrated processes of work and their outcomes on projects and allows constructors to standardise their best practices effectively. This case study of a mega infrastructure rail project in Australia is a relatively brief treatment of a complex process, its factors and its results.

The project work package delivery was improved, including lower cost, as they were sequentially built. For the future, rapid urbanisation and climate change effects are increasing in Australia, and contractors must respond efficaciously for all stakeholders for the greater society to benefit. Mastering Lean principles such as Kaizen Events can help mitigate or minimise long-suffered construction industry problems.

KEYWORDS

Lean construction, SESA, system engineering, kaizen event, continuous improvement

INTRODUCTION

This case study explores and examines the multistep process to significantly improve delivery involving four projects. The paper's research question is, 'Has the application of Kaizen Events improved the SE processes in this megaproject's sequentially scheduled work packages?'

RISING PROJECT COMPLEXITY

A high degree of internal and external complexities has caused many difficulties in construction and hindered the successful delivery of mega-construction projects (Kardes et al., 2013). Common evidence is that significant differences exist in the performance of different types of large construction projects; for example, according to Flyvbjerg (2014). the average cost overrun rate for rail projects is 44.7 per cent, whereas for road projects are 20.4 per cent. Systematic understanding and effective control for complexity are crucial components of project management (Bosch-Rekveldt et al. 2018)

Fast-Berglund et al. (2013) assert that construction complexity positively correlates with installation errors. In mega construction projects, many errors may occur during the construction process due to the complication of multiple technical and management process streams. The accumulation of such errors will lower the overall quality of the project and might even affect the function and operational efficiency of the project. A well-accepted stability theorem (May–Wigner) concludes that increasing system complication inevitably leads to chaos (Sinha, 2005). Aslaksen 2008 concludes that construction project complexity has increased due to several factors such as material science, equipment utility and value (both installation and facility), and design along with increased government regulations.

INCREASING CONSTRUCTION NEEDS

Rapid Urbanisation

Urbanisation is a manifestation of improving human society and economic development; it is critical for social and economic development (Gong 2022). The 21st century is one of urbanisation. Along with this phenomenon, the world's population will increase. White et al. assert (2010) that lifestyles are also changing in the 21st century. As a result, people will demand larger dwellings and other facilities. The three phenomena together point to a need for construction that may outpace contractors' ability to meet it.

Climate Change Effects

The increased consistency, duration, and severity of high-temperature weather have increased recently due to changes in climatic conditions. Australia is highly vulnerable to this hazard. A growing number of studies in Australia have been conducted each year over the last decade related to the heatwave phenomena (Pörtner et al. 2022). Dealing with heat would require upgrading current buildings and other structures, thus, further increasing construction demand. Due to climate change, chaotic weather events such as wildfires, storms and floods will increase the destruction of the built environment. Eingrüber and Korres (2022) assert that the speed and intensity of flooding will accelerate with climate change. There is a high probability of increased and erratic rainfalls accompanied by higher winds in many parts of the world (Moradkhani et al. 2010). Climatic causes play a prominent role in the deterioration of building fabric, and climate change is projected to accelerate the built environment deterioration rate (Johns and Fedeski 2001). The International Panel on Climate Change (IPCC) asserts that costs for maintenance and reconstruction of urban infrastructure, including building, transportation, and energy, will increase with global warming (Pörtner et al. 2022)

KAIZEN EVENT

The factors that guide a Kaizen Event, the continuous improvement of processes, were introduced based on presenting a scientific model for implementing improvements founded on a sequence of questions that enable identification, analysis and problem-solving, called the Scientific Thinking Mechanism (Shingo 2010). Furthermore, Imai (1996) asserts that kaizen implementations to result in practical solutions is based on three general activities: evaluating data, communicating problem-solving methods and keeping the Kaizen Event culture active. Specifically, Kaizen is an intensive Step Change process improvement where the team focuses on improved methods of perfecting execution. It occurs in eight intensive steps enabling this greater efficacy:

1. Choose the theme/focus of the application (determined according to administrative policies according to priority, importance, urgency or economic situation);
2. Analyse the context;
3. Collect and analyse to identify the root cause;
4. Establish countermeasures based on data analysis;
5. Implement countermeasures;
6. Confirm the effects of countermeasures;
7. Establish or revise standards to prevent recurrence;
8. Review the previous processes and start working on the next steps.

SYSTEM ENGINEERING

The International Council on Systems Engineering (INCOSE) defines SE as "an interdisciplinary approach and means to enable the realisation of successful systems.". Blanchard (2004) more succinctly stated that it is an orderly process that brings a system into being that integrates humans, materials, equipment, tools, information, technology, and money to function in delivering a specific outcome. Johansen and Hoel (2016) define Systematic Engineering as "an assurance that the project fulfils all functional requirements within the set time, cost and quality requirements, planned and verified by a structured process managerially driven from design and planning to handover". However, there is little documentation by the industry and light research by academia to understand the performance of practitioners and the product (Beste 2020).

In the implementation in the construction industry, the need for System Engineering (SE) is becoming greater since construction project complexity is increasing (Aslaksen 2008); its economic value is growing to USD 15.5 trillion worldwide in 2030 (Pacheco-Torgal 2020) and failing to consistently deliver projects to the satisfaction of the project owner and end-user (Boyd and Bentley 2012). Raworth (2017) asserts that all industries need to be "savvy with systems" to succeed in the 21st century. Therefore, the economy's common understanding needs to be updated from its pre-millennium knowledge to one of the complex current systems of many interdependent parts SE can rapidly and reliably integrate business and technological processes that construct infrastructure, building and processing facility projects (Aslaksen 2008).

Constructing the built environment involves many complicated tasks that must be carried out with extreme care while economising on costs. Most construction project functions are costly, and even a minor mistake can cause significant financial liabilities. Therefore, a steady and careful management process is required (Lu et al. 2013). In this case study, SE was executed on an existing process and did not have the luxury of a legacy-free or "green field" operation. Lynghaug et al. (2021) note that manufacturers pursue SE to improve a product or process. Once embedded, the improvement is produced in high volumes. In the construction sector, design and construction efforts are spread across project stakeholders, often one-off actions that result in lessons learnt that are usually minimally captured.

Beste (2020) proposed further studies of SE with more data from an international perspective to complement the existing research and improve the discipline. Furthermore, it is critical to understand many stakeholders' views, such as the design team, contractor and customer, to increase the clarity of the dynamics.

There exists a high conflict level in the construction industry. Reasons for this conflict include delays, cost overruns, and quality problems. The unreliability of multifactor productivity and these factors might be interrelated (Lynghaug et al. 2021). They also note that the implementation of the Systems Engineering methodology is highly dependent on the level of competence among employees in the projects in which the interdependence of tasks is disrupted by a lack of conscientiousness and industriousness by a worker(s)

As the construction effort starts with designing the work of co-dependent but standalone companies (i.e., contractors-main and sub, suppliers and designers), Lynghaug et al. (2021) assert that in practice, SE performs as a Systems-of-Systems improvement process, creating a methodology in which stakeholders work interdependently to accomplish the complex task of delivering better safety, quality, cost, schedule and sustainability. Axelsson et al. argued that the lack of a Systems-of-Systems approach is a significant reason construction productivity has stagnated. The roots cause seems to be a focus primarily invested in the resilient design of the standalone infrastructure constituent parts rather than how infrastructure components can be integrated to comprise a dynamic and valuable system (Vora et al. 2017)

The V-model is well-recognised in Systems Engineering. The approach moves a re-engineering review through design and decomposition subcomponents such as concept analysis, functional analysis, and design synthesis. In the second half of its sequence, satisfying integration, verification and integration, including operation and maintenance requirements of the completed project, is its focus (Elm et al. 2008, Beste 2020). See Figure 1.

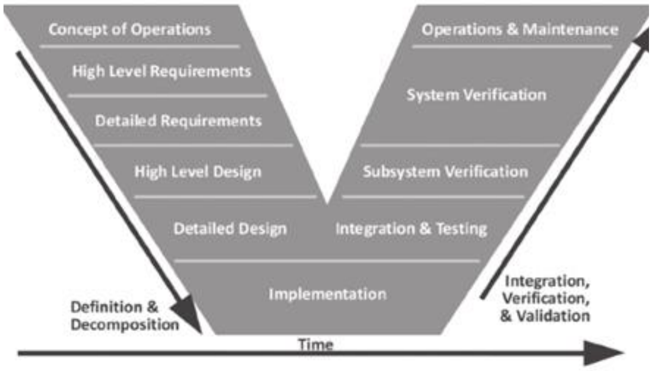

Figure 1: The V-model is the Core Framework Utilised in System Engineering (Elm et al. 2008)

Lynhaug et al. (2021) found problems with verification and verification (V&V) related to ambiguous technical and business specifications. These ill-defined requirements are partly blamed on the lack of budget and time for V&V activities in the early phase—subsequently, this lack of clarity results in imprecise contract language, schedule delays, and verification failures. Cotterman et al. (2005) assert that there are five general factors to consider in system engineering. They are 1) Concept of Operations 2) Business Case 3) Best Practices 4) Standards and Regulations 5) Lessons Learnt.

The term, System of Systems (SoS) was created decades ago to crystallise a definition for an approach to execute complicated projects such as construction infrastructure. Its attractiveness is that it combines disparate functions synergistically towards a common goal. However, SoS engineering has to be customised to individual complex ventures due to their independence, heterogeneity, evolution, and emergence factors. (Nielsen et al. 2015, Lynhaug 2021). Clark (2009) asserts that SE synergises the value of the components when:

1. the elements are integrated (i.e., have interfaces)
2. these elements might be (or not) members of a common domain (such as a product line or rail project)

CASE STUDY

Dozens of highly similar infrastructure projects were procured and scheduled in Australia, starting in 2016 and planned to continue until 2025. Due to their nature and limited resources, they were sequentially constructed, allowing for robust implementation using a continuous improvement approach to spur innovation. This case study is based on similar rail projects – two current and two future states.

MOTIVATION

The stakeholders found that after finishing their first two infrastructure projects as part of this Alliance Contract, the mega project's system engineering and safety assurance processes were inefficient and unreliable. A traditional Kaizen effort could not succeed in several areas without a more sophisticated approach. Upon inspection, they were found to lack communication clarity and process annunciation. Examples include a lack of defined roles and responsibilities, resulting in unpredictability, waste, and program risk. The Project Director stated, "The system engineering and assurance process (system, outputs and definition) is inefficient and lacks defined roles and responsibilities for alliances developing rail infrastructure projects resulting in uncertainty, waste, and program risk."

METHODOLOGY

A re-engineering initiative was started under the System Engineering and Safety Assurance (SESA) team which included the preparation and review of Safety Assurance Reports (SARs) and Safety In Design (SID), risk/hazard identification, mitigation & management throughout the project life cycle. This paper will refer to it as System Engineering or SE. Requirements management, including Requirement Allocation and Analysis Traceability Matrix items (RAATM) for the asset delivery's complete 'V' cycle. System interface and integration management, including Human Factors and other key systems' integration in design development and risk management support.

The focus was on improving the next two projects in the scheduled sequence. To launch the process, a 1-day Kaizen Event workshop was planned and followed by short discussion sessions with the core team to facilitate breakthrough events and manage the transition from the current state to the future. As a result, on multiple projects implemented the desired future state. The stakeholders formed a SE transformation team to examine the performance of two rail infrastructures, labelled Project 1 and Project 2, with explicit instructions to audit practices, analyse results and recommend improvements. Information organisation was critical for the team to effectively and efficiently learn, implement, and monitor the lessons learned from the first cohort of projects analysed. Also, they had to annunciate and discuss their calculations and assumptions to benefit from a discussion.

The V-Model lists many generalised tenets of the projects, such as "Operations" and "Design" factors - See Figure 1. Table 1 contains the ratios to compare these four projects accurately.

- The SE cost is a combination of the Joint Venture, Designer and End-User costs
- Total cost is critical to calculating to form accurate measures, including ratios relating to worker hours, general and administrative expenses and return-on-investment
- The projects initially analysed Project 1 and Project 2 had a similar scope of work for the SE team. It is critical to have similar work packages for a creditable improvement comparison.
- SE team spent more time on Project 1 than Project 2 to set up initial processes and form the team (assumed an add of 30% - the first three months with more management time). Initial set-up is a one-time expense that should be removed from the first project or proportionally expensed to all projects.
- A weighting system was calculated and applied to other work packages to enable the team to compare the SE cost to Project 1 and Project 2 average when the scope of work was different (e.g., Project 3 compared to Project 2 ratio is 1.05; staff room added 5%, set up a time with V/Line (the State-Wide Rail Operator) added 5%, Signalling upgrade added 5%, package value -10% impact)
- The weighted cost of the SE team on Project 3 was 0.749% of the AOC (0.419% less than Project 1 & Project 2 average)
- The weighted cost of the SE team on Project 4 was 0.864% of the AOC (0.303% less than Project 1 & Project 2 average)
- The average weighted cost of the SE team on Project 4 and Project 3 was 0.361% of the AOC, less than Project 2 and Project 1 average

- The designer cost used in the model is based on the invoiced figures. However, the cost of Designer and Asset Owner cost is estimated assuming a $150 hourly rate for managers and $120 for other resources that bill out at 160 hours per month

SE was the chosen approach since changing administrative projects to a more precise (and tedious) one would cause the comparison to be suspect. The project leaders commissioned a group of SMEs to jointly assess the percentage to increase or decrease for variations from the baseline projects. This multi-professional integrated approach has been proven to evaluate differences and estimate impacts more accurately for individuals working alone.

Table 1: Component Coefficients to Compare Projects Against Baseline Determined by the Projects' SMEs

Ratio Criteria	Ratio %	Project
Initial Set up/Team forming	+30%	Project 1
V/Line set up	+5%	Project 3
Not connecting to the existing line	-15%	Project 4
Car park	+15%	Project 4
Staff room	+5%	Project 3
No Line upgrade	-10%	Project 4
Signalling upgrade	+5%	Project 3
Greenfield	0%	Project 3
Scope change	+30%	Project 4

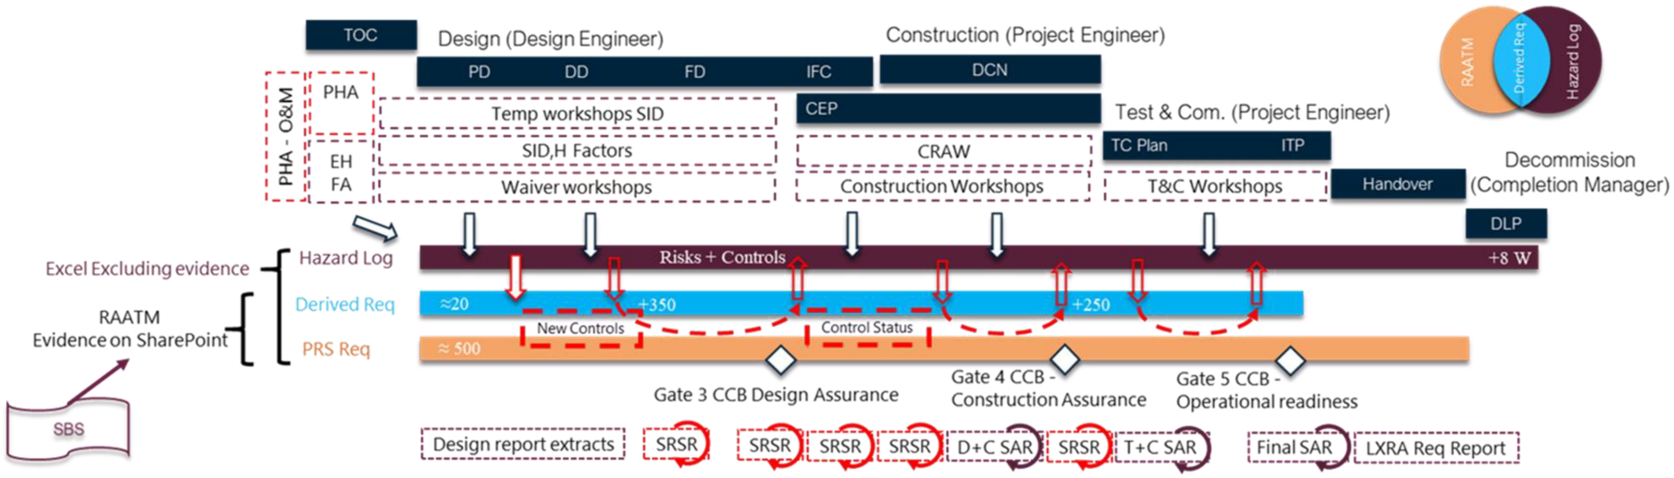

Figure 2: Current State of Projects 1 and 2

Major Issues and Improvements Needed:

- Duplicated effort for evidence reporting and report compilation
- No single source of truth for derived requirements
- Construction Operation &Maintenance risks & controls not tracked in Hazard Log
- Hazard Log can't be amended
- Controls in Hazard Log are unclear
- Hazard Log not consulted when evaluating work packages
- No time/opportunity to act on partially & non-compliant requirements
- Hazard Log management is not continuous across Design & Construction
- Resource burns out

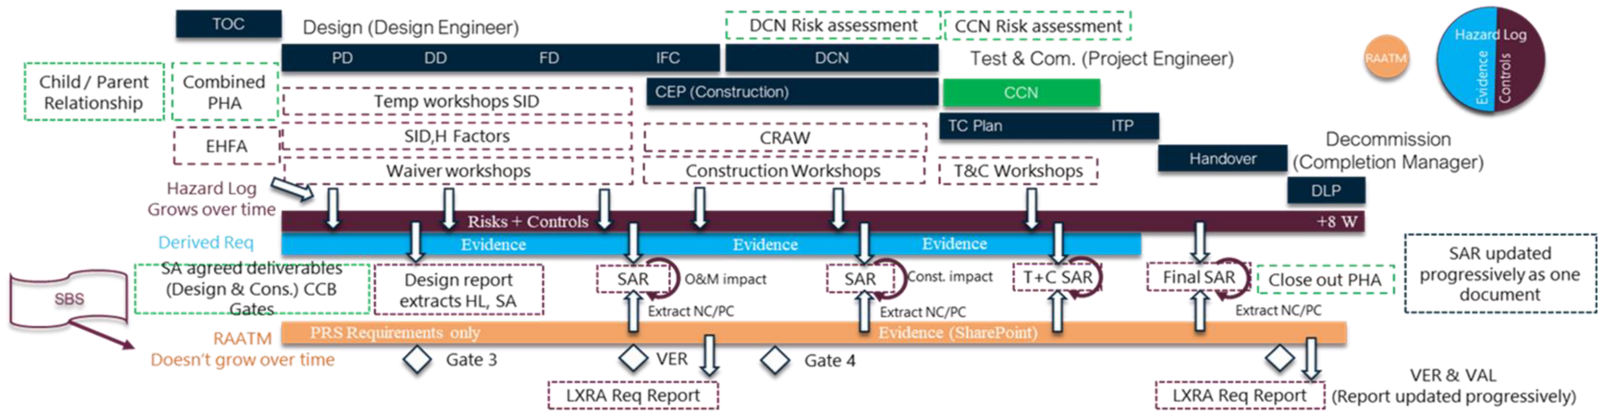

Figure 3: Future State Projects 3 and 4

CHANGES FOR IMPROVED (BEST) PRACTICES:

- Hazard Log, including reference to evidence. Complete information for others to work from – no rework
- Hazard Log progressively updated. Contemporaneous notes thus less error due to memory loss
- RAATM is used only for Project Requirements Specifications (PRS) requirements. A deeper understanding of governing standards for project
- Clear roles & responsibilities using the Responsibility, Accountability, Consultative and Inform (RACI) Matrix. Clear assignment of the lead responsible person who will deliver the task
- Combined Preliminary Hazard Analysis (PHA) workshops & reports. Two activities combined into one – more efficiency
- Visual Management Centre (VMC) for Short Interval Control. "One version of the truth" approach – less confusion and double-checking activity
- Progressive assurance through an extract of Hazard Log (SRSR). Documented quality documented at the time of confirmation.
- Focus on Unique & Novel Assets + Material + Construction Methods. Unfamiliar items and activities need more time upfront to increase cycle time when utilising
- Hazard Log consulted when evaluating projects. History is invaluable to the improvement of safety, quality and productivity

Table 2: Project Cost and Saving Comparison (AUD) – First Two versus Last Two Packages

Package	Actual Outturn Cost (AOC)	SE Cost	% of SE Compared to AOC - Weighted	Achieved Saving Compared to Projects 1 and 2
Project 1	$77,786,146	$1,191,900	1.179%	NA
Project 2	$72,556,966	$839,000	1.156%	NA
Project 3	$127,941,091	$1,006,100	0.749%	$535,527
Project 4	$90,186,517	$919,600	0.864%	$273,609
Total SE Difference Projects 1 & 2 and 3 & 4		**$56,400**		
			Total Saving	**$809,136**

BENEFITS

The alliance team recognised and articulated several benefits to the SE approach that they created and implemented.

- Significant reduction in resources required to manage SE processes once systematised.
- Less staff frustration and potential staff turnover due to the routine and familiarity of a system.
- High-quality safety assurance report (SAR) to improve asset owner's confidence in alliances; thus, the director may spend more time managing their organisation's everyday functions.
- Direct child/parent relationship with Project Hazard Authority making closing hazard list (hl) items easier.
- Eliminate duplication and thus increase process speed, higher asset utilisation and fewer costs.
- Eliminate or reduce project risks minimising schedule disruptions and unbudgeted costs.
- Standardised assurance report template making training, recording and analysis easier.
- Better utilisation of resources (less stressed equipment and safer crews). Since these inputs are always constrained, this can lessen switching between projects, i.e., Fewer inefficient start-ups, closedowns and transfers of people and equipment,

DISCUSSION

An intensive collection of information, including data and observations, is needed at the beginning of a Kaizen Event initiative in construction. In addition, SE requires data (qualitative and quantitative) and other information, such as an existing state process map, to be collected and analysed to transition between current to future states.

Where they exist, construction projects' trade and discipline-oriented silos lead to sub-optimal interfaces accompanied by verification and validation challenges. This was true in this case study. As is well documented, the construction industry differs fundamentally from the manufacturing domain, emphasising the differentiation of the product design – due to the customer need for a unique product due to local conditions such as the project's purpose, location, material availability, equipment selection and local technical mastery - rather than standardising process design in its engineering of systems effort.

The complexity is not only trade sequencing but also structure and services integration. Since products have increased sophistication than the skilled craft to install them, a new system conflict or unintended consequence may appear with the latest design. The process seems to require a review and possible update, just like a firm's strategic plan. The issue is which firms will re-engineer the design and construction process as their stakeholder groups constantly change. Prime contractors and project owners are in the hundreds in most regional markets. This issue suggests that Lean Construction researchers and practitioners must focus on the enterprise rather than the project as a starting point to accomplish the SoS approach that Nielsen et al. (2015), Lynhaug (2021) suggest.

SUMMARY AND CONCLUSION

According to Flyvbjerg (2014), rail construction has twice the risk of budget overrun when compared to road projects. This problem appears to signal the need for a detailed and holistic improvement approach to both. SE fits this requirement. The principle of Kaizen was utilised to streamline the SE process. This can be characterised as SoS. It is essential to point out that practices and insights will stay with the stakeholder firm for use again, while others are unique to the infrastructure project thus, not readily applicable to the next one.

Construction has many barriers to improvement and innovation. This may also be part of the reason that hampered many companies from developing this SoS approach. However, it is clear that an opportunity exists; this case study demonstrates that with the addition of a minimal cost (AUD 56,000) of targeted investment based on a thorough review, a significant saving (AUD 809,000) can be realised. Total savings on the portfolio of ten projects are predicted to be between AUD 5.8 and 7.1 million, due to be completed later this decade. For accurate outcomes, the SE team used the audited cost of the SE process and the resulting AOC after the completion of each package. At the time of publishing, a final result has not been finalised and announced.

Kaizen is a valuable process for long-term and consistent improvement. Tedious and tireless upfront work is needed to ensure a high probability of successful transformation in Mega Projects. Given the low margins and increasing complexity of construction, it appears to be a minimum requirement. With the impending dual crises of rapid urbanisation and climate change effects, it seems crucial to society's future.

MASTER SCHEDULE OPTIMISATION WITH THE USE OF FLOWLINES AND PERFORMANCE DATA

Danny Murguia[1], Asitha Rathnayake[2], and Campbell Middleton[3]

ABSTRACT

In the UK construction industry, Gantt charts and the Critical Path Method (CPM) are the institutionalised and accepted tools for managing construction programmes. Together with the lack of a consistent measurement framework, little is known about current productivity levels and the opportunities for improvement. Using the case of four buildings in London, this paper aims to develop a strategy to optimise the duration of master schedules using real project data and optimised production rates. Data were collected during the structural works and translated into master-level flowlines. Key performance metrics were extracted: start-to-start duration (between levels), number of concrete pours per level, batch area, and production rates. The results showed a high spread of variability in performance within and between projects. However, higher production rates are associated with shorter start-to-start durations between consecutive levels, a higher number of slab concrete pours per level, smaller batch areas, and higher prefabrication levels. The results were applied to the building with the lowest performance. Increasing the number of slab pours would reduce the programme by 39% and increase the production rate by 65%. Whilst more performance data is required to build up a robust database, these initial findings can provide contractors and clients with evidence that there is room for improvement. A client was engaged during this research and is willing to prescribe flowlines and performance metrics in future projects.

KEYWORDS

Batching, flowlines, master schedule, performance, productivity.

INTRODUCTION

In 2013, HM Government issued "Construction 2025", an industrial strategy which sets outs how the industry, represented by the Construction Leadership Council (CLC), and Government *"will work together to put Britain at the forefront of global construction over the coming years"*. The strategy set out ambitious targets including 33% lower costs, 50% faster delivery, 50% lower emissions, and 50% of improvement in exports. The presumption in favour of off-site construction, new talent and skills, digital design and smart construction, low-carbon construction, industry growth, and leadership are the core pillars of this vision. A decade on, however, there is still no clarity on whether these targets are achievable or how much progress the industry and Government have made. The presumption in favour of off-site construction

[3] Professor of Construction Engineering, Department of Engineering, University of Cambridge, UK, prof@construction.cam.ac.uk, orcid.org/0000-0002-9672-0680

has triggered several demonstrator projects and industry and academic efforts to measure performance. For instance, Jansen van Vuuren and Middleton (2020) published data from 46 school projects with varied levels of off-site construction. However, this study revealed that the data does not provide conclusive evidence to establish a correlation between off-site construction and improved performance. Moreover, the authors argued that there is a need to rethink how performance is measured. Bassi et al. (2022) presented data from several off-site housing projects in Bristol. Whilst programme reduction was achieved, cost reduction was not accomplished due to the small pipeline of work for manufacturers; and it is expected that cost benefits will be achievable in the future. Thus, despite the ambitious targets, there is no evidence of ongoing performance improvement.

The Construction Productivity Taskforce (CPT) is a group of major UK clients, contractors, and consultants. The CPT aims at identifying and trialling new ways of making the construction sector more productive. The authors of this paper are working with the CPT to collect, interpret, and analyse construction data to set benchmarks, identify areas for improvement, and produce new knowledge on how the industry operates. Whilst some previous research have presented case studies of lean applications in the UK construction industry (Sarhan & Fox, 2012; Drysdale, 2013; Daniel et al., 2018; Tezel et al., 2018), the reality is that major clients and contractors are unaware or have little knowledge of lean construction techniques for production planning and control. As such, the current paper uses lean construction concepts and techniques to demonstrate the potential presence of waste in the construction process and suggest possible interventions that clients and contractors can make to achieve higher levels of productivity. The scope of this research is situated at the master planning level where clients and contractors negotiate the project duration and the interdependencies between work packages. Observing potential performance improvement at the master planning level is the first level where waste can be eliminated. Consequently, further layers can be observed and analysed at the activity level as presented in the companion paper (Rathnayake et al., 2023).

This research has collected performance data from four residential and commercial buildings in London. By using high-level strategies such as batching and master-level flowlines, data were analysed quantitively to determine the causes of variability in performance within and between projects, and to demonstrate the potential performance improvement that can be achieved. The paper is structured as follows. First, a brief background is presented. Second, the case studies are described including the type of data collected. Third, the results are presented and interpreted with an emphasis on master planning duration improvement. Finally, the results are discussed, and this is followed by conclusions and a description of future work.

BACKGROUND

LEAN IN THE UK CONSTRUCTION INDUSTRY

There is some evidence in the lean construction literature that lean techniques have been implemented in the UK construction industry, particularly in highway projects from the client perspective (Drysdale, 2013). For instance, Daniel et al., (2018) showed the effect of procurement methods in the Last Planner System (LPS) implementation whilst Tezel et al., (2018) presented the results of continuous improvement and visual management techniques. Daniel et al., (2017) investigated the adoption of collaborative planning (CP) as opposed to the LPS implementation among UK contractors. The study showed that collaborative planning is a method used by contractors to plan construction activities with subcontractors with a focus on programme and time compression. As such, it lacks several components of the LPS such as the make-ready process, look-ahead planning, constraint analysis, and consideration of flow and learning. Some previous studies (e.g., Johansen & Porter, 2003) argued that the LPS can be applied to UK building constructions after the consideration of cultural barriers. For instance, subcontractors have commercial pressures from Tier 1 Contractors and "push" planning takes precedence over production and continuous flow. Moreover, commercial managers do not fully vet subcontractors' production capability and there is little consideration of the relationship between price and performance. Sarhan & Fox (2012) confirmed that UK construction organisations are far behind in a comprehensive lean approach due to the lack of awareness and understanding and suggested that large public sector clients are ahead of adoption and can incentivise the rest of the industry. Regardless of the levels of adoption, there is a void in the literature regarding performance in the UK construction sector and how this can relate to partial or full, formal or informal, implementation of lean concepts. Thus, this study aims to collect evidence from construction projects and use concepts such as flowlines and batching to identify high-level process waste and areas of improvement at the master planning level.

FLOWLINES AND MASTER SCHEDULES

Location-based scheduling model projects as a series of locations in which activities flow through different units in turn. The flowline method is a location-based scheduling method that graphically represents activities as a single line where the line passes from the lower left corner (start of location, start of duration) to the upper right corner (end of location, end of duration), and represents a crew passing through a location (Kenley & Sepännen, 2010). Moreover, it is possible to represent several crews as a fast way to model production. For the case of work packages at the master-level planning, all crews and activities can be modelled as a single line before splitting into several lines for each crew. Flowlines were used in previous research as a powerful tool for visual management in construction (Brioso et al., 2017). Lehtovaara et al., (2021) presented a client-driven project's operation strategy at the master programme level for collaborative iterations and transparent communication of construction plans. They suggested the following Key Performance Indicators (KPIs): total gross area (m^2), the quantity of work per gross area (e.g., tonnes of rebar per gross area), lead time (how fast the whole production is completed from start to finish), batch-specific lead time (how fast a batch or location is completed from start to finish), and production's tightness (average area occupied by a single worker). The authors argued that clients would drive the operations process by requiring these performance indicators in procurement which in turn would guide contractors in designing the production system accordingly. Thus, flowlines and performance indicators can be integrated to detect waste in the production system and drive performance improvement.

BATCHING

Large batches in the production system lead to an increased amount of simultaneous use of space for several tasks and result in increased lead times whereas smaller batches compress the lead time, but create vulnerability in the production system, especially in projects with high variability (Lehtovaara et al., 2021). Ward & McElwee (2007) argued that mass production is the prevalent modus operandi in the UK construction sector which is contrary to the fundamental principle of lean thinking of continuous workflow. They have shown that the concept of batch reduction or increased number of batches is not fully understood in construction and sites run on large batch areas of whole floors. After collecting data from projects, they simulated the programme savings by reducing batch areas. Maturana et al. (2003) also simulated construction scenarios and showed that the increased frequency of concrete pouring reduces workers' idle times in the structural phase of a multi-storey building. Similarly, Valente et al. (2013) showed that reducing the batch size from an entire floor to an apartment reduces the fit-out phase programme. Thus, there is evidence of potential improvements using the batching technique. However, there is little evidence of how batching drives performance during the structural phase of building projects.

METHOD

Three major residential and commercial projects in London were selected for this study. The scope of data collection and analysis was the superstructure structural frame. A summary of the buildings is presented in Table 1. These projects were considered suitable to examine performance as they depict new buildings managed by Tier 1 contractors, have a mixture of traditional in-situ and off-site construction, and were built under normal conditions (i.e., not extreme weather or stoppages). As-built construction data were collected from a variety of sources, including documents, installation reports, site visits, workshops, interviews, and access to image data such as 360 images and CCTV. Data were triangulated to ensure reliability. For instance, concrete pour installation data was reviewed using CCTV images and delivery data. The "level" was selected as the unit of analysis as opposed to the typical monthly progress measurement found in the three projects. The key independent variables extracted were:

- Gros Internal Area (GIA) in m^2 per level
- Planned & actual start date (installation of the first vertical element on the level)
- **Planned & actual end date (last concrete pour on the level)**
- Number of horizontal concrete pours per level
- Average Batch area per pour (m^2)
- Level of prefabrication (dummy variable 0: Null; 1: High).

Flowlines was selected as the tool to visualise the master-level programme with a location breakdown structure on a level-by-level basis. The rationale for this was the need to present to construction stakeholders, who are mostly familiar with Gantt Charts, a better tool to visualise and understand the actual construction programme and the relationships and interdependencies of timeframes between consecutive levels. The following outcome variables were extracted:

- Production rate: the GIA divided by the planned/actual duration per level
- Start-to-start duration: the duration between the start date of two consecutive levels.

Quantitative methods such as correlation analysis and multiple regression were applied to the data to deduce the relationships and dependencies between the variables.

Table 1: Case studies description (note that A & B are from the same project)

Building	Use	Levels	Structural frame
A	Offices	9	Twin walls, structural steel, in-situ slab concrete pour
B	Offices	9	Twin walls, structural steel, in-situ slab concrete pour
C	Offices	11	Traditional in-situ reinforced concrete
D	Residential	12	Offsite components, in-situ slab concrete pour

RESULTS

The first step in the data analysis was to calculate the planned and actual production rates. Figure 1 presents a plot with the results. Each data point represents a level. All data points above the diagonal show that the actual outperformed the plan whereas all data points below the diagonal indicate that the actual underperformed the plan. It is noteworthy to highlight that the number of data points above the diagonal is far less than the data points under the diagonal. Moreover, the data points above the diagonal hardly exceed the planned performance whereas the data points below the diagonal are far below the expected performance. Thus, these projects show significant performance issues that must be understood to improve productivity.

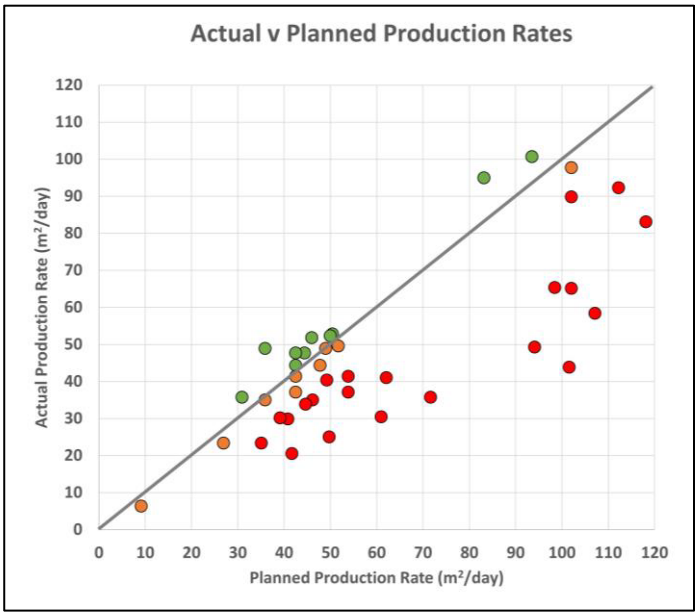

Figure 1: Planned versus actual performance (all buildings)

Table 2 presents the results for production rates, start-to-start durations, number of pours and average batch area for all buildings. Buildings A and B have 1 or 2 pours per level and the biggest batch area (> 600 m^2) which are associated with the highest start-to-start average durations and the lowest overall production rates. The number of concrete pours and batch area are well-known parameters to improve the performance of the production system (Valente et al., 2013; Ward & McElwee, 2007; Alves & Tommelein, 2004). However, these concepts were not fully implemented in the projects under study.

Table 2: Summary of Results

Variables	Unit	A	B	C	D
Production rate (PR)					
Minimum	m^2/day	23	23	21	44
Maximum	m^2/day	49	49	53	101
Median	m^2/day	40	39	32	74
Overall	m^2/day	46	31	59	115
Start-to-start duration (St-to-st)					
Minimum	day	20	20	10	8
Maximum	day	38	28	29	23
Median	day	26	24	14	10
Pours per level (Pours)	-	2	1	3	4
Batch area (Batch)	m^2	619	668	300	357
Prefabrication (0 = No; 1 = High)	-	1	1	0	1

MASTER-LEVEL FLOWLINES

From a master schedule point of view, the aim is to shorten the overall lead time by 1) reducing the start-to-start duration between levels and 2) maximising the level-by-level production rates. Figure 2 presents the master-level actual flowlines of building A and the associated production rates. The highest production rate was achieved in level 7 (49 m^2/day) whereas the lowest production rate was in level 9 (23 m^2/day). The overall production rate of 46 m^2/day is the building's GIA divided by the overall duration. On the other hand, the highest start-to-start duration was between levels 1 and 2 (38 days) whereas the lowest start-to-start duration was between levels 6 & 7 and 7 & 8 (20 days). Moreover, Figure 2 shows an overlap between consecutive levels. This overlap was described by Kenley & Sepännen (2010) as *splitting* which is the result of breaking the work into sections to improve production. Using the metaphor of a *telescope*, the aim is to shorten the telescope by increasing the overlaps between levels. However, Building A had the bigger batches, the longer start-to-start durations and thus, the less overlap or *splitting* between levels.

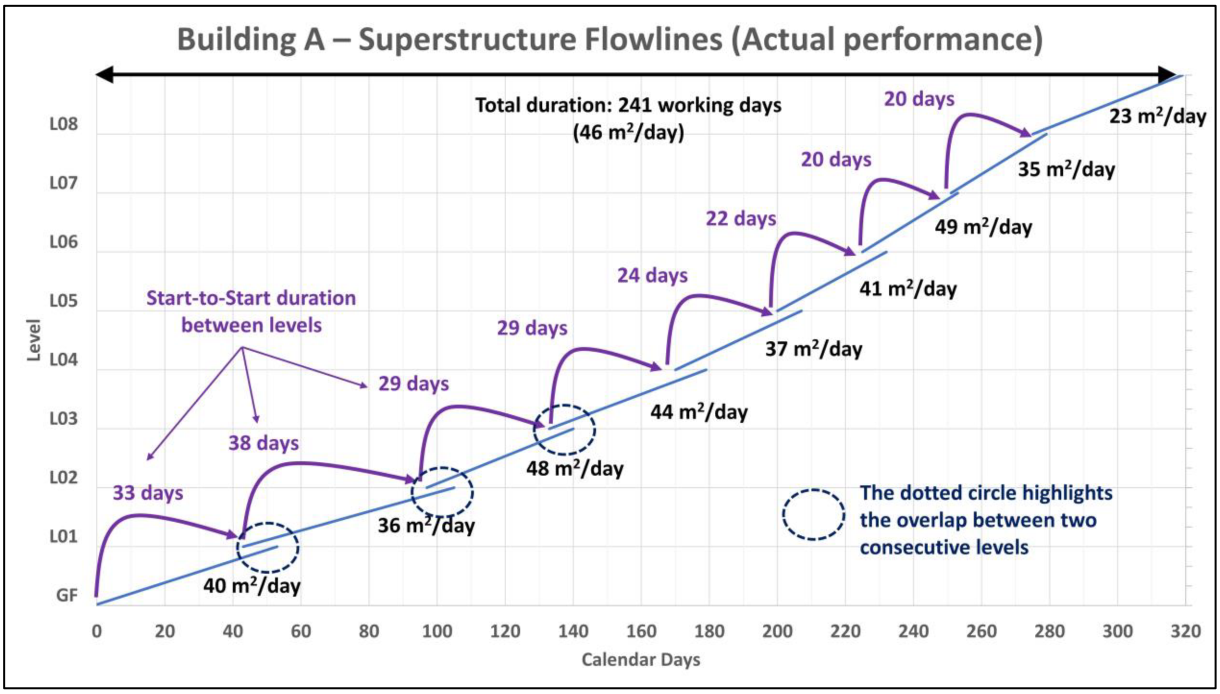

Figure 2: Master-level flowlines for the superstructure of Building A

LOOKING FOR PATTERNS IN THE DATA

Table 3 presents the results of the correlation analysis of the pooled dataset. The results show that 'Production Rate' is significantly correlated to 'Start-to-start duration' ($r=-0.602$, $p<0.01$), 'Number of pours' ($r=0.527$, $p<0.01$), and 'Prefabrication' ($r=0.497$, $p<0.01$). However, there is not a significant correlation between 'Production Rate' and 'Level' or 'Batch area'. Moreover, 'Start-to-start duration' is significantly correlated to 'Number of pours' ($r=-0.537$, $p<0.01$), 'Batch area' ($r=0.700$, $p<0.01$), and 'Level' ($r=-0.436$, $p<0.01$). Nonetheless, there is not a significant correlation between 'Start-to-start duration' and 'Prefabrication'.

To further understand the relationships between these variables, Figure 3 presents the plots of the first dependent variable of interest, production rate, against start-to-start duration, number of pours, batch area, and prefabrication. First, the highest production rate (80 m^2/day and above) is associated with start-to-start duration values between 9 and 12 days. However, these are also associated with production rates below 60 m^2/day. Nonetheless, a start-to-start duration of 20 days and above are *only* associated with production rates below 60 m^2/day. Second, there is an upward trend between the number of pours and the production rate with values above 80 m^2/day with 4 and 5 pours, whilst 3 or fewer pours achieve 60 m^2/day or less. Third, a batch area between 330 and 420 m^2 is associated with the highest production rates. Surprisingly, batch areas under 300 m^2 are associated with lower production rates comparable with a batch area of 500 m^2 or more. However, a closer examination shows that these data points correspond to unusual levels such as level 1, which in most cases were transfer slabs or the top levels which correspond to complex structures in the roof. Thus, the variability of the data does not support any potential relationship between the batch area and the production rate. Finally, projects with the highest levels of prefabrication (dummy variable = 1) are associated with the highest production rates whilst the lowest production rates are associated with projects without off-site components (dummy variable = 0).

Table 3: Correlations between variables (** p<0.01)

	Level	St-to-St	PR	Pours	Batch	Prefab
Level	1.000					
St-to-St	-0.436**	1.000				
PR	-0.146	-0.602**	1.000			
Pours	-0.099	-0.537**	0.527**	1.000		
Batch	-0.434**	0.700**	-0.113	-0.658**	1.000	
Prefab	0.023	-0.032	0.497**	-0.173	0.479**	1.000

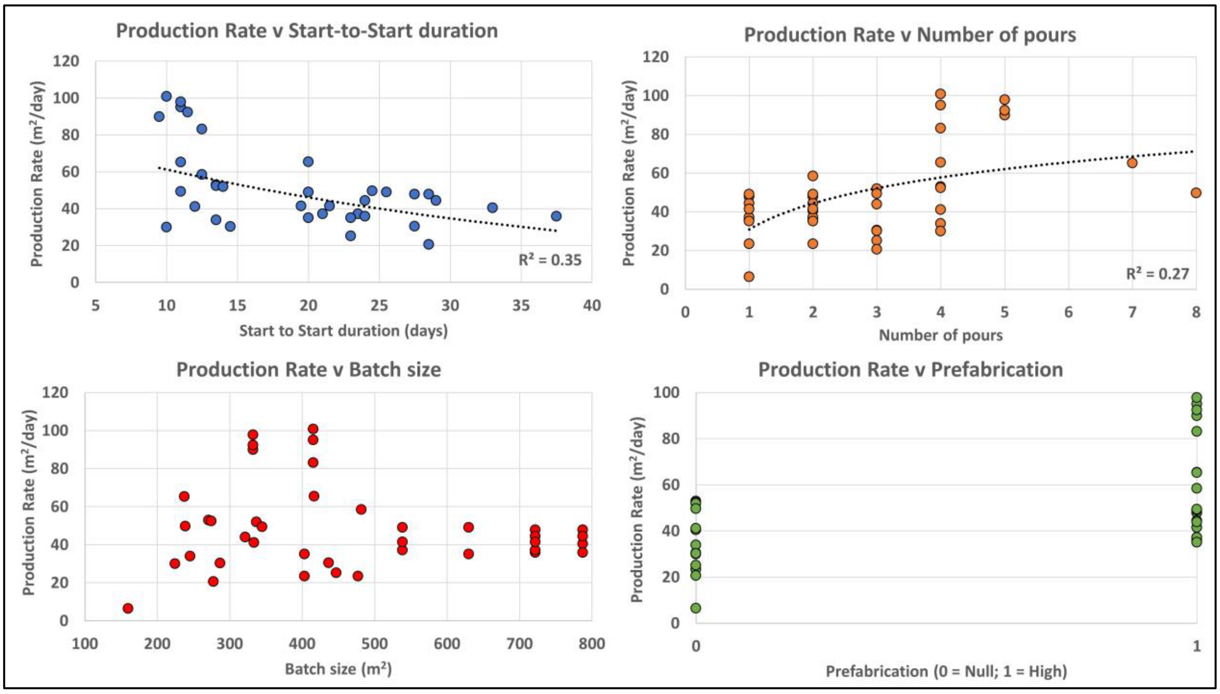

Figure 3: Relationship between production rate and variables under examination

Figure 4 depicts the plots of the second dependent variable of interest, start-to-start duration, number of pours, batch area, prefabrication, and level. First, batch area and start-to-start duration show a high linear correlation. A batch area of 400 m^2 or below is associated with the lowest start-to-start durations. Second, there is a modest relationship between the number of pours and start-to-start duration. For instance, 3 to 5 pours are associated with the lowest start-to-start durations whilst 1 to 2 pours are associated with values of 20 days and above. Third, there is not a clear relationship between prefabrication and start-to-start duration although values of 10 days and above are only achieved in prefabricated projects (dummy variable = 1). Finally, there is a downward linear trend between level and start-to-start duration. Moreover, values between 10 and 15 days happened across all levels. Thus, this is an indication that level is not a predictor of start-to-start duration.

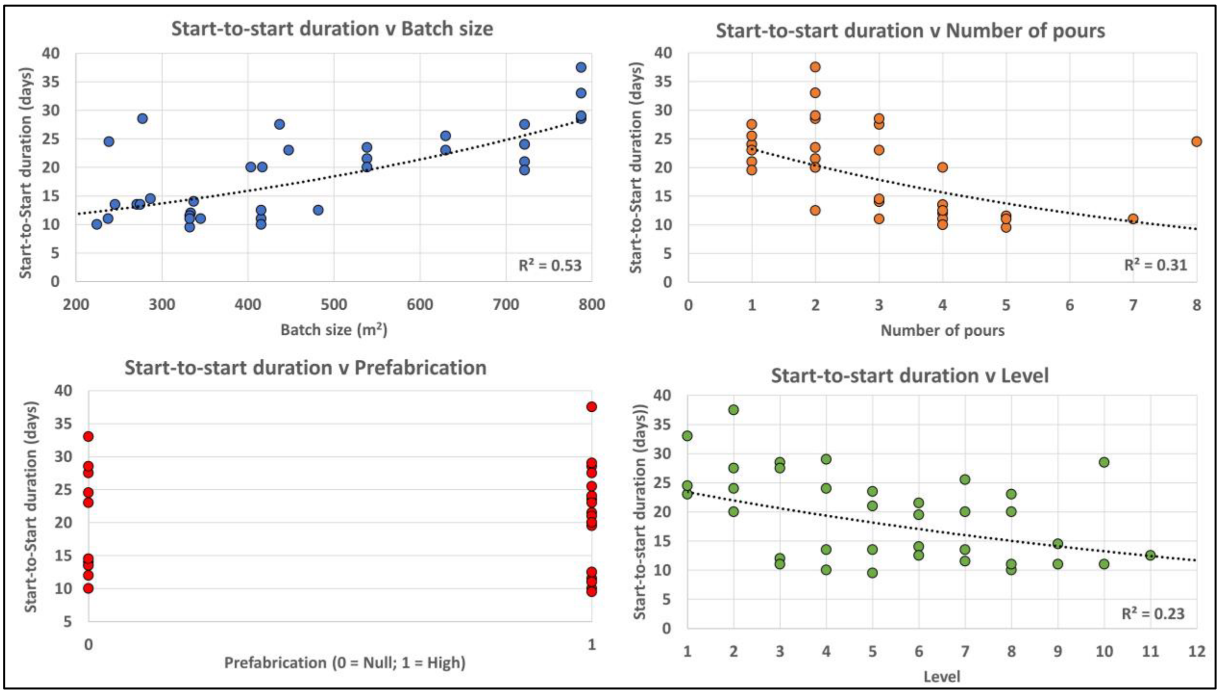

Figure 4: Relationship between start-to-start duration and the variables under examination

MULTIPLE REGRESSION ANALYSIS

A multiple regression analysis was conducted to model the production rate and the start-to-start duration. The results in Table 4 show that start-to-start duration, prefabrication, and the number of pours explain 69% of the variance of production rate whereas batch area was not found to be a significant predictor. These results suggest that all things being equal, every additional start-to-start day reduces the production rate by 0.8 m^2/day. Moreover, projects with a high level of prefabrication perform 26 m^2/day higher than projects without prefabrication. Finally, every additional pour (or batch) per floor increases the production rate by 6.5 m^2/day. Moreover, the results also show that batch area and prefabrication explain 61% of the variance of start-to-start duration whilst the number of pours and level were not found to be significant predictors. These results suggest that all things being equal, every additional 100 m^2 of a batch area increases the start-to-start duration by 3.6 days. Moreover, projects with a high level of prefabrication have 7 start-to-start days shorter compared to projects without prefabrication.

Table 4: Multiple regression results (N=40)

Variable	β	SE	t	p-value
Dependent variable: Production Rate (R^2=0.693)				
Constant	28.633	10.137	2.825	0.008
Start-to-start duration (St-to-St)	-0.832	0.317	-2.622	0.013
Prefabrication (Prefab)	26.220	4.349	6.029	0.000
Number of pours (Pours)	6.485	1.497	4.331	0.000
Dependent variable: Start-to-start duration (R^2=0.606)				
Constant	6.483	2.100	3.086	0.004
Batch area (Batch)	0.036	0.005	7.539	0.000
Prefabrication (Prefab)	-7.148	1.851	-3.861	0.000

These results suggest that at the master level planning, the strategy to increase the production rates is to reduce the start-to-start duration and increase the number of pours per level. In turn, the strategy to reduce the start-to-start duration and increase the number of pours is to reduce the batch area. Moreover, prefabrication has a significant impact on reducing the start-to-start duration and increasing the production rate. In summation, the outcome variables of interest can be explained by the data and planners can consider these relationships during the structural frame's production system design at the master programme level with the use of flowlines.

PERFORMANCE IMPROVEMENT

The next step in the methodology is to use the performance data results to simulate potential optimisation scenarios at the master programme level and assess whether production rates and programme durations can be improved. To do this, building A was selected due to the presentative GIA, the lower number of pours per level, and the lower production rates compared to buildings C and D. Table 5 presents the results of this process. The first step is to increase the number of pours to assess its effect on the production rates and start-to-start durations. For instance, 4 pours of approximately 394 m^2 were selected for levels 1 to 4, whilst 3 pours of approximately 359 m^2 were selected for levels 5 to 7. The estimated start-to-start duration is calculated using the multiple regression results indicated in Table 4 using the batch area (m^2) and prefabrication (0 = null, 1 = high). The estimated start-to-start durations are shown in Table 5 and the actual values achieved onsite are shown in parentheses. Thus, there is a substantial reduction in the start-to-start values which is in line with potential programme reduction. Similarly, the optimised production rate was calculated using the multiple regression results presented in Table 4. The estimated level-by-level production rates are shown in the last column of Table 5 and the actual values achieved onsite are shown in parentheses. Thus, there is a substantial production rate improvement between levels 2 and 8. Finally, the level duration was estimated using the estimated production rate and the GIA. The estimated durations are shown in Table 5 whilst the actual performance is shown in parentheses. For levels 2, 3, and 4, the estimated duration is 23 days which is a substantial improvement from 44, 33, or 36 days.

Table 5: Master programme optimisation results (Building A)

Level	Batch	Batch area	Prefabri cation	Start-to-start duration: Estimated (Real)	Level duration: Estimated (Real)	Production rate: Estimated (Real)
1	4	394	0	21 (33)	42 (39)	37 (40)
2	4	394	1	14 (38)	23 (44)	69 (36)
3	4	394	1	14 (29)	23 (33)	69 (48)
4	4	394	1	14 (29)	23 (36)	69 (44)
5	3	359	1	14 (24)	17 (29)	64 (37)
6	3	359	1	12 (22)	17 (26)	64 (41)
7	3	359	1	12 (20)	17 (22)	64 (49)
8	2	404	1	14 (20)	14 (23)	56 (35)
9	2	404	0	N/A	33 (35)	24 (23)

Finally, Figure 5 presents the overlay of the actual flowlines and the potentially optimised flowlines. The flowlines show that the superstructure programme is shortened from 241 to 146 working days, a reduction of 39%. Similarly, the overall production rate increases from 46 to 76 m^2/day; an improvement of 65%.

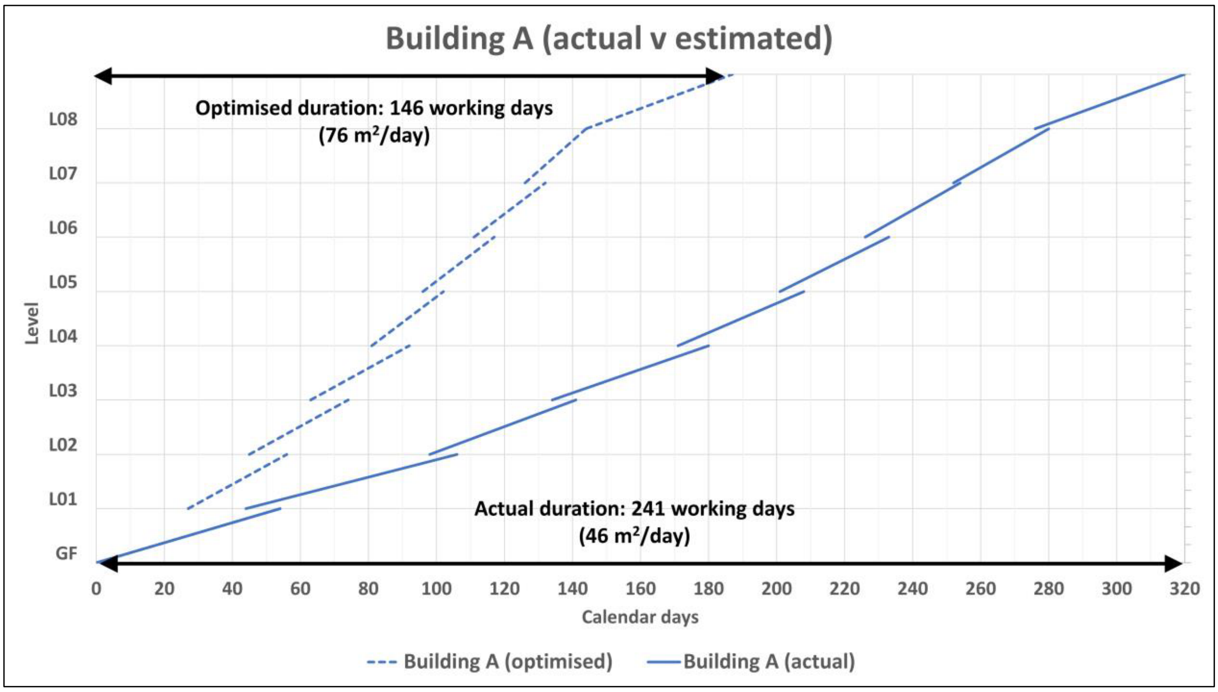

Figure 5: Actual v optimised flowlines for the superstructure (Building A)

DISCUSSION

Data were collected and analysed retrospectively and presented to the industry partners involved in this research. Therefore, the interpretation of the data and the identification of high-level strategic variables is pivotal for understanding what is going on and making decisions. Contractors typically report the SPI (schedule performance index) from the Earn Value Management methodology. This research has shown that additional high-level metrics are needed to compare actual performance, identify the gaps with plans, and look for improvement opportunities. Industry partners who were unfamiliar with flowlines have identified the tool as a powerful means to communicate master programmes, scrutinise the start-to-start durations between consecutive levels, and decide on the best production rates applicable to the project. The use of historical data is fundamental for benchmarking.

First, the data has shown substantial performance issues that were unknown or not fully understood by project stakeholders. The visualisation of master-level flowlines and the level-by-level basis production rate stand in sharp contrast with the weekly or monthly SPI. SPI only shows whether the project is ahead of time or delayed, whereas the production rates are leading indicators that can be timely presented to detect productivity issues. Moreover, the effect of batching on production rates and start-to-start duration becomes clearer. For instance, building D has the shortest average start-to-start duration (10 days) and the highest production rate (115 m^2/day) whereas building A has the longest average start-to-start duration (26 days) and one of the lowest production rates (46 m^2/day). These are associated with the number of batches and the batch area. Furthermore, the iteration of these variables in the early stages of planning can improve the overall slope of the work package's flowline and thus determine the optimum duration. This level of interpretation is certainly difficult to achieve with traditional Gantt charts, as expressed by several project stakeholders.

Second, lean techniques or the Last Planner System (LPS) were not implemented in these projects. However, the concept of batching was tacitly implemented in buildings C and D. Some stakeholders argued that in the UK construction industry, there is a central logic that can be expressed as *"the larger the concrete pour, the better."* This was demonstrated in buildings A and B which had 2 and 1 pours respectively, making it impossible to shorten the start-to-start durations and optimise performance. This logic reflects that planners and supply chain value larger pours to optimise resources on the pour day. This finding was also highlighted in 2007 by Ward & McElwee who argued that the UK construction sector works to large batch sizes to ensure continuity of the same activity for as long as possible. The site logistics of Buildings A and B did not indicate a specific requirement for one or two batches, thus, it was a management decision underpinned by this logic. Moreover, Tier 1 Contractors do not have enough visibility of the construction flows, crew utilisation, and performance issues of their subcontractors. For instance, subcontractors mobilise personnel between projects and send more workers to the site on pour days to meet the contractor's programme. Building D, however, had in-house workers. The contractor maximised labour utilisation by having multi-skilled labourers who can perform several activities to ensure workflow continuity.

Third, more data granularity is needed to understand the differences within projects. The companion paper (Rathnayake et al., 2023) presents data at the activity level and shows that the excess of work-in-progress time had a significant influence on production rates. Moreover, there is an opportunity here to implement the LPS and correlate the PPC metric and reasons for non-completion with master-level production rates. In this research, some performance issues were detected from CCTV cameras and weekly reports. However, these were not captured consistently to ensure a thorough understanding of what went wrong and why. Finally, the variables used in this research are in hands of planners and project managers (i.e., how many batches, batch size, start-to-start duration, and prefabrication). This presents an opportunity to develop a causal model using larger datasets that can inform optimised parameters for new construction programmes. Additionally, this model can be utilised to simulate the performance of new projects, enabling planners the consideration of multiple scenarios for decision-making.

CONCLUSIONS

This research proposes an approach to analyse as-built construction data using master-level flowlines with the aim of optimising project duration. The study collected empirical data from four large buildings located in London. The results of the analysis indicated a significant disparity between planned and actual production rates. To address this issue, master-level flowlines were developed and presented to project stakeholders to improve their understanding of the construction process and ultimately enhance project performance. Two performance metrics were selected to optimise the duration of the work package: start-to-start duration (between levels) and production rates. The results showed a high spread of variability in the performance data within and between projects. However, higher production rates are associated with shorter start-to-start durations, a higher number of slab pours per level, smaller batch areas, and higher prefabrication levels. The results were applied to the building with the lowest performance. Increasing the number of pours from 2 to 4 would reduce the programme by 39% and increase the production rate by 65%. Whilst more performance data is required to build up a robust database, these initial findings can provide contractors and clients with evidence that there is room for improvement. The client was engaged during this research and is willing to prescribe flowlines and performance metrics in future projects. Finally, this work can also be extended to the analysis of the relationships between the superstructure and the next work packages such as cladding and fit-out. The review of the work in progress between work packages, start-to-start durations between levels, and production rates could drive significant performance improvement for the entire project and therefore achieve industry aspirations.

ACKNOWLEDGEMENTS

We would like to thank our industry partners for the access to actual construction data, their engagement with this research, and the visionary approach to data-driven decision-making.

CAN ADVANCED WORK PACKAGING BECOME A LEAN METHOD?

Italo Sepúlveda[1], Luis F. Alarcón[2], and Beda Barkokebas[3]

ABSTRACT

Advanced Work Packaging (AWP) is rapidly becoming a popular methodology to improve efficiency in construction projects. It is an innovative approach to project management that focuses on the planning, organization, and control of construction tasks on the job site is based on the idea that by organizing work effectively and reducing lead times, it is possible to maximize efficiency and productivity in construction. Nevertheless, Lean Construction (LC) practitioners identified significant shortcomings in AWP such as the lack of attention to buffers while arguing that this methodology is not effective in a practical setting. In this context, this research presents a literature review identifying the criticism of LC practitioners to AWP while identifying similarities and possible synergies where both approaches can complement each other to render better results during the delivery of construction projects. This research identifies the implementation of the Last Planner System® (LPS®) as means to address significant AWP shortcomings identified by LC practitioners while taking advantage of AWP's structured approach to better apply LC concepts. Therefore, the identified synergies and combination of both approaches will contribute to more efficient processes and improvement of construction practices.

KEYWORDS

Advanced work packaging, workface planning, lean construction, integration, collaboration.

INTRODUCTION

Construction projects have the primary objective of meeting construction deadlines, however, we constantly observe cases where this is not met as a result of productivity loss in the industry (Sanni-Anibire et al., 2022). Low productivity has an impact on a country's Gross Domestic Product (GDP), as it accounts for 3% to 8% of its GDP (Hasan et al., 2018). In fact, the construction industry has been struggling to meet increasing productivity demands (Bock, 2015). The Construction Industry Institute (CII) and the Construction Owners Association of Alberta (COAA) proposed AWP as a methodology to increase on-site productivity (Farghaly & Soman, 2021). According to the CII (CII, 2013), AWP methodology is a comprehensive project management approach primarily employed in the construction and engineering industries. Its main objective is to enhance project efficiency, predictability, and productivity. AWP achieves this by effectively planning and organizing work from the project's conception to completion. It involves breaking down projects into manageable work packages and coordinating design, procurement, and construction activities. AWP involves a series of steps

that are aimed at defining the project's objectives and scope, and at organizing the construction process in a structured and efficient way. These steps typically include planning the construction sequence and identifying the necessary work areas and resources, breaking down the work into manageable units, coordinating the engineering and procurement activities, and preparing the installation and commissioning plans. By following this methodology, project teams can improve their productivity, reduce rework and delays, and enhance the quality and safety of the construction process. These several steps aim to align engineering, procurement, and construction through the creation of specific work packages for each of these activities, which allows for consistent and effective planning throughout the project (Guerra & Leite, 2020).

Koskela (2002) proposed the concept of LC as a new approach to construction, based on the principles of the Toyota production system. LC's main premise is to reduce waste while adding value to the client. Unlike AWP, LC emphasizes a culture that supports workers and continuously improves the production system (Court et al., 2022).

LC provides a range of benefits for construction projects. First, the elimination of waste in construction processes reduces costs and optimizes resource usage. Second, by increasing worker productivity through waste elimination and process improvement, LC leads to greater efficiency and effectiveness in project management. Third, the reduction of delivery times through waste elimination and process optimization decreases indirect costs. Fourth, the continuous improvement of processes in LC leads to a better quality final product, which reduces indirect costs and increases customer satisfaction. Fifth, LC places a strong emphasis on workplace safety, helping to identify risks and reduce workplace accidents. Finally, by promoting collaboration and effective communication among work teams, LC aids in identifying waste and optimizing processes, leading to increased customer satisfaction through cost reduction, quality improvement, and delivery time reduction.

Both LC and AWP differ in terms of their methods and development contexts. However, LC focus on waste reduction and value creation, coupled with its emphasis on a culture that supports workers and continuously improves the production system, makes it a powerful approach for achieving successful and profitable construction projects.; while AWP optimizes the planning and execution of work activities in construction projects to improve project outcomes and deliver projects more efficiently and effectively (Court et al., 2022). Despite these differences, researchers state that AWP and LC have significant similarities between them. Indeed, Mao et al. (2022) argue that AWP has its roots based on LC. An important production system in LC, the LPS® focuses on creating a reliable and predictable workflow between different stakeholders of a project with the last responsible person to perform the work in mind (i.e., the LPS®) (Lean Construction Institute, 2023). As such, AWP can support LPS® by providing the participation of the last planner during planning sessions of work packages(Hood et al., 2021). As a result, the gap between the planning and execution phases can be minimized.

The authors believe that, besides differences between LC and AWP, methods in both approaches can complement each other thus resulting in an improved project development and execution. Therefore, this article aims to discuss the complementarity between LC and AWP, considering their common objectives, differences, and possible synergy between them.

RESEARCH METHOD

The present study is a preliminary exploratory search conducted to identify possible critiques in the application of the AWP methodology. Sources of information related to construction and project management were searched, including indexed journals, technical documents, and conferences. The methodology used is depicted in Figure 1.

Once possible critiques of the AWP methodology were identified, information on LC principles that could be applied to enhance and complement the AWP methodology was sought. The search also focused on similar sources of information.

Overall, the exploratory search aimed to discover relevant and valuable information to address the research question of whether AWP could become a Lean method. The investigation was not conducted exhaustively but focused on discovering new ideas and perspectives that could enrich the discussion.

The methodology utilized in this research involved conducting an exploratory search, which revealed that Workface Planning (WFP) is a crucial component of the AWP approach. WFP is a methodology used for detailed planning and efficient execution of work in the field, which enables early identification of issues and challenges in work execution, allowing for informed decision-making and early risk mitigation. Combining WFP and AWP maximizes efficiency in the construction process, reduces waste, and ensures project quality and safety by providing a structured approach to work management from planning to final delivery.

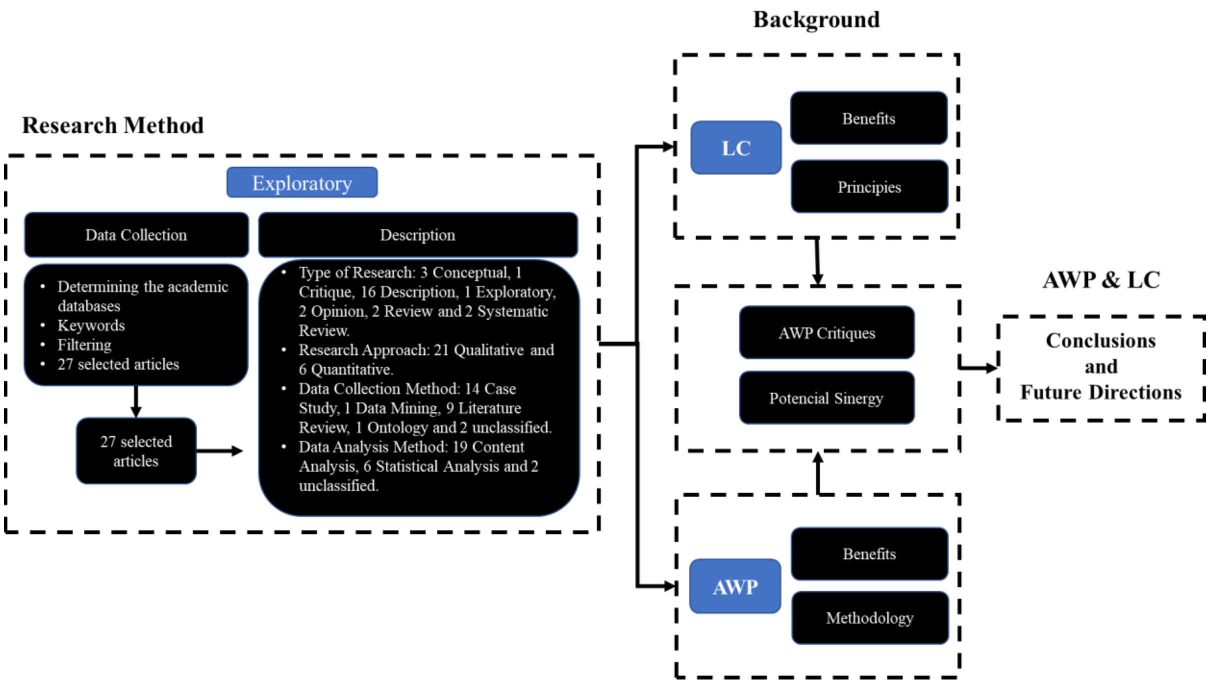

Figure 1: Research method

RESULTS AND DISCUSSION

The research included 25 articles on AWP and its interactions with LC. WFP. Figure 2 shows the volume of publications using these keywords indicating a low number of studies around this topic over the past years.

Through the exploratory search, the researchers found that Workface Planning (WFP) is a critical element of the AWP approach, as it allows for efficient execution and informed decision-making, early risk mitigation, and overall project efficiency, thus providing valuable information that can inform the discussion on whether AWP could become a Lean method. WFP is a fundamental component of the AWP approach, used for detailed planning and efficient execution of work in the field. WFP is a methodology that focuses on managing work packages in the field, allowing work teams to concentrate on effective execution, while AWP is a methodology for managing work across the project, from planning to final delivery. By enabling early identification of issues and challenges in work execution, WFP allows for informed decision-making and early risk mitigation, which contributes to overall project efficiency. When combined, WFP and AWP are tools that maximize efficiency in the construction process and reduce waste, while ensuring project quality and safety. Together, they allow for more efficient and effective management of work in the field, from planning to final delivery.

It is possible that the growing interest in the AWP and WFP methodologies can be attributed to several factors. In 2016, there may have been a greater dissemination of information and experiences regarding the application of AWP and WFP in construction projects, which may have generated interest in the methodology among researchers, professionals, and companies seeking innovative solutions to improve efficiency and quality in project management. Furthermore, the increasing complexity and cost of construction projects may have also contributed to the growing interest in AWP and WFP, as these methodologies can offer a promising approach to addressing these challenges.

In 2022, the interest in the AWP methodology may have been driven by the increasing demand for more efficient and sustainable solutions in the construction sector. The COVID-19 pandemic may have accelerated the need to adopt more advanced practices and methodologies for project management, which may have led to a greater interest in the AWP and WFP methodology. The pandemic has highlighted the importance of flexibility, adaptability, and resilience in project management, which are key principles of the AWP and WFP methodologies. Therefore, it is possible that the growing interest in these methodologies will continue as the construction industry seeks to improve project outcomes in an increasingly complex and uncertain environment.

BACKGROUND ON AWP

Driven by its recognition in the industry, the CII developed several studies to investigate improvements to the WFP methodology. As a result, CII proposed AWP as an improved version of WFP by providing several case studies and maturity models to identify its benefits (Hamdi, 2013; Ponticelli et al., 2015). The literature identifies benefits in several areas associated with the use of AWP as demonstrated in Table 1. According to Table 1, cost and productivity are commonly improved areas by AWP while benefits in quality and safety are only indicated by half of the authors. Farghaly & Soman (2021) applied AWP on a case study to monitor and control project deliverables in which shorter durations as a result of improved installation sequences onsite. Furthermore, a comparison between traditional projects and other projects under AWP was carried out; in the investigated projects, AWP showed better results in terms of cost, schedule, quality, and safety (Ponticelli et al., 2015). Following the same line, the use of AWP reveals a 25% increase in productivity, a 10% cost decrease, safety improvements, and lesser construction rework compared to traditional projects (Simhadri et al., 2017).

The article by Guerra and Leite (2020), presents a case study on how engineering and construction 3D models can be integrated to support AWP implementation. The article, by

Ponticelli, O'Brien, and Leite (2015), presents case studies demonstrating the benefits of AWP in industrial construction. The article, by Simhadri, Srivastava, and Warren (2017), discusses a case study on how AWP can enhance project control. Finally, the article, by Farghaly and Soman (2021), presents a case study on the development of an ontology to support information management and AWP integration. All four case studies involve the implementation of AWP in various project types, such as petrochemical plants, power plants, gas processing plants, and large-scale oil and gas projects. The case studies highlight the advantages of AWP, including reducing rework, improving communication and collaboration between project stakeholders, increasing productivity, and providing a structured approach to planning and execution.

Table 1: Identified benefits of using AWP.

Benefit	**(Ponticelli et al., 2015)**	**(Simhadri et al., 2017)**	**(Guerra & Leite, 2020)**	**(Farghaly & Soman, 2021)**
Cost	X	X		X
Planning	X	X	X	
Quality	X	X		
Safety	X	X		
Productivity	X	X		X

The use of AWP on a project requires the creation of several work packages. The owner's team is responsible to organize these packages according to the various contracts involved in the project. To do so, AWP establishes a workflow based on early integration in which work packages are defined based on requirements from field personnel. Hence, AWP is a construction-driven approach that adopts the fundamental philosophy of "start with the end in mind". Field personnel will execute these work packages as defined in the first stage. Figure 3 depicts the AWP methodology.

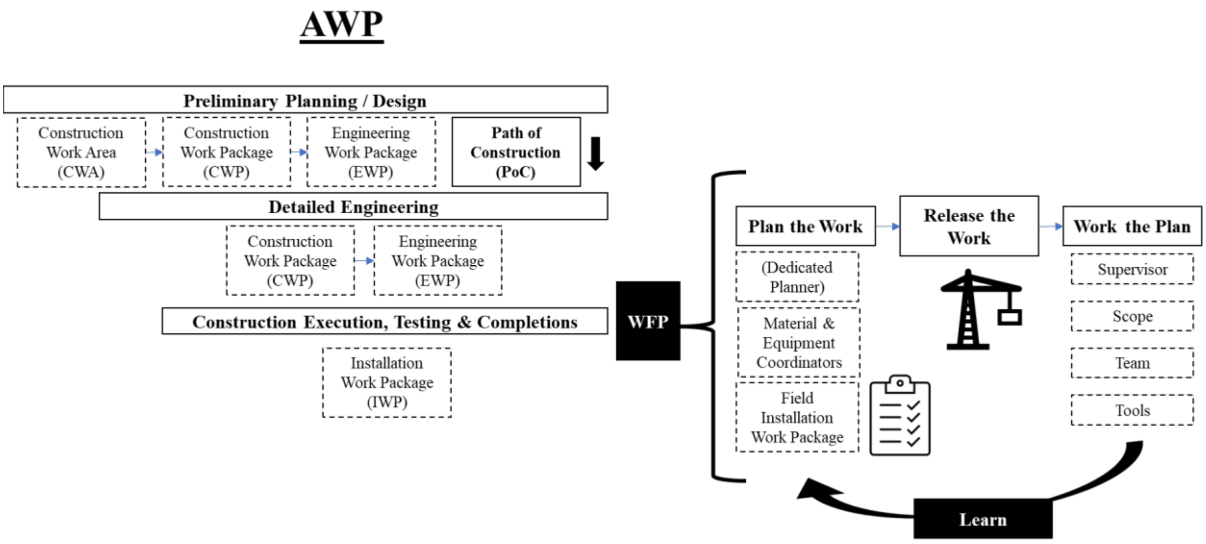

Figure 3: AWP methodology.

As noted in Figure 3, a key requirement in this process is collaboration between construction and engineering during the planning phase to create a constraint-free work environment on the field. This collaboration ensures the project is designed following a sequence that supports construction and its supply chain is organized by breaking down the project scope into work packages (CII, 2020).

AWP IN THE CONTEXT OF LC

The field of application for AWP and LC can be identified by examining relevant literature. According to the CII (CII) (2020), AWP is most used in industrial construction projects, such as those in the energy, chemical, and petrochemical industries. AWP is also applied in projects that require high levels of coordination and collaboration among different stakeholders. On the other hand, Koskela et al. (2002) describe LC as a new theory-based approach to construction, and its main premise is to reduce waste while adding value to the client. LC has been applied in a variety of construction projects, including healthcare, education, commercial, and residential buildings, as well as infrastructure projects. In summary, while AWP is mainly applied in industrial construction and projects requiring high coordination, LC is applied more broadly in a variety of construction projects.

Despite being lauded as an efficient methodology, AWP has gathered critics among the LC community. Ballard and Tommelein (2015) argue AWP is not effective since it focuses its efforts on the creation of work package documentation while not paying attention to production inventories and the creation of a push system as result. Moreover, they recommend the use of discrete event simulation to test the performance of AWP. Moreover, Tommelein (2016) argues that AWP results in large size of work crews, uncertain in schedules, and conflicting transformation processes from systems to product components and locations. Furthermore, Tommelein (2016) claims that supply chains in AWP are not considered as a challenge, which provides an additional complexity to any engineering project. Another critical point is the protection of the production system with a high inventory. As in the previous case, the use of discrete event simulation modelling is proposed to test the performance of AWP. Aligned with this, other studies sharing similar criticism are demonstrated in Table 2.

Table 2: AWP Critiques and Observations

Category	Criticisms/Observations	(Ballard & Tommelein, 2015)	(Tommelein, 2016)	(Fischer, 2021)	(Arbulu, 2019)
Planning	• Focus on document creation and packetization.	X			
	• Lack of synchronization between procurement, equipment, and deliveries.	X	X		X
	• Construction Work Package (CWP) are not made explicit in good form.	X			
	• Forced (Engineering Work Package (EWP) and Purchase Work Package (PWP).			X	
	• Planners are positioned as the ones who will do the thinking for the crews.			X	
Installation Work Package (IWP)	• Installation Work Package (IWP) focused on hours and not on performance.	X	X		
	• Installation Work Package (IWP) decoupled from the constructive logic of a work breakdown structure.			X	
	• Performance protection only protected by high inventory.	X	X	X	X
Production System	• Lack of vision of Balanced Production System.	X	X		X
	• Lack of concepts such as: Buffer, Flux, Push vs Pull, Lead time, and throughput.			X	
Resources	• Underloaded field resources.		X		
Trade Capability	• It is believed that the trade is incapable of effectively planning its own work.			X	

Arbulu (2019) defines AWP as a strategy to place large inventory stocks of materials and information to protect the production system despite not considering the predecessor work-in-process management, capacity, and process variability. Furthermore, Arbulu, (2019) argues that larger buffers generated by AWP will incur to higher project cost despite buffers being estimated by a combination of capacity, time, and inventory. Similarly, Fischer (2021) criticizes AWP pointing out errors in the planning process and the lack of knowledge of construction sequences from planners, which generates disassociation between the AWP packages and the actual work breakdown performed on construction sites due to the logic of construction processes. Indeed, when using AWP, three types of constraints are identified: engineering, supply chain, and site. These are the constraints that must be managed properly to ensure that the construction crew can develop their work as planned (Farghaly & Soman, 2021). Wang et al. (2016) provides a framework for constraint management applicable to both AWP and LPS®. One of the primary objectives in LC is to minimize the inventory and stablish a pull system while developing a culture based on value, mutual trust, and respect to support production. On the other hand, AWP is based on a structured approach (Court et al., 2022). Despite the criticisms presented in this section, the present work identifies potential synergies between LC and AWP as described in the following sections.

POTENTIAL SYNERGY BETWEEN LC AND AWP

Despite the identified differences, AWP and LC share the objective of improving efficiency and quality, constraint management, and stakeholder integration. Court et al. (2022) establishes the main difference between these approaches, Lean is a culture based on values of trust and mutual respect. Indeed, one of LC's main premises is the importance of achieving the project objectives under an environment of collaboration and integration that is enhanced (Alarcón et al., 2013). Table 3 presents a summary of the similarities and differences between AWP and LC.

Table 3: Comparing AWP and LC: Similarities and Differences

Similarities	Differences
Both AWP and LC aim to improve efficiency and quality, constraint management, and stakeholder integration.	LC is based on a culture of trust and mutual respect, while AWP is a methodology focused on work packaging.
Both methodologies focus on early planning, and AWP uses Interactive Planning Sessions while LC employs the Big Room.	LC emphasizes the importance of achieving project objectives in a collaborative and integrated environment.
Constraint management is a key aspect of both AWP and LC, with AWP using Workface Planning and LC using Last Planner System® (LPS®).	AWP focuses on work packaging, while LC focuses on creating a culture of continuous improvement.
The technology applied to implement AWP or LPS® is important for the success of both approaches, with both benefiting from the use of Building Information Modeling (BIM).	LC and AWP differ in their approach to planning and executing work.
Incorporating LC concepts or techniques into the AWP structure can potentially remediate criticisms of AWP and enhance its continuous improvement process.	AWP and LC have different structures and cultural focuses.

The similarities and differences between AWP and LC can be better illustrated through Figure 4. Initially, the focus on early planning is identified in both methodologies. LC considers the Big Room as a key element to meet all the needs of the stakeholders. Big Room seeks to help better coordination of complex engineering projects (Nascimento et al., 2018). Similarly, AWP uses Interactive Planning Sessions to define an integrated plan for project execution from design, construction, commissioning, and delivery to the customer despite no evidence of any specific techniques applied during the session. Hence, LC can contribute to AWP to motivate collaborative work and, consequently, improve how the work is performed while taking advantage from the structured work packages from AWP, when structured work packages are taken in AWP, it provides several benefits. It allows for the optimization of resources, reduces rework, increases productivity, and improves communication and collaboration among the project team. Structured work packages provide a clear understanding of the work to be performed, the required resources, and the expected outcome, facilitating effective planning, scheduling, and execution. Additionally, the structured approach ensures that work is completed in a logical and systematic order, which helps prevent delays and errors. Overall, taking structured work packages in AWP helps to improve project efficiency and effectiveness.

Another similarity between both approaches is the execution phase. In AWP, constraint management is based on WFP. Both the LPS® and AWP are gaining more attention in the recent years because they consider richer information related to project constraints, which infers better quality decisions (Mao et al., 2022).

The technology applied to implement AWP or LPS® is also a fundamental aspect in order to achieve success in either AWP or LPS®. Figure 4 shows the similarities between the technology pertaining to AWP and LC. The work environment in AWP achieves a better development with the incorporation of technologies such as Building Information Modeling (BIM) contributing to an important support to the AWP methodology, as also LC. BIM is defined as a set of methodologies, technologies, and standards that allow designing, constructing, and operating a building or infrastructure collaboratively in a virtual space (Succar et al., 2012). Therefore, BIM offers a reduction of fragmentation in the supply chain and a better platform for construction management (Wu et al., 2021). In terms of linkage with AWP, BIM methodology is presented as an AWP modernization (Tixier et al., 2017). Similarly, the petrochemical industry values the complementarity between AWP and BIM (Guerra & Leite, 2020) as it strengthens the value stream of the project, allows efficient, and aligned engineering. Therefore, the use of BIM methodology is aligned with both AWP and Lean objectives.

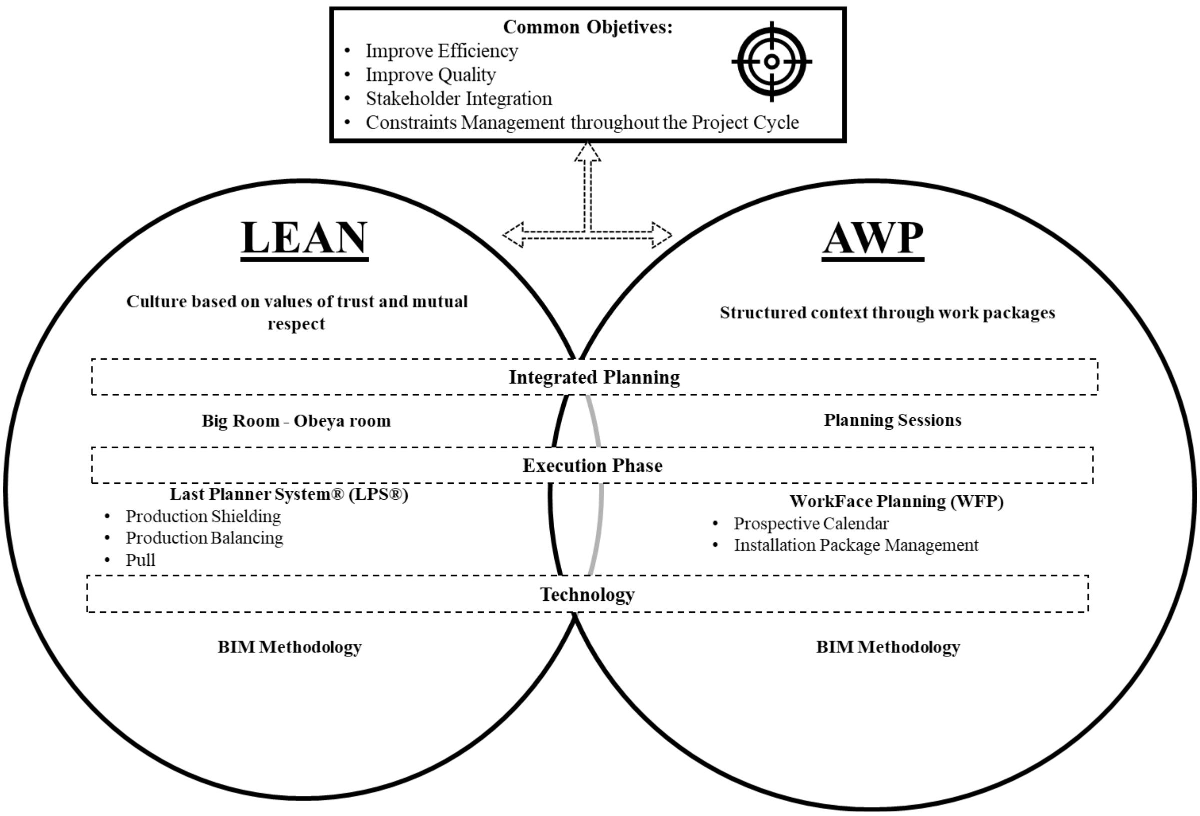

Figure 4: Agreement between Lean and AWP

Finally, aiming to present possible synergies between LC and AWP, Figure 5 shows which elements should be taken from LC and AWP to conform the proposal. The identified synergies rescue the work structure proposed in AWP while considering that each event or decision is supported by LC concepts or techniques. This paper acknowledges the criticisms of AWP which can be remedied by incorporating the DNA of LC in the AWP structure. Both WFP and LPS® are planning systems, seek that the work is executed in a fluid manner, prioritizing a construction rhythm, that allows to benefit the master planning. Figure 5 shows direct feedback to the work planning phase in AWP as in LPS® planning, this feedback process harbours a learning opportunity from the project constraints. In WFP the installation packages are established in a descending way which turns continuously improvement achieved from the information of constraints that is obtained from the field a more challenge and complex process. On the other hand, in LPS® the lessons learned from a project constraint is collected from the field personnel that executed the work and thus facilitating the assimilation of improvements in a continuous manner. As such, AWP can benefit from LPS® by incorporating this approach for continuous improvement in its methodology.

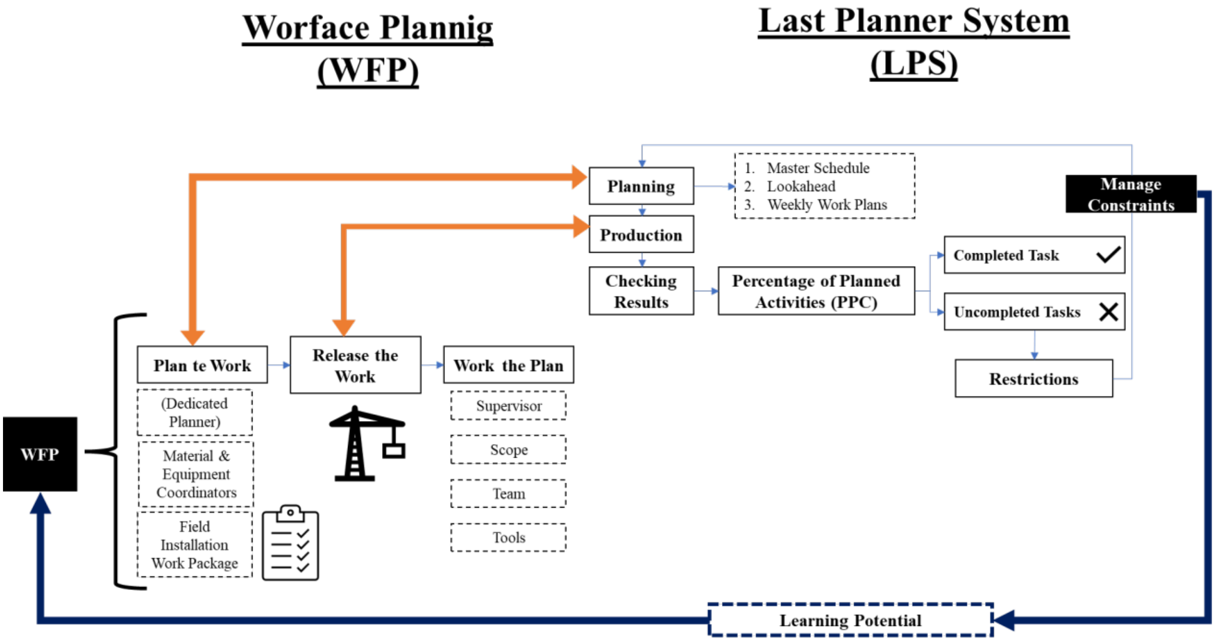

Figure 5: Comparison between Last Planner System® and Worface Planning.

The literature presents some criticism towards the Advanced Work Packaging (AWP) approach, particularly from the perspective of Professor Glenn Ballard and Irisi Tommelein. Despite this, there is evidence of learning opportunities for both Lean Construction (LC) and AWP methodologies. The interaction between these methodologies is worth exploring to identify the possibilities of improving AWP with contributions from LC, while also evaluating the possibilities of implementing the identified synergies. The low volume of publications related to AWP presents an opportunity to carry out academic work and strengthen this approach. For example, Halala and Fayek (2019) propose a framework to assess the costs and benefits of AWP in industrial construction. Additionally, Hood et al. (2021) provide evidence of the linkage between AWP and the LPS®. The incorporation of the identified synergies into AWP will open a field of research possibilities, which complement those already established in the literature.

CONCLUSIONS

Despite studies considering LC and AWP opposite approaches to construction, there is also evidence in the literature of learning opportunities on both ends. Taking this into account, the possibilities of improving AWP with contributions from LC holds a significant potential for its future development while maintaining the possibility to learn from other production planning approaches as well. The low volume of publications related to AWP presents an opportunity to carry out academic work and strengthen this approach. It is necessary to promote case studies that allow quantifying the promised benefits of AWP, as well as evaluating the possibilities of implementing the identified synergies. Before adopting LC concepts into AWP, it is necessary to take into account what factors are modified in the AWP approach when using LC techniques and what is the balance between an AWP and LC methodology. The incorporation of the identified synergies into AWP will open a field of research possibilities, which complement those already established in the literature such as the evaluation of multiple aspects of AWP implementation to quantify both its costs and benefits (Halala & Fayek, 2019).

The potential synergies between AWP and LC can significantly enhance the future development of AWP, as both approaches share similar objectives of improving efficiency and quality, constraint management, and stakeholder integration. LC emphasizes the importance of achieving project objectives under a collaborative and integrated environment, while AWP provides a framework for effective planning and execution of construction projects. By incorporating LC concepts into AWP, such as the balanced production system and synchronized procurement, equipment, and deliveries, AWP can benefit from increased performance and productivity. The bidirectional learning between AWP and Lean could also enable achieving a competitive level for Industrialized Construction, where people, process, technology, and culture are critical factors to consider. Therefore, it is necessary to evaluate the possibilities of implementing the identified synergies and promoting case studies that allow quantifying the promised benefits of AWP.

There is a clear opportunity to evaluate the interaction between LC and AWP methodologies, as there is already evidence on record where the linkage with the LPS® (Hood et al., 2021). A potential avenue for future research involves exploring the application of AWP to other project types. The literature proposes utilizing AWP for modular construction due to the high number of disciplines involved within a limited space. Thus, although AWP is essential, further research is needed to deepen its application in other areas. Furthermore, it is crucial to emphasize that bidirectional learning between AWP and Lean could enable achieving a competitive level for Industrialized Construction by taking into account critical factors such as people, process, technology, and culture.

HANDOFFS BETWEEN TAKT TRAIN WAGONS: A SYSTEMATIC LITERATURE REVIEW

Mikal Andreassen[1] and Frode Drevland[2]

ABSTRACT

Recent years have seen increased use of takt planning. With takt planning, trades are organized as wagons in a train moving through takt areas in the building. Using takt plans may result in hundreds of handoffs, where finished takt areas are passed on to the subsequent wagons in the train. How these handoffs are carried out can significantly impact a project.

This paper aims to gain an overview of the research literature on takt handoffs in construction projects. The paper identifies and analyses what has been written about handoffs in the takt literature through a structured literature review. The study identified 122 papers on takt in construction. While none of the identified papers dealt directly with handoffs, 22 had some discussion of handoff-related issues.

From the literature, the paper identifies several issues related to takt handoffs and possible solutions – most notably: 1) To ensure successful handoffs, capacity buffers and progress control may help ensure that the takt areas are completed on time. 2) Requirements for what wagons must do before handoff should be clear to avoid problems that can delay the entire train. 3) Contracts that structure payments after handoffs of fully finished areas will incentivize the wagons to finish their takt areas before the handoff. 4) A handoff protocol can be a helpful tool for structuring handoffs.

KEYWORDS

Lean construction, takt planning, handoff

INTRODUCTION

Over the past decade, takt planning has experienced increased attention – both within the lean construction community (Halttula & Seppänen, 2022) and the construction industry as a whole (Lehtovaara et al., 2021). The method has been used in several countries, such as the United States (Frandson et al., 2013), Germany (Haghsheno et al., 2016), Norway (Vatne & Drevland, 2016) and Finland (Lehtovaara, Heinonen, et al., 2020).

The term takt is probably best known in connection with music, where musical works are broken down into beats with a fixed frequency (Haghsheno et al., 2016). This principle has been transferred to the construction industry, where projects are broken down into work packages that can be carried out within a chosen time interval. Several specific approaches exist to manage projects in this way – notably Takt Time Planning (e.g. Frandson et al., 2013) and Takt Planning and Takt Control (e.g. Binninger et al., 2017). Both aim to create continuous project flow by balancing work packages so they can be carried out at a steady frequency – i.e., takt (A.

Frandson et al., 2013). This paper uses *takt planning* to refer to all takt-based planning approaches.

Building projects involve multiple trades with interconnected tasks that must be completed in a specific order. The workflow is characterized by chains of dependent tasks, which Tommelein et al. (1999) refer to as parades of trades. These occur in several areas of building projects, such as structural, technical and interior work. A parade of trades is similar to an assembly line; however, instead of the product moving through workstations, the workstations move through the product.

Takt-planning typically visualizes parades of trades as trains (Haghsheno et al., 2016). Each wagon in a train has workers, primarily from only one trade, who have fixed work tasks. When organized in the correct order and joined in a train, all tasks are represented by a wagon in the takt train. The fact that the train runs on rails illustrates the dependence between the wagons – no wagons can pass each other. Furthermore, the wagons are typically tightly coupled – i.e., there is no buffer between them. Therefore, if one wagon slows down, so will all the following wagons.

Takt planning divides a project into several parts, called takt areas or zones (Binninger et al., 2017; A. Frandson et al., 2013). The train moves through these takt areas in a specific order, so each wagon is alone in one takt area at a time. Each wagon's time in a takt area is called the takt time. Since the takt time is the same in all takt areas, the size of the areas must be adjusted so that the workload for one wagon is equal in all areas. At the end of each takt time, each wagon must hand off its takt area to the subsequent wagon.

Previous authors have used both *handoff* and *handover* to refer to a wagon completing its work in a takt area and the next wagon taking over the area. However, since the term handover is also used for handing over the final project deliverable to the owner, this paper will use the term handoff to avoid ambiguous terminology. More precisely, we define handoff as the situation where there is an interface between work operations (Lehtovaara et al., 2022), and finished work is handed off from one trade to another for further work (Biotto et al., 2017).

Takt planning has several advantages, but to achieve these, the interface between the train wagons is crucial (Frandson et al., 2015), and the handoff of work is necessary for further work to be carried out (Lehtovaara et al., 2022). In other words, good handoffs are essential to ensure that a takt plan is well executed. The tight coupling between the wagons in the takt train entails that untimely handoffs will cause severe issues for the construction process. In addition, handing off unfinished takt areas also causes issues. For example, handoffs of unfinished takt areas can increase the number of production delays (Dahlberg & Drevland, 2021).

While the literature acknowledges the importance of takt handoffs, no authors have published any works focused on the handoff of takt areas between takt wagons. The past decade has seen published over a hundred papers about takt in construction – encompassing many vital aspects of takt planning – but none dedicated to handoffs. To aid future research in this field, this study identifies and analyses literature on handoffs between takt train wagons in construction through a systematic literature review. This study was carried out as part of a larger Design Science Research based study on ensuring good handoffs when using takt in construction projects.

METHODOLOGY

We conducted a systematic literature review based on the methods described in Snyder (2019). The study relied on two databases to identify literature; Scopus and IGLC.net. Scopus is one of the world's largest databases for peer-reviewed literature and contains literature from the most prominent journals in many disciplines, including construction. Most peer-reviewed literature on takt can be found here – including most papers published through the IGLC. However, Scopus can be a year or two behind the IGLC conferences and what has been published on IGLC.net. Therefore, we conducted a supplemental search in the IGLC.net database.

Figure 1 illustrates the flow for identifying, screening, and including papers. Given that takt is a rather specific term and that the total body of literature on takt in construction is limited, we were able to start with broad search terms. First, in Scopus, we used the search string "TITLE-ABS-KEY (takt AND construction)" to identify all the works in the database related to takt in construction, yielding 106 papers. Then, with the IGLC.net database, we searched for "takt" and found a total of 84 papers; 68 were duplicates of the ones already identified in Scopus, leaving us with 122 papers.

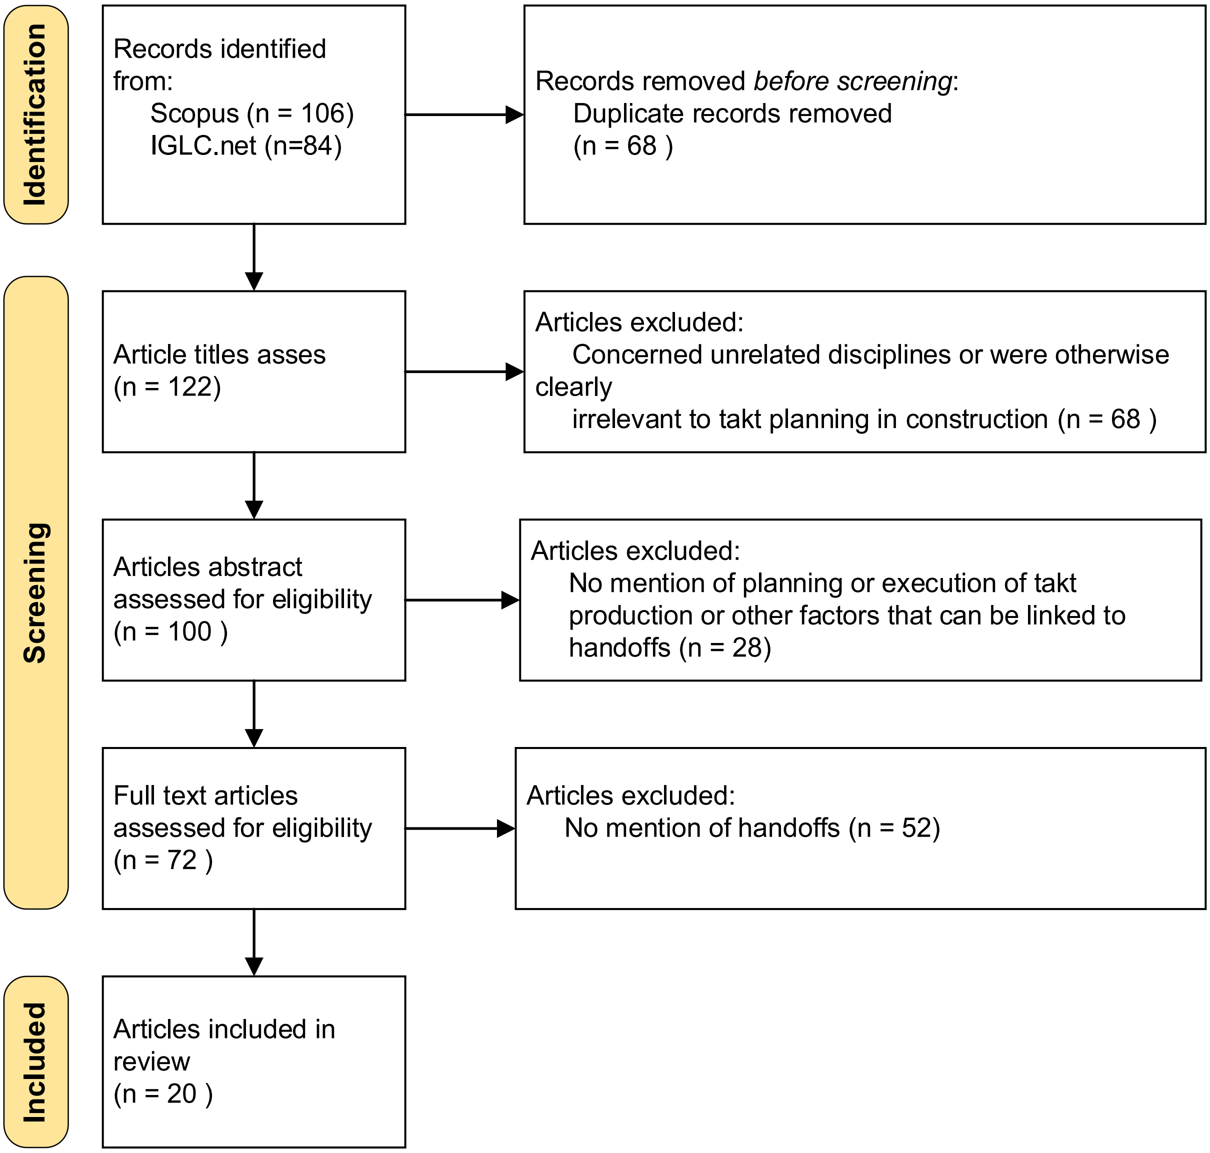

Figure 1: Literature review flowchart (based on Page et al., 2021)

In a systematic literature review, there must be clear selection criteria for the process to be transparent and accountable (Snyder, 2019). We carried out the selection process in three steps. In the first step, we reviewed the titles and excluded 22 papers that concerned unrelated disciplines or were otherwise clearly irrelevant to takt planning in construction. After that, in the second step, we reviewed the abstracts of the 100 remaining papers. Here we excluded papers whose abstracts did not mention planning or execution of takt production or other factors that can be linked to handoffs. In the third and final step, we read the full text of the remaining 72 papers and selected papers to include. Reading the full text was done to ensure we would catch all information related to handoffs. In the end, we found 20 papers that had content related to handoffs in takt.

The review relied on thematic coding analysis – per the guidelines of Robson & McCartan (2016) – to analyze the identified papers, using the computer tool *NVivo* (n.d.) to code the findings. All the selected articles were loaded into NVivo and read carefully. The codes used were created along the way and adapted as the analysis revealed new aspects of handoffs.

RESULTS

This section presents the results of the literature review. We start by making some general observations regarding what exists of literature, who has written it, and how handoff in takt ties in with the Last Planner System. Following that, we review the very limited part of the literature that describes in any detail how handoffs have been carried out in actual projects. Next, we describe several problems related to handoffs described in the literature and their suggested remedies. Thereafter, we cover how takt handoffs can be used for quality assurance purposes. Finally, we summarise the main findings from the literature review in a tabular format.

GENERAL OBSERVATIONS

What literature exists on takt handoffs?

Of the articles identified, none specifically were on handoff between takt wagons. Instead, most considered various aspects related to the planning and execution of takt plans; However, some considered planning methods in building and construction in general.

Who has written about handoffs in takt?

While conducting an extensive bibliographic analysis is outside the scope of this paper, we made some overarching observations regarding who has written anything about takt handoffs. Although there are many different contributors from around the world to the general field of takt, the papers we identified regarding handoffs cluster primarily around three international communities: The American – affiliated with Berkley (Frandson et al., 2013, 2014; Frandson et al., 2015; Frandson & Tommelein, 2016; Linnik et al., 2013; Salem et al., 2018; Tommelein & Emdanat, 2022), the Finnish – affiliated with Aalto University (Keskiniva et al., 2021, 2022; Kujansuu et al., 2020; Lehtovaara et al., 2021, 2022; Lehtovaara, Seppänen, et al., 2020) and the Norwegian affiliated with NTNU (Dahlberg & Drevland, 2021; Gardarsson et al., 2019; Haugen et al., 2020). Interestingly, while the German community behind the Takt Planning and Takt Control approach has been prolific in producing papers on takt, none of their publications directly concerned the handoff of takt areas.

LPS as the foundation of reliable and predictable handoffs

Several authors point to reliable and predictable handoffs as principles derived from the Last Planner® System (LPS) (Haugen et al., 2020; Kalsaas et al., 2014; Lehtovaara et al., 2022; Salem et al., 2018; Tommelein & Emdanat, 2022). In the context of LPS, takt planning will be a method used to stabilize production and make work events more predictable (Kujansuu et al., 2020; Lehtovaara et al., 2021; Linnik et al., 2013).

HOW ARE HANDOFFS CARRIED OUT?

Among the literature, few authors mentioned actual procedures used for handoffs in projects. Kujansuu et al. (2020) investigated a project that used weekly takt. The project contributors were satisfied and thought this fit well with their familiar weekly routines. They could use the last day to complete the takt area and carry out inspections and handoffs. One contractor in (Lehtovaara et al. (2021)'s study also preferred the use of weekly takt starting Mondays with handoffs on Fridays. Apart from these studies, only Haugen et al. (2020) mentioned any procedure used for handoff in real projects. However, the procedure was used to study the implementation of takt plans. To collect data, a handoff protocol was used. To ensure untampered data, the protocol was made jointly between the wagon that finished and the wagon that was to take over a takt area. In the protocol, they had to note – among other things – whether the wagon had tidied the area, whether they had completed the area 100%, whether they had had to do rework in the previous takt areas, and whether they had carried out the work within regular working hours. If the area was tidied and 100% complete, it was called a perfect handoff, and the next wagon should thus be able to work independently of the previous one.

WHY DO PROBLEMS ARISE WITH HANDOFFS?

While the literature contained limited information about how projects concretely carry out handoffs, we found significantly more information about problems related to handoffs. Several prominent issues emerged from the literature review. Lehtovaara et al. (2022) highlight work not completed on time, not fully completed, of poor quality, in an illogical production sequence, or lacking the prerequisites to be completed. Yaw et al. (2020) also point out that multiple handoffs provide more chances of problems with the handoff. The interviewees of Dahlberg and Drevland (2021) voiced that delays in deliveries of materials, equipment and other necessary assumptions are the most common reason why work was not completed on time, thus resulting in takt areas not being handed off. Work not being finished for handoff was a common thread across several articles.

Takt areas not completed in time for handoff

For takt planning to be useful, all train wagons must finish their work before the time set for handoff (Frandson et al., 2015). If a wagon is delayed with its work and does not hand off the takt area on time, this will immediately affect the following wagon (Lehtovaara et al., 2022). Takt planning, therefore, uses capacity buffers to help ensure that takt areas can be handed off on time (Frandson et al., 2015).

A wagon in a takt train should only utilize 70-80% of its available working capacity (Lehtovaara et al., 2021). This way, workload variability can be managed, and delays avoided. In theory, the work should, on average, take less time than the takt time. This extra time is not wasted but can be used. For example, to prepare the takt area for handoff, assist unfinished takt areas, correct previous work, work in buffer areas outside the takt plan, quality assurance, or innovation and work on continuous improvement (Frandson et al., 2015; Lehtovaara et al., 2021, 2022). Lehtovaara et al. (2021) saw a correlation with good production control among the projects that managed to utilize this additional capacity.

The investigations of Kujansuu et al. (2020) indicate that production becomes more stable when efforts are made in the handoffs between the wagons. Lehtovaara et al. (2022) and Frandson et al. (2014) support the claim that clear handoffs in takt provide a more transparent and stable production. To achieve this stability, and ensure that the areas are ready for handoff in time, Lehtovaara et al. (2022) point to the importance of production control – including meetings, measurements and visual aids that will indicate whether the wagons are on schedule or not.

According to Frandson et al. (2015), controlling progress at shorter intervals than the takt time is crucial to determine as early as possible whether the handoffs will occur as planned. In practice, projects can do this through short daily meetings called “daily huddles”, which aim to coordinate the wagons and uncover any problems so that all of them will complete their work on time for handoff (Frandson et al., 2013; Lehtovaara , et al., 2020). With longer takt times, such as weekly takt, some also use weekly meetings for production control (Dahlberg & Drevland, 2021). These meetings should be held halfway through the takt time so that any delays are detected when there is still time to take measures to make the handoff happen on time. If it is impossible to catch up with the delay in the same week, the project can use a more invasive measure; to stop the takt train. Doing so prevents unfinished takt areas from being handed off; however, it also delays the train's later wagons by the same time the train remains stopped. This delay will not be possible to catch up without making significant changes to the timetable.

Dahlberg and Drevland (2021) found that wagons handing off unfinished takt areas can lead to even more delays later in the takt train. The reason for this is the irrational way wagons must work to circumvent the unfinished previous work, and the lack of sound conditions to carry out their work. It also results in wagons having to return to previously completed areas to correct the non-completed work. All of this can contribute to what they call a parade of delays. Salem et al. (2018) saw a similar effect. They observed that work that was not 100% finished but handed off to the next wagon created costly additional work. The shortcomings could be anything from the workspace not being cleaned to leaving larger tasks behind. According to Linnik et al. (2013), the work in a takt area is only complete when it is ready for handoff for the next wagon. Therefore, it needs to be clear what it takes for a takt area to be considered complete.

Different perceptions of what finished takt areas mean

According to Salem et al. (2018), some people consider their work "done" when they have done enough to allow them to continue in the next workspace. In other words, this does not include the work a wagon must do for subsequent wagons to work unhindered. Furthermore, it does not include tidying up or other work they must complete before they wholly finish an area. This thinking illustrates the difference between being "done" and "done-done."

Salem et al. (2018) found several causes of not being "done-done". In one of the case projects they refer to, no individuals were held responsible for post-work clean-up, and there were no processes to ensure that the areas were tidied after the work was completed. Frandson et al. (2013) point out that the handoff of takt areas actually provides such an opportunity to ensure that the previous work is completed.

According to Bølviken et al. (2015), handoffs must confirm that the work in a takt area has been completed and is of the right quality. Salem et al. (2018) argue that the quality of the work handed off must meet the standards of both the wagon that carried it out and the following wagons. A handoff is an interface between wagons – a lousy finish of one wagon's work will give a bad start for the next. The challenge is that the earlier wagons have few incentives to facilitate the later ones, as there are usually different people who perform the tasks.

Another finding made by Salem et al. (2018) was that there was a lack of a clearly defined standard for what was a finished area. In interviews conducted by Lehtovaara et al. (2021), it emerged that it should be clear which tasks, inspections, and tidying wagons must do before handing off an area to the next wagon. In their research, Haugen et al. (2020) used two requirements for handing off takt areas. These requirements were no more detailed than 1) specifying that the areas should be tidied and 2) the work should be 100% finished. Salem et al. (2018) provide several examples of work that must be completed to be "done-done": Tools, equipment, materials and temporary structures must be cleared away, defects must be corrected, and the area must be tidied. Linnik et al. (2013) argue that the takt plan should specify all the activities that must be done before the handoff.

Lack of incentive to finish

Keskiniva et al. (2022) investigated how contracts between main contractors and subcontractors could be adapted to takt production. One finding was that the subcontractors were incentivized not to finish in the takt areas before handoff because of how their work was compensated. Salem et al. (2018) support this finding, arguing that the traditional way of paying the subcontractors does not consider that the work will be handed off.

Traditionally, renumerating subcontractors have been based on measurements of the amount of work performed (Salem et al., 2018). There are several ways to measure the amount of work done, but no matter which one is used, the subcontractors will make an extra effort to improve the metrics on which they are measured. Doing so comes at the expense of what is not measured – for example, quality or whether the area handed off is 100% finished. According to Keskiniva et al.(2022), such measurement and compensation schemes encourage subcontractors to leave small tasks unfinished in the work areas rather than finishing up in full before moving on

An alternative approach is to divide payments based on milestones, as proposed by Keskiniva et al. (2022). Under this method, subcontractors receive a percentage of the contract amount upon reaching predetermined milestones, encouraging them to complete work quickly and providing easy progress monitoring. Frandson et al. (2013) highlight the benefit of takt planning in measuring progress in smaller and more precise segments, and Keskiniva et al. (2022) recommend linking payments to completed work packages corresponding to takt areas to incentivize and motivate subcontractors to finish their work on time.

More handoffs lead to more problems

Yaw et al. (2020) proposed minimizing the number of handoffs as a strategy to improve handoffs – based on the reasoning that fewer handoffs lead to less time spent waiting and transferring work areas. Supporting this, in a study of six projects, Lehtovaara et al. (2021) found that the takt plans implemented with smaller batch sizes, and thus more handoffs, required more follow-up and effort from managers. They mention the organization of handoffs as a notable reason for the increased need for management. This notion could be related to the observation that small batch sizes gave less time to carry out the takt area handoffs.

Small batch sizes in takt planning have advantages such as shorter construction time (Lehtovaara et al., 2021) and lower cycle time for control of progress (Dahlberg & Drevland, 2021; Frandson et al., 2013). Yaw et al. (2020) argue that a conflict arises between the desire for smaller batch sizes and the benefits of reducing the number of handoffs. Furthermore, they say that the large number of handoffs in construction projects is due to tradespeople being so specialized that they can perform only certain tasks. A recommendation for reducing the number of handoffs is thus to make use of interdisciplinary work teams so that all trades can finish in the work areas without having to visit them several times.

HANDOFFS AS A QUALITY ASSURANCE TOOL

Several authors point out that if the handoff of takt areas is carried out in a good way, then this provides an excellent opportunity to regularly quality assure the work that has been done (Frandson et al., 2013; Haugen et al., 2020; Kalsaas et al., 2014; Lehtovaara et al., 2021; Tommelein & Emdanat, 2022). In the same way that the numerous and regular handoffs in takt planning provide immediate feedback on progress, projects can also use handoffs for quality assurance (Frandson et al., 2013). Lehhtovaara et al. (2020) point out that errors can be corrected immediately among the advantages of using handoffs for quality assurance. The need to return to previous takt areas for rework – disrupting the work of others – disappears. Instant feedback about errors also makes those who cause an error aware of it. Thus, they avoid making the same mistake several times. Over time, they make fewer errors, yielding improved quality. Quality assurance in the handoffs can thus prevent subsequent cars from continuing to work in areas with errors (Tommelein & Emdanat, 2022).

SUMMARY OF FINDINGS

Table summarises the main findings presented and discussed previously in the results.

Table 1: Summary of findings

Findings	Source
Handoffs provide an opportunity to regularly verify progress and ensure quality	Bølviken et al. (2015), Frandson et al. (2013), Haugen et al. (2020), Kalsaas et al. (2014), Lehtovaara et al. (2020), Lehtovaara et al. (2021), Tommelein & Emdanat (2022)
Activities and completion criteria for wagons should be planned and clearly defined	Frandson & Tommelein (2016), Lehtovaara et al. (2021), Linnik et al. (2013), Salem et al. (2018)
Better handoffs contribute to stabilize production	Frandson et al. (2014), Kujansuu et al. (2020), Lehtovaara et al. (2022)
A Monday-to-Friday weekly takt with handoffs on Fridays aligns with workers' familiar weekly routines	Gardarsson et al. (2019), Lehtovaara et al. (2021)
The use of a handoff protocol can facilitate the process of handoffs	Haugen et al. (2020)
Problems with handoffs include work not completed on time, not fully completed, of poor quality, in an illogical production sequence, or lacking the prerequisites to be completed	Dahlberg & Drevland (2021), Lehtovaara et al. (2022)
Handoffs of unfinished work lead to more delays and costly additional work	Dahlberg & Drevland (2021), Salem et al. (2018)
Capacity buffers are utilized to ensure that work is completed on time for handoff	Frandson et al. (2015), Lehtovaara et al. (2021), Lehtovaara et al. (2022)
Production control monitor progress in intervals shorter than the takt time to ensure timely handoffs	Dahlberg & Drevland (2021), Frandson et al. (2013), Frandson et al. (2015), Keskiniva et al. (2022), Lehtovaara et al. (2020), Lehtovaara et al. (2022)
Payment of subcontractors should be linked to takt areas to incentivize the completion of work	Frandson et al. (2013), Keskiniva et al. (2022), Salem et al. (2018)
Smaller batch sizes have advantages, but also increase the number of handoffs, which increase the likelihood of problems occurring	Dahlberg & Drevland (2021), Frandson et al. (2013), Lehtovaara et al. (2021), Yaw et al. (2020)

DISCUSSION AND CONCLUSIONS

The purpose of this paper was to conduct a structured literature review of the literature on the use of takt planning in production to identify what has been written about handoffs between takt wagons. None of the articles identified directly concerned takt handoffs, but several papers had some material concerning handoffs. However, from the analyzed articles, the literature review identified several factors for enabling and supporting good handoffs.

One of the key aspects of ensuring good handoff between the wagons is to ensure that the takt areas are completed in time for the handoff. If a takt area is not completed, it will immediately affect the rest of the takt train. Measures that help ensure that takt areas are completed on time can be using capacity buffers and production control – in the form of meetings that follow up progress.

Setting precise requirements for what should be done before handoff can also help ensure a good handoff. People will have different notions of what lies in the term done and, thus, what they must do before the handoff. The consequences of such a vague understanding of the term can be grave. For example, if a wagon hands off an unfinished takt area, it can affect the conditions that later wagons have for carrying out their tasks, leading to delays. Therefore, what a wagon must do before handoff should be clarified and clearly communicated.

Another finding was that the contracts with the subcontractors might provide incentives not to complete the takt areas. To ensure good handoffs – and that all wagons are entirely done in the takt areas – it may be necessary to adapt contracts specifically to takt production. By basing the payments on the handoff of finished takt areas, contractors will be incentivized to hand off takt areas that are "done-done" – i.e., 100% finished.

The literature review uncovered little regarding actual handoff procedures used in projects. Only one study contained detailed information about how handoffs were handled, employing a handoff protocol. Nevertheless, we would argue that such a handoff protocol can contribute to sound handoff. For example, in a handoff protocol, a takt wagon can record that it has carried out its work as described and that the area is tidy and ready for the next wagon. This way, a structure is created for how handoffs are carried out.

Summarizing the above leads us to four main recommendations for takt handoffs:

- Ensure that takt areas are completed on time through the use of capacity buffers and production control
- Set precise requirements for what should be done by a wagon before handoff
- Use contracts adopted for takt construction
- Consider a handoff protocol to structure the handoff procedure.

Concerning further work, it is evident from the literature review that there is a need to study takt handoffs on construction projects in more detail – how are they carried out, and how can we best enable them? Additionally, it may be worthwhile to investigate the impact of takt handoffs on project performance, such as productivity, quality, and safety. Moreover, future studies could investigate the role of technology in facilitating takt handoffs and improving their effectiveness.

As mentioned in the introduction, this literature review is the first step of a more extensive Design Science Research based study on ensuring good handoffs when using takt in construction projects. Presently, we are investigating the practices of a major Norwegian contractor – aiming to develop better tools and guidelines for them to ensure good handoffs.

LEAN HEALTH CHECK FRAMEWORK

Parastoo Eivazi Ziaei[1], Diana Salhab[2], Ritu Ahuja[3], and Farook Hamzeh[4]

ABSTRACT

Lean construction is an approach that prioritizes enhancing quality and value while minimizing waste. Lean management comprises of principles and concepts that must be observed to effectively implement Lean management and leverage its benefits. In line with Lean concepts and principles, appropriate behavior and culture must be properly implemented to achieve successful Lean management, hence necessitating the use of an established health check assessment to evaluate the level of Lean maturity. This study aims to introduce a health check assessment to ascertain the level of maturity of Lean behavior and culture in the construction industry. The health check assessment was formulated by identifying Lean success factors, which were further validated by Lean experts. The methodology employed to achieve the study objectives follows a Design Science Research (DSR) approach, which involves creating a health check framework and evaluating it through an expert panel interview among project parties in a real case study project. In addition to the Lean expert panel interview, other performance metrics, such as percent planned complete (PPC) and constraint information, were collected. The proposed framework was validated, and the results indicate that there may be a correlation between effective team communication and project performance.

KEYWORDS

Lean construction, Lean maturity level, framework, Lean health check.

INTRODUCTION

Planning plays an essential role in construction projects. It tackles uncertainties in a project and improves the efficiency of processes while providing a better understanding of project objectives (Chan et al. 2004). However, the construction industry faces several challenges in conducting reliable planning, scheduling, and budgeting, which leads to additional uncertainties and inefficiencies. To address these challenges, modern project management has been developed over the past forty years (Kerzner, 2017), including Lean project management, which focuses on delivering high-quality products while minimizing waste and maximizing value and quality (Ballard & Howell, 2003). The delivery process of Lean management is characterized with clearer objectives where the product and process can be designed simultaneously, and the production control applies entirely during a project's life cycle (Howell, 1999). This is achieved within an environment of strong communication which is a fundamental aspect of Lean philosophy. Put simply, in the construction context, planning, project management, and communication are closely related and interconnected. Effective planning lays the foundation

for successful project management, and clear communication is essential for both planning and project management to be successful.

The decision-making process in construction projects is influenced by communication between team members; thus, miscommunication and involved parties' behaviours throughout the process might lead to creating more new tasks (Hamzeh & Aridi, 2013). Put differently, since construction teams are multidisciplinary and temporary, having effective communication to exchange information and collaborate to reach the same goal is crucial. In addition to communication and collaboration, there are some other Lean success factors like transparency, safety, and waste minimization (Bayhan et al., 2019). As can be seen, some critical factors should be considered in Lean implementation to achieve the highest potential. Therefore, this research aims to provide a Lean health check framework to understand the Lean maturity level on a project. The framework consists of first identifying Lean success factors through extensive literature review, which are then validated by an expert panel and used to develop an expert panel interview. The interview is designed and distributed among the participants of a real project and the results are analyzed along with some last planner system (LPS) metrics. Finally, team performance is analyzed, and lessons learned are collected.

LITERATURE REVIEW

THE NEED FOR LEAN CONSTRUCTION

According to PMI's "*A guide to the Project Management Body of Knowledge*," project management is the application of knowledge, skills, tools, and techniques to project activities to meet project requirements. Project planning is essential for controlling project success as it provides the project parties with detailed information about execution dates and resources (Zwikael, 2009). Project management is accomplished through the appropriate application of five process groups, which are: initiating, planning, executing, monitoring and controlling, and closing. Managing a project goes further to include the management of integration, scope, time, cost, quality, human resources, communications, risks, and procurement (PMI 1996; Ballard, 2000).

In the 19th century, Bar and Gantt charts were used for planning and scheduling industrial and construction projects. Afterwards, the Critical Path Method (CPM) was established as a more developed version of the Gantt chart for production management, and it has been widely used since the late 1950's (Henrich & Koskela, 2006). CPM relies on creating construction schedules by breaking the project down into activities and assigning them to task leaders. The traditional project management methods work by delivering project objectives on the activity level through a transformational approach, and while disregarding flow and value generation. Therefore, when activities fall behind their schedule, specific measures must be taken to reduce the cost and duration of delays (Howell, 1999; Diekmann & Thrush, 1986). As a result of shortcomings in traditional project management methods, Ballard and Howell (1998) stated that there is a need to develop a new management system for making sound decisions when it comes to productivity and project progress.

Another reason for introducing a new management system was to reduce variability. A poor management system leads to unexpected conditions and renders objectives unstable and unachievable (Ballard, 2000; Thomas et al., 2002). Unstable conditions are mainly due to variability in performance; so, it is vital to have a new management system that could decrease such variability. Consequently, Lean construction was introduced as a production system that tackles variability and waste. Lean concepts originated in the manufacturing industry. According to Lean manufacturing principles, construction workflow variables are imped system performance (Howell, & Ballard, 1994; Tommelein, 1998).

Lean philosophy began with the Toyota Production System (TPS), and it was developed by Taiichi Ohno. TPS' main concepts include customer value identification, waste reduction by eliminating non-value-adding activities, creating a continuous flow, and seeking continuous improvement (Koskela, 1992; Howell, 1999). Additionally, Lean production focuses on managing a process through achieving value efficiency and providing helpful tools and methodologies for appropriate planning (Faniran et al., 1997).

LPS technique is an essential application of the Lean production system, which helps to control planning, and minimize uncertainties and complexities by involving subcontractors and lower-level management in the planning and control process (Hamzeh et al., 2019; Viana et al., 2017). Moreover, the LPS production planning and control system increases workflow reliability on construction projects (Ballard & Howell, 1998). Several metrics have been developed as part of LPS environment, and among these metrics, Percent Planned Completed (PPC) is the most common. PPC measures the reliability of weekly work planning and tracks the performance of reliable promising. It is calculated by dividing the number of planned activities completed at the end of a short period over the total number of activities promised to be completed at the beginning of that period.

LEAN CONSTRUCTION AND IMPLEMENTATION

Koskela and Ballard (2012) examined that developing new ways of thinking and integrating elements of production management and project management into a comprehensive system for construction is essential for the effective delivery of projects through Lean. Certainly, the transformation towards Lean construction will lead to changes in the culture and its people (Green et al., 2008), at both the temporary organization (project) and the management level (Ballard and Howell, 1998).

According to Hamouda et al. (2014), Lean behaviour is defined as a behaviour that adds or creates value, and this behaviour will impact Lean management. The authors also mentioned that behaviour change is the key factor to improve performance. Implementing sustainable Lean concept is required to change the culture by focusing on Lean behaviour. The authors examined that collecting and documenting the critical success factors of Lean implementation will help to change the culture and create more focus on Lean behaviour.

Bayhan et al. 2019 stated that there should be a clear strategy to implement the Lean culture effectively and enhance its potential. A clear strategy will also help decrease the waste in the system which is one of the main Lean principles. Therefore, the authors introduced a list of enablers and barriers to Lean implementation. In addition, other researchers introduced Lean success factors and barriers (Tayeh et al., 2018; Netland 2016; Salem et al., 2015). Thus, this research aims to implement a Lean health check framework as a clear strategy according to the Lean success factors which have been collected through the literature review and Lean experts' knowledge.

LEAN IMPLEMENTATION SUCCESS FACTORS

Many researchers addressed the critical success factors of Lean construction. For instance, Demirkesen and Bayhan (2020) proposed a success model for implementing Lean philosophy in the construction industry. The model uses Delphi method to administer data collected from a questionnaire conducted with eight experienced civil engineers. It targets identifying seven categories of success criteria and uses an analytical network process to reveal links between the success attributes. The study found that Lean training, availability of Lean tools and techniques, and market share were the most important success factors for Lean implementation.

In another study, Li et al. (2020) proposed a method for assessing the lean construction management performance (LCMP) using the analytic network process-fuzzy comprehensive evaluation (ANP-FCE) model. The LCMP evaluation index system was achieved through literature review and questionnaire surveys. The ANP and Super Decisions software were used to calculate the weights of the indices and the FCE was adopted to carry out a comprehensive evaluation of LCMP. The proposed method can help decision makers identify the strengths and weaknesses of LC management of the evaluated project.

Watfa and Sawalha (2021) identified critical factors necessary for successful implementation of Lean Construction and developed a conceptual framework for adopting it. The authors conducted a literature review and a survey of local construction companies to identify 13 Critical Success Factors (CSFs) categorized into four main constructs: Managerial, Organizational, Structural, and External Factors. The study proposes a preliminary roadmap to guide construction companies in adopting Lean techniques.

Another study by Shaqour (2022) focused on the challenges faced by the construction sector and suggested that the adoption of lean construction approaches can help in reducing waste and enhancing performance. Data was collected from 162 construction professionals, and the study found that the adoption of lean tools positively affects time, cost, quality, safety, environment, and relationships. However, the study also found that while construction professionals apply lean tools in construction sites, their knowledge level of lean concepts is less than the adoption level.

METHODOLOGY

According to Van Aken (2004), scientific disciplines can be classified into formal sciences, explanatory sciences, and design sciences depending on the mode of producing scientific knowledge. In design sciences, knowledge is created through the implementation of a solution that is able to employ or alter a particular occurrence (Vaishnavi and Kuechler, 2007). Therefore, according to Alsehaimi et al. (2012), design science (or constructive research) can assist in developing and implementing innovative managerial tools and tackling different managerial construction problems. Therefore, this approach seems to be appropriate for conducting research in construction management. March and Smith (1995) state that the design science research (DSR) process has two fundamental parts: creating artifacts that can address real-world issues and evaluating their performance in use.

According to Hevner (2007), DSR contains three primary cycles, which are:

1. The relevance cycle: it involves the development of an artifact to resolve a relevant problem identified in a specific environment.
2. The design cycle: it facilitates iterations in the design and assessment of the artifact until a satisfying product is obtained.
3. The rigour cycle: it uses existing past knowledge, skills, and artifacts in the application area to ensure innovation beyond the known.

This research implements the DSR methodology to develop a framework for LPS and social health checks. Three main stages of the research approach are shown in Figure 1, which are: the need for a framework, framework development, and testing of the framework.

Figure 1: Research Methodology Steps

DEVELOPING THE FRAMEWORK

According to the literature review, it was found that there is a need to develop a framework to assess the Lean maturity level of a project. After realizing the need for such a framework, literature review has been conducted to collect the Lean success factors which have been further validated by Lean experts. The collected factors are then used to design questions and create an interview to be run on a real project. The Lean expert panel interview will help to understand the Lean implementation level of the project.

In addition to the interview results, some performance metrics are needed to compare the interview results and Lean project performance. Lean project performance indicators like PPC and constraint information can be used as data-driven decision-making approach to understand the team performance, identify their strengths and weakness, and summarize lessons learned from the project. Since project performance and Lean implementation are time-related, the above-mentioned steps should be done every month to have a clear idea about the strengths and weaknesses. Figure 2 illustrates the health check framework and the steps in detail.

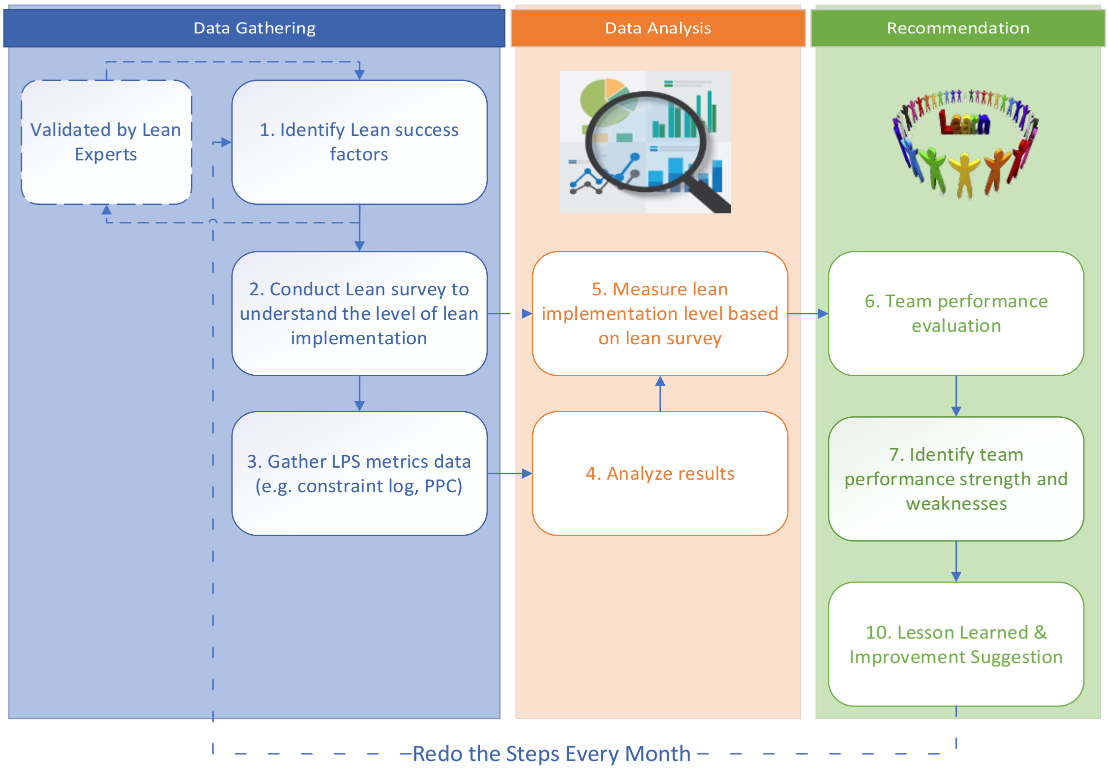

Figure 2: Lean Health Check Framework

DESIGNING THE INTERVIEW

The Lean expert panel interview has been designed to understand the level of Lean implementation in projects based on the Lean success factors collected through literature review (Bayhan et al., 2019; Castillo et al. 2018; Kallassy and Hamzeh 2021; Power et al. 2021; Simmons et al. 2020; Zheng et al. 2020). At first stage, around 90 factors have been collected, which were then reduced based on the research goal pertaining to focusing on the effect of communication on Lean maturity level. The process of reducing the factors and designing the questions has been validated by the Lean experts and finalized as shown in Table 1. After finalizing the factors and questions, the Lean expert panel interview is conducted to understand the Lean implementation level. Table 1 summarizes the factors and questions which have been finalized by Lean experts and project managers and implemented on real projects.

Table 1: Lean Success Factors and Interview Questions

Categories	Interview Questions to Rate Each Factors
Respect for people	"Communication is formalized and communicated when required. "
Teamwork	"The company is flexible in communicating with trades during the execution phase and whenever needed without waiting for RFI." "The company trusts the word given by the trade partners and provides an opportunity to the trade partners for decision making."
Communication & Collaboration	"There is a knowledge-sharing culture in the company." "The company creates the handover structure and schedule of deliverables." "The company cooperates with trades to build trust and commitments
Transparency	"The information on which tasks will be performed during the week is transparent and available to the trades."
Safety	"The company prompts employees about safety in the workplace every day during the daily huddles."
Problem Solving-Learning	"The company is using problem-solving techniques to determine the reasons for variance are identified and discussed during the weekly trades meetings."
Consistency and Standardization	" The company standardizes the best practices and defines certain rules for the trades."
Waste minimization/consciousness	"Handoff quality is good, and no need to rework." Work activities and tasks are planned in such a way to minimize the DOWNTIME."
Innovation	"There is continuous support from the top management."
Continuous improvement–Quality	" The company continually reports the project status and updates the progress." " The company has meetings to discuss lessons learned in the middle of the project." "There is an ongoing effort to teach the Lean concepts and further specialization."
LPS	"The information on which tasks will be performed during the week is transparent and available to all workers of the construction." " The company provides the information regarding what task should be done, when, and by whom. " The company keeps a record of the lessons learned on-site for future projects." "There is a systematic update of the master plan when it is necessary." "Trades are involved in constraint identification and providing solutions."

TABLE TESTING THE FRAMEWORK

The proposed Lean health check framework and dashboard have been tested in one real project as a case study. The case study is a school rehabilitation project in Vancouver, Canada. The project was selected because the Lean management system and the last planner system were used for production planning and control. This case study aims to examine Lean maturity and behaviour and find the gap to improve the weakness. To do so, first, the Lean expert panel interview has been conducted to understand the level of Lean implementation in the project. Second, the performance indicators like PPC and constraint information have been collected from the software that the company was using as their planning software. After collecting all the information, the dashboard has been created to have a current project performance and Lean maturity indicators. The proposed framework suggests that the process should be repetitive every month to understand the process improvement, however, we were able to collect the data to complete the process only one time because of time and data collection limitation.

RESULTS AND DISCUSSION

The interview was conducted on the LimeSurvey platform and was accessible for one month to collect the results. Each respondent was asked to rate the Lean success factors between 1 (low) and 5 (high). After getting all the answers, the average of the results was used to check the Lean maturity level for the project and the result was finalized by designing a radar chart, which can be seen in Figure 3. Figure 3 shows the categories of the success factors with the answers' averages. The interview results in Figure 3 show that communication and collaboration are the lowest and transparency and LPS are the highest among other factors.

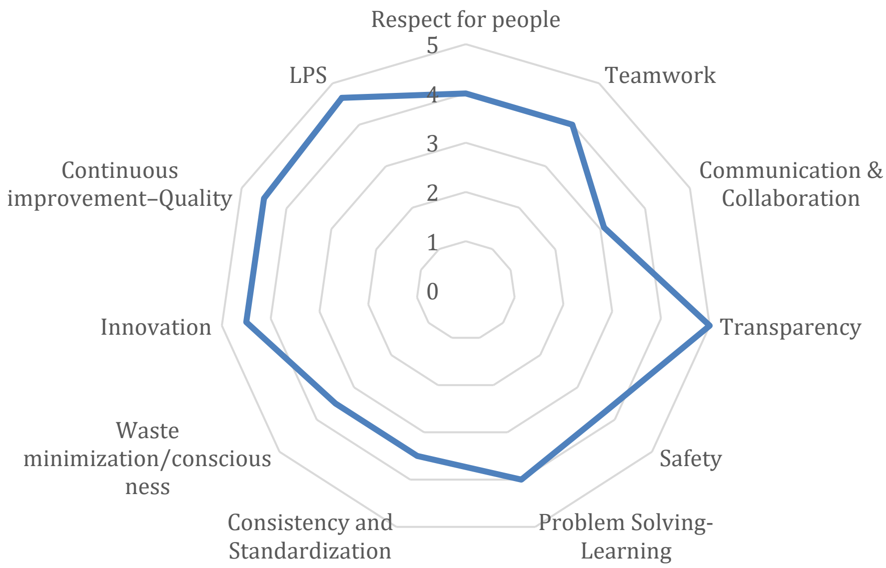

Figure 3: Lean Maturity Level

In addition to interview results, LPS-related metrics like PPC and constraint information were collected from the software used by the company to compare the actual results to parties' opinions. The average PPC was 65% during the study, which is shown in Figure 4. The PPC result shows that the company was struggling to complete the planned tasks and as a result, the PPC rate was not high enough. At the same time, the interview results show that the company has a high LPS implementation rate, and the actual LPS-related metrics show through the questionnaires that there is optimism around LPS implementation.

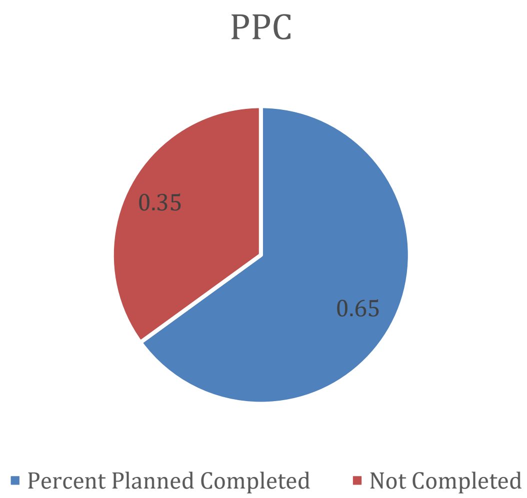

Figure 4: Actual Percent Plan Completed

In addition, the constraint log information has been collected to uncover the reasons for having lower PPC. The constraint information log shows that 135 constraints had to be removed to execute specific tasks, and among the 135 constraints, only 25 were removed on time and 21 were removed ahead of time. During the study period, 40 constraints had not been removed yet, and they were behind in removing 46 constraints. The behind tasks were divided into two sections which are behind by more than 50 days and behind by less than 50 days. The results show that 22 tasks were behind by more than 50 days. Figure 5shows the results in more detail.

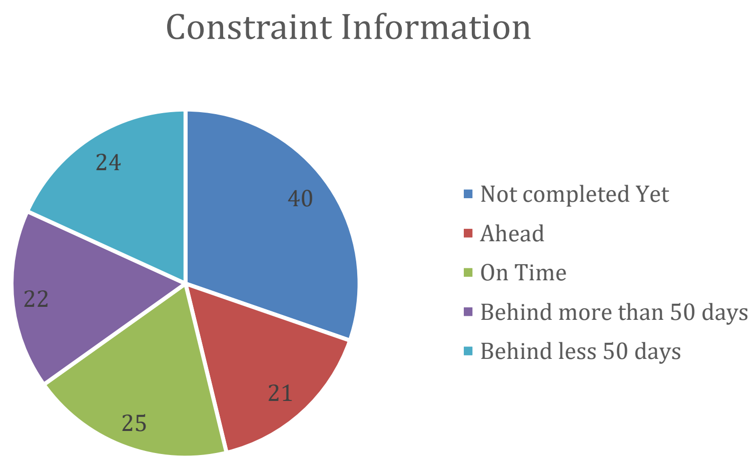

Figure 5: Constraint Log Information

PERFORMANCE DASHBOARD

After collecting all the required information, a dashboard was created to have a clear understanding of the current project's performance. It contains visualized Lean expert panel interview results, actual PPC, goal, and constraint logs. On the top of the dashboard, the user will see the interview results and the middle of the dashboard shows the average and the standard deviation of the interview results which help in visualizing the variability. At the bottom of the dashboard, the user will see all the LPS metrics information that has been collected from the planning software, which can be seen in Figure 6.

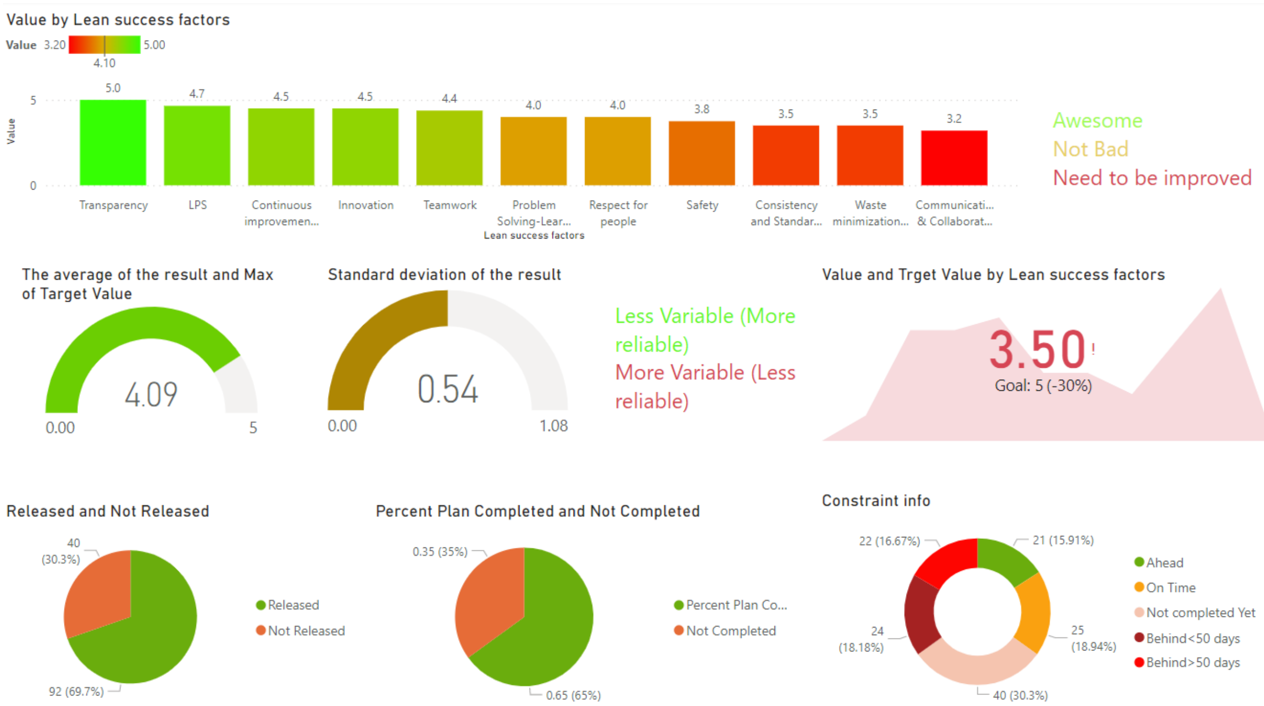

Figure 6: Performance Dashboard

The dashboard for the project adopted as a case study is generated. As can be seen in Figure 6, the interview results show that the company has a high rate of transparency and a low rate of communication and collaboration. In addition to the interview results and LPS-related metrics, the dashboard shows that the company is 30% behind its goal. Therefore, the framework and the dashboard will help reveal the weaknesses and strengths and find room for improvement of Lean implementation.

CONCLUSION

Lean project management is part of modern project management because it focuses on increasing quality and value while decreasing waste. Even though Lean is widely used worldwide, it is still new to many construction professionals, and partial implementation of Lean and LPS will limit its potential. Implementing Lean not only improves production control, but also helps build relationships among construction teams and strengthen social networks; accomplishing an effective Lean environment requires effective communication to collaborate and exchange information. Therefore, increasing the level of communication and collaboration will help individuals and companies implement a more mature Lean system in their projects. Accordingly, this research introduces a Lean health check framework to understand the level of Lean implementation on a project and it also helps to find room for improvements.

The proposed framework has been tested on a real project and the interview results show that the team was optimistic about how they are implementing LPS; however, the data shows that they are struggling with constraint identification and removal, which can directly affect LPS proper implementation (Perez & Ghosh, 2018; Hamzeh et al., 2015; Hamzeh, Zankoul, & Rouhana, 2015; Ballard, 2000). The interview results also show that the level of communication and collaboration is low and needs to be improved. According to Alarcón and Calderón (2003), the communication-transparency factor is one of the main factors that can directly impact PPC results. Thus, more involvement and training would be valuable to increase the Lean maturity level. The authors also noticed that PPC is higher on projects with a collaborative approach. Therefore, by considering the mixed method approach, which is a combination of interview results and data-driven decision-making, there could be a relationship between LPS implementation and the parties' interaction. As a result, there is a need to study such relationship in future research. In addition, some limitations of this study should be addressed in future research such as testing the framework on multiple projects and considering additional factors like project nature and complexity.

ANALYSING THE IMPACT OF CONSTRUCTION FLOW ON PRODUCTIVITY

Asitha Rathnayake[1], Danny Murguia[2], and Campbell Middleton[3]

ABSTRACT

Construction is one of the least productive industries. A significant reason for this is not viewing the construction process as a combination of flows, i.e. continuous streams of workers, materials or equipment. This paper aims to improve our understanding of construction flow by demonstrating how it can be quantified and how its impacts on productivity can be measured. We discuss two main types of flow: 1) process/location flow, representing the flow of activities performed at a single location and 2) operations/trade flow, representing the activities performed by a single trade through different locations. Based on the literature, we develop a set of metrics for each type of flow. Then, we measure their influence on productivity by using data from four buildings' superstructure work packages. The process flow is compared with the productivity of individual locations, and the operations flow is compared with the productivity of separate crews. The results show that the excess work-in-progress time between successive crews and the mean and variability of production rates for different crews at each location (process flow metrics) can explain 72% of the variation in location productivity. Similarly, the level of work discontinuity (operations flow metric) can explain 52% of the variation in trade productivity. We believe this paper presents convincing evidence of the importance of construction flow in improving productivity.

KEYWORDS

Flow, productivity, work in progress/process (WIP), variability, resource continuity

INTRODUCTION

Productivity, defined as the ratio of output to input, is an indicator of efficiency. The construction industry is globally known for being one of the least productive sectors (Barbosa et al., 2017). This is reflected in the UK's construction industry, which has only shown a 1% improvement in productivity (measured as the gross value added per hour worked) on average from 1997 to 2021. In contrast, the manufacturing sector and the whole economy have improved by 182% and 29%, respectively, in the same period (ONS, 2023). Productivity is a means to an end and not an end in itself. Low productivity indicates low performance in other areas, such as cost overruns, schedule delays and high carbon emissions. Therefore, identifying the underlying reasons for low productivity can help address a number of performance issues affecting the construction industry.

Koskela (1992) argued that traditional managerial methods, such as critical path models, often overlook non-value-adding activities leading to low productivity in construction. The

author suggested viewing construction as a flow of material and/or information from raw material to the end product. Flow can be defined as a continuous stream of something (Kalsaas & Bølviken, 2010). The lean literature discusses different types of flow, including workflow, worker flow, material flow, equipment flow, trade flow, assembly flow, operations flow, process flow, product flow, information flow and portfolio flow (Tommelein et al., 2022). Some of these flows are incorporated into lean managerial practices.

Despite the efforts of the lean construction community to popularise the concept of flow, a recent survey conducted among construction practitioners from the US, China, Brazil and Finland found that nearly half of the respondents relied only on traditional Critical Path Method-based systems for project management (Olivieri et al., 2019). This shows that the construction industry is yet to fully embrace the concept of flow. There have been efforts to define (Sacks, 2016) and quantify (Sacks et al., 2017) the impact of different types of flow on project performance. However, the impact of flow on project performance has not been adequately measured, highlighting a research gap that needs to be addressed. This paper aims to fill this gap by providing quantitative evidence of how different aspects of construction flow affect performance. We use productivity as an indicator of overall performance.

CONSTRUCTION FLOW

MAIN TYPES OF CONSTRUCTION FLOW

Modern ideas about construction flow derive from the concepts of production flow in manufacturing. More specifically, they can be traced back to the Toyota Production System, which is a system of increasing production efficiency by eliminating waste. It was developed by the Japanese automobile manufacturer Toyota during the mid-20th century (Ohno, 1988). As part of this system, Shingo and Dillon (1989) defined production as a combination of processes and operations. In other words, there are two types of flow in a manufacturing process: 1) process flow which represents the flow of material in time and space, transforming from raw materials to the finished product and 2) operations flow which represents interaction and flow of equipment and operators in time and space, to accomplish the transformation. This distinction is necessary because operation improvements made without considering the process can lead to overall inefficiencies (Shingo & Dillon, 1989).

The concepts of process and operation need to be re-evaluated in the context of construction. Unlike in manufacturing, the construction product is stationary, and the workstations (workers or equipment) move from location to location (Bertelsen et al., 2007). Hence, construction can be introduced as a combination of two types of flow: 1) process/location flow, which represents the flow of activities performed at a single location and 2) operations/trade flow, which represents the activities performed by a single trade through different locations (Sacks, 2016; Tommelein et al., 2022). Simply put, operations flow concerns how individual construction activities can be done faster, whereas process flow concerns how different activities can be sequenced better to improve overall speed. For the rest of the paper, we focus on these two types of flow.

FEATURES OF A GOOD CONSTRUCTION FLOW

According to Koskela (1992), the purpose of visualising construction as a flow is to reduce non-value-adding activities such as moving, waiting and inspecting. In this section, we examine a few concepts that can be used to achieve this, derived mainly from the field of manufacturing.

Optimum Batch Size

In manufacturing, batch size (more specifically, the transfer batch size) is the number of products accumulated at a workstation before being transferred to the next station (Hopp & Spearman). According to Little's law (Hopp & Spearman, 2011; Little & Graves, 2008), as the number of products accumulated at all the workstations in a steady-state production system is gradually increased, two observations are made: 1) the time spent by a product stays constant until a certain point and starts increasing and 2) the rate of output of the entire process increases until the same point and stays constant. If all the workstations produce the same output per unit of time, this optimal point is achieved when the total number of products is equal to the number of machines, i.e. batch size equals one (Hopp & Spearman, 2011).

In construction, having too many products in the process equates to having too many unfinished locations. Following the manufacturing argument, if all the crews in a project generated the same output per unit of time, it would be good to have the number of unfinished locations in the process to be equal to the number of crews, leading to a batch size of one for each crew. However, the steady-state assumption is usually invalid for construction as the production rates of different crews change over time and production durations are limited by project size (Walsh et al., 2007). Hence, more variables are needed to define a good construction flow for real-world conditions. We define a few such variables in the following two subsections.

Less Variability

Variability is the quality of non-uniformity of a class of entities (Hopp & Spearman, 2011). The ideal scenario of a batch size of one introduced in the previous subsection is an average value, as Little’s law deals with averages. Real-world systems almost always have variability (Hopp & Spearman, 2011; Little & Graves, 2008). We can explain the importance of this for construction as follows. In a project, the work done by one crew, e.g. slab formwork, usually feeds another crew, e.g. slab reinforcement. If one crew has high variability, their production rate may be fast one time and slow another time. When they are fast, they will go through the entire location and end up idle until the upstream crew can release the following location. When they are slow, the crew will hold up a location making the downstream crew idle. Both these scenarios lead to a loss of productivity. This is true even when each crew produces the same average output per unit of time, and each crew has a batch size of one. According to the previous subsection, for projects obeying Little’s law, these two conditions should lead to optimum productivity. However, in real projects, variability can have a detrimental effect on productivity.

Hopp & Spearman (2011) discussed two types of variability: 1) variability which occurs at individual workstations and 2) variability which occurs between the transfer of jobs or parts from one station to another. These two correspond to the operations flow and process flow we defined earlier. Variability is quantified as the coefficient of variation, i.e. the ratio of standard deviation to mean, of the operation time (time per location) or arrival rate (locations per unit time). Less variability is an indication of a good construction flow.

Less Excess Work-in-progress Time

In manufacturing, work-in-progress is the total inventory between the start and end of a process (Hopp & Spearman, 2011). Unlike the ideal scenario of a batch size of one introduced earlier, real-world systems may have larger batch sizes (leading to higher work-in-progress) to reduce setup times, as buffers or due to other reasons. Buffers can include inventory, time and capacity allowances to account for the variability discussed earlier (Hopp & Spearman, 2011). In construction, additional or standby resources have to be allocated to address risks. We define excess work-in-progress time as the time corresponding to the additional inventory between two crews that could have been avoided. According to the manufacturing principles introduced above, less excess work-in-progress time is an indication of a good construction flow.

Low Level of Work Discontinuity

Planning for continuous resource use helps maximise productivity and is one of the primary objectives of location-based scheduling (Kenley & Seppänen, 2010). Here, resources include workers and equipment. Perfect continuity is achieved if a particular location starts just after finishing the preceding location with no break. However, in reality, discontinuities occur between successive levels. Besides the apparent loss of productivity due to not working, discontinuous work also increases schedule risk as the crews may not return to work or crew compositions may change (Seppänen & Kankainen, 2004). We identify that resource/work continuity corresponds to a good operations flow.

METHODOLOGY

The aim of this investigation is to identify how construction flow affects the overall productivity of a project and demonstrate how these results can be used to interpret and improve productivity. The research methodology consists of three steps: 1) defining the parameters, 2) collecting project data and 3) analysing the data.

DEFINING THE PARAMETERS

Productivity Metrics

The literature presents various productivity metrics that extend beyond the conventional labour productivity measure. For a thorough and comprehensive summary of these metrics, readers are encouraged to refer to Rathnayake and Middleton (2023). In this study, our focus centres on evaluating the efficiency of the entire crew rather than individual labourers. Hence, we used production rate, i.e. the ratio of output to time, as the indicator of productivity.

Two metrics, overall location production rate and overall trade production rate, are used as the dependent variables of process flow and operations flow metrics, respectively. We define them in Tables 1 and 2. Both metrics use the unit of square metres of floor area per day. For process flow, locations with different floor areas need to be compared. The reciprocal of the production rate is the time taken to complete 1 m^2 of floor area, which is a relative measure. Hence, no adjustment is needed to allow comparison. For operations flow, different activities need to be compared. Using the common output of floor area allows this.

Process Flow Metrics

Table 1 presents the process flow metrics we used in our analysis. They are based on the features of a good construction flow mentioned earlier. All the metrics are scaled to allow comparison among different locations and between projects. Both process and operations flow metrics use floor area instead of time for scaling, as floor area is the constant defining factor of a location or a building, whereas time can vary. Figure 1 visually represents the metrics of a hypothetical project in a flowline chart. A flowline chart is the most common tool to visualise the flow of work through locations. Each activity is represented by a line where the X-axis corresponds to time and the Y-axis corresponds to locations. The process flow advances through time at each location. Blue, green and red lines represent activities 1, 2 and 3 performed by crews 1, 2 and 3, respectively.

The average batch size of a location is calculated as follows (see Figure 1). Consider activity 1 (in blue), which takes nine days to be completed in location 1 ($t_{1,1}$). For the first five days of this period, only location 1 has unfinished work. For the next four days, both locations 1 and 2 have unfinished work. This gives an average of (1*5 + 2*4)/9 = 1.44 unfinished locations during this period. Similarly, the time taken to complete activity 2 at location 1 ($t_{1,2}$) is 16, and the average number of locations with unfinished work during this period is 1.75. $t_{1,3}$ is 1, and the average number of locations with unfinished work is 1. If this is considered a factory, each location corresponds to a product, and each crew corresponds to a workstation. $t_{1,1}$ is the time spent by location 1 being worked on by crew 1. The average number of unfinished locations of crew 1 during that period is the batch size of crew 1 in the process. Similarly, crews 2 and 3 have their own batch sizes. The average batch size of the entire construction process at location 1 is the weighted average of these different batch sizes with respect to time which is then scaled to the floor area, i.e. $((1.44*t_{1,1} + 1.75*t_{1,2} + 1*t_{1,3})/ t_{1,all})/a_1 = ((1.44*9 + 1.75*16 + 1*1)/25)/a_1 = 1.68/a_1$.

The hands-off duration between two consecutive activities is normally defined by the takt-time in the production system design (Frandson et al., 2014). Since the projects under consideration did not formally implement takt-time planning or similar methods, it is difficult to determine the excess work-in-progress times (i.e. durations beyond the takt-time). As an alternative, we assumed that the lowest work-in-progress time maintained by a location with respect to its area is the minimum required time for that building. The rest of the locations are analysed relative to the lowest time (with respect to its area) for the building, i.e. $(w/a)_{min}$.

Table 1: Process/Location Flow Metrics

Metric	Definition	Calculation (See Figure 1)	Unit of Measurement
Average batch size	The ratio of the weighted average batch size of crews at a location to the floor area. Batch size is the average number of unfinished locations worked on by a crew between the start and end dates of a location	Explained above	$1/m^2$
Variability of location production rates	Coefficient of variation of all crew production rates in one location	(Standard deviation of $a_1/t_{1,1}$, $a_1/t_{1,2}$, $a_1/t_{1,3}$)/ (Mean of $a_1/t_{1,1}$, $a_1/t_{1,2}$, $a_1/t_{1,3}$)	Unitless
Excess work-in-progress time	The ratio of the total time between the start of each successive activity and the floor area of a location minus the lowest value for the entire building	$(w_{1,12} + w_{1,23})/a_1 - (w/a)_{min}$	$days/m^2$
Mean location production rate	Mean of all crew production rates in one location	Mean of $a_1/t_{1,1}$, $a_1/t_{1,2}$, $a_1/t_{1,3}$	m^2/day
Overall location production rate (dependent variable)	The ratio of the floor area to the total duration of a location	$a_1/t_{1,all}$	m^2/day

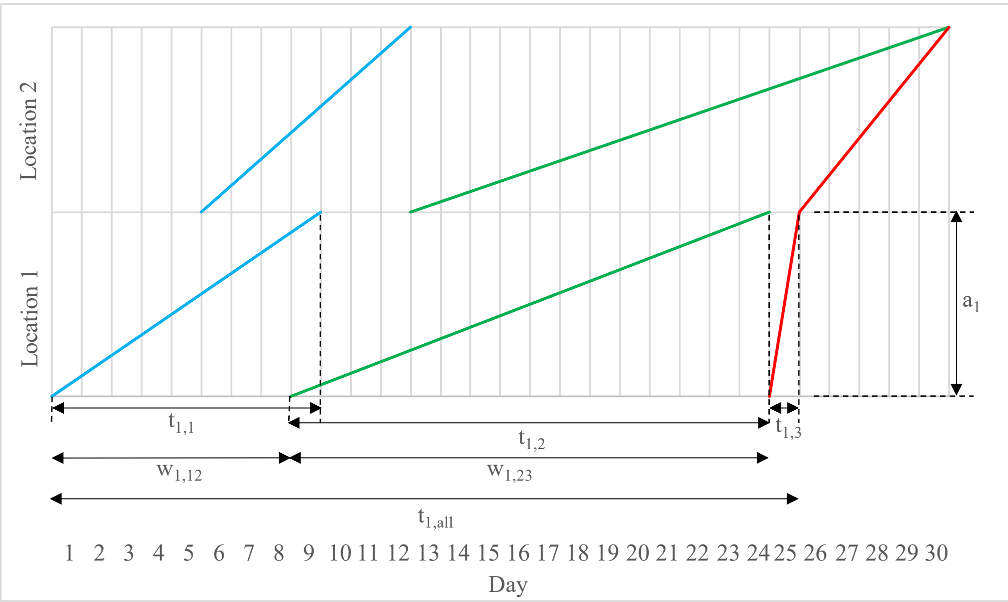

Figure 1: Calculating Process Flow Metrics

a_1 = floor area of location 1
$t_{1,all}$ = time taken to complete location 1
$t_{1,1}$, $t_{1,2}$, $t_{1,3}$ = time taken to complete activities 1, 2 and 3 at location 1
$w_{1,12}$, $w_{1,23}$ = time corresponding to work-in-progress between activities 1, 2 and 2, 3 at location 1

Operations Flow Metrics

Table 2 presents the operations flow metrics we used in our analysis. Figure 2 visually represents the metrics of a hypothetical project in a flowline chart. The four blue lines represent an activity performed by a crew in four locations. The operations flow advances diagonally along flowlines as the trade moves through each location.

Table 2: Operations/Trade Flow Metrics

Metric	Definition	Calculation (See Figure 2)	Unit of Measurement
Level of work discontinuity	The ratio of total time spent by a crew without working in between locations to the total floor area of the building	$(d_{12,1} + d_{23,1} + d_{34,1})/ (a_1 + a_2 + a_3 + a_4)$	days/m^2
Variability of trade production rates	Coefficient of variation of one crew's production rates in all the locations	(Standard deviation of $a_1/t_{1,1}$, $a_2/t_{2,1}$, $a_3/t_{3,1}$, $a_4/t_{4,1}$)/ (Mean of $a_1/t_{1,1}$, $a_2/t_{2,1}$, $a_3/t_{3,1}$, $a_4/t_{4,1}$)	Unitless
Mean trade production rate	Mean of all location production rates by one crew	Mean of $a_1/t_{1,1}$, $a_2/t_{2,1}$, $a_3/t_{3,1}$, $a_4/t_{4,1}$	m^2/day
Overall trade production rate (dependent variable)	The ratio of the total floor area of all the locations to the total duration taken by a crew to complete them	$(a_1 + a_2 + a_3 + a_4)/ t_{all,1}$	m^2/day

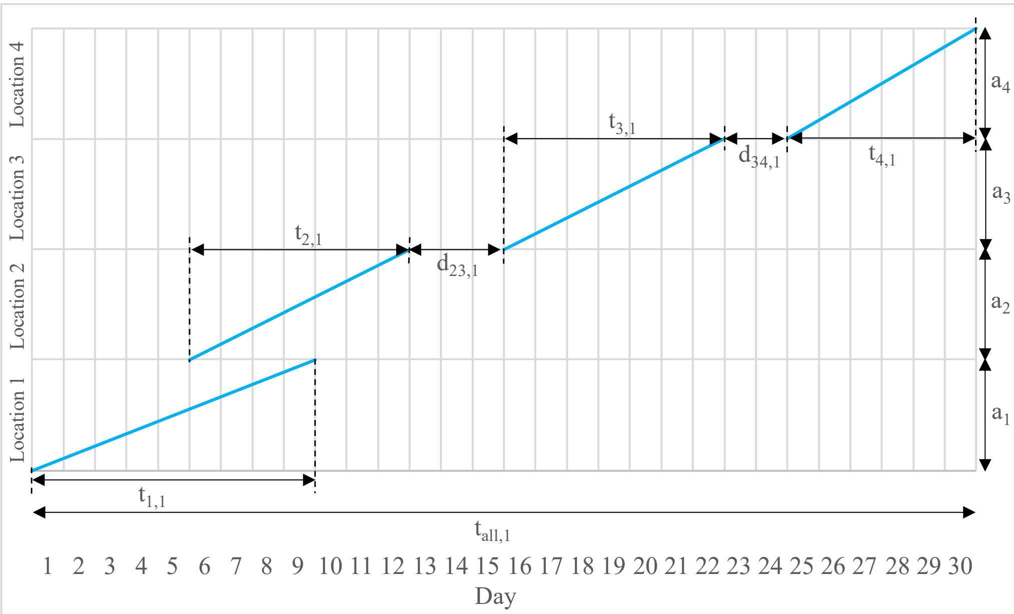

Figure 2: Calculating Operations Flow Metrics

a_1, a_2, a_3, a_4 = floor areas of locations 1, 2, 3 and 4
$t_{all,1}$ = total time between the start and end dates of crew 1 in the four locations
$t_{1,1}$, $t_{2,1}$, $t_{3,1}$, $t_{4,1}$ = time taken to complete locations 1, 2, 3 and 4 by crew 1

$d_{12,1}$, $d_{23,1}$, $d_{34,1}$ = discontinuities between locations 1,2; 2,3 and 3,4 for crew 1

Note that $d_{12,1}$ is 0 because work commenced at location 2 before finishing at location 1.

COLLECTING PROJECT DATA

We used installation and labour data from the superstructure construction of four buildings in London. Buildings A and B are eight-story buildings with steel frames and in situ concrete slabs. Their total gross internal areas are about 10,400 m^2 and 5,700 m^2, respectively. Building C is an eleven-story building with a traditional reinforced concrete structure. Its total gross internal area is about 14,200 m^2. Building D is a fourteen-story building with precast columns and lattice slabs. Its total gross internal area is about 19,000 m^2. A, B and C are commercial buildings, whereas D is residential. The first level of buildings A, B and D were not considered because they used different structural systems with separate activities and crew arrangements. Levels 10 and 11 in Building C and 12-14 in Building D were not included due to data unavailability.

We used three data sources: 1) records of site cameras, 2) installation records by subcontractors and 3) discussions with site personnel. We did not use the master plans updated by planners due to their low accuracy. This is because progress was updated about once a week and had many inconsistencies compared to site camera records and other sources.

ANALYSING THE DATA

Unlike in manufacturing, where a product is a discrete entity, in construction, a location can be defined to have any size. The projects used in this research did not use location-based scheduling. Hence, there were no predefined location breakdown structures. However, each level in a building had a general sequence of slab concrete pours, and the crews usually worked in that sequence. Therefore, a location was defined as the building area corresponding to a major slab pour. Accordingly, process and operations flow metrics were calculated, and IBM SPSS 28 was used to conduct correlation and regression analyses between the variables defined earlier.

RESULTS

There were 86 locations and 19 crews across the four buildings. Figure 3 presents their flowline charts. Buildings A and B belong to the same project, and the subcontractor used a single steel fixer crew for both buildings. The time spent by the crew in the other building is shaded. It corresponds to Portfolio flow as defined in Sacks (2016), which represents the workflow from project to project (in our case, from building to building). The flowlines in Buildings C and D are arranged closer together and seem to have relatively smooth flows with fewer breaks. Conversely, Building B has the worst flow quality, with flowlines spaced apart.

CORRELATION ANALYSIS

Tables 3 and 4 present the results of the linear correlation analysis of process and operations flow metrics. The four flowline charts show that slab concreting usually takes only a day in each location. This is an outlier when analysing process flow metrics. Hence, it was not included in the calculations for the mean and variability of location production rates. Note that adjustments were also made for holidays and weekend working hours.

REGRESSION ANALYSIS

Multiple linear regression of the process flow metrics yields Equation 1 for the overall location production rate. This model has an R^2 value of 0.72. Similarly, the multiple linear regression of the operations flow metrics yields Equation 2 for the overall trade production rate. This model has an R^2 value of 0.52. The variance inflation factor of each independent variable was much less than 5, indicating a low multicollinearity level.

$$\text{Overall Location Production Rate} = $$
$$- 224.96 \text{*Excess WIP time} - 8.41 \text{*Variability of Location Production Rates}$$

+ 0.10*Mean Location Production Rate + 26.15 Equation 1

Overall Trade Production Rate = - 3756.20*Proportion of Breaks + 117.09 Equation 2

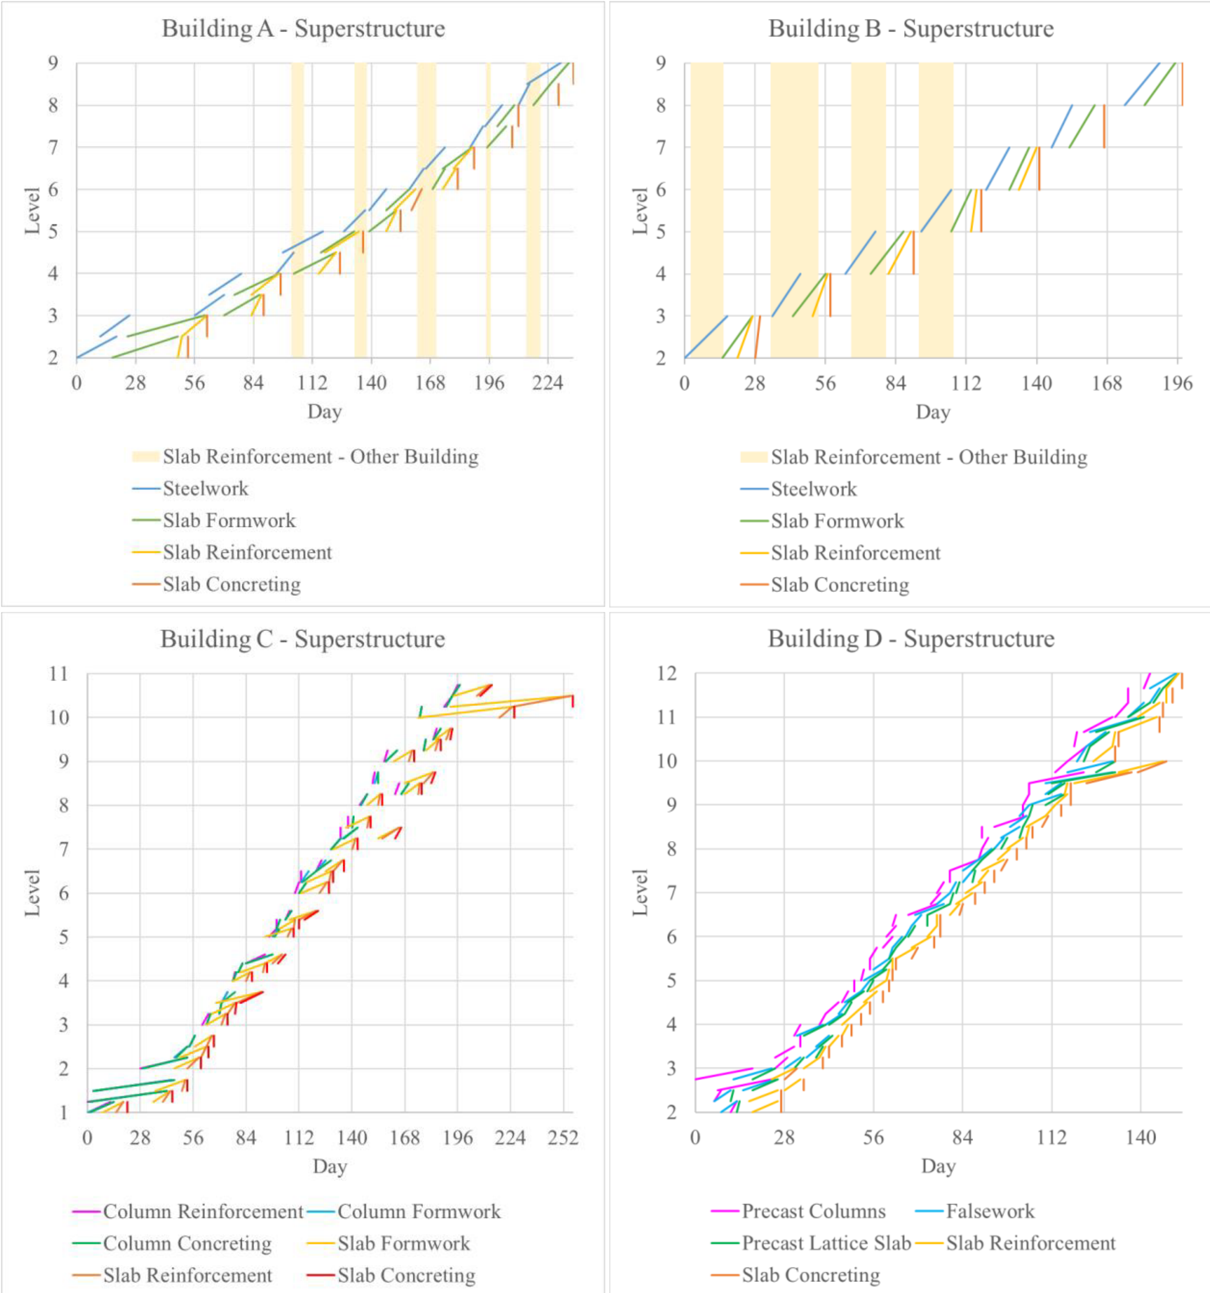

Figure 3: Flowline Charts of Building A, B, C and D Superstructure

Table 3: Correlation Results of Location Productivity with Process Flow Metrics ($p<0.01$)

Metric	Pearson Correlation Coefficient (r)	Coefficient of Determination (R^2)	Correlation Category
Excess work-in-progress time	-0.75	0.57	Strong negative
Mean location production rate	0.59	0.34	Moderate positive
Average batch size	-0.49	0.24	Moderate negative
Variability of location production rates	-0.35	0.12	Weak negative

Table 4: Correlation Results of Trade Productivity with Operations Flow Metrics ($p<0.01$)

Metric	Pearson Correlation Coefficient (r)	Coefficient of Determination (R^2)	Correlation Category
Level of work discontinuity	-0.72	0.52	Strong negative
Mean trade production rate	Not significant	-	
Variability of trade production rates	Not significant	-	

EXPLANATION OF RESULTS

Tables 5 and 6 explain the results of metrics with a relatively high degree of correlation. The regression results are explained for two hypothetical cases: a 300 m^2 location with 5 crews for process flow and a 10,000 m^2 building with 20 locations for operations flow. The average batch size is not considered as it does not appear in the regression equation, even though it has a significant linear correlation with location productivity. This might be because it does not bring additional significant information to the model. It has a moderate linear correlation of 0.56 ($p<0.01$) with the excess work-in-progress time showing similar effects on location productivity.

Table 5: Explanation of Process Flow Results

Metric	Correlation Analysis	Regression Analysis (for a 300 m^2 location with 5 crews)
Excess work-in-progress time	If the gaps between the start dates of successive activities at a location are reduced, there is a strong chance that the location's production rate will be increased.	If each of the five crews can start one day early, the overall location production rate will increase by about 4 m^2/day.
Mean location production rate	If the mean production rate of each crew at a location is increased, there is a moderate chance that the location's production rate will be increased.	If each crew can improve their production rate by 1 m^2/day, the overall location production rate will increase by about 0.1 m^2/day.

Table 6: Explanation of the Operations Flow Results

Metric	Correlation Analysis	Regression Analysis (for a 10,000 m^2 building with 20 locations)
Level of work discontinuity	If a crew can reduce the non-working period between different locations, there is a strong chance that the crew's production rate will be increased.	If a crew starts each of the 20 locations one day earlier, the overall trade production rate will increase by about 7 m^2/day.

FACTORS THAT AFFECT CONSTRUCTION FLOW

We identified several aspects of construction flow that can be improved to increase overall productivity. The question now is what factors affect construction flow. We explored one such factor: the number of locations per floor in a building. We compared the slab reinforcement and slab concreting activities which are common to the four buildings.

Buildings B, A, C and D had an average of 1, 2, 3 and 4 locations per level. In these four buildings, the slab reinforcement crews spent approximately 77%, 61%, 34% and 14% of the total days onsite without work due to the unavailability of a location to conduct work. Similarly, the slab concreting crews spent approximately 94%, 90%, 57% and 53% of their total days without work. This shows a direct inverse relationship between the number of locations per level and the level of work discontinuity. Dividing large slabs into many smaller locations can help ensure the availability of work for the crews.

This issue also has productivity implications. Site attendance records reveal that the crews were present almost every day. Still, when work was unavailable due to the unavailability of a location, they were allocated to support tasks such as cleaning and moving materials. This results in the underutilisation of skilled workers who are paid higher salaries, which is a productivity loss. We expect to uncover similar factors affecting construction flow in the future, e.g. the effect of having offsite components.

DISCUSSION

OPTIMUM SIZE OF A LOCATION

The results show that having less excess work-in-progress time, i.e. reducing the gaps between the start dates of successive activities, significantly impacts overall productivity. As mentioned earlier, having less work-in-progress is a feature of a good construction flow. Therefore, it is understandable that it leads to better productivity. However, according to the flowline charts (Figure 3), there are many locations where activities started before ending the previous activities. The results lead us to believe that having more than one crew working simultaneously at a location can improve productivity. But previous studies show that this can lead to congestion and, ultimately, low productivity (Kenley & Seppänen, 2010). The underlying issue is that all the projects in this study used traditional scheduling methods, such as Gantt charts, based on critical path techniques instead of location-based methods. There were no predefined location breakdown structures, and the locations' sizes varied across building levels and with time. Also, the planned location sizes of the buildings were too large. The average location size of buildings A, B, C and D were 626, 655, 311 and 403 m^2, respectively. These were too large for the crews who, on average, had only 4-5 workers. With these location sizes, it is possible for two or even three teams to work in different areas of a location without leading to congestion. Hence, the correlation and regression results hold. However, the goal should be to have a higher number of small locations. Using location-based scheduling could have achieved that. Murguia et al., (2023) present a more detailed analysis of this topic.

MEAN AND VARIABILITY OF PRODUCTION RATES

According to operations flow results, ensuring continuity of work or resource use strongly improves trade productivity. However, surprisingly, the results show that trade productivity is not significantly affected by the mean or variability of crew production rates at different locations. From a flowline perspective, it means that productivity is more influenced by the gaps between the flowlines and not by their gradient or the variation of the gradient. Hence, in actual projects, there is a significant opportunity to improve project performance by better dividing/sequencing the activities than by having crews work faster or more consistently. Note that the size of the dataset limits operations flow results. We are working on collecting more data to solidify these findings.

Synchronising production rates of different crews is an important step of location-based scheduling (Kenley & Seppänen, 2010). Yet, process flow results show that variability of location production rates only has a small effect on location productivity. The results might be because trade production rates (except for slab concreting) are already reasonably synchronised in the projects (see the flowlines in Figure 3). Both these results show the benefits of using actual project data for the analysis, as opposed to planned or simulated data. Our results show the construction flow issues that real projects must address to improve performance.

OTHER FACTORS AFFECTING CONSTRUCTION PRODUCTIVITY

The two linear regression equations developed have R^2 values of 0.72 and 0.52. This means the developed metrics explain 72% and 52% of the variation in location and trade productivity. There are other factors that may not be directly linked to flow-related metrics. For example, when using flowlines, we assume that crews work continuously in a location during the period denoted by a flowline before moving on to the following location. In reality, workers may not fully utilise their time due to different reasons. Moreover, some projects in our analysis used offsite components such as precast columns and composite beams. They could have also led to differences in productivity. Rathnayake and Middleton (2023) presented a review of various such factors that affect productivity. A complete model for construction productivity should include factors that are both related and unrelated to flow. Finally, construction productivity is a combination of location and trade productivity. In the future, we will explore how much each flow type can impact overall project productivity.

CONCLUSIONS

This study aimed to identify what aspects of construction flow affect productivity and quantify this impact. There are two main types of construction flow: 1) process flow, which represents the flow of activities performed at a single location and 2) operations flow, which represents the activities performed by a single trade through different locations. Using literature, we developed a set of metrics to describe these two types of flow. Then, we used the data relating to the superstructure construction of four buildings to measure these metrics. Their impact on productivity was quantified through correlation and regression analyses. The process flow was compared with the productivity of individual locations, and the operations flow was compared with the productivity of separate crews.

Four process flow metrics, excess work-in-progress time, mean location production rate, average batch size and the variability of location production rates, were found to have strong negative, moderately positive, moderately negative and weak negative linear correlations with location productivity, respectively. The linear regression equation developed using these factors explained up to 72% of the variation in location productivity. One operations flow metric, the level of work discontinuity, was found to have a strong negative relationship with trade productivity, with the former explaining up to 52% of the variation in overall crew productivity.

We found that the sizes of the locations used by the projects were too large when compared to the crew sizes. This meant that productivity could be improved by having multiple crews working simultaneously at a location. However, for better efficiency, work should be planned in smaller locations using a technique such as location-based scheduling.

This study presents initial evidence of the potential improvements in performance achievable by focusing on construction flow. We are working on strengthening the current dataset to solidify these findings. In the future, we expect to expand these findings to cover other work packages and other aspects of flow.

ACKNOWLEDGEMENTS

We would like to thank our industry partners for entrusting us with actual construction data and their continued engagement with this research project.

THE PICO FRAMEWORK FOR ANALYSIS AND DESIGN OF PRODUCTION SYSTEMS FOR CONSTRUCTION

Li-Or Sharoni[1], Rafael Sacks[2], Timson Yeung[3], Otto Alhava[4], Enni Laine[5], and Jhonattan Martinez Ribon[6]

ABSTRACT

PICO is a framework that provides a conceptual guide for production system analysis and design in the construction industry. It has four key components: Production control mechanism, Information and communication system, Commercial terms, and Organizational structure. Each component is highly interdependent and has a set of detailed parameters and enumerated values. A comprehensive literature review, case studies, and analysis highlighted the knowledge gaps in current production system design frameworks. The PICO framework was originally devised to design a production system suited for short-takt production in residential construction, but it has been developed into a comprehensive mapping tool for the design and analysis of construction production systems in general. The paper shows an application of the framework to a takt system as a case study and an example of its application. The framework expands the current understanding of production systems in construction, offering new insights and a comprehensive approach to designing new production systems.

KEYWORDS

Production system design, production planning, and control, residential construction, Integrated Project Delivery (IPD), Transformation-Flow-Value (TFV).

INTRODUCTION

Production systems consume inputs (people's work, capital, information, equipment, materials) to produce goods and services by integrating physical and information flows constrained by capacity and other limitations (Nahmias and Cheng 2009). The Lean construction community has long advocated for greater control over operational flows in the production system to reduce waste and improve efficiency (Wandahl et al. 2021).

Current understandings of production systems in construction rely on the Transformation, Flow, Value (TFV) theory (Ballard et al. 2001; Koskela 2000) and the Lean Project Delivery (LPD) approach ("Lean Project Delivery" 2023). The TFV theory proposes that its three concepts should be integrated and balanced to optimize the production system. The theory

serves as a tool for conceptualizing production system performance, supporting efforts to identify and eliminate waste (Bølviken et al. 2014). While TFV is useful in detecting waste within the production system, it does not provide a structured framework to identify and configure production systems systematically. The LPD project management approach strives to enhance flow and diminish waste ("Lean Project Delivery" 2023) through the presentation of principles that can be implemented in various forms.

The PICO framework presented here is a tool for applying the LPD methodology through use of a set of detailed parameters based on TFV theory. The framework provides a detailed view of the existing decision variables involved in designing a production system in construction. In the current era, with various lean methods available, the PICO system offers a comprehensive approach that allows the designer of a production system to characterize the way to achieve LPD goals. The framework aims to define the interrelationships between production system components comprehensively and holistically. We first present the background and research methodology, followed by the PICO framework and a case study demonstrating the framework's application in a residential project in Finland.

BACKGROUND

The PICO framework supports the development of production systems within the construction industry while aiming to bridge the current knowledge gaps. Implementing lean construction methods marked a significant shift in the language of production within the construction industry, affording managers a fresh perspective on the production system. However, while several theoretical frameworks such as TFV and LPD were developed in this regard, they lacked the necessary level of detail and did not furnish operational tools for applying the principles (Ballard et al. 2001). Consequently, any stakeholders tasked with providing solutions to pertinent issues were left wanting information on the mutual effects and available possibilities. Furthermore, the industry's attitudes toward technology and its role in production have not changed significantly over the past two decades. This chapter thus presents the historical backdrop of the construction production system theories upon which the current production systems are built and present the knowledge gap the PICO framework aims to bridge.

HISTORICAL OVERVIEW

The history of the design of production systems in construction can be traced back to the early 20th century when the construction industry started adopting industrial production principles to increase efficiency and improve productivity. This was exemplified by the use of assembly line techniques in constructing skyscrapers in the US in the 1920s and 1930s, which allowed for the efficient and coordinated construction of large-scale buildings (Sacks and Partouche 2010; Ward and Zunz 1992). In the 1950s and 1960s, the industry embraced advanced production techniques such as prefabrication and modularization to manufacture building components off-site and reduce construction time (Hashemi 2013). In the 1970s and 1980s, construction researchers and practitioners developed formalized models and frameworks, including the influential Construction Industry Institute's (CII) "Research Team" model (Tucker 2007).

In the 1990s and 2000s, the construction industry continued to evolve, and production system design became increasingly important as global competition increased and the need for cost-effective, high-quality construction solutions became more pressing. In response to this, researchers and practitioners developed several new models and frameworks, such as the Integrated Project Delivery model (IPD)("Integrated Project Delivery: A Guide" 2007). These models emphasized the importance of collaboration, communication, and integration to achieve optimal project outcomes.

LEAN PRODUCTION SYSTEM

Lean construction production methods and systems are increasingly popular in academic and research settings due to their proven ability to enhance productivity (Howell and Ballard 1998; Thomas et al. 2002; Wong 2018). In the construction industry, production systems refer to the methods and techniques used to organize and manage the various processes involved in construction projects (Ballard and Howell 1998). Koskela (2000), offered a lean theory of production, conceptualizing it through the lens of the Transformation, Flow, and Value (TFV) views. The TFV approach highlights the importance of maximizing value, minimizing waste, and efficiently producing the product. Transformation focuses on converting inputs to outputs. Flow considers the flows of materials, resources, information, and products through space and time, and the Value pertains to methods for capturing requirements and achieving quality in the eyes of the consumer. Ballard et al. 2001 proposed a set of business objectives for project-based producers based on the TFV theory, which instructed adopters to “Align stakeholder interests” or “Reduce variability”, for example. These guidelines provide a valuable decision-making framework covering various global organization production aspects.

Subsequently, it was recognized that incorporating changes during production without considering the integration between stakeholders in the production process was a challenging task. The IPD contract method was developed to address this issue (“Integrated Project Delivery: A Guide” 2007). It is a collaborative project delivery approach that involves the owner, designer, and builder working together as a team from the early stages of a project to achieve project goals, such as reducing waste, improving quality, increasing efficiency, and maximizing value. IPD is based on a shared risk-and-reward contract that promotes collaboration and communication among team members. The primary objective of IPD is to create an integrated and efficient project delivery process that benefits all stakeholders.

Mossman (2010) introduced a model with three domains that apply to every construction project, as illustrated in Figure 1. This production system design model emphasizes the critical need to consider and align the commercial terms, operating systems and organizational structures to implement the Lean Project Delivery approach (“Lean Project Delivery,” 2023). A lean project's success depends on effectively integrating the elements of these domains.

Figure 1: Production system design in construction (Mossman et al. 2010, p.10)

The organizational domain involves the integration of the owner, designer, and contractor. The operating system refers to the implementation of production control methods and tools, such as the Last Planner System (LPS), Value Stream Mapping (VSM), and Building Information Modelling (BIM), and the commercial terms pertain to the incentives of the various stakeholders, such as the traditional Design-Bid-Build (DBB) model prevalent in the industry, Design-Build (DB), Collective Risk Management, and Profit and Loss Sharing.

These theories and frameworks present objectives and low-resolution production system design guidelines. There is no comprehensive tool that categorizes and clusters the variables of each domain to offer a holistic understanding of the interdependence of every decision made. The theories presented in the literature lack a comprehensive framework that can be practically applied to an operative production system and an understanding of the interconnectedness within the system.

RESEARCH AIM AND METHODS

The aim of this work was to devise a new conceptual framework for production system design that considers all aspects of the project, including people, methods, means, economics, motivations, and the interactions among them.

We employed a two-cycle methodology (Figure 2) following the iterative improvement principle of design science research (Hevner 2007). The first is the Explore cycle, and it comprises three iterative steps: 1) qualitative analysis of the literature and previous studies on construction production systems, 2) observing current production systems from case study projects in literature and other self-collected projects, and 3) examining the current paradigm of production system design through the findings from the first two steps. The second is the Elaborate cycle, in which we consolidate the learnings from the Explore cycle to arrive at a coherent and holistic production system design framework. The three steps within this cycle are 1) devising a list of production system design parameters, 2) validating the framework through case studies, which involved site visits, interviews with project managers and foremen, and workshops with senior management of the construction company, and 3) co-creating production system design concepts through discussions with the construction company.

In the following sections, we present our proposed conceptual framework, explaining each component in detail. Then, we apply this framework to a case study residential project in Finland to demonstrate how it can contribute to the analysis and improvement of the production system design.

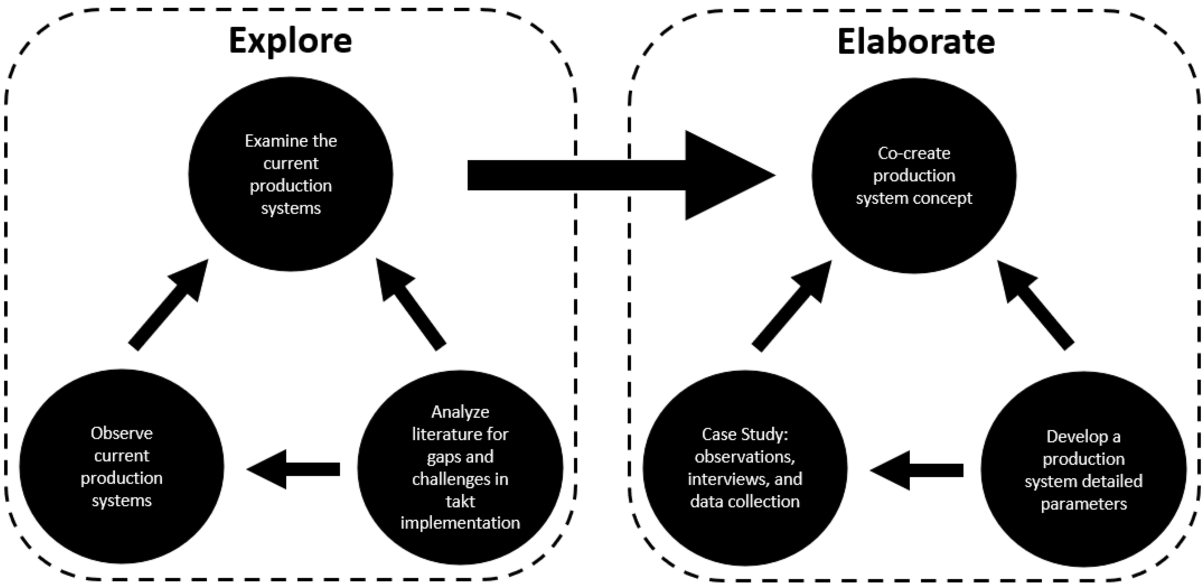

Figure 2: Research methodology (adapted from Hare et al. 2018).

A NEW CONCEPTUAL FRAMEWORK

To address construction projects' complexities and their dynamic nature, we propose a new conceptual framework for production systems that considers all aspects, including people, methods, means, economics, motivations, and their interactions. The framework, designated with the acronym 'PICO', consists of four components: (P) Production Control Mechanisms, (I) Information and Communication Systems, (C) Commercial Terms, and (O) Organizational Structures, presented in Figure 3. The full PICO framework is defined in an Excel worksheet that provides a detailed breakdown of the parameters relating to each part of the production system, descriptions and a set of possible values for each parameter. This tool serves as a map of decision variables in the design of a production system for construction. Through this approach, we can identify underlying issues and develop solutions that consider the interconnectedness of the production system. The framework considers adoption of lean principles and new monitoring technologies.

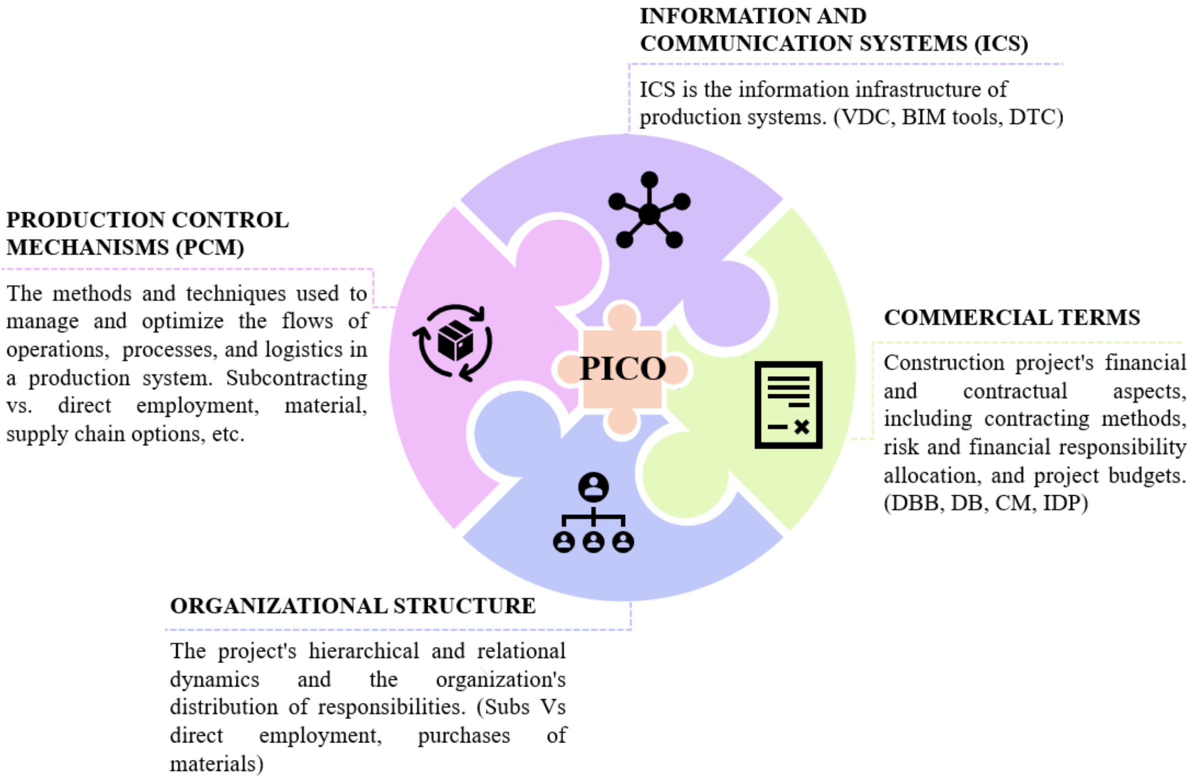

Figure 3: PICO Production System Design Framework

P - PRODUCTION CONTROL MECHANISMS (PCM)

PCM refers to the methods and techniques used to manage and optimize the flows of *operations*, *processes,* and *logistics* in a production system. PCM encompasses the 'operating system' concept defined by Mossman et al. (2010). . Among operating system tools, there are the Critical Path Method (CPM), Location-based Management Systems (LBMS), Last Planner System (LPS), Virtual Design and Construction (VDC), pull methods, Takt scheduling, and combinations of them (Kenley and Seppänen 2009; Scala et al. 2022).

Operations flow refers to the flow of production resources, such as labor and equipment, flowing through time and space (Shingo 1989 p.3).

Process flow refers to products within a building, such as apartments, classrooms, or hotel rooms, or road sections, such as bridges, lanes, or ramps. These serve as the units of production in construction and can be considered analogous to the individual products that are defined in Shingo's process-oriented definition. The policy driving process flow should seek continuous flow for those products, with zero waiting times of the products between activities, to optimize throughput, reduce cycle time and minimize Work-in-Progress (WIP) (Ballard 2001; Sacks 2016). This aspect is often neglected in traditional construction systems. Note that the units of production (products) are not the same as the locations in a location-based planning system (Kenley and Seppänen 2009), although in some cases, they may overlap.

Logistics flow refers to the movement of consumable resources, such as consumable product information (e.g., shop drawings) and raw materials, through time and space. The nature of construction sites necessitates distinguishing logistics as a flow in its own right. Good logistics flow implies managing the movement of materials so that suitable materials are delivered to the correct location at the right time in the appropriate quantity. Logistics necessitates a distinct operational approach and may involve prefabrication, pre-assembly, or fabrication on-site.

I - Information and Communication Systems (ICS)

ICS is the information infrastructure of production systems. Whereas all construction companies use basic digital tools – databases and design and detailing software, scheduling and accounting systems, and so on – many apply more sophisticated production systems, often with VDC, cloud-based information control, and site monitoring technologies. Project management tools like VICO, VisiLean, and SiteDrive are applications of these concepts used to accomplish production system goals. When designing a new production system, appropriate and effective integration of ICS is essential. Advanced ICS are indispensable for developing future production systems such as Digital Twin Construction (DTC) (Sacks et al. 2020).

C - Commercial Terms

Commercial terms refer to a construction project's financial and contractual aspects, including contracting methods, risk and financial responsibility allocation, and project budgets. The most common commercial terms in the construction industry include traditional methods such as Design-Bid-Build (DBB), Design-Build (DB), and Construction Management at Risk (CM), which differ primarily in terms of the level of risk and financial responsibility assumed by each party. Choosing the appropriate commercial terms is central to enabling the desired production system and depends on factors such as a project's size and complexity, the available resources, and the specific design and execution requirements. The commercial terms between the general contractor and trade crews who perform work, including employment conditions and compensation, as well as the purchasing and procurement of materials and assignment of risk, are pivotal in the design of the production system. They significantly impact a system's overall efficiency and effectiveness and should be carefully considered, crafted, negotiated, and agreed upon.

O - Organizational structure

The organizational structure pertains to the project's hierarchical and relational dynamics and the organization's distribution of responsibilities. For instance, the General Contractor (GC) may employ the project manager, foremen, subcontractors, or workers directly or as independent subcontractors, while the logistics and material supply management may be delegated to the GC or subcontractors. The organizational structure serves to clarify the roles and responsibilities of everyone involved in the project.

Overview

Table 1 provides a partial view of the PICO framework breakdown of its aspects and their parameters (the complete framework is available online - (Sharoni et al. 2023)The framework supports comprehensive planning for, and examination of, any project's production system components and interdependencies. The first two columns in Table 1 display the system aspects and their parameters. The third column provides the parameter values for a case study, which will be detailed in the next section.

Every decision made during the design of a new production system must consider the interdependence of its components and the tools available for its development. For instance, when setting a contract with subcontractors, the parameters must include factors such as the expected work rate, responsibility for delivery of materials to the site, procurement of materials, work performed on and off-site, budget, schedules, methods of communication, and human resources management. The contract should also address the type of payment, payments for changes during work, etc.

Table 1: Applying part of the PICO framework to a case study project. The complete framework is available online (Sharoni et al. 2023)

Aspects	Parameters	Case Study Example: Weekly Takt Residential Project
	P - Production Control Mechanisms (PCM)	
Work Packaging	Location Decomposition Work Breakdown Structure Product Decomposition Scheduling Buffer Policy	Floor and building Trade specialization Floor and building One hour
Production planning and control methods	Look ahead planning/ constraint filtering Short-term work planning	CPM; Last planner system - workable backlog CPM; Last planner system - WWP, PPC
Product changes	Coordinating Documenting	Daily meetings, WhatsApp, and E-mails Self-report to a digital platform (Sitedrive)
	I – Information and Communication Systems	
Operations flow information	Trades (Workers) production rate	Experienced based trade type production rate
Process flow information (Product)	Product fabrication information LOD requirements Product detailing process	Medium (LOD 300) Subcontractors provide shop drawings for review
Logistics flow information	Materials location monitoring frequency Control Technologies	Weekly Digital self reporting
Platforms/ Software	Production status dashboard system Schedule Procurement	SiteDrive Word, Excel, Miro, Sitedrive BIM models, e-mail, Zeroni, WhatsApp
	C – Commercial Terms	
Contract	Type Intervening Phase	DBB Final design
Control and flexibility	Design Control Flexibility for changes	Limited Minor changes
	O – Organisational Structure	
Hierarchy	Departments/Groups/Crews	Developer, Clients (apartment purchases), Design, IT, Accounting, HR, Procurement (includes safety and quality), logistics, and suppliers.
Functional role parameters	Deliverables	Developers, Designers, Accounting, Procurement, business unit managers, site managers, foremen, subcontractors, trades, team leaders, workers, and suppliers.

CASE STUDY: TAKT SYSTEM FOR A RESIDENTIAL PROJECT

This section examines the application of the PICO framework to a case study project of a residential building project in Finland that implemented a weekly takt time approach during the interior phase. The construction company responsible for the project, FIRA Oy, reported a 20% reduction in project duration thanks to use of the takt method. However, it was noted that there were still opportunities for further improvement. Why did the production system fail to achieve the throughput aims of its designers? The PICO framework enabled rigorous analysis of the weaknesses of this case study system, as detailed below. The parameter values for the case study project are available online (Sharoni et al. 2023).

PRODUCTION CONTROL MECHANISMS

FIRA Oy utilizes a variety of control mechanisms in its production systems, including Location-based Planning and Control, Last Planner System (LPS), and takt scheduling. When implementing takt production, FIRA employs lean principles that have been partially adapted to suit the company's nature, prevailing market regulations, and cultural factors.

Operation: Trades and constraints between them are identified and implemented in a master schedule that maintains a weekly takt. While the schedule aims to present the workflow, not all trades and tasks are planned nor appear, causing a lack of documentation and an inability to monitor essential work. The takt schedule shows dominant trades but not prerequisite tasks performed by other small trades and subs, such as measurement and marking, drilling openings, sealing of openings, etc. Moreover, installing windows takes one working day per floor; yet the planned takt schedule allows the trade a week. Thus, there is work waiting for workers most of the week. Even if the trade is requested to arrive on a particular day, the trade arrives during the week subject to prioritization of other commitments. The rest of the week is dedicated to prerequisite work that was not on the schedule. The prerequisite task implementation depends on the site team's knowledge, experience, and vigilance. The extension of buffers allowed the site crew to prepare and complete the prerequisite tasks, maintaining the planned operation flow, increasing flexibility, and exhibiting a higher tolerance for errors and coordination problems. The example points out the lack of (1) detailed operation design, (2) incentive for subcontractors to arrive on time when they are aware of the project's flexibility, (3) and lack of preserving professional organizational information. All three hinder reducing the takt and will find an answer in the other PICO domains.

Process: The chosen production unit for the case study building is a floor that aligns with the location breakdown structure (LBS). The production process aims to establish a manufacturing methodology with minimal variation between floors and a work breakdown structure (WBS) comprising 300 tasks. Reducing the production unit to a room would significantly increase the number of tasks involved in planning, operating, and monitoring, as arranging different trades in the same apartment would present safety and logistics operations challenges. Manual planning of 300 tasks is already a human challenge, and extending this to over 10,000 tasks in a full-scale project would be infeasible without an automated tool.

Logistics: The procurement department, site team, and subcontractors retained responsibility for purchasing materials. However, the material ordered by the procurement department was delivered to the site by a logistics company in pre-packaged kits aligned with the LBS. This allowed for efficient delivery control as the kits were delivered directly to the operation location, reducing handling and obviating the need for storage areas. Efficient logistics support is crucial for successful takt production but requires significant resource investment. The benefits include lower transportation costs, reduced waste, and high team satisfaction. However, advanced material information is necessary for successful implementation, and last-minute orders cannot be accommodated.

INFORMATION AND COMMUNICATION SYSTEMS

The production system's schedule was created using Tocoman (https://www.tocoman.fi/) software, detailed in Word and Excel, planned on a Miro board, and then manually transferred to the SiteDrive platform. Foremen then further detailed the schedule on Excel and SiteDrive. The project design models were compiled with BIM software, and the on-site communication used 2D drawings that were updated whenever significant changes were made. Small changes or clarifications regarding details were done through direct communication and were not continuously updated in the model. The project manager was required to use multiple platforms for functions like financial planning, logistics, coordination with designers, quality and safety control, procurement, and more. Even in the best-case scenario, these platforms are only marginally interoperable. This lack of integration leads to prolonged planning, increased risk of human error, and low-resolution work, ultimately transferring responsibility to the next person in the production chain. Efficient information and communication systems have been recognized as crucial in reducing and accelerating takt production. To effectively implement shorter takt, less than a day, it is essential to have access to detailed design information and a seamless connection between procurement and material location systems. In addition, real-time progress updates, supply chain information, and the ability to quickly adapt to unexpected events are crucial in achieving success.

COMMERCIAL TERMS

The company's commercial terms with the owner are those of a DBB contract. The fixed design limits the company's ability to adapt to its production capabilities and planning priorities. Labour (subcontracted crews) are compensated using a piecework product-based system. However, in the event of any delays caused by the GC, additional payment in the form of hourly compensation may be provided to the subcontractors. The company employs specialized trade labor crews with a specific scope of professional responsibility. While prefabrication is challenging for interior construction phases, the bathrooms of all apartments (excluding those with saunas) were prefabricated in a factory, complete with all finishes, sanitary equipment, tiles, showers, and mechanical systems, ready for delivery and installation. The company works with the subcontractors using an open book method and invests in higher wages. However, the company needs to examine the correct contract method between the GC and the subcontractors, both in the scope of work type (multitasking, cleaning) and the payment method, to balance buffers implementation and payment for empty work slots.

ORGANIZATIONAL STRUCTURE

The project's organizational structure is an intricate network of connections and interactions between various stakeholders. The owner is responsible for hiring the design team and the GC. The GC communicates with subcontractors through its procurement department and its site team, which oversees the site operations. The GC also operates a logistics centre, where materials are packaged and delivered directly to the operation location to ensure efficient delivery control. The subcontractors provide specialized trade crews with a leader for each trade. Although the traditional three-party structure of owner, GC, and design team still holds, the complexity of the GC's production system expanded the project's organizational structure. Like many other companies, Fira experiences disconnection between headquarters and the site team. The soft element of an organizational structure is challenging to research and measure, connecting people and processes. However, the research indicates that the headquarters' process to implement new work methods and technology, such as takt, does not align with the understanding and needs of the site team. Additionally, duplication of purchasing responsibilities, for example, between subcontractors and the company, and contradictions between managers and internal customers hinder the implementation of changes, efficient information flow, and improvement.

From this analysis, it becomes apparent that certain parameters contribute to the optimization of the production system, such as the implementation of large buffers due to the non-detailed planning of the schedule. Conversely, other parameters can cause delays, such as a lack of planning detail. Increasing the level of planning detail can shorten the takt, reduce buffers duration, and enhance control over the production process. However, to increase the level of process detail, several requirements must be met, including greater control over product design, increased involvement of the GC, and the collection of preliminary information on the contexts and limitations between trades. Nevertheless, increasing detail alone is not sufficient to translate it into a significant financial advantage. A control system is also required for short-term management that includes the management of tasks, manpower, and materials. The case study, together with the parameters outlined in the accompanying Excel sheet, presents a complicated and intricate production system. Nonetheless, this framework provides a crucial starting point for comprehending and mapping production systems in the construction industry.

DISCUSSION AND CONCLUSION

A comprehensive approach to production system design in construction is needed, one in which every possible modification within the system is considered part of an interconnected network. To design any new production system for construction, such as a short-term takt system, for example, it is crucial to evaluate the entire production system, including aspects such as the role of the general contractor in the early design phase, the establishment of a logistics canter, the integration of technological tools to enhance takt planning, and the formation of a new organizational structure with dedicated departments. These innovations should be adopted strategically and holistically, considering their impact on the overall production system, including the flow of resources, communication, collaboration among stakeholders, and technology integration in construction processes.

The components and parameters outlined in the PICO framework are interrelated and interdependent, and their values should be set holistically. New technologies or methods should not be implemented in isolation, but rather as parts of coherent systems. In today's fast-paced and ever-evolving construction industry, incorporating a new tool for monitoring the construction process or adopting a new approach like takt, without considering the underlying production system structure, can lead to limited or suboptimal results.

This paper emphasizes the importance of redesigning the production system structure. The literature argues that the role of human capital within the production system is the key factor in a manufacturing industry's success, perhaps even more than the production system design itself, as the company's success depends on the efforts and capabilities of its intellectual capital and its staff's ability and capacity to innovate (Fane et al. 2003). However, when internal structural conflicts impair a system and the system lacks mechanisms for control, operation, management, and forecasting, even the most talented and skilled individuals may have limited ability to succeed.

Note that, although this paper presents the framework for production system design and details the PICO domain parameters and the connections between them, due to space limitations, a comprehensive analysis of the full impact of each parameter on the others is beyond the scope of this paper.

In conclusion, the challenge of improving the construction process is significant, and many possible solutions exist. However, clearly defining and understanding the issues at hand is essential, and the goal of the PICO framework is to enable just that. This work contributes to the scholarly community by expanding the current understanding of production systems in construction and presenting a new framework for defining and implementing new production systems, such as shorter-term takt production. The clear definition of construction products as distinct from locations is a key feature of the PICO framework and should enable standardization of work. A sequel paper will present the application of the framework to compare four different production systems and the consequent derivation of a production system with a takt time of one day or less.

ACKNOWLEDGMENTS

We thank Fira Oy for engaging in this research within the framework of the project and sponsoring the case study visit. We are grateful to the Fira Oy team for making time for interviews, sharing documents, and accompanying the site visits, and for their openness and honesty were essential in reaching a meaningful understanding of the research questions.

IMPLEMENTATION OF LEAN THINKING TO IMPROVE MASONRY CONSTRUCTION AND DESIGN

Samaneh Momenifar[1], Karl Keyrouz[2], and Farook Hamzeh[3]

ABSTRACT

Masonry construction provides multiple functions with a single element, is cost-effective, durable, and provides a visually appealing finish. In addition, its flexibility in design and reasonable construction cost makes it more attractive. Specifically, characteristics of load-bearing masonry make it a viable choice for residential buildings, hence a viable solution to address housing demands. However, evidence shows this type of building is less desired nowadays due to its reputation as having traditional shapes and low productivity in the construction process.

Lean thinking has been widely applied in the construction industry. However, lean applications in the masonry industry can be widened. In this research, site visits, consultations with industry professionals and stakeholders, and an extensive literature review have been conducted to understand existing problems of design and construction of load-bearing masonry systems in Canada. To address the discovered problems, several lean thinking solutions are proposed with the focus on consideration of complex wall configurations and providing early feedback in the conceptual design stage of masonry buildings. Development of one-piece flow for mortar transportation and generative design tools are two of proposed solutions. Development of intelligent BIM and construction simulation models are presented as future research ideas to validate the proposed lean solutions.

KEYWORDS

Masonry, generative design, simulation, lean thinking.

INTRODUCTION

Compared to other structural systems, masonry's competitiveness is threatened by several myths and assumptions architects hold, such as the high cost of masonry construction and its constrained formal options (Gentry et al., 2009). Waste in the construction industry leads to many problems, such as decreased productivity, cost overruns, schedule delays, and safety issues (Senaratne & Wijesiri, 2008). Also, productivity assessment implemented on the masonry construction process revealed low productivity and waste in this type of construction. The presence of waste negatively affects the value delivered to customers (Abbasian Hosseini

et al., 2012). Moreover, more recent studies also show the factors that most affect masonry construction are related to rework and lack of safety, required tools or material on a construction site (Svintsov & Abd Noor, 2022) which further leads to waste on construction sites and consequently decreases the value produced for the customer. Implementing lean principles in construction processes can help to identify non-value-adding activities and improve the process, as demonstrated in the masonry industry. Implementing lean construction principles has been shown to reduce waste and improve cycle time and efficiency (Abbasian-Hosseini et al., 2014).

Masonry-bearing walls have a long history in construction, dating back centuries, and have been used in various building types, from simple structures to grand monuments and public buildings (Cross, 1965). During the early 20th century, brick construction for multi-story buildings was primarily replaced by steel and reinforced concrete framed structures, but brick was often used as cladding (Hendry et al., 2017).

The decline in the popularity of masonry construction is believed to have been caused by the introduction of new materials and construction methods, the desire for faster construction, and the development of new load-bearing structures and lightweight facade systems (Sweis et al., 2008). According to our investigation, the decline in masonry construction in Canada is attributed to several reasons, some of which are presented in the literature review. The rest are spotted in construction site visits and consultations with industry practitioners. This paper aims for lean improvements in the current state of masonry in three categories: masonry design, construction, and unit. In masonry design, the design fixation phenomenon is presented as a significant challenge in the current design practice of masonry systems. This leads architects to opt for more straightforward and more conventional solutions instead of innovative ones. Integrating Building Information Modelling (BIM) and generative design can help overcome this by providing architects with a tool to design complex masonry walls that are structurally feasible and constructible. Many innovations have happened in masonry units, including materials, systems, mortar additives, ties, and reinforcements. The recent introduction of masonry units with integrated insulation has gained significant attention in the industry, offering a simpler and more streamlined construction process. The use of alternative masonry blocks that do not require cement and moving towards panelized construction in the design of new masonry units is recommended in this category. In masonry construction, the current implementation of lean in the masonry industry has proven to be effective in reducing waste and increasing efficiency. However, the complexity and variability of wall configurations, especially L-shaped and T-shaped walls, have posed challenges to implementing lean in the masonry industry. The future of masonry construction can be improved using lean thinking steps here. Some of these steps are developing a just-in-time schedule for bricks and mortar components delivery and using pull-driven scheduling when planning the bricklaying of different sections of a building composed of Concrete Masonry Units (CMUs).

LITERATURE REVIEW

Masonry load-bearing walls have a long history of use in construction, dating back centuries. They have been used in many building types, from small, simple structures to grand monuments and public buildings (Cross, 1965). Brick construction for multi storey buildings was replaced by steel- and reinforced concrete-framed structures in the first part of the 20th century, but they were frequently covered with brick (Hendry et al., 2017). The John Root-designed Monadnock Building in Chicago, which stands sixteen stories tall and has walls that are 1.82 meters thick at the base, was "the final triumph of traditional masonry building" in 1891 (Cross, 1965).

It is believed that the introduction of new materials and construction methods, the desire for faster construction with fewer workers on-site, and the development of new load-bearing structures and lightweight facade systems have led to a decrease in the popularity of masonry (Sweis et al., 2008). One of the leading causes of this was that solely empirical criteria were used for proportioning load-bearing walls up until around 1950. It resulted in unnecessarily thick walls that wasted material and space and took a long time to construct (Sinha, 2002). The development of structural codes of practice, which made it possible to determine the required wall thickness and masonry strengths more reasonably, improved the situation of masonry buildings in several countries after 1950. Although initially limited in scope, these standards of practice were based on research projects and building experience. They offered an adequate framework for the design of structures up to thirty stories. The development and enhancement of the various structural codes for masonry structural design over the past 20 years has resulted from extensive research and real-world experience. Because of this, the structural design of masonry buildings is getting closer to being on par with steel and concrete (Hendry et al., 2017).

In terms of architectural design, modern architecture conflicts with masonry. Using steel or concrete frames and curtain wall skins in construction has led to the dematerialization of design, while masonry construction is rooted in using materials. This user has created an ambivalent relationship between modern architecture and masonry (Collins, 1998). In addition, there is a notion that architects are not pushing the boundaries of masonry, even though the masonry business and research community have consistently advanced with improvements. Such improvements aim for new masonry unit types with sustainable and green construction and integrated insulation (Subasic, 2022), structural analysis methodologies, and more effective building procedures (Beall, 2000; Beall & Jaffe, 2003). It has been noted by Heyman (Heyman, 1996) that the decline in masonry as a building material has led to a decrease in expertise and knowledge in masonry design, detailing, and construction, particularly in the use of non-planar forms of load-bearing masonry structures. Researchers (Gentry et al., 2009) claim that the perception of masonry as a conservative and risky building technique when aiming for innovative shapes, combined with a shortage of specialized knowledge and computational tools, limits its acceptance and acceptance ability to compete with other building methods. Therefore, most new masonry buildings use traditional and conservative solutions.

The sequential and complex construction process of masonry buildings causes inconsistent information flows in design and construction. Design management entails managing the flow of information and coordinating individuals and teams involved in the design process (Al Hattab & Hamzeh, 2018). Design workflow consists of transferring information and deliverables between teams and individuals, and it has become more complex due to advancements in design specifications, end-user needs, and technology. The production of large amounts of information and the pressure of deadlines and budgets increases the risk of design errors and conflicts. Poor design flow can lead to several types of waste, including excessive rework and revision cycles, design errors, reduced quality, increased costs, and schedule delays, ultimately decreasing the value generated for end-users (Ballard, 2002).

It is confirmed by industry practitioners in Canada that masonry wall systems are facing competition from other wall systems such as wood, glass, steel clad, and precast (Jordan Kuntz, 2022). According to our site visits and consultations with industry practitioners, there are multiple reasons behind this phenomenon, some of which are mentioned in the literature. In this paper, reasons behind the decline in the prevalence of masonry use are presented into three categories: masonry design, masonry unit, and masonry construction.

METHODOLOGY

Building with masonry requires significant manual labor, and the implementation of innovative solutions needs to be expanded. Another hurdle facing the masonry industry is the unawareness of new masonry forms and construction techniques by professionals in the field. This study evaluates the current construction and design methods used in masonry construction and the possible lean improvements that can be applied in the industry. The authors hypothesize that by looking at the design and construction of masonry systems, it is possible to provide potential lean solutions that will be of value to the industry and the professionals in it. Lean principles have already been implemented in the masonry industry, but their current applications have been limited. As such, this study presents what has been done in the masonry industry to improve the design and construction of masonry systems and the potential possible lean applications. The reviewed literature first identifies the research problems. Then, multiple construction site visits, consultations with masonry industry practitioners, and the conducted literature review formed the basis for recommending lean solutions. These lean thinking solutions are hoped to decrease waste in design and masonry construction practices. The methodology diagram developed by the authors as a research framework is shown below in Figure 1. In the first phase, a literature review on design principles of masonry systems and lean improvement is conducted. Then, several site visits from masonry construction projects and discussions with superintendents and masons are implemented. Consultations with active industry practitioners were the last step of phase 1. During phase 2, authors tried to address the discovered problems with lean solutions, and in the previous phase, future research opportunities for implementation and validation of proposed lean solutions are presented.

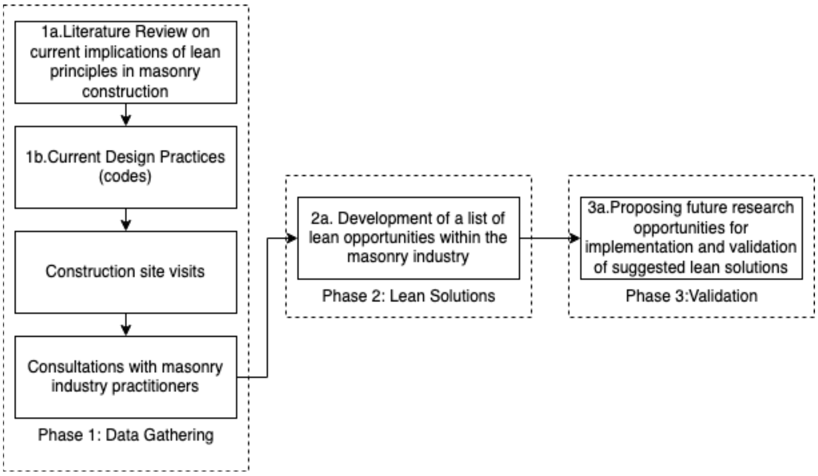

Figure 1: Research Methodology

To develop a list of lean opportunities in the masonry industry, site visits were performed to identify the problems currently affecting masonry productivity and, more specifically, in the bricklaying process. In addition, in a 2-day masonry Hackathon held at the University of Alberta, discussions with industry stakeholders and professionals of diverse backgrounds in naming, structural, thermal efficiency, and robotics brought to light some previously unknown aspects of existing problems in the masonry industry.

MASONRY DESIGN

Researchers claim that a phenomenon known as design fixation (Jansson & Smith, 1991; Purcell & Gero, 2006) is happening in current masonry design due to lack of early feedback: The lack of early feedback during the conceptual design stage can result in uncertainty, leading architects to avoid unusual and potentially more innovative solutions and instead opt for more straightforward and more conventional solutions. This is more likely when the number of parts involved in a problem is high, such as in the case of a masonry wall, cladding system, or tiled roof. Furthermore, the tendency to follow conventional configurations is often justified by adhering to traditional construction wisdom (Cavieres et al., 2009), which can result in a missed opportunity for innovation and progress in the design and construction of masonry structures. Hence, it is essential for architects to have access to the necessary knowledge resources and to receive early feedback during the conceptual design stage to help guide their decisions and minimize the risk of design fixation (Cavieres et al., 2011). The authors conclude that when masonry designers are equipped with constructability knowledge of innovative masonry configurations, the state of masonry in both design and construction will be significantly improved.

However, masonry designers have a limited number of digital tools at their disposal to represent and investigate novel brickwork arrangements. The amount of work architects must spend modeling and detailing a building with hundreds or thousands of masonry components becomes expensive without such technologies (Bettig & Shah, 2001). This means current technological advancements are not being widely adopted into masonry design practice.

BIM is expected to revolutionize the construction industry by introducing more standardization, consolidation, and integration in the construction process. BIM will shift the construction process from being project-based and reliant on unique customer specifications to a more product-based approach, utilizing off-site manufacturing and prefabrication (Heigermoser & de Soto, 2022). BIM will enable the integration of generative design solutions, a design approach many researchers have proved effective in creating more creative masonry wall configurations. Masonry units offer a wide range of configurations and formal results, which can be intensively explored through parametric modeling, making the representation of complex geometries and assemblies easier and more realistic, leading to innovation in the design of masonry buildings. Some research focuses on promoting the use of concrete masonry systems in contemporary design practice by incorporating masonry construction knowledge into the design process through state-of-art computational technologies. The goal is to improve the design and construction processes by enabling the creation, testing, and evaluation of a more considerable number of design alternatives from the start. This way, an important focus will be on building envelopes' formal variability and geometric complexity. The methodology described is a simplified system that helps architects design complex masonry walls in the initial stages of the design process. The system uses continuous updates in a CAD environment and Building Information Model to validate, shape, and bind architectural decisions. Its purpose is to provide architects with a tool to design structurally feasible and constructible walls, giving them confidence in their design decisions (Gentry et al., 2009).

Generative design (GD) is a computational design method that uses algorithms and parameters to generate a range of design solutions based on specified constraints and objectives. The process involves inputting design criteria, such as desired functionality, material properties, and manufacturing limitations, and then allowing the computer to generate and evaluate different design options. The final design solution is chosen based on the best combination of performance, cost, and other factors. Integrating generative design and BIM combines the benefits of both approaches to create a more efficient and effective design process (Nagy, 2020). By combining the intelligent design capabilities of generative design with the automated construction information generation of BIM, the GD-BIM integration can help ensure that the algorithm's designs are feasible and constructible. At the same time, it can enhance the BIM's capabilities in the early design phase by providing more accurate and detailed design information. This results in a more streamlined design process that saves time, reduces errors, and improves overall outcomes (Ma et al., 2021).

BIM and Lean Construction are both approaches that have significantly impacted the Architecture, Engineering, and Construction (AEC) industry. BIM primarily focuses on digital transformation in the construction industry, and Lean Construction focuses on improving the production management process. Studies have shown that the simultaneous application of both approaches can enhance the productivity of projects and improve efficiency (Sacks et al., 2010). It is concluded that implementing the lean-BIM approach in the design process of masonry structures will enable the introduction of non-conventional shapes, which require a smoother construction procedure on construction sites.

MASONRY UNITS

The invention of Portland cement in the early 19th century significantly altered the composition of masonry mortar. It allowed the production of concrete masonry units to replace traditional building materials like brick and stone. This invention marked a turning point in the evolution of masonry construction. Researchers state that most of the changes to masonry in the 20th century have been focused on improving production methods and refining the properties of unit masonry materials, such as making them stronger, lighter, or easier to produce, rather than introducing innovations to the masonry system itself. Such innovations can be listed in four primary groups of products and materials:

1. Masonry units and materials: the building blocks, such as bricks, stone, or concrete masonry units.
2. Masonry systems: the overall construction method, such as load-bearing masonry or cavity wall construction.
3. Mortar additives: ingredients added to mortar to enhance its properties, such as water resistance or workability.
4. Ties and reinforcement: elements such as ties or steel reinforcements provide stability and support to the masonry structure. For example, dry stack masonry units were introduced to eliminate mortar and have smoother construction. Also, Carbon fiber-reinforced plastic (CFRP) ties were brought to this industry to facilitate the reinforcement process and have multiple-wythe masonry wall (Beall, 2000).

Among all innovations introduced in masonry units, units with integrated insulations, such as InsulTech (Figure 2), have gained more attention. Such alternative masonry units can be made from various materials, and their shapes and applications are like traditional masonry units (Subasic, 2022). Constructing these units is simpler and more streamlined than conventional construction methods. However, other aspects of this unit, such as shape and structural reinforcement, are the same as traditional ones.

The main concern with the recently proposed masonry units is their compliance with thermal structural and fire safety codes. Also, according to masonry industry practitioners, the idea of having masonry blocks that do not need cement can be beneficial, as the shortage of cement supplies in Canada has indeed impacted the masonry industry, leading to a lack of masonry units and decreased productivity. Using alternative masonry blocks that do not require cement could solve this problem, allowing the industry to continue operating despite the cement shortage.

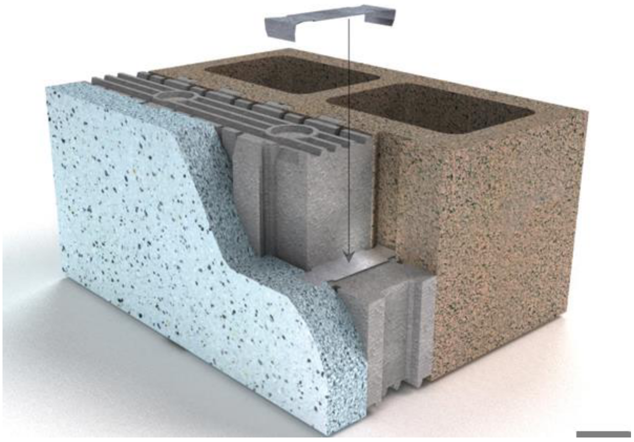

Figure 2: InsulTech masonry unit (Echelon, n.d.)

MASONRY CONSTRUCTION

Based on literature review, it was identified that waste, in all its forms, renders projects slow and vulnerable to conditions on construction sites which consequently restricts the value that can be delivered to the customer. Moreover, waste in all its forms on construction sites reduces flow and value generation (Abbasian Hosseini et al., 2012). Variability and complexity in the construction industry implement lean principles in construction processes, an attractive solution to identify Non-Value Adding (NVA) activities and subsequently improve the process. Implementing lean construction principles in the construction industry, specifically, the masonry industry has been proven to reduce waste in cycle time and efficiency. Using simulation modeling, it was concluded that more than 70% of the bricklaying activities are NVA (Abbasian-Hosseini et al., 2014). Hence, applying lean principles would make the process more efficient by reducing the time needed for NVA activities. Moreover, lean principles have been applied to the bricklaying process using Value Stream Mapping (VSM) to identify waste (Melo et al., 2017). It was determined that reducing transport times and excess inventory reduced NVA time and lead time. Another study (Bajjou & Chafi, 2021) showed that NVA constituted 85.2% of the bricklaying cycle time, with waiting (or idleness) having the most significant share. These studies applied lean principles to identify areas of waste in the masonry industry and change how bricklaying and masonry construction is done on construction sites. Hence, there is a need for more extensive use of lean in the industry. Moreover, such studies fail to include the different and more complex types of wall configurations. Current research also involves the implementation of sustainable solutions, which consists of adding robots on-site to create semi-autonomous bricklaying systems. (Usmanov et al., 2021) creates a digital layout plan for robotic bricklaying. However, such a system only considers orthogonal walls and does not consider more complex wall shapes or configurations.

The data gathered concerning masonry construction was done by multiple site visits of a school gymnasium being built entirely using CMUs as a structural element. The visits aimed to identify the difficulties encountered in masonry construction. During the visits, common types (patterns) of wall configurations using CMU blocks were identified. The goal of the visit was reached after observing the bricklayers perform their work. Therefore, the data gathered was based on the spotting and discerning of patterns of construction the bricklayers would follow. The frequency of those patterns to create different types of wall configurations and based on the current literature review, the most common types of wall configurations were found as shown in Figure 3:

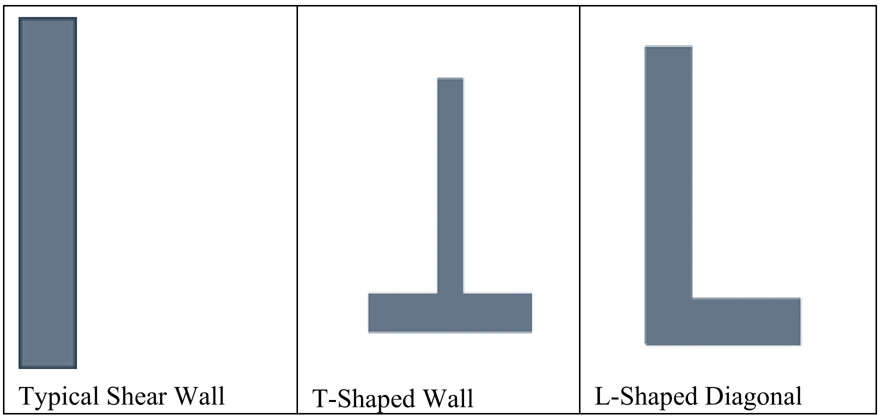

Figure 3: Most common wall configurations

Typical shear walls were found to be the most common type of masonry walls being built. Bricklaying such walls consists of several steps: lift brick, spread mortar, knock, level, and remove excess mortar. CMUs lifting leads to work-related musculoskeletal disorders (WMSDs) due to the repetitive stress of the bricklaying steps on the workers' bodies (Wang et al., 2015). The repetitive motions lead to decreased productivity over time as WMSDs disorders occur. Moreover, the current bricklaying process requires constantly refilling mortar and brick stations at the wall construction sites. The existing masonry practices are done for the different shapes of walls, but specific issues were noticed to emerge in more complex shapes (such as L and T). For L-shaped and T-shaped walls, it was observed that many problems that hinder productivity happen during construction. Most notably, the bonded wall components forming the L or T shape should be built simultaneously due to the presence of the intersection part between the two members forming the shape. Such configurations are complex to build and hence require more time to build than a typical shear wall. In addition, the variability in the geometrical design of masonry walls leads to the difficult reproducibility of such wall-shape configurations on-site. This leads to decreased productivity on construction sites. Moreover, as wall shape configurations become increasingly complex, the quantities of equipment and material needed increase. Indeed, when faced with different structural scenarios (over-opening such as lintels, change in wall thickness, etc.), there is an increase in the time required to perform the bricklaying process.

Moreover, the visits to construction sites show that the identified patterns lack productivity, with construction being highly variable, and are subject to the construction site layout planning done beforehand. Hence, there is a need for the implementation of lean concepts in masonry construction.

LEAN THINKING SOLUTIONS

Masonry construction suffers from problems in productivity and is plagued by a myriad of difficulties ranging from heavy lifting, causing a strain on the Musculo-skeletal system of bricklayers as well as non-optimal construction designs that would take more time to be built, affecting the masonry industry in both the design and construction phases. Current lean improvements in masonry systems have identified many problems impacting the bricklaying process, namely the inventory and transport issues. However, current research fails to consider a holistic integration of all parts of the bricklaying process, whether autonomous, semi-autonomous, or human-driven only, to implement lean solutions and reduce waste.

Based on the findings in the literature and after the multiple on-site visits, we present the opportunities from a lean perspective in this section. Opportunities in masonry construction (Figure 4) focus on bricklaying itself in masonry construction. Applying lean to masonry construction can increase site productivity while reducing the efforts needed for current bricklaying practices. Moreover, using lean methods would enable faster design and construction processes to deliver better value to the customer.

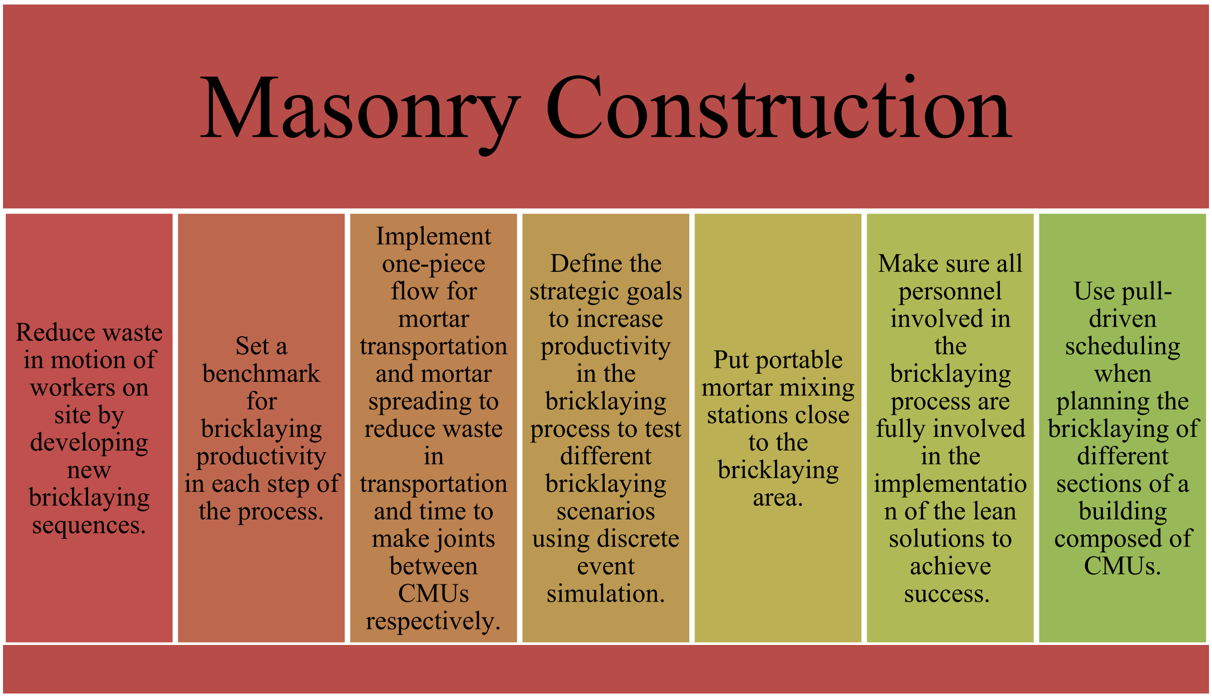

Figure 4: Opportunities in Masonry Construction

Figure 5 shows the wasted opportunities that can be applied in masonry design. Using lean practices in masonry design makes it possible to develop optimal designs in the pre-construction stages of projects. Based on the observations from site visits, having knowledgeable designers on the construction process and labor intensity of different wall configurations can help a smoother construction process. Also, according to discussions with various masonry industry experts, integrating advanced tools with a holistic masonry design approach is missing in current design practice. Here, we present some lean solutions to such problems in masonry design.

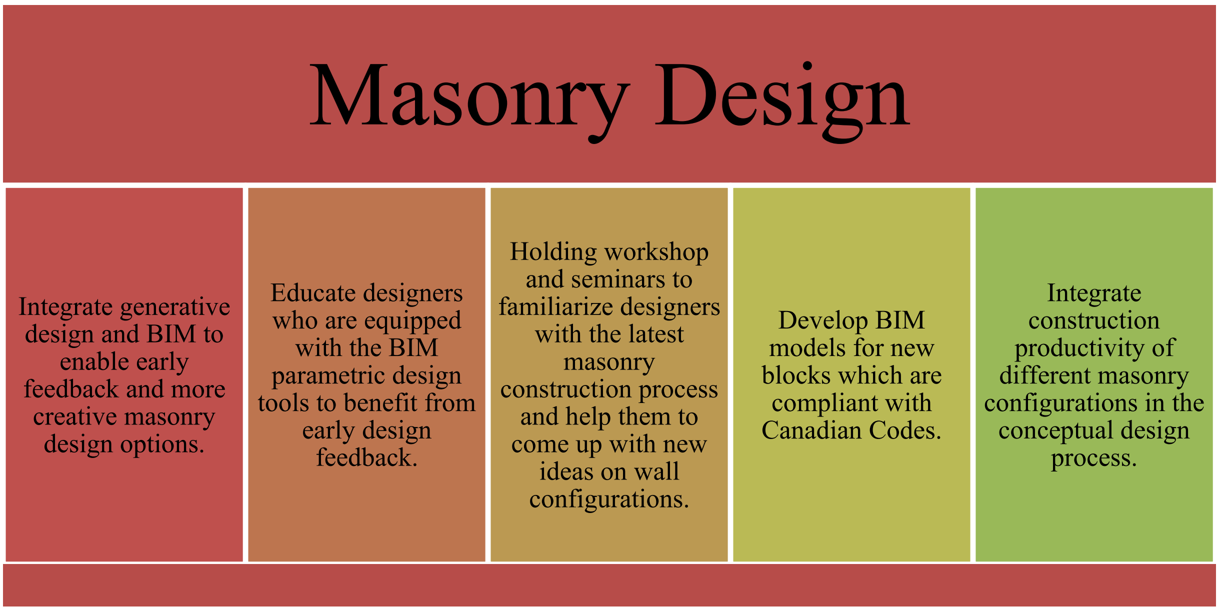

Figure 5: Opportunities in Masonry Design

Lean opportunities can also be applied to masonry blocks by creating blocks with more sustainable materials and better block shapes and designs. Figure 6 shows the lean solutions applied to masonry units:

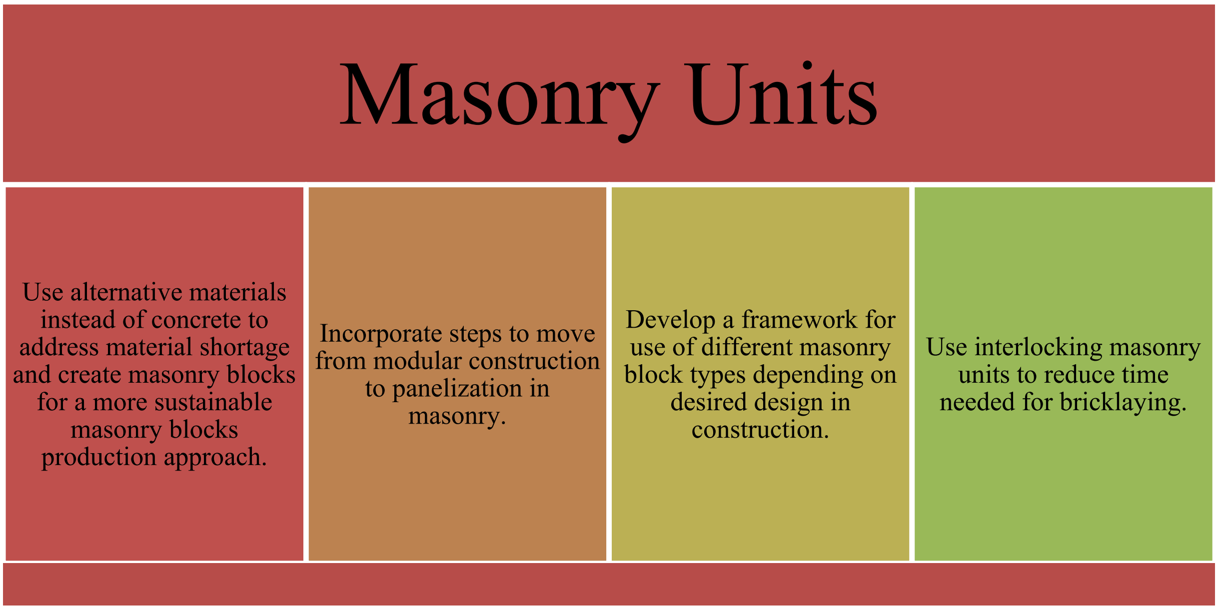

Figure 6: Lean opportunities for masonry units

CONCLUSIONS

Based on the literature review, multiple construction site visits, and discussions with industry practitioners, it has been found that the implementation of lean principles in the masonry industry can reduce waste and improve efficiency. Value Stream Mapping (VSM) and simulation modeling have shown that many bricklaying activities are non-value adding (NVA), with the largest share being waiting. However, current research focuses on orthogonal walls and lacks consideration of more complex wall configurations. L and T-shaped walls are one of the complex shapes that need to be taken into consideration when trying to improve the masonry construction process. Therefore, there is a need for more extensive use of lean principles in the masonry industry. The lack of early feedback during the conceptual design stage can lead to design fixation in masonry design, resulting in architects choosing more straightforward, more conventional solutions instead of more innovative ones. BIM is expected to revolutionize the construction industry by enabling generative design solutions, allowing for exploring a more comprehensive range of design alternatives and improving the design and construction processes. Integrating generative design and BIM can lead to a more efficient and effective design process. At the same time, the simultaneous application of BIM and Lean Construction can enhance the productivity and efficiency of projects. Implementing a lean-BIM approach in masonry design will allow for the creation of non-conventional shapes and a smoother construction process. Future research is needed to validate the effectiveness of proposed lean solutions in improving masonry design and construction. To validate the proposed methods in masonry design, intelligent BIM models can be built to benefit from generative design tools and algorithms in reaching an optimized wall layout design. In construction, we can validate our solutions using Discrete Event Simulation as they allow us to check the effect the implementations have on construction productivity and refine the models and solutions as results of the simulations become available. Moreover, the use of lean principles should not only be limited to orthogonal walls but also to non-orthogonal walls too and a study for finding the root causes of disappearing construction material in Canada should also be further investigated. Recommendations proposed for masonry block improvements can be validated by incorporating new block characteristics and geometry into the intelligent BIM model and masonry construction simulation model.

ACKNOWLEDGMENTS

We would like to thank all workers and masons on construction sites who helped us study the masonry construction process closely.

DIGITAL SHOPFLOOR MANAGEMENT IN CONSTRUCTION – A CASE STUDY

Darius P. Heller[1]

ABSTRACT

Lean Management is considered a very promising approach to improving productivity in the construction industry. Shopfloor Management (SFM) is receiving increasing attention in theory and practice, as it has an impact on daily routines of all organizational levels. This paper presents over two years of experience in adopting and implementing SFM at a general contractor, which focuses on industrial and custom new buildings. The underlying company is following a clear and organizationally manifested approach toward Lean Management since the mid-2000s. Hence, the SFM methodology needed to be embedded in the already existing methods conceptually, before it could be rolled out. After two years of implementation, rollout to over 80 projects with an equivalent of approx. 1 billion € volume was achieved. Also, a consistent cascade from the construction site to top management was established, i.e. all levels of the organization have transitioned to the new way of working (and leading) inherent to SFM. In parallel, under the application of a strictly agile approach, the SFM cascade was digitized with a special focus on data reuse and integration of systems to ensure consistency, accuracy, and up-to-date information. The overall impact of SFM in the company underlying this case study to date is positive, and an initial approach is proposed to measure the impact in this paper.

KEYWORDS

Lean construction, collaboration, benefits realization, shopfloor management, digitization.

INTRODUCTION

The company underlying this case study is a general contractor with a regional footprint and with the majority of projects creating new buildings for non-residential usage. Some of its ten business units attempt to gain efficiencies through reuse, but the majority of buildings are customer-specific and produced on-site (no prefabrication) by subcontractors. Lean Management is being implemented since the mid-2000s when a dedicated team was created to drive and support the lean journey.

The main goals of implementing Lean Construction (strategically) in this case can be described from company, project, and people perspectives:

- *Company* - establish a culture of continuous improvement based on standards and project-overarching build-up of best-practice knowledge, leading to an increase in revenue and margin through productivity gains.
- *Project* - achieve project objectives as committed to customers (e.g. completion date), and reduce the lead time of projects to improve competitiveness.
- *People* - achieve a sustainable, motivating, and performing work environment.

The company sees itself to be a pioneer regarding Lean Management implementation in the construction industry, but as described in the problem statement later in this paper, the impact

[1] PhD Student and Research Associate, Institute for Construction Management, University of Stuttgart, Germany, darius.heller@ibl.uni-stuttgart.de, orcid.org/0000-0002-1887-3833

of Lean Management remained behind expectations. Hence, the company analyzed other enterprises outside the construction industry for further inspiration on Lean Management and discovered the concept of SFM. Starting in 2018, a team continued to investigate SFM and received the mandate to adapt and implement SFM. In this paper, a full view of the adaptation, implementation, and impact review of SFM is presented. The author acknowledges, that various other general contractors are also implementing SFM, and hopes that those companies might contribute to this research as well based on their experience.

LITERATURE REVIEW

The term shopfloor management (SFM) as it is used in this paper refers to a broader methodological approach that builds on the understanding of lean leadership as described by Liker & Convis (2012) or Suzaki (1993), as opposed to a narrower understanding of operational techniques and mechanisms to plan and control production activities (e.g. production scheduling, shift capacity planning). The word shopfloor itself refers to a focus on the teams that work mostly in direct production (Grütter et al, 2002). Bertagnolli (2018) further defines SFM to consist of the four structural elements communication, visualization of key performance indicators (KPIs), problem-solving, and process control. Hertle et al. (2017) describe SFM as a procedural model. The structural and procedural definitions align with the understanding used in this paper. Beyond literature from within the lean management domain, it is important to review publications from adjacent domains such as operations management. Dombrowski et al. (2018) present case studies in which work team performance has been improved by concepts similar to SFM. Also, less associated with the domain of lean management, but rather performance management is the article by De Leeuw & Berg (2011). In it, the effect of SFM-like interventions on productivity and motivation has been investigated. A survey of approximately 100 companies from various industries and sizes created the insight that 71% of respondents confirm productivity gains from introducing a performance management system. Regarding the digitization of SFM in general, an overview of publications is provided by Jelínková & Prochazkova (2023), showing a strong increase between 2015 and 2020. Meißner et al. (2020) developed a target state for digital SFM (not construction-specific), defining what improvements should result from digitization in the categories of identification of deviations, shopfloor meetings, problem-solving, as well as standardization and stabilization. Publications on SFM adaptation to construction reach back to 2010 (Hofacker et al., 2010), with a pure focus on the production process on-site. Lootz (2018) describes the application of SFM to a ship-building context, integrating more processes (e.g. engineering) and also covering all levels of the organization (i.e. an SFM cascade). Romano (2022) describes the practical experience of the implementation of a digitized version of SFM in a large construction company. Binniger, M & Wolfbeiß, O. (2018) present specific implementation experience from a construction company in Germany using a special pen to digitize information.

Based on the literature review in total, the author believes SFM is a necessary element on any lean journey, and that the method should not only be seen as a set of KPI boards, but as a shift towards lean leadership with the corresponding behaviors and values.

PROBLEM STATEMENT & SOLUTION CONCEPT

After a brief outline of the problem statement, differentiated into the three perspectives *company*, *project*, and *people*, the approach to SFM as a solution will be explained in detail.

PROBLEM STATEMENT

From a *company perspective*, revenue was increasing slightly year-over-year, but the margin was stagnating at a market average level for multiple years. A key problem was that losses from a few projects led to a significant negative impact on the margin of all projects and thus on the entire company over several years. Management usually received information about negative deviations in projects at a time when there was no more possibility to influence the impact. Also, comparing business units showed strong deviations in the stability of both revenue and margin, even though the business models were identical (only differing by region).

At the same time, from a *project perspective*, the company was lacking quantification of project performance in a holistic sense. The financial outcome was available as a metric, but timeliness, quality, or customer satisfaction were not quantified.

From a *people perspective*, individuals invested considerable time in meetings and reporting to ensure information flow to (a) subcontractors, (b) within the project team, and (c) to higher management levels. Typically, the time consumed to communicate and coordinate was so high, that other required processes were not feasible with the team's capacity. For example, preventive quality assurance was either not existent or executed at a minimum in most projects. In general, for all management roles, it was not possible to receive a holistic view with up-to-date and actionable items within the roles' range of responsibilities. A management role (e.g. project leader, business unit head) had to first compile information from various sources (e.g. Customer Relationship Management system, financial controlling, procurement systems, systems to manage drawings, comparing milestone schedules with Last-Planner, etc.). This information was then used to conduct meetings, in order to create a full picture through a time-consuming dialogue. Often, by the time conclusions were made, the situation was outdated. In the best case the problem was resolved, in the worst-case the problem could not be mitigated anymore and/or has become worse.

Summarizing the problem statement, the company's general management approach can be described as lagging, and there was a chronic state of unsatisfying information even though time invested in information processing and communication was significant.

SOLUTION CONCEPT

The SFM methodology was selected as a solution concept because it seemed to address many aspects of the problem statement and at the same time was consistent with the company's overall goals of implementing Lean. SFM would replace traditional ways of communication and reporting with a short-cyclic, dialogue- and metric-oriented, standardized management routine which was claimed to be very efficient by strongly increasing the relevance of and reducing time spent on communication on all levels of the organization simultaneously (Bertagnolli, 2018). This effect has been recently also confirmed by research (Wester & Hitka, 2022), based on an SFM implementation in a company in Germany (steel industry).

In total, it was expected that SFM would reduce the negative impact of loss projects from a company perspective, help achieve committed goals from a project perspective, and at the same time free up time and reduce stress by decreasing interruptions from a people's perspective. The key elements of the solution concept are as follows:

- Stand-ups with a weekly cadence were defined internally on all levels of the organization to form a SFM cascade (like on page 359 in Fiedler, 2019). Stand-ups with contractors (on-site) were executed daily. The structure of stand-ups is displayed in table 1. The stand-ups were executed in person, hybrid, or virtually.
- The duration of the stand-ups was planned to be 15-20 minutes, focusing the dialogue on the main issues and not attempting to solve them during the stand-ups.
- The contents of the stand-ups were structured in advance by means of SFM boards with topics and KPIs. An overview of the contents is given in tables 2 and 3.
- The SFM boards were defined for four roles initially: on-site leader, project leader, business area leader, and managing director. In this paper, the focus will be on the boards for on-site and project leaders, as these are most relevant to the shopfloor.

In case deviations on the SFM boards of the on-site and project leaders exceeded a predefined threshold, the issue was escalated to the next level. A choice could be made if the escalation is informative, or required action by the higher management level.

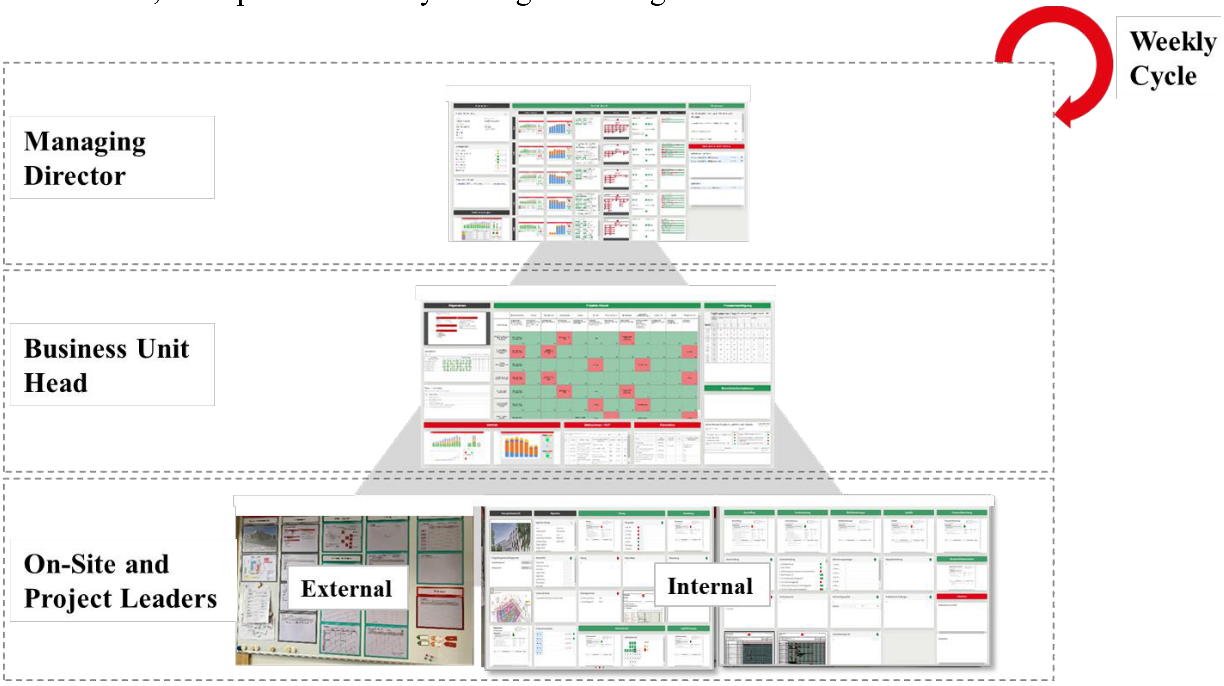

Figure 1: SFM Cascade

The following table shows how the stand-ups were synchronized to ensure up-to-date information throughout the organization. Conceptually, a cascade fully synchronized on a single day would have maximized the timeliness of information, but due to central functions that participate in multiple stand-ups on the project level (especially procurement), a second day was also required for project-level stand-ups.

Table 1: Schedule for SFM Stand-Ups

Stand-up type	Weekday		
	Mon-Wed	Thursday	Friday
Internal	no stand-ups	any time: project leaders	08:00-10:00: project leaders 10:00-11:00: business unit heads 11:00-12:00: managing directors
External	on-site leaders: preferably in the early morning (daily)		

From the view of a project leader, the 15-20-minute stand-up can be executed on Thursday, or Friday before 10:00. Between 10:00-11:00, all project leaders participate in the stand-up of their respective business unit head which is expected to take up to one hour (some business units have 15 projects running in parallel, others 5). Consecutively the business units' heads participate in the stand-up of their managing director. Also, the duration can be up to 1 hour depending on the number of business unit heads per managing director. It is conceptually clear that not only the proportion of organizational units (e.g. number of projects per business unit head) is a driver for the duration of stand-ups, but also the number and severity of issues, as well as the communication behavior of the participants.

The contents on both SFM boards can be distinguished into actual KPIs versus topics that are a useful basis for communication. This is not strictly in line with SFM theory but was thought sufficient to still achieve the desired impact by posting topics on a board that regularly are the cause of phone calls or multiple emails per day.

The following tables 2 and 3 depict the KPIs / topics which were used for the on-site and project leaders. Each line item was a sheet of paper (or later a digital tile) on the SFM boards.

Table 2: Contents of SFM Board for on-site leaders

No.	Title	KPI / topic
1	Health & Safety	# days since the last incident
2	Logistics (1)	One-week calendar to enter planned events (e.g. use of crane)
3	Logistics (2)	List of materials to be supplied by general contractor
4	Planning	List of plans and their revision for the current week
5	Production	# of people on-site planned vs. actual and deviation per trade
6	Quality	Rework overdue by more than one day
7	KAIZEN	Lessons learned for continuous improvement
8	Actions & escalations	List of actions and escalations if a threshold is exceeded

The SFM board for on-site leaders was typically located in a container accessible to contractors. As mentioned above, daily stand-ups were executed in the morning to assess each of the KPIs / topics.

Table 3: Contents of SFM Board for project leaders

No.	Title	KPI / topic
1	Health & Safety	# days since the last incident
2	Sampling	Overdue sampling
3	Planning (1)	Risks identified per planning partner
4	Planning (2)	Overdue drawings

12	Process Map	List of work packages and their status

The SFM Board for project leaders was initially located either in a container on-site or in the office of the project leader. The location of the SFM board for project leaders was an issue, because project leaders typically worked both from the construction site, but also from the office. The participants of the stand-ups were also split into those that worked on-site, and those that worked from the office (e.g. procurement).

OVERALL LEAN CONCEPT WITH SFM

SFM needed to be integrated into the existing Lean concept, which has evolved since the mid-2000s. For this purpose, a short overview of the existing Lean concept is given in table 4.

Table 4: Levels of existing Lean concept

Level	Main elements of the Lean concept
Company	• Retrospective after each project (approx. ½ day in the project team) • In-depth analysis of loss projects • Idea Management
Project	• Process Map • Project Team-Meeting (discontinued with SFM) • Project Reporting (discontinued with SFM)
On-site	• Last-Planner-System • Logistics (in- and out-bound) • Quality (preventive and reactive)

The first level, *company*, is a level that is often missing from the author's view when implementing Lean Construction. Its objective is to manifest and accelerate a learning curve across the entire company and project portfolio. To achieve this objective, the approach is to make ways of working transparent and to exchange lessons learned in a systematic way. It was expected that SFM supports this level because the recurring process of exchanging lessons learned was integrated into SFM.

The second level, the *project*, was implemented by means of a standardized Process Map, which contains a work breakdown structure in combination with quality gates. The Process Map is digitally provided to the teams quoting or executing a project as a guideline to complete the required work. Each work package is scheduled and executed by the responsible person in the team. The completion is tracked in the digital tool and aggregated to the project leaders. In regular intervals of two weeks, the project team and the leadership met to review the progress of the work packages. After the review, a one-page report containing KPI and potential escalations was created by the team, which was intended for review by higher management.

SFM conceptually overlaps with the second level in three areas. (1) the weekly stand-up and the bi-monthly team meeting. (2) the use of KPI, and (3) the function to escalate. It was decided to replace the bi-monthly team meeting with the weekly stand-up, reducing the planned time spent on this process from 4 hours per month to 2 hours per month. To keep track of the work package progress in the Process Map, information on the degree of completion of work packages was included in the SFM board of the project leader (automatically generated). The report containing KPI was also replaced by the SFM boards. With SFM, a more sophisticated set of KPIs was defined by differentiating by organization level (previously not the case). Potentially the most impactful decision concerning (3) was to replace the existing reporting with stand-up meetings also for higher management (i.e. cascade) and to define thresholds for each KPI and organizational level.

The third level, *on-site*, was based on the Last-Planner-System with the corresponding tools and meeting structure. According to Hofacker et al. (2010), SFM conceptually is an addition to the Last-Planner-System by providing a daily routine with multiple topics relevant to short-term production management (e.g. materials required, staff on site). It was intended that communication otherwise happening during the day and leading to interruptions would be combined in the daily stand-up, creating an efficiency gain and leading to smoother communication patterns.

The following picture illustrates the three levels with the main elements relevant to SFM:

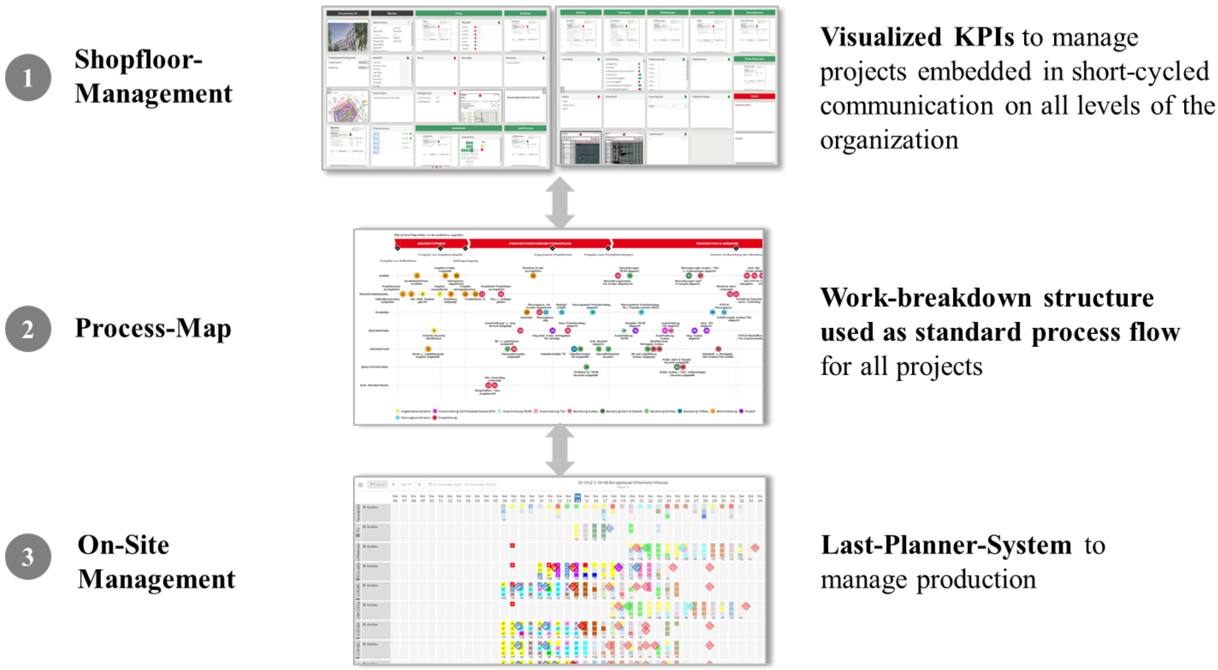

Figure 2: Extract of Lean concept relevant to SFM

IMPLEMENTATION APPROACH

After an explanation of the general approach to introduce SFM, the digitization approach is elaborated in more detail due to its high relevance from the view of the author.

General Implementation Approach

With regard to change management, the planned approach was to proceed in four steps:

1. *Conceptualize* with stakeholders from two of ten business units, and thereof representatives of all organizational levels. The stakeholders started with external benchmark visits before conducting internal workshops.
2. *Pilot and Refine* – after piloting one project from each of the two business units with the close involvement of leadership, the methodology was refined based on the outcomes and experience of the pilots.
3. *Rollout* to all new projects while applying a just-in-time training for each project team individually. In parallel, the so-called cascade for the business area leads and managing directors was built-up (equaling three conceptual levels of SFM).
4. *Review* the maturity of implementation of SFM on a per-project level regularly, make the maturity assessment transparent to the project leader, and give advice on how to improve and integrate it into regular reporting to managing directors.

A duration of two years was planned from the start of conceptualization to the start of rollout. The introduction of SFM was managed by a person with strong experience in lean management.

Digitization Approach

The company decided to implement a custom-developed digital solution following a strictly agile / SCRUM-based approach as outlined in Brenner (2019), p. 141 - 143 based on the following key principles:

- a usable version of SFM had to be available within three months, to not deviate too strongly from the overall timeline to rollout SFM to all new projects.
- the digital version had to be an identical copy of the paper-based version to reduce the complexity of two SFM versions – in terms of the contents - in parallel.
- the SFM board had to be optimized for large touch screen use, to maintain the "look and feel" of a physical SFM board.

The development teams were in a near-shore location managed by a consultant in Germany. Weekly calls were set up to prioritize scope with a fixed budget and monthly release cycles. For each of the contents on the SFM boards, three data integration steps were differentiated and implemented in an incremental approach:

(1) It is possible to access the underlying data with a maximum of one click. This was achieved by the simple linking of documents. (2) It is possible to reuse data values from other systems and display them on the SFM boards. (3) The SFM board displays the result of a computation, hence actually assisting in the interpretation of data. As an example, the system would compare the dates of actual drawing delivery (from a cloud-based platform) with the scheduled and thus expected delivery dates (in a specialized scheduling software), and deliver a key performance indicator such as weekly schedule adherence in percent.

DISCUSSION

To date, there is no literature specifically attempting to quantify the impact of SFM on the KPI of construction companies. Hence, the following measurement approach is a proposal subject to adaptation based on further research and feedback.

The business impact from a *company perspective* is considered to be lagging and a direct correlation to SFM difficult to prove. Still, an attempt was made by tracking the total (negative) earnings impact from loss projects. The measurement showed a clear reduction of this KPI, as shown in table 5. The revenue of the company was more or less the same at the two points of measurement.

With respect to the *project perspective*, an analysis of on-time completion was conducted. Measurement of on-time completion was not measured previously in the company. As a consequence, data first had to be collected and cleaned for example by analyzing causes of prolonged construction in detail: if the customer added scope to the project, the target completion date was deferred, hence the project was on-time if the deferred date was met. As table 5 shows, also a clear improvement could be observed. One must note, that this improvement might have been influenced by factors (external/internal) beyond SFM. There was no ex-ante prolongation of schedules to improve on-time completion.

From a *people perspective*, time savings in combination with better information quality were positive impacts. To explain in more detail, this perspective will be further differentiated into individual, project team, and management (business unit heads and managing directors):

For *individuals*, it was estimated that the time previously spent to process information required to fulfill one's management role (independent of level) was at least 2-5 hours per week. Example tasks are: reviewing information in systems, lists, or reports, fetching information by email or personal interaction, or conducting meetings. Because this value strongly depends on the working style and organizational performance level, it varies strongly. With SFM there is a range of 30-60 minutes per week to achieve at least the same information level. Also, SFM led to a reduction of interruptions because the stand-ups offered a structure for communication instead of the multitude of people involved in a construction project communicating with each other. This reduction of interruptions has not yet been quantified.

For *project teams,* an average of 30 minutes (vs. 15-20 minutes as expected) is required per week, hence 2 hours per month, for the project leader's stand-up compared to the previous 4 hours per month for team meetings. Only these figures from the people perspective were included in table 5, since they have less variance than the figures for individuals. Feedback was clear that the information shared during a stand-up led to a much better result in terms of all team members being synchronized. Ideas to solve problems were shared in the team much more dynamically, which is expected to benefit the project-level mid-term.

Also, *management* reflected uniformly that the quality of information (i.e. the value resulting from the time spent sharing information) was better than before. The information was more complete, up-to-date, and accurate than previously. As another clear impact, the relevance of issues communicated was higher (due to thresholds defined uniformly in the company). If the negative impact of an issue did not exceed the threshold, the team continued to solve the issue without investing time in communication with the next hierarchy level.

The impact on all levels needs further investigation. The author recommends companies aiming at introducing SFM, invest more in baseline quantification and in keeping track of the impact on a regular basis.

Table 5: Overview of indicators to evaluate impact of SFM

Perspective / Indicator	First quantification	Second quantification	Change	Hypothesis on cause-effect logic
Company sum of negative earnings from loss projects	100 points (as indexed baseline; end 2020)	37 points (mid-2022)	-63%	By recognizing deviations earlier and creating more effective solutions
Projects on-time completion of projects	100 points (as indexed baseline; 2020; n=53)	126 points (2021; n=45)	+26%	Higher awareness of schedule deviations (target / actual) compared to Last-Planner alone
People time spent in project meetings	4 hrs/month (2 x 2 hrs)	2 hrs/month (4 x 0.5 hrs)	-50%	Efficiency of stand-ups due to structured communication

With respect to the *contents* of the SFM boards, the general agreement was that all topics are relevant to successfully manage from the view of the respective role. At the same time, especially from the group of project leaders, it was noted that the SFM board contained too many elements to be handled efficiently. Also, major feedback was that the project leaders claimed to already know most of the information that was written on the SFM boards. The response to this was two-fold: (1) after multiple discussions with project leaders during refinement / continuous improvement of the SFM methodology, the outcome remained to be that all topics on the SFM boards are required for their management role. Regarding the feedback of already existing knowledge, an assessment showed that the change in communication behavior (resulting from SFM) was not fully achieved on an individual level: it is ineffective to continue the communication/information processing approach applied over years and apply SFM in parallel. The project leaders need to change the communication approach by regarding the SFM stand-up as the primary source of information, and ask the team members to provide their information not ad-hoc during the week, but instead during the stand-up (except for very time-critical issues). This change was underestimated and is a learning which may help other companies in the adoption of SFM.

The next learning concerns the *digitization* approach. The agile / SCRUM-based approach was very positive regarding flexibility and output. But the decision to implement a paper-based version on the project level before digitizing should be critically reviewed. The majority of negative feedback received was that the paper-based version was not only inefficient (writing by hand data that is available in systems and then feeding the issues over the threshold into the management cascade), but also created paper waste that can be avoided, and caused limitations to involve the full team during stand-ups. Team members concerned with the planning and procurement process could not be well integrated into a stand-up unless it was conducted in the office. This is not the intention of SFM, because the stand-up should take place on the construction site. Using a digital board allows the entire team to access it, independent of location (and time). Due to the SCRUM approach applied in software development, a usable version of the digital SFM board was available after only three months. With respect to the overall timeline of two years from the start concept to the start rollout, it is recommended to build the digitization into the timeline and start with the digital version earlier. This is contrary to the recommendation given on page 120 by Leyendecker & Pötters (2020). A relevant difference may be, that the company underlying this case study had a strong history in Lean. From an IT equipment perspective, the pilot projects showed that a very large touch-screen was not required for SFM. A regular (non-touch) screen on-site was fully sufficient to execute a stand-up. Because all sites were already equipped with a screen and a team meeting area, no additional investment was required.

In total, the expected positive effects of digitization outweighed the potential risks outlined by Clausen et al. (2020), with the exception of on-site leaders. Digitization of the boards for external stand-ups was discontinued, because on-site leaders gave feedback that the digital version was considered a too high barrier and culturally incompatible.

CONCLUSIONS

Over 2 years of implementation have created valuable experience regarding the adaptation of SFM to the construction industry. The results presented show measurable positive impact from all the perspectives (company, projects, people). Given the benefits outlined in this paper, the author expects a strong increase in SFM implementations in construction in the next years. Further research is required regarding the measurement of the impact created by SFM. The indicators presented in this paper are the first proposals, which should be further discussed. Also, it will remain a challenge to separate the causes leading to changes in such indicators aside from SFM, to isolate as much as possible the pure impact of SFM.

The paper shows that early adoption of a digital SFM system will increase acceptance and hence facilitate rollout. As the availability of technology to process large amounts of data advances, more intelligent features can be included in such a digital SFM system. This is positive and critical alike because it should be well understood that SFM is – at the core – a fundamental management approach, not just a set of boards or an IT tool showing numbers on a display. Companies seeking to embrace SFM should be aware that its successful implementation will strongly depend on the readiness to create teams that are more autonomous than in traditional hierarchical and functional setups, and that the teams are motivated to not only solve issues in the individual project but also to identify root causes of issues in the sense of company level continuous improvement and learning.

ACKNOWLEDGMENTS

Special thanks go to all project teams that have contributed to making SFM successful but trying out the method and then helping to refine it. Also, thank you to the leadership supporting the SFM methodology and the change coming with it. Finally, I would like to acknowledge the feedback given by all reviewers of this paper.

AN EXAMINATION OF IGLC TAKT LITERATURE - LEARNINGS & OPPORTUNITIES

William Power[1], Derek Sinnott[2], and Patrick Lynch[3]

ABSTRACT

Takt is gaining attention in the Lean Construction (LC) community and is recognised as an enabler for continuous improvement and a more complete implementation of LC. Adopting Takt from its manufacturing roots to construction has not been straight forward. International Group for Lean Construction (IGLC) research has adapted Takt principles and practices creating several models for its application in construction.

This study is an integrative literature review of papers in the IGLC index with 'Takt' in the title. Forty-eight papers were critically analysed, and key findings were themed by content analysis.

Findings show increasing interest in Takt studies since 2012 with Finland, Germany, US, and Norway respectively producing most papers. Takt has evolved from early application of Toyota Production System concepts and, with the addition of production and LC theory, has developed towards a more complete production planning and control framework with the potential to stabilise construction inputs, outputs, customer value, and quality. Takt research is beginning to impact project delivery with positive results witnessed as well as numerous challenges and improvement opportunities being identified. It is now recognised as a viable and proven production system that can initiate systemic improvement in construction delivery.

The research suggests every project should consider Takt from the outset in its high-level strategic planning and continue to assess where several sub Takt-plans can contribute to the execution of the project, assisted by LPS and the broader suite of LC techniques.

KEYWORDS

Lean construction, Takt planning, Last Planner® System, continuous improvement.

INTRODUCTION & LITERATURE REVIEW

Construction project management has predominantly relied on the Critical Path Methodology (CPM) for over 60 years, but its traditional use has been critiqued for failing to address the needs of production management (Ballard and Tommelein, 2021). Over-running tasks, in addition to scheduled tasks being 'forced' to commence because they have been committed by the CPM schedule, cause excessive and unnecessary work-in-progress and knock-on coordination, safety, quality, cost, and people related issues on projects. Academics and

practitioners alike have debated the shortfalls of CPM and have suggested alternative methodologies (Lean, Last Planner® System, Agile, Scrum, Takt) for the management of project controls, scheduling, planning, and execution. Recent years has seen an academic-led advancement of Takt planning studies in LC. Researchers Seppänen, Lehtovaara, Koskela, Ballard, Tommelein, Frandson, Drevland, Dlouhy, Schöttle, Nesensohn, Binninger, and Haghsheno have led and advanced application methodologies for utilising Takt concepts to enhance construction planning and production management. These studies illustrate how construction can incorporate Takt time as a work structuring methodology to align the production rates of trades by pacing work sequentially through planned zones creating continuous workflow, reliable handoffs, and an opportunity to continuously improve the production system (Frandson et al., 2013). Takt time regards 'space' as a resource to be considered when planning construction projects and designing production operations (Frandson et al., 2015).

TAKT PLANNING

The word 'Takt' or 'Taktzeit' in German means 'beat', 'rhythm', 'cadence' or 'meter', implying the regularity with which something gets done. In the production context, Hopp and Spearman, (2011) defined Takt time as: '…the unit of time within which a product must be produced (supply rate) in order to match the rate at which that product is needed (demand rate)'. It is a design parameter used in production settings that asserts if a process proceeds too quickly it will overproduce, and if it goes slower there will be a bottleneck (Frandson et al. 2013). Another critical consideration is that in construction workers move around the work as opposed to the work moving to the worker, for example, through a manufacturing assembly line (Ballard and Howell, 1997). Frandson et al. (2013) suggests the difference between Takt time planning and other location-based planning methods is this balance between 'work waiting on workers' and 'workers waiting on work.'

Takt time is easiest to understand in a machine-paced flow line, where each workstation along the assembly line must complete its work during the time the product is in its work zone. If the necessary work is not completed, the product proceeds to the next workstation in an incomplete state causing disruption to operations flow (Frandson, 2019). To minimise worker movement, work zones are kept as small as possible, with consideration given to the speed of the line and the capability of each workstation (Hopp and Spearman, 2011). By addressing process flow instead of solely maximising labour efficiency, Takt production accommodates the development of overall flow, especially when strategic buffer management occurs in contrast to the traditional use of large time and space buffers (Lehtovaara et al., 2021).

Several approaches to Takt implementation in construction have emerged from the literature. Takt Planning and Takt Control (TPTC) is highly structured and top down oriented (Dlouhy et al. 2018) and demarcates areas and repeatable 'Standard Space Units' (SSU) for each different function (such as an office). Work packages are then developed, and assignment metrics are calculated to assess the work content per work package. Takt areas then become combinations of SSUs (Binninger et al., 2017).

Allowing the trades involvement and consideration of the work sequence is a more bottom-up approach incorporated in Takt Time Planning (TTP) (Frandson et al. 2013); securing promises and social commitments speaks more to a softer collaborative environment. Focusing on maximising the amount of production activities performed with continuous use of resources is a critical element of TTP. This is possible by applying LPDS and TPS principles, and by taking advantage of the environment LPS provides (Frandson et al., 2014). TTP evolved by considering the use of 'space' and accommodating capacity buffers by scheduling less work than required to allow for variation (Tommelein, 2017).

'Work Density' is expressed in unit of time per unit of area and can be defined as: *Given a certain work area, work density describes how much time a given trade will require to do their work in that area, based on the product design and the scope of work done by that trade for a given task in the schedule (thus depending on the work already in place and work that will follow), the means and methods the trade will use to do their work while accounting for their crew's capabilities and crew size*, (Tommelein, 2017).

Takt production visualises the construction process in a way that includes work packages, work sequences, and Takt areas (Haghsheno et al., 2016; Dlouhy et al., 2016). Construction can utilise Takt time as a work structuring methodology to align the production rates of trades by pacing work sequentially through planned zones creating continuous workflow, reliable handoffs, and an opportunity to continuously improve the production system; Takt time is a design parameter for labour-paced flow of work (Frandson et al., 2013). Frandson et al. (2014) posits the objective of Takt time planning is to help create a more stable environment for the LPS by actively designing continuous workflow for trade activities wherever possible. LPS then provides the control mechanism and stability of the production system.

RESEARCH METHODOLOGY

RESEARCH OBJECTIVE & QUESTIONS

The paper reports on a review of only IGLC literature related to Takt planning. The primary objective is an examination of how Takt planning research has evolved and developed through the work of the IGLC academic community and how Takt is being interpreted and developed for use in construction. This will be achieved by answering several research questions. LC originated in the early 1990's with Ballard, Howell and Koskela's work in developing LC theory and LPS. Over subsequent years a growing body of knowledge has seen the development of specific tools for LC as well as the adoption of methodologies from other sectors. The first research question asks: What are the learning opportunities from the timeline and geographical spread of LC Takt publications? The second asks: How has LC Takt planning evolved over time? and the third question asks: What are the challenges/risks when implementing LC Takt planning?

METHODOLOGY

The methodology to identifying and evaluating relevant Lean literature consists of an integrative literature review (Snyder, 2019) of IGLC research publications (available at: https://www.iglc.net/papers). Figure 1 presents the methodology utilised.

Figure 1: Integrative literature review methodology utilised.

In accordance with best practice described by Snyder (2019), the integrative literature review containing the keyword "Takt" in the title searched the entire IGLC database from years 1996 to 2022 inclusive. This search yielded 84 results. These were read, and some were discounted due to lack of relevance and for clarity the search was narrowed to only those papers with "Takt" in the title, reducing the selection to 48 IGLC conference papers. Each paper was critically analysed, and emerging themes were evaluated by content analysis in accordance with Creswell and Poth (2016). Findings were collated and key themes are discussed.

LIMITATIONS

The study is restricted to IGLC literature with the word 'Takt' in the paper title. The authors acknowledge there are numerous studies within the IGLC index that refer to and contribute to the development of the construction Takt body of knowledge. Additionally, there are several publications available outside of IGLC that have not been considered in this study.

FINDINGS AND DISCUSSION

RESEARCH QUESTION #1. WHAT ARE THE LEARNING OPPORTUNITIES FROM THE TIMELINE AND GEOGRAPHICAL SPREAD OF LC TAKT PUBLICATIONS?

Examination of the timeline of IGLC publications with 'Takt' specifically in the title highlights no publication before the 2012 conference. The initial paper in 2012 (Fiallo and Howell, 2012) was followed with papers at every subsequent conference, the peak being nine studies in 2019. Figure 2 presents the number of studies per year.

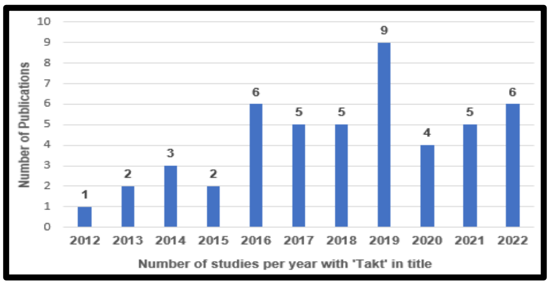

Figure 2: Number of studies.

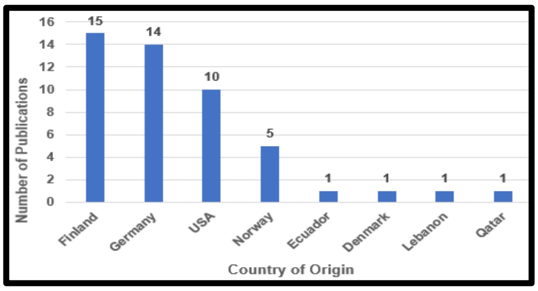

Figure 3: Geographical distribution.

The geographical distribution of studies is spread across eight different countries (Figure 3) with Finland and Germany leading the way with 29 out of 48 (representing 60% of the selected sample). Interestingly, the 2012 paper was a case study on an Ecuadorian project with Ripconciv Contractor and the lead author was both a Professor of Civil Engineering and a Lean Construction Coordinator with the case company. The co-author, the late Greg Howell, was President of the Lean Construction Institute. There has been an increasing focus on Takt planning research primarily driven by academic institutions in Karlshrue Institute of Technology, Aalto University, Norwegian University of Science and Technology, and UC Berkeley. Industry support has primarily come from the Boldt company, Sutter Health, BMW AG, Fira Oy, Skanska Oy, Consto, Veidekke, and Civil Soft Ltd. The research methodologies utilised are dominated by case studies with 35 of the 48 papers examined (73%) using this method.

RESEARCH QUESTION #2. HOW HAS LC TAKT PLANNING EVOLVED OVER TIME?

While the first paper with Takt in its title didn't appear in IGLC until 2012, it is important to acknowledge that earlier contributions identify the importance of Takt concepts and how they could assist construction planning, for example, Bulhões et al. (2005). Takt concepts (value generation, customer focus, demand rate, throughput, production rate, bottlenecks, value stream mapping) were introduced from the Toyota Production System (TPS) onto construction planning on a case project (Fiallo and Howell, 2012) and highlighted the effectiveness of Takt time as a communication tool for translating project goals to production daily goals. Significant schedule reduction (11 months to 5.5 months) on an exterior cladding installation was presented by Frandson et al. (2013) by developing a production schedule with a 4-day Takt time. This study offered a distinct process of six phases for identifying a Takt time to be used in production planning and was based on repetitive activities on the case site. At the same time Linnik et al. (2013) experimented in Takt application to non-repetitive work (interior framing phase) on a

Sutter Health hospital project. The study concluded that Takt planning does not require segregation of repetitive and non-repetitive areas and its application enhanced labour productivity through simplification and transparency of workflow and the drive for improved design of operations.

Also on the non-repetitive application theme, Tommelein (2017) reported on the 'work-density method' which proposed formalisation of a five-step process for collaborative Takt planning of non-repetitive work. Several papers bridged the gap from both LPS and Location-based planning to Takt planning and helped practitioners understand how they could transition towards keeping work flowing continuously (Frandson et al., 2014; Seppänen, 2014; Frandson et al., 2015; Schöttle and Nesensohn, 2019). Many studies (Faloughi et al., 2015; Emdanat et al., 2016; Heinonen and Seppänen, 2016; Vatne and Dreveland, 2016; Frandson and Tommelein, 2016) advanced knowledge by applying Takt concepts on individual case projects. However, the authors assert three critical bodies of work have contributed to the advancement of Takt planning knowledge; the work of Professor Haghsheno and the researcher teams from Karlsruhe Institute of Technology; Professor Tommelein and the researcher teams from UC Berkeley; and Professor Seppänen and the research teams from Aalto University. Despite having a lesser quantity of papers at IGLC the contributions from Norway and the individual cases from Denmark, Ecuador, Lebanon, and Qatar have contributed positively and enhanced the body of knowledge.

Haghsheno et al. (2016) took the approach of controlling takted construction processes by agreeing that ideal process analysis and the standard room units preceded determining the effort levels required for each activity. The goal is to level out the work packages ensuring the single unit of Takt time is not exceeded. Attention is focused on the detailed analysis and integration of customer demand, space, crew size, output, and buffer allocation to achieve stable construction processes. Key to this study's success was the focus on shorter cycle Takt time and quality completion of tasks. An interesting difference in approach is Frandson et al. (2013)'s use of a four-day Takt time, and Frandson and Tommelein (2016)'s use of a five-day Takt time as opposed to the Karlsruhe researchers who preferred to get as close as possible to a short-cycle or single day Takt. An exception to this is Dlouhy et al. (2016) who filled 'wagons' to achieve a five-day Takt time to level with longer duration activities. Binninger et al. (2017) used two and half day Takt on the first floor and five-day Takt on the ground floor of the case project. When Dlouhy et al. (2018, p.892) examined 10 construction case studies they found an average Takt time of 4.4 days and add '…Takt Time can have duration from a few minutes up to one week.' Studies show that in construction projects the Takt time generally lies between half a day and one week. This study asserts an opportunity exists for researchers to collaborate and agree the ideal process and approach towards establishing Takt time for the wide variety of scenarios that exist in construction and along its supply chain.

When reporting on the case of combining Takt with prefabrication, Chauhan et al. (2018) aggressively sought a one-day Takt time and again highlighted success by combining multiple Lean concepts. In a seven-story apartment project, Lehtovaara et al. (2019) combined a one-day and five-day Takt when interior finishing 42 apartments of varying layouts and floor areas. In summary of this point, Binninger et al. (2018) analysed 80 construction projects where Takt planning was used and found approximately 75% used a Takt time of one week. In contrast, an example of Heinonen and Seppänen (2016) describes a Takt time of 15 minutes which presented excellent improvements in cruise ship cabin refurbishment and posed the challenge to construction that improvement goals set in construction have been too low, possibly due to lack of external pressure or demand. Binninger et al. (2017) conclude that every project could have a different Takt time while noting that in practice a weekly Takt is often selected due to the instability of construction processes.

The contributions presented in table 1 assess the emerging themes from 41 of the 48 analysed papers that have emanated from four research institutes. Table 1 highlights the broad range of technical, tactical, cultural, and softer aspects to be considered in Takt implementation. Interestingly, recent years has seen more interchange of ideas and views with collaborative studies presented, for example, Lehtovaara et al. (2022).

Table 1: Principal research contributions (41 of 48 papers)

Authors	Content focus & contribution
Haghsheno & Karlsruhe researchers	Shortest possible Takt time – measuring tasks in decimal minutes, one-hour Takt time tested, single day is recommended; quality completion of tasks; Introduced three levels – Process Analysis, Takt Planning, Takt Controlling. Takt Planning and Takt Control Method (TPTC); Case studies in automotive sector construction projects (BMW); Takt learning simulation game; Use of Takt in equipment installation; Introduced flexibility - decoupling of Takt area, empty buffer wagons, phase interlinking, soft start, and train stoppage; Takt applied on large scale project; introduced double packaging and sequencing; comparing construction and equipment phase Takt planning; Focus on buffer management; Takt workflow.
Tommelein & UC Berkeley researchers	Six sequential phases of Takt planning process; Takt Time Planning Method (TTP); Determine Takt time by overall duration allowed or consider available resources, identify bottleneck, improved bottleneck becomes demand rate. Case studies primarily in Sutter Health projects. Four- or five-day Takt time. Introduced 'Work Density Method' to find repetition in non-repetitive work. Formulated five steps for collaborative Takt time planning; Visual digital tools; Takting the Parade of Trades Model; applying Failure Mode & Effects Analysis (FMEA) to control Takt;
Seppänen & Aalto researchers	Linked existing research on location-based techniques to Takt for construction; Cruise ship refurbishment showed huge benefits terms of quality, productivity, work-in-progress and cycle time and highlighted Takt potential; combining Takt and pre-fabrication; focus on short Takt times (15 minutes – cruise ship, one day on prefabrication); Discussed impact of logistics and external variation; compared US (Californian) and Finnish approaches and maturity level; Model describing Takt maturity; Takt in renovation project; Client's perspective on value-creation and flow; Introduced visual management and digital technology as part of Takt Control; Continuous improvement system; applying FMEA to control Takt.
Drevland, Lædre, Andersen & Norwegian University of Science and Technology researchers (NUST)	Proposed aligning salary / payment terms to facilitate Takt; consideration of Takt overhead costs; suggest development of guidelines for consistent Takt implementation; considers early division of the project into many smaller phases and postpone the details until the individual phase is to be performed; highlight impact of delays in disrupting Takt.

Four specifically different approaches become evident from analysis of the studies. A synopsis of the steps in each approach is presented in table 2.

Two alternatives to define the overall Takt time are suggested by Frandson et al. (2013). The first is based on the duration to complete work and the second is to consider available resources, identify the bottleneck, study if the bottleneck's rate can be improved, and use the improved rate as the achievable demand rate (Heinonen and Seppänen, 2016). Setting the Takt time in Heinonen and Seppänen's (2016) study was a mathematical exercise dependent on the number of cabins, scope (man-minutes / cabin) and project duration (mandated by the owner) as it was impossible to compromise on the customer's lead time due to the owner's high opportunity cost. The calculated Takt time must accommodate both contractor's and owner demand perspectives and can be adjusted through reduction of buffer times or through further optimisation and acceleration to adjust customer demand (Haghsheno et al., 2016).

Table 2: Suggested process steps in selected approaches

Authors	Suggested Process Steps
Linnik et al. (2013)	1) Identify the trades that will work in the phase and how their tasks will be grouped together. 2) Gather information from trade partners. 3) Sequence trade groups and the trades within groups, identify bottleneck trades in each group, and roughly estimate their achievable production rates within the Takt areas. 4) Balance workflow determining Takt time in each sub phase. Adjust area structure if needed. 5) Use Takt time strategy to plan for resources, materials, and information.
Frandson et al. (2013)	1) Gather information. 2) Define areas of work (zones). 3) Understand the trade sequence. 4) Understand the individual trade durations. 5) Balance the workflow. 6) Establish the production plan.
Haghsheno et al. (2016)	1) Process analysis. 2) Agree working steps. 3) Establish standard room units. 4) Determine effort values. 5) Takt harmonisation. 6) Add buffers. 7) Takt control.
Heinonen and Seppänen (2016)	1) Defining Standard Workflow Within Construction Train – scope of work, set of tasks, workload value per task in minutes, Takt time is the time the system has available, select optimal crew size, assess logical and resource dependencies, bundle standard set of tasks (repeated each Takt time by same crew) into wagons, size buffer into Takt time, define material delivery and garbage collection points. 2) Define logistics – design one-piece flow of materials at first point of packaging, material delivery trollies, pick one cabin at a time. 3) Management roles and responsibilities – train drivers, (co-driver, logistics manager, logistics foremen)

While many of previous case studies were conducted on aspects of a single project, for example, internal drywall or on selected floors, Dlouhy et al. (2018a) reported Takt success on a large-scale project in Mexico. Extending beyond the pure construction phase, Dlouhy et al. (2017, 2018b) compared Takt in the construction and equipment phases of the same project and found recognisable benefits in collaborating and considering interfaces to upstream and downstream phases. Managing inputs and controlling variation is an essential component of Takt and was a specific focus of Chauhan et al. (2018) and Tetik et al. (2019) when examining prefabrication and logistics management in the context of Takt planning. On a similar theme, Vatne and Drevland (2016) found Takt implementation made it easy to spot errors and continuously steer the production proactively. However, despite much improved throughput time (reduced by 30%) and the project being lauded as successful, Alhava et al. (2019) found the flow of the Takt process allowed next tasks to proceed without full root cause assessment of errors, therefore allowing the errors to be repeated. This illustrates how using selected LC methodologies can highlight improvement opportunities in the existing process. However, to ensure delivery system advancement it is important that each opportunity is addressed by utilising the entire suite of LC methodologies - ultimately the project and stakeholders will develop their own Lean Project Delivery System. Table 3 summarises the key contributions of Takt to improving construction delivery.

Table 3: Takt contributions to improving project delivery.

LC Takt contributions to improving project delivery
Initiation & driving of continuous improvement culture.
Introduction of disciplined process analysis to trade workflow & supply chain inputs.
Focus on error-proofing and FMEA.
Importance of softer aspects alongside scientific approach.
Improved communication through visualisation of production goals.
Introduction of Lean concepts from TPS (value generation, customer focus, demand rate, throughput, production rate, bottlenecks, value stream mapping).
Visualisation of buffers.
Focus on balancing trade cycle times – from 15 minutes to a single day or 5 days (as determined mathematically).
Bringing stability to constructions supply chain inputs & logistics organisation to help control variation.

Stabilising inputs and effective logistics organisation are critical components of construction planning; Vatne and Drevland (2016) highlight this in a residential construction case study. Using Takt to plan materials and information inputs and well as coordinating Just in Time (JIT) deliveries is highlighted by Linnik et al. (2013, p.616), where Takt allowed supervisors and construction engineers more time to '…support the trades in determining quality requirements and in performing first run studies to test and refine the design of construction operations. They can spend more time on material and quality planning, and on root cause analysis of accidents, defects, and plan failures to avoid similar problems in the future.' An examination of flow in Takted projects (Binninger et al., 2019) found significant difference between planned and actual flow efficiency; the authors posit consideration of and balancing the mix of short delivery times of the product from the client perspective and stability and consistency of resources from the subcontractor's perspective. Flow and value-creation specifically from the client's perspective was examined by Lehtovaara et al. (2021), noting the proactive role of a client helps to put customer value in the centre of Takt production. Takt was also found to contribute positively to the flow of the trades while noting the importance of trust between stakeholders (Kujansuu et al., 2020). Practitioner awareness and knowledge of LC and Transformation, Flow, Value theory, as well as practice in all function of LPS, is an important enabler of Takt implementation;

logistics, supply chain, and multi-interface management requires technical and theoretical understanding of multiple LC and production system concepts.

The importance of the softer aspects also emerged in a comparison of collaboration and trade partner commitment in Californian and Finnish Takt implementations; Kujansuu et al. (2019) found the strong Lean culture established by the Californian companies allowed more reliance on social aspects and trust between stakeholders. People engagement, openness to new ways of working, and cultural aspects were highlighted as challenges by Schöttle and Nesensohn (2019). This highlights the importance of having the softer and people-related aspects of change-management in place when projects are introducing 'new' methodologies that challenge traditional approaches within construction delivery.

The strong knowledge on the technical aspects of production planning established a platform to build the Finnish model of Takt implementation. A study by Lehtovaara et al. (2020) recognised the construction sector was missing an opportunity to develop a shared understanding of systemic Takt production implementation. Academic discussion had primarily focused on how to technically implement Takt production in single projects while a few pioneering clients and contractors had experimented with aspects of Takt on elements of projects. However, a study of Takt application on a large-scale project ($1Billion) by Abou El Fish et al. (2022), allied to Dlouhy et al. (2018a) highlighted how Takt helped the construction team to properly control, organise, and place resources into projects to achieve desired goals. In an examination of Takt as an enabler for LC, Tommelein and Emdanat (2022) suggest Takt should be considered at early project strategic level, thereby assisting align design and supply chain. They add that a Takt implementation should be viewed as foundational to a framework that supports continuous improvement efforts. Additionally, Tommelein and Emdanat (2022, p. 876) conclude '…teams interested in implementing LPS on their projects start by designing their production system using Takt, and then design their LPS implementation to take advantage of all the opportunities production management and control offers.'

In conclusion, Takt research is beginning to impact project delivery with positive results witnessed as well as numerous challenges and improvement opportunities being identified. Takt started from consideration of directly applying production concepts from TPS, evolving from LBMS and LPS practices, considering technical and mathematical aspects, and testing hypothesis on different construction projects across geographical locations and cultures. Takt is now recognised as a viable and proven production system that can initiate systemic improvement in construction delivery.

RESEARCH QUESTION #3? WHAT ARE THE CHALLENGES/RISKS WHEN IMPLEMENTING LC TAKT PLANNING?

Vatne and Drevland (2016) identified a key challenge to Takt implementation on projects where the payment system (piece work) doesn't align with splitting of work packages into multiple Takt trains. This concern was also voiced in Lehtovaara et al. (2019) and Binninger et al. (2018) and was mitigated by a commitment to fully pay the subcontractors for a three-day trial even if no work was completed. According to Binninger et al. (2017), Takt has undergone criticism due to its scheduling rigidity during construction and its perceived hinderance to adjustments on a project. Handing over unfinished Takt areas tends to lead to more delays later because of irrational work sequences and correctional work (Dahlberg and Drevland, 2021), concluding that Takt is a fragile production system needing daily monitoring and readjustment. Extra management resources are possibly required as, according to Binninger et al. (2018), close supervision and comprehensive documentation are required to achieve and maintain low Takt times. Caution must also be exercised as Alhava et al. (2019) discovered the implementation of digital methods found a lot of waste in the project; despite reporting a successful project and achieving a 30% cycle time reduction a lot of waste was made visible.

The intensity of Takt planning can catch subcontractors and material suppliers unawares meaning procurement and payment models must align to suit (Lehtovaara et al., 2019). Additionally, incomplete design cannot become a cause of bottlenecks, drying times and critical tasks must be thoroughly planned, and Takt must become a holistic approach as opposed to just managing an individual construction phase (Lehtovaara et al., 2019). In a collaborative research paper (UC Berkeley and Aalto University) Lehtovaara et al. (2022) examined FMEA as a countermeasure to Takt failure and offer a framework for Takt control that uses the FMEA process logic. This study presented a systematic guideline for problem-solving in a Takt control context and illustrated examples of failures, failure modes, root causes, and control actions to assist in applying the framework.

CONCLUSION, RECOMMENDATIONS, & OPPORTUNITIES

It is evident from the IGLC literature that Takt has become a much-researched topic that has acquired attention from academics and practitioners alike. The examined studies are unanimous in agreement of advantages accruing from Takt implementation and a broad list of disruptive issues are presented. However, the authors assert such 'making-do' issues are an everyday aspect of construction delivery and it is only when such an intense but fragile framework like Takt challenges the status quo can practitioners truly acknowledge the amount of variation and variability that exists.

Takt is now recognised as viable and proven production system that can initiate systemic improvement in construction delivery. To ensure continued advancement it is important that each identified improvement opportunity is addressed by utilising the entire suite of LC methodologies and ultimately the project and stakeholders will develop their own Lean Project Delivery System and culture. Allied to the development of this improvement culture is the importance of having the softer and people-related aspects of change-management in place as efforts that challenge traditional construction delivery approaches can meet active or passive resistance.

Despite the pioneering research and advancement, studies have highlighted the need for a consistent globally agreed framework that aligns thought leader's ideal-state perception of Takt implementation. This would accommodate geographical distinctions, cultural and softer aspects, and encourage a more holistic implementation both upstream and downstream of the specific construction execution phase. Researchers must also be cognisant that innovation must be encouraged as consistently testing hypotheses and methodologies on live projects exposes the daily challenges that stifle productivity improvement within the sector.

Every project should consider Takt from the outset in its high-level strategic planning and continue to assess where several sub-Takt plans can contribute to the execution of the project, assisted by LPS and the broader suite of LC techniques.

IMPLEMENTING LEAN METHODS FOR FACILITY MAINTENANCE MANAGEMENT

Kiran Rambhau Janjalkar[1], Abhishek Raj Singh[2], and Venkata Santosh Kumar Delhi[3]

ABSTRACT

The breakdown of facilities in a built environment results in inconvenience to the stakeholders due to the downtime (DT) experience. The facility DT can be brought down through proper facility maintenance management (FMM). Within FMM, different processes occur to make the facility work normally. These activities of FMM are sometimes planned and often executed when a facility undergoes breakdown. This study targets to understand the implementation ability of lean methods in situations when a service of a built environment has failed and the FMM system tries to bring it back to normal functioning. An educational institute's FMM process to address DT is mapped using value stream mapping (VSM), and delays associated with the current process are captured. This mapping helped in identifying delay causes like material unavailability and administrative delay. The research utilizes the 5S (Seiri, Seiton, Seiso, Seiketsu, Shitsuke) and Just In Time (JIT) methods of lean to improve the FMM process, and implementation of these methods resulted in achieving resolution time closer to the time expected by the stakeholders utilizing the facility.

KEYWORDS

Facility maintenance management, lean philosophy, 5S, JIT, VSM

INTRODUCTION

The concept of facility management (FM) is defined as an integration of people, process, technology, and place that can ensure the functionality of the built environment (Atkin & Brooks, 2015). Within FM, the facility maintenance management (FMM) shares the most (65% ~ 85%) of the FM cost (Chen et al., 2019). Any built-up facility requires maintenance to perform satisfactorily and makes the buildings habitable and serviceable for the stakeholders. Unlike residential buildings, the built-up facilities of an educational institute are designed to serve different functions to a large population of stakeholders. With an increase in globalization, the facilities available at an educational institution become a criterion for the stakeholders to make decisions (Cubillo et al., 2006; Price et al., 2003). The Institute facilities are essential in attracting researchers by providing a suitable environment for faster knowledge creation (Fleming & Storr, 1999). Good infrastructure for educational institutes creates the chance to attract and sustain global talent.

Maintaining such facilities has a significant cost that could vary from 15% to 70% of the initial investment cost depending upon the type and size of the project (Fraser, 2014). Generally, these maintenance costs are proportional to the downtime (DT) of the system or an asset

(Mostafa et al., 2015). The DT can be defined as the time interval when the system/equipment is down for maintenance activity until it is back to its normal working condition (Tinga, 2013). The DT is impacted due to the presence of non-value-adding activities (NVA) and wastes in the process of maintenance (Sawhney et al., 2009). Due to increased DT, there is a chance of overloading the existing working facilities, which may further lead to the failure of the existing system. Frequent occurrences of increased DT in facilities management may have a severe impact on the reputation of any organization (Atkin & Brooks, 2015). Hence, efficient FMM is imperative for the smooth functioning of the day-to-day operations of an organization.

The lean philosophy provides waste minimization methods while creating value for the stakeholders (Denzer et al., 2015). Lean philosophy mentions the elimination of waste (Viana et al., 2012) and reducing NVA to improve the process (Mostafa et al., 2015). Previous research studies have focused on lean implementation for construction and supply chain management, but a narrow focus is given to FM (Gao et al., 2020; O'Reilly et al., 2019). With a rising focus on FM as a strategic element for revenue generation, the FMM is recognized as an essential process (Mostafa et al., 2015). The present study attempts to highlight the NVA in the process of addressing the complaints of the stakeholders in an educational institute. The focus remained on investigating the applicability of lean tools for FM, and some lean methods like 5S, Just-in-Time (JIT), and Value Stream Map (VSM) are utilized to bring down the DT. The study considers unplanned DT for facilities and presents a lean approach to handling and improving the process of FMM in an educational institute.

REVIEW OF LEAN-FM SYNERGY

The FMM comprises but is not limited to activities that are scheduled and planned. In the event of a system breakdown, the stakeholders suffer due to unplanned DT. An unplanned DT request for maintenance indicates a 'pull' of value from the system. Similarly, lean works on the principle of creating value for the stakeholders, i.e., the services upstream should be produced when the stakeholders downstream require them (Gao et al., 2020). In an educational setup, the service DT impacts the habitants, and a quick-fix approach is traditionally adopted. It is essential for these services to be functional to deliver value to the stakeholders. The breakdown of any service in an educational institute is an unanticipated event that makes it challenging in comparison to other sectors like construction, and supply chain management, where lean implementation is proven beneficial. This study attempts to utilize some lean tools like 5S, JIT, and VSM to deliver value to the stakeholders just-in-time.

5S AND JIT FOR FM

The philosophy of 5S originated in Japan (Chandrayan et al., 2019). It is an acronym for five different Japanese terms 'seiri (organization of the workplace, sorting, elimination of unwanted inventory), seiton (neatness, set in order, place for everything), seiso (cleaning, shine), seiketsu (standardization, constant place for things, constant rules for organization of things), and shitsuke (sustain, discipline)' (Kobayashi et al., 2008). The Western literature from the UK and USA mentions 5S as a technique or a tool to improve working conditions. The lean studies report the implementation of 5S as an easy and uncomplicated process (Bayo-Moriones et al., 2010). Alongside process improvements, the 5S implementation is also reported to channel other lean tools like JIT (Kobayashi et al., 2008). The JIT concept was framed by Taiichi Ohno in Japan (Kumar & Panneerselvam, 2007). The JIT emphasizes continuous waste reduction and eventually eliminating all forms of waste (Brown & Mitchell, 2017). The JIT concept of lean focuses on providing the required items at the right place and right time. Research studies indicate the JIT implementation in synergies with pull planning systems to generate value (Mumani et al., 2022). In attempts to understand the bottlenecks of push-pull systems, another tool highlighted in lean literature is VSM.

VSM FOR FM

VSM is an essential tool associated with lean methodology and is extensively used to map information and process flow (Sawhney et al., 2009). VSM is an effective tool for identifying and resolving the issue that can be seen in current approaches. This allows for the maximization of performance at the project level (Pothen & Ramalingam, 2018). It helps to map the process and identify the wastes and their sources in the process. Application of VSM is a five-stage process that starts with selecting an activity, developing a current state map, analyzing waste and developing a future state map, proposing an action plan, and its validation. The lean research presents the applicability of VSM to map processes using one key metric of value-adding time. These maps primarily capture the process flow through icons and symbols, following which the value-adding activities, non-value-adding activities & non-value adding but necessary activities time are measured (Mostafa et al., 2015). Although the planned FMM activities might appear as non-value adding to the stakeholders when an unplanned DT strikes, the FMM becomes a value-adding activity.

RESEARCH DESIGN

The DT of services at an educational institute impacts the habitant's academic achievements and brings a bad reputation to the institution (Lok & Baldry, 2015). Therefore, to mitigate the ill effects of service breakdown, an efficient FMM system is needed. This study reviews the existing FMM system at an educational institute and presents opportunities to improve using lean methods. Figure 1 presents the sequential procedure followed in this study to understand the implications of implementing lean methods to FMM. The initial stage of this research starts with collecting data related to the DT encountered by the stakeholders of the built-up facilities in the institute considered for this study.

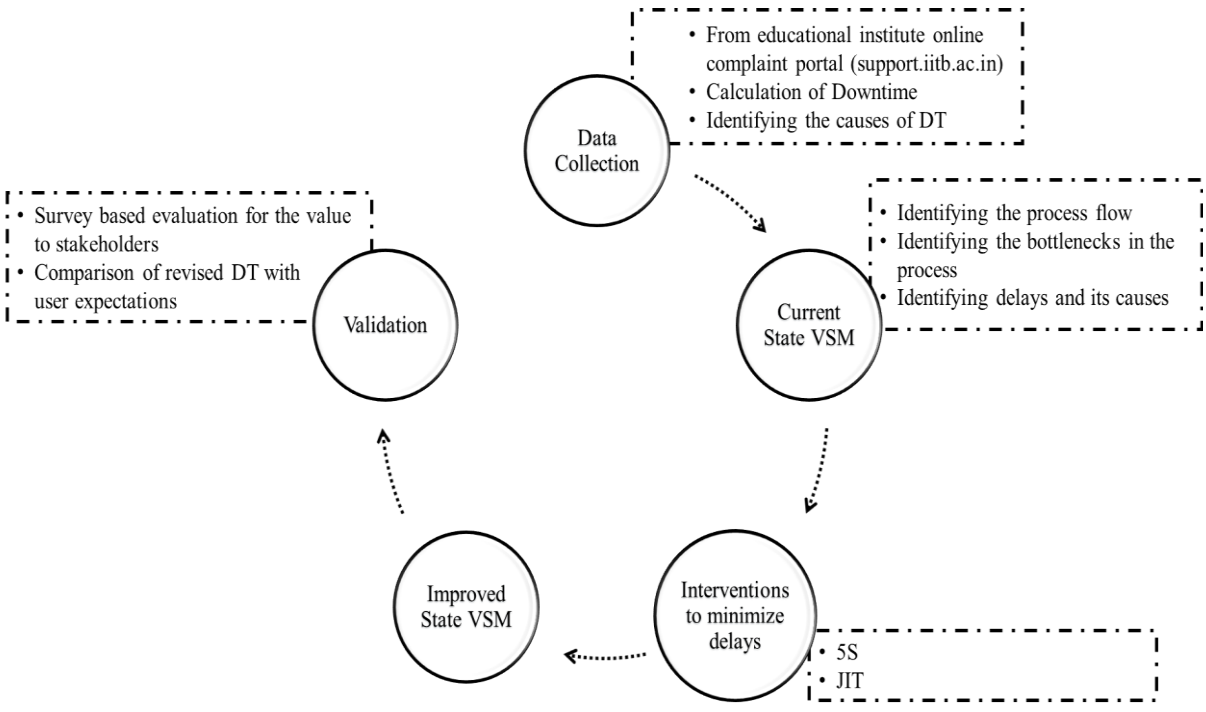

Figure 1: Methodology followed in this Study

Upon data collection, the current state VSM for the existing FMM process is mapped, targeting two different delays, and bottlenecks in the FMM process are identified. Although the current state VSM is followed with future state VSM in lean research, the researchers for this research targeted to implement 5S and JIT methods of lean to address the bottlenecks identified from current state VSM. After the implementation of lean methods, an improved state VSM is developed to understand the improvement achieved. Finally, to verify the observed improvement in the improved state VSM, the resolution time expectations of the stakeholders residing in the institute are compared with the achieved time to resolve complaints.

DATA COLLECTION AND CURRENT STATE MAP

In an attempt to understand the delays in FMM, a web-based DT complaint registering portal is utilized to collect the complaints of the stakeholders. The support portal can be accessed through a web address mentioned in Figure 1. This portal allows the stakeholders to report any maintenance requirements from the 17 student accommodation buildings of the institute. After a complaint is raised, it is transferred to a concerned administrative section, following which a required action is initiated against the complaint. For our context, the Down Time (DT) is the duration between registering a complaint and closing the same. As per internal guidelines, registration can only be done by the users through the portal and closed by the concerned staff after verbal confirmation by the users.

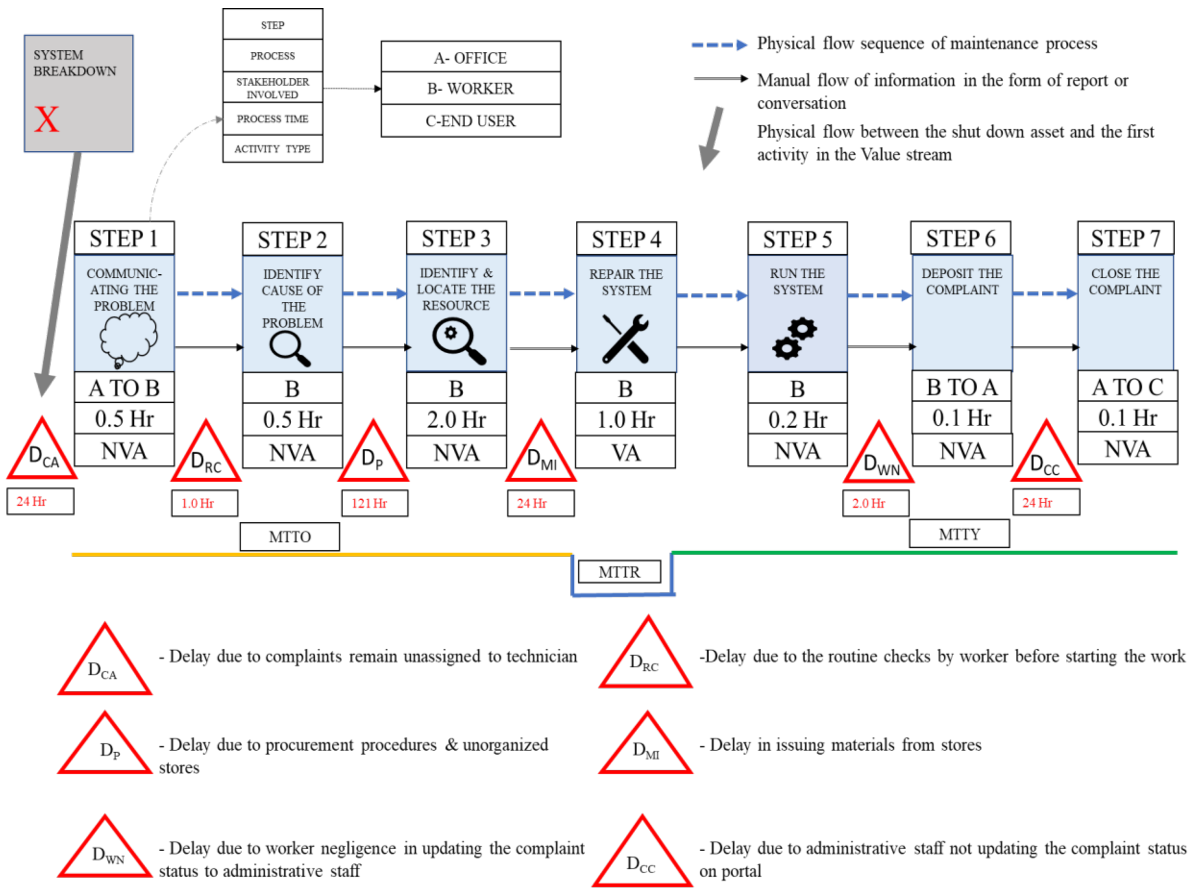
The VSM of the current process is prepared to map the activities, and the associated time with each activity is mapped accordingly to get an understanding of Mean Maintenance Lead Time (MMLT) (Sawhney et al., 2009).

CURRENT STATE VSM

The first step in plotting the current state is determining the steps and processes involved in the existing FMM system of the educational institute. The maintenance process is triggered by detecting and reporting the failure of an asset or system (Marttonen-Arola & Baglee, 2020). Such type of maintenance comes under corrective and unplanned maintenance strategies.

Once a maintenance work request is raised on the support portal of the institute, the concerned administrative person collects the requests and forwards it to the concerned technician of the department only after a bulk of requests are accumulated. Then, the technician performs a manual inspection of the reported problem by making a visit to the respective building from which the end-user has placed the complaint.

Then a request for necessary resource requirements to rectify the defect is raised by the technician. The requested resources will be made available to the technician either from the inventory if the material is available with the institute material store or is procured from retail vendors. Then, the technician will fix the complaint, take confirmation from the user, and deposit the complaint to the office for closure. The office staff will then mark the complaint status as resolved on the complaint management system. Figure 2 presents the current state of the maintenance process, where seven main activities are identified in the process communicating the problem, identifying the problem, identifying, and locating the required resources, repairing the system, running the system, depositing the complaint, and closing the complaint. The process time (PT) associated with each activity in the developed current state VSM is taken from the visual observations and experts' opinions.

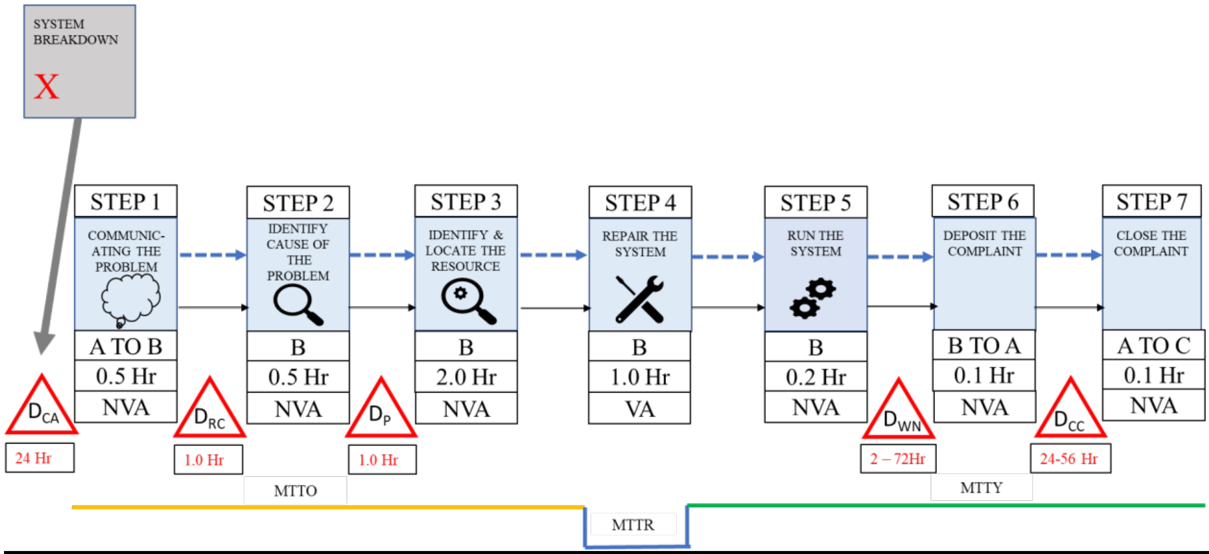


200.4 hrs.	Mean Maintenance Lead Time	MMLT
173.0 hrs.	Mean time to organize	MTTO
1.0 hr.	Mean time to repair	MTTR
26.4 hrs.	Mean time to yield	MMTY
1.0 hr.	Value adding time	VAT

Figure 2: Current State Map for Complaints Delayed Due to Material Unavailability

In the entire process of rectifying the defect, only repairing the system activity is value-adding to the end-user, whereas the rest of the activities remain non-value adding. From the above Figure 2, the Mean Maintenance Lead Time is 200.4 hours, i.e., approximately eight days, and there is a significant delay of 121 hours in locating the resource termed as delay D_P in Figure 2, resulting in a long DT of the services. It is identified that a significant time portion is spent on organizing resources to address the end-user problem. This is due to the time lost in searching for materials in the inventories, and sometimes the material is not available with the store department resulting in procuring the resources from the market; such delay in material search and procuring results in longer DT of the system.

Therefore, to understand the delays in the system where the actual DT of services is lesser than the recorded DT, another VSM is prepared, as shown in Figure 3.



MMLT	MMTO	MMTR	MTTY	VAT
56.4-158.4 hrs.	29.0 hrs.	1.0 hr.	26.4-128.4 hrs.	1.0 hr.

Figure 3: Current state map for complaints delayed due to administrative delay

From Figure 3, the maximum MMLT is 158.4 hours, i.e., approximately six days. The end user is not concerned about delays D_{WN} and D_{CC} because the complaint is resolved in 30.0 hours, and the services are working again. However, such complaints cause overloading of the complaint management system, which overall affects the efficiency of the facilities management system. The delay in updating the status of the complaints on the portal does not provide the current availability of the resources for attending to any other system breakdown, thus resulting in a delay in attending to the complaints that keep on piling up due to administrative negligence. Timely updating of the complaint status will bring down the MTTY and help in identifying resource availability. Consequently, by bringing down the MTTY, the other DT associated with other system breakdowns can be brought down by the timely resolution of the complaints. Hence, it is essential to reduce waste associated with material procurement and delays in updating complaint status.

RESULTS

The data for this study is collected on the complaints raised between August and September 2022. A total of 349 complaints were received, among which the carpentry and plumbing works are found to be the major complaints. Other complaints include masonry, fabrication, and cleaning-related works. A breakdown of complaints is presented in Table 1.

Table 1: Complaint data of 17 buildings

Month	Plumbing	Carpentry	Other	Total
August 2022	88	106	20	214
September 2022	62	61	12	135

Upon receiving the data of complaints registered in the period mentioned in Table 1, the complaints are studied with the help of the concerned technicians to extract the possible reasons for the delays. From the obtained complaints data, ten causes of delays are identified, as shown in Figure 4, namely workmen (technician) unavailability, material unavailability, duplicate complaints, multiple departments involved, major modification work required, works require outsourcing, unique material requirements, delays due to external sources, end-user unavailability, and administrative delay.

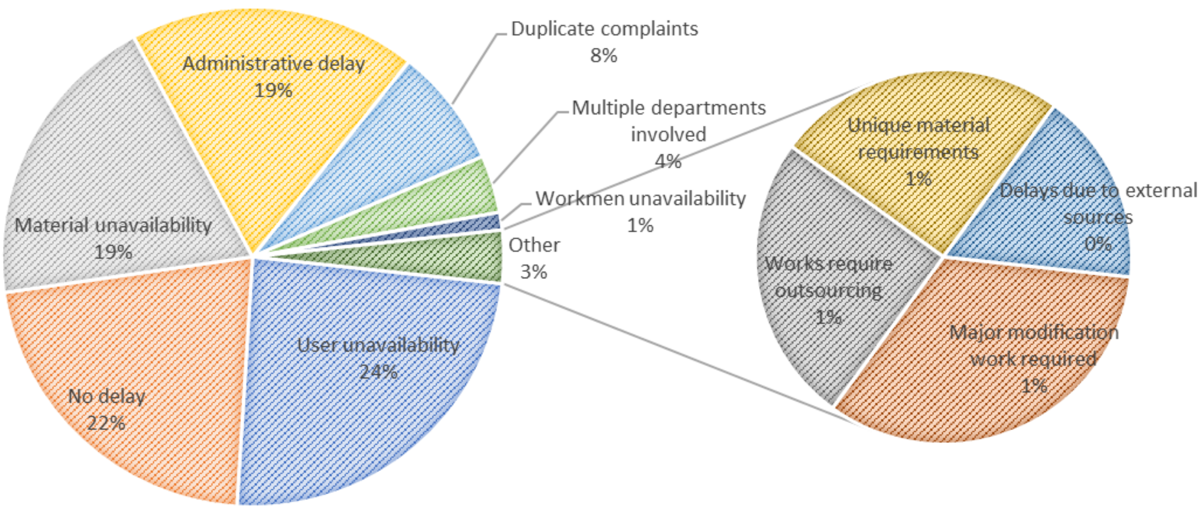


Figure 4: Distribution pattern for no delay and reasons for delay

It is observed that a significant share (24%) of the DT is due to the unavailability of the user when the maintenance team comes to address the problem raised by the stakeholder. This share of facility DT is hard to address as the end user for whom the value generation is targeted by addressing the raised concern is unavailable. Thus, such complaints and the DT are not addressed in this study. Following user unavailability, 22% of the raised complaints are addressed as quickly as possible, and the services are restored with no delay. Since the FMM comprises but is not limited to the involvement of administrative, technical, and end-user stakeholders, the other 38% share in the delay of addressing complaints is shared equally by the administrative and the material unavailability to address the problem. 19% of complaints indicated DT associated with material unavailability. It is primarily due to the initial time lost in searching for the appropriate material for replacement or sometimes due to the unavailability of the material in the inventory. It is observed that the unavailability of the material is identified upon a significant amount of time lost in searching the inventory maintained by the maintenance department, consequently increasing the DT.

Another share of complaints (19%) results in delay because of system inefficiency in closing the complaints and marking them resolved. It means that the raised complaints are attended timely, but they are not closed immediately upon successful resolution on the portal by the administrative staff and thus are categorized under administrative delay. This category of the complaint will be considered under as waste category, as the delayed closing of the complaint will not have any impact on the DT of the facilities.

Two categories of complaints - material availability and administrative delay, are selected for the application of appropriate lean methods.

INTERVENTIONS TO MINIMISE DELAYS

From the current state of VSM, it is clear that there are wastes involved in the process flows. The MTTO is approximately 173 hrs. which equates to more than a week's time to organize the resources to carry out the actual repair. There are multiple delays associated with the delayed resolution of complaints due to material unavailability, as shown in Figure 2. Among these delays, the D_{CA} of almost a day indicates the delayed assignment of the task to the technician. A provision of immediate allotment after receiving a complaint is introduced to address this delay. After allotment of the task to the technicians, delay D_{RC} is observed where the technicians have to manually inspect the nature of the registered complaint, and such visits result in loss of time due to travel to the location of service under DT. In an attempt to minimize the travel time only for inspection, an option of uploading the photographs of the service requiring maintenance is asked from the user in an online complaint portal of the educational institute.

This approach of collecting information related to the service requiring maintenance is developed so that upon receiving the complaint along with photographs, the material procurement step of the process can be initiated as soon as possible. Within MTTO, a significant delay is noticed between the process of 'Identifying the cause of the problem' and 'Identifying and locating the resource.' Although the process of identifying and locating resources takes two hrs., the initial search process for the resources consumes the delay time and results in longer DT. The authors observed that the delay in resource search also results in vain if the appropriate material is not found in the institute's inventory.

Upon noticing the material unavailability, the material procurement step from external sources starts. Therefore, the search time spent locating an unavailable material in the inventory results in unnecessary longer DT of the system. Thus, to minimize the search time for unavailable material, the inventory unit is redesigned by implementing the 5S concept of workplace design, as shown in Figure 5. As the cluttered place of storing materials became organized, the situation of the available inventory became more precise, and such organization is also implemented in record keeping of the inventory.

Figure 5: 5S Implementation in the Inventory Room

Upon identifying material unavailability, the procurement of materials is initiated, for which a separate contract is created that results in a time delay. Some lean literature presented that this type of waste can be eliminated by adopting the Just in Time (JIT) lean concept. The JIT highlights no requirement for inventory, and the material is directly procured from the suppliers. Therefore, to implement JIT, an annual maintenance and supply contract is proposed for materials used in the buildings for which complaints are received. So, the vendor can be asked to carry out the maintenance work when required. In this way, the delay due to material procurement is reduced to an extent, and DT is shortened.

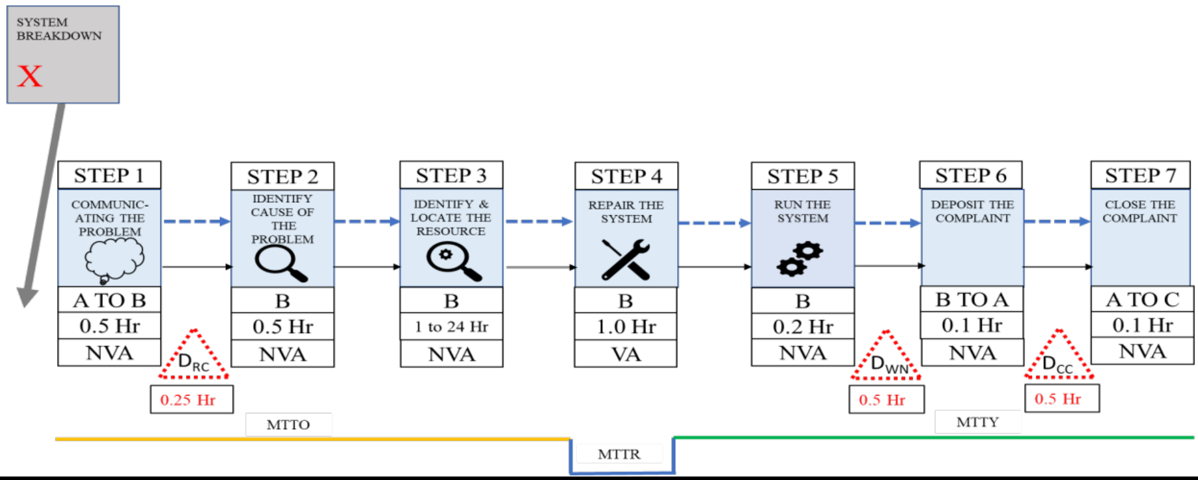
Thus, how the wastes related to the process before the repair work starts and the material unavailability are attempted to be minimized by applying lean philosophy.

Other delays D_{WN} and D_{CC} is related to the closure of the registered complaint that results in MTTY. These delays do not create value for the end user, but it overloads the complaint management system and impacts the efficiency of the FMM system. This waste can be easily eliminated by transferring the information as soon as the complaint is attended to and the services return to normal functioning. It is proposed that the status of the complaint upon successful resolution should be reported JIT to the administrative staff for closing up the complaint and releasing the resources from the task. This JIT reporting will not only bring down the recorded DT on the portal but will also affect the other services under DT, as the resources are now available to address those complaints.

DISCUSSION

The implementation of web-based direct allotment of complaints and allowing users to report issues with photographs of the service under DT are implementations of computer-based (Smith & Hawkins, 2004). This approach of reporting the issue improved the information flow between the stakeholders and indicates the essentiality of information flow for improved flow in the process (Dave et al., 2014). Also, lean concepts like 5S and JIT are now incorporated into the current FMM process flow, and the process mapping is done to assess the impact. 5S is implemented in the institute's stores, where the material is kept and collected by technicians for attending to the complaints.

JIT is implemented where an annual maintenance contract (AMC) is prepared for the supply of various materials and services as and when required. This will reduce the material waiting time in the process. These lean methods for process improvement are incorporated into the existing process to bring down the MTTO. Figure 6 shows the proposed improved VSM.



MMLT	MMTO	MMTR	MTTY	VAT
4.65-27.65 hrs.	2.25-25.25 hrs.	1.0 hr.	1.4 hrs.	1.0 hr.

Figure 6: Improved State VSM for FMM in an Educational Institute

It is evident from the VSM that the delays contributing to MTTO are now reduced. It might be argued that the PT of identifying and locating resources has increased, and this increased time is not commonly observed but only extends when the AMC contractor does not have the required material. Although the end-user is not delivered any value in this time period, the delay in the FMM system is now transferred to the AMC provider process flow. Outsourcing non-core activity is suggested as a lean practice that enables collaborations (Cudney et al., 2020), and improved services can be availed (Lok & Baldry, 2015). Another delay time in MTTY is handled by making the information flow follow the JIT concept of lean philosophy.

USERS' EXPECTATIONS ON DT VS ACHIEVED RESOLUTION TIME

The study results are limited to an educational institute where students worldwide come and study. These students reside in 17 student accommodation buildings located within the institute's premises, and thus the service DT for the facilities is considered for improvement;

those are reported as complaints on the institute portal. To understand the improvements obtained from implementing lean in the FMM process of the institute, a survey is drafted for the authorities in these 17 buildings. The drafted survey asked questions related to the expectations of the end-users in terms of the expected time to procure materials to address the DT and the expected resolution time for a complaint raised on the portal. The authorities in charge of maintaining the facilities at each student accommodation building participated in the survey. A total of 23 responses are collected, and it is indicated by the authorities, as presented in Table 2, that they expect a time duration varying from 1 hour to 3 days to be spent in the procurement of materials in instances when the material is not available in the institute's inventory.

Table 2: Distribution of Expected Time Indicated by Stakeholders

Duration	1.0 to 3.0 hrs.	4.0 to 10.0 hrs.	11.0 to 20.0 hrs.	21hrs. to 1.5 days	1.5 to 3.0 days
Material procurement	13%	22%	17%	26%	22%
Resolution of complaint ticket	65%	17%	0%	9%	9%

The respondents also indicated that the resolution time for a complaint registered with the FMM of the institute should not exceed 3 hours when the required material is available, as shown in Table 2. This duration remains less than the achieved MMLT after incorporating lean methods into the FMM process.

Although the achieved MMLT remains higher than the stakeholders' expectations, the lean method implementation has achieved a resolution time closer to a minimum of 5 hours. This resolution time indicates lesser DT; thus, lean implementation in the FMM process of an education institute has created value for the stakeholders.

CONCLUSION

The study presented a lean approach to improving the FMM process of an educational institute. Lean methods like 5S, JIT, and VSM are employed in this research, where VSM proved helpful in mapping the FMM process and highlighting delays in the existing process. The 5S and JIT implementation indicated improvements by reducing the DT observed due to delays in the process of the FMM. The primary delays identified in this study are related to material unavailability and administrative delays. The reduced delays indicate the process followed in the educational institute considered in this research. However, the results are not typical but indicate process improvement through implementing lean methods in the FMM. The study presents an implementation of lean in a reactive scenario when a service experiences DT whereas the essence of FMM is to prevent DT; therefore, the study will be continued to identify the advantages of lean in a proactive FMM scenario.

A VDC FRAMEWORK PROPOSAL FOR TIME OPTIMIZATION IN DIAMOND DRILLING OPERATIONS FOR MINING

Luis Alonso Salazar Araujo[1], Michele Trefogli Voto Bernales[2], and Alexandre Almeida Del Savio[3]

ABSTRACT

A Virtual Design and Construction (VDC) framework proposal is presented for time optimization in diamond drilling operations for a mining exploration project. The mining project is located in the Huancavelica region of Peru and is currently in the underground exploration phase through diamond drilling drillholes. The geology team uses diamond drilling samples to estimate the total mineral reserves of the mine, and they have projected 13,278 meters to be drilled. The VDC framework proposal's application allowed a better understanding of diamond drilling processes to support the variability source reduction related to equipment, maintenance and operational tasks. The results showed a time optimization in the diamond drilling operation of 10%.

KEYWORDS

VDC, diamond drilling, mining explorations, project management, process optimization.

INTRODUCTION

Mining exploration projects focus on generating new prospects and exploring them to locate and define the ore bodies that lie in them (Marjoribanks, 2010). The present investigation was conducted in a mining project's exploratory phase located in the department of the Huancavelica region of Peru by diamond drilling. This exploratory project aims to estimate ore reserves by exploring identified veins. The diamond drilling exploration consists of drilling holes previously identified and approved by the geology department with a specified depth angle and azimuth. For this project, the drilling depths were an average of 300m long. The geologists first analyze the cylindrical-shaped rock samples collected from the drilling process and then send them to a laboratory for further investigation. According to Uvarova et al. (2015), this exploration campaign is summarized in drilling, collecting, logging, and cutting diamond cores for laboratories that will analyze them.

For the exploratory activities of the project, a company specialized in diamond drilling was commissioned. They had two drilling machines of similar size and capacity during most of the project and worked in conjunction with the exploration department of the mining company. This department was responsible for indicating the points to be drilled and preparing the samples for subsequent shipment to the chosen laboratory.

The drilling company's operations started in April 2022, and several drilling samples were obtained during the first 5 months of work. However, the recovered cores' quality was below the exploration department's standards. It was observed that the drilling speed was higher than usual, resulting in defective samples. This situation obligated the company to issue an order to the drilling company to slow down the speed, reducing the number of cores but increasing the core quality. This order changed the expected production from 20% to only 0.05% over the monthly target, as shown in Figure 1.

The objective of the exploration campaign of the mining company was to use the cores obtained between the start of the exploration on April 18, 2022, until October 31, 2022, for reserves estimation. There was no established metric for the number of cores to be obtained at the end of the established period. However, considering the minimum goals agreed upon with the drilling company, 1,100 meters per machine per month, this period should be completed with at least 13,278.06 meters of diamond cores. Due to the drilling speed reduction, the target value of 1,100 meters per month was barely reached, resulting in 1,453.01 meters being executed in the remaining two months.

The literature review revealed several studies on productivity optimization in exploratory mining projects and diamond drilling operations, but these studies differed considerably. For instance, Boeksr (1930) proposed a new design of a diamond drilling machine capable of reaching greater depths and speeds. In contrast, Gao (2021) focused on optimizing time through a new method of performing depth measurements of diamond drill holes. Another study by Mustafa et al. (2021) investigated optimizing productivity by controlling drilling parameters to increase drilling speeds.

To not affect the estimation of mineral reserves, which depend on the exploratory campaigns, a VDC framework was developed focused on increasing productivity and complying with the standards of the exploration department.

Virtual Design and Construction (VDC) is a methodology created by the Center for Integrated Facility Engineering (CIFE) at Stanford University in 2001. According to Del Savio et al. (2022) and Rischmoller et al. (2018), VDC refers to utilizing multidisciplinary performance models in design and construction projects. VDC is composed of: Client Objectives, Project Objectives, Production Objectives (Production Metrics), Controllable Factors, Integrated Concurrent Engineering (ICE), Building Information Modeling (BIM), and Project Production Management (PPM) (Del Savio et al., 2022). The VDC components are summarized in a framework called VDC Framework, which integrates them and enables better management for developing a project. By fulfilling their controllable factors and production objectives, the PPM, ICE, and BIM components seek the success of the project's objectives, which, consequently, also achieve the client's objectives since they are directly linked to each other. According to Rischmoller et al. (2018), process (PPM), organizational (ICE), and information (BIM) knowledge must be integrated to produce the highly integrated systems necessary for a high-performance project.

The literature review shows limited examples of the VDC methodology implementation in mining projects, mainly because its application has been initially focused on the construction industry. Del Savio et al. (2022), who complied 7 case studies of the VDC application, showed that this methodology achieves optimization of costs, time, resources, and quality of the projects, which is why it was decided to apply and demonstrate its potential use and advantages in the mining industry.

This research seeks to demonstrate the efficacy of the VDC methodology as a viable alternative for overseeing mining exploration initiatives that involve diamond drilling. By implementing the VDC methodology, this study aims to highlight how it can optimize the exploration process, improve the quality of collected data, and ultimately lead to better decision-making in the mining industry.

METHODOLOGY

The methodology used for the research development includes collecting data from one of the project's drilling rigs during the first 5 months of operations from a 7-month project. It was collected from the daily reports sent by the contractor and entered into a database made for the exploration progress on an Excel file. The data collected corresponds to the physical progress, the detailed use of working hours for each shift, and the work processes used. With the information collected, it was identified the main sources of variability that generated a lower number of drilling hours. The methodology consisted of developing the VDC framework, defining its components, establishing the new processes with PPM, and identifying the variability sources. The corresponding results were obtained for each component of the VDC Framework.

DATA OBTAINED

The project worked with two drilling rigs during most of the project. Drilling rigs DE-130 and H-200 models were used, being the H-200 model replaced by a DE-140 model on August 21, 2022. The DE-130 drilling rig, which worked from the beginning of the project on April 18, was withdrawn on October 12, 2022, leaving only the DE-140 drilling rig until the end. Due to these circumstances, the data collected that served for the VDC implementation was from the DE-130 drilling rig, which has complete data for the 5 months before the order to decrease the drilling speed, and it is with the work of the DE-140 drilling rig that the VDC methodology was implemented. The drilling rig changes caused a week's loss in which the project lost at least 300m of samples considering the average daily drilling.

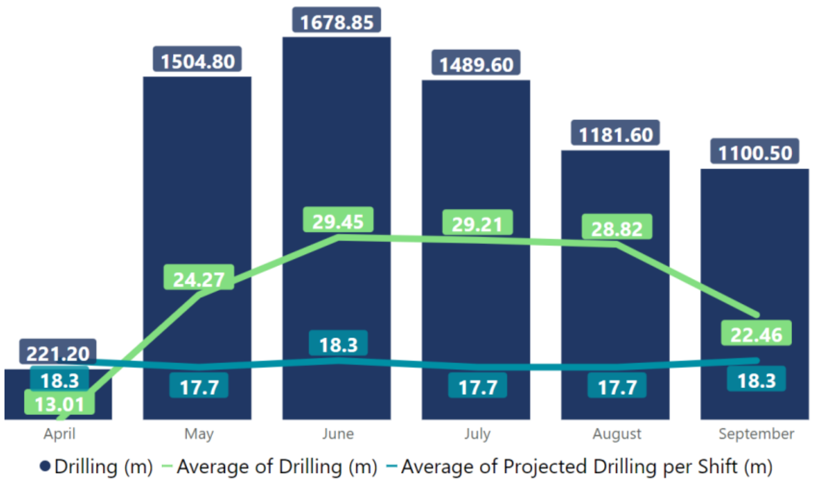

Figure 1: Monthly and daily drilling performance for the DE-130 drilling rig

As shown in Figure 1, the DE-130 rig performed well, surpassing its monthly drilling target of 1,100 meters by 24.59% (except for April 2022, when it started operations). It maintained an average throughput of 26.65 meters/shift during high-speed drilling months but decreased to 22.46 meters/shift (down 16%) in September 2022, slightly exceeding the monthly target by 0.05%.

Two main variability sources were identified, working in collaboration with the DE-140 team (Figure 2): those attributed to the drilling and mining companies. These variability sources were identified through the processing of data and the creation of statistical graphs, as shown in Figure 3. The lost hours were classified by type and then shown on graphs, allowing their better understanding and effect on the project.

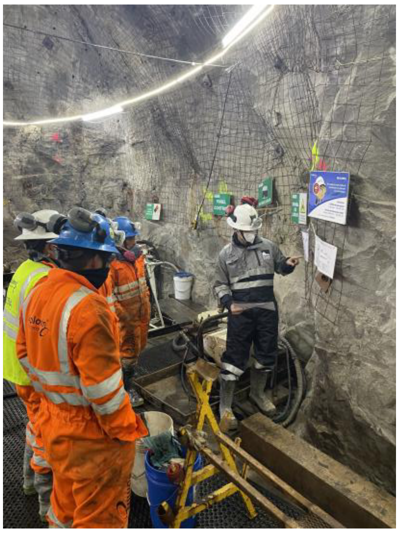

Figure 2: Introducing the DE-140 team to VDC.

Among the sources of variability attributable to the drilling company shown in Figure 3, corrective maintenance (maintenance caused by malfunctions of the drilling rig) and operational delays (delays caused by the drilling team's operations) stand out, accounting for 10.31% and 10.00% of the drilling hours executed.

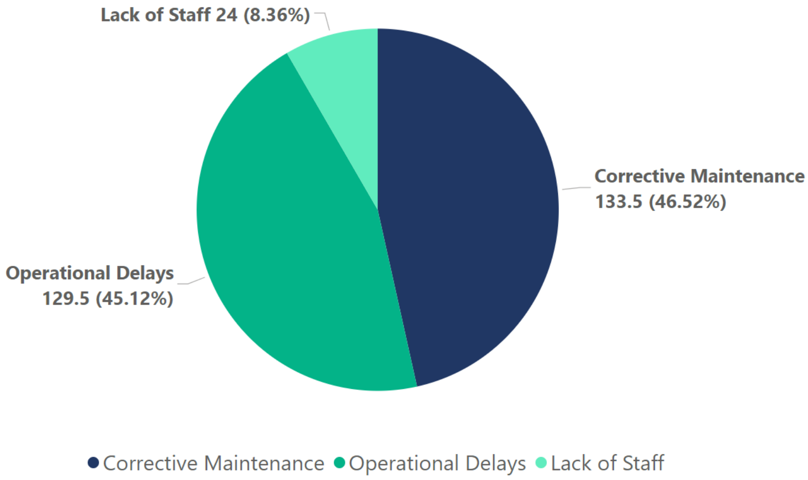

Figure 3: Variability sources attributable to the drilling company

The sources of variability attributable to the mining company correspond to the standby times that are the company's responsibility. The three sources of variability identified and shown in Figure 4, corresponding to standby, total 82.5h and are equivalent to 6.38% of the drilling hours.

The process flow shown in Figure 5 was obtained by observing the joint work of the mining and drilling companies and by interviews with the key stakeholders, such as the operations chief and mine superintendent. A considerably basic process flow is evident in which there is no differentiation by area involved or integration between them. The process consisted of the morning and night meetings before the beginning of each shift, finishing with the sending of the daily report before the next day's morning meeting.

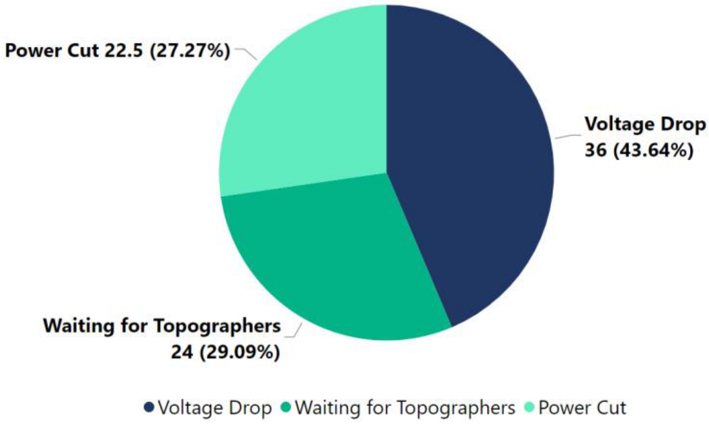

Figure 4: Sources of variability attributable to the mining company

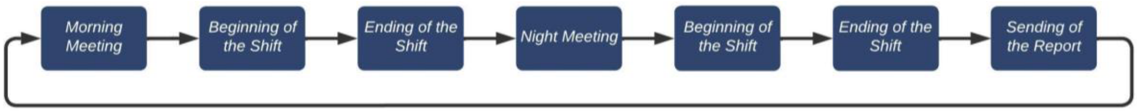

Figure 5: Work process before VDC

PROPOSAL APPROACH

The work proposal for implementing VDC in the project should focus on meeting the client's objective of 13,278.06 meters of drilled cores to estimate reserves. Next, the project's objective was defined. Focused on implementing time optimization by mitigating sources of variability to increase production to 14,606.87 meters of core drilled, which is 10% more than the client's objective. Once the implementation objectives were defined, the PPM, ICE, and BIM components were designed.

The PPM component, focused on the processes and operation, has as a production objective the reduction of variability sources to less than 10% of drilling hours and, as a controllable factor, the review of improvement proposals obtained in the ICE sessions. The ICE component, focused on the organization, has as a production objective the resolution of 100% of the improvement proposals by the stakeholders received during its sessions and the number of ICE sessions performed per day as a controllable factor. Finally, the BIM component, focused on information integration, was implemented through control dashboards that were connected to an Excel database, where PPM production objectives are displayed in an interactive and easy-to-understand manner so that all team members could see updated project information and make decisions not only in the ICE sessions but also in the field. It had as a production objective the time to receive drilling reports, which should be <=15 minutes from the departure of the drilling rig from the mine, and as a controllable factor, the number of dashboard updates per day. The BIM production objective is due to the time it takes to send the daily reports since they were only used to record the progress and calculate the valuations. Both reports were sent together once a day, which caused a delay in the reception and processing of the information.

RESULTS AND DISCUSSIONS

IMPLEMENTATION OF PROPOSAL

The VDC implementation approach is translated into the VDC Framework, which groups the VDC components in a graphical and interrelated way to fulfill their integration. In addition, it includes explicit specifications of customer and project objectives, performance measurement, and project models (Kunz & Fischer, 2020), as seen in Figure 6.

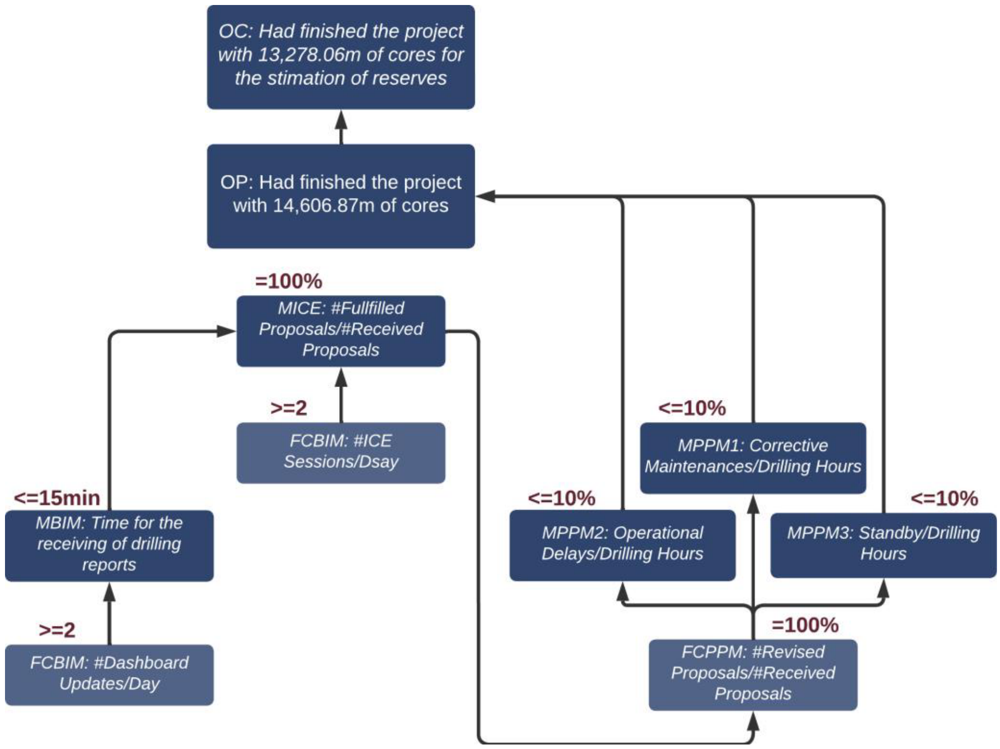

Figure 6: VDC Framework

The VDC Framework allows optimal visualization of the methodology and its implementation. Likewise, the process flow between the different areas shown in Figure 5 had to be updated according to the new needs demanded by the proposed VDC implementation, as shown in Figure 7.

According to the VDC Framework, the updated process flow integrates the different areas, focusing on productivity by sharing information and reducing query response latency, enabling decision-making before and during operations.

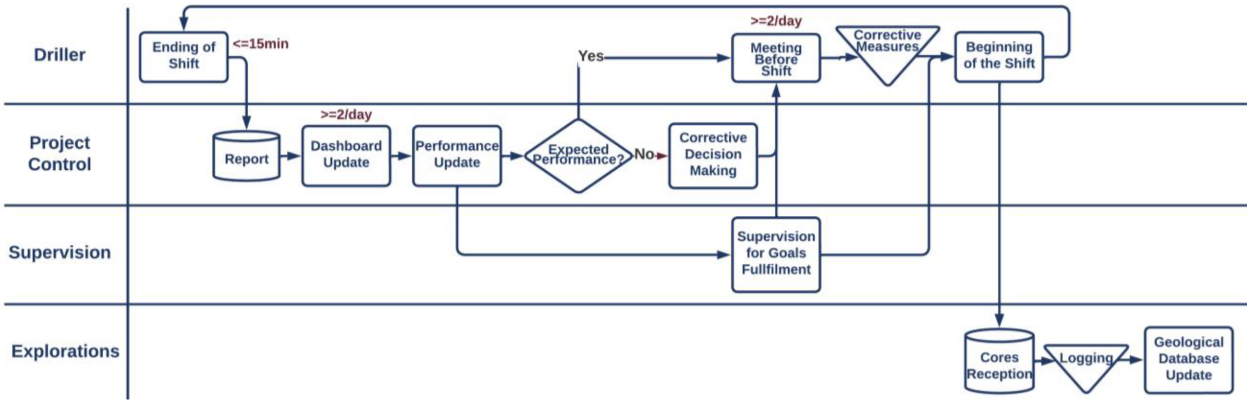

Figure 7: Work Process with VDC

Proposal Validation

The project specialists validated the proposal: the exploration director, general superintendent, project superintendent of the mining company, and the operations manager of the drilling company. Each one of the project specialists was interviewed to obtain their feedback.

VDC Objectives

The specialists stressed the importance of complying with the exploration department's decision and preventing the drilling team from focusing only on the meters drilled. This could lead them to increase the drilling speed to meet a physical progress goal.

PPM

The experts agreed that increasing production by mitigating the previously identified sources of variability was a viable alternative for meeting the objective.

ICE

The specialists agreed and supported disseminating the ICE sessions held during the on-call sessions. Previously, the agenda of these sessions was the distribution of information on the work to be performed during the on-call period. With the implementation of the ICE sessions, information began to be shared with all involved, and decisions began to be made during the sessions. The main topics of these sessions were the measures to be implemented to lower the variability shown on the dashboards from the VDC component.

BIM

Before starting the VDC implementation, the stakeholders witnessed the initial development of the dashboards, as shown in Figure 8. They showed interest in them, even requesting their distribution to know the project's status. Once implemented, they were aligned with the current information integration system.

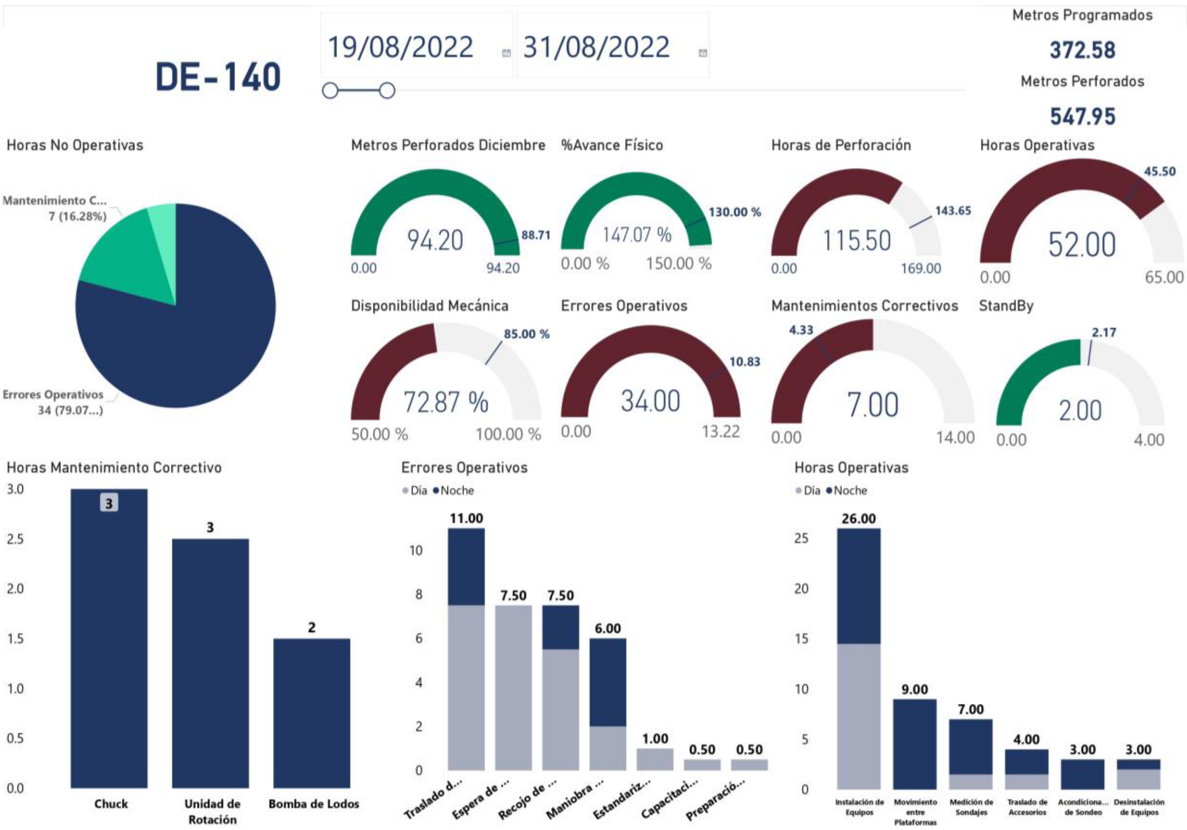

Figure 8: The dashboard for the integration of information

Client's Objective

The client's target of completing the project with 13,278.06 meters of core was surpassed, finishing the project with 15,794.20 meters drilled, which is 18.95% above the target.

Project's Objective

The project's target of 14.606.87 meters of core drilled was also surpassed by 8.13% above the target.

PPM, ICE and BIM

The results of the PPM, ICE, and BIM production objectives are shown in Table 1.

Table 1: PPM, ICE and BIM production objectives

Components	Production Objectives	Objective	Result
PPM	$\frac{Corrective\ Maintenances\ Hours}{Drilling\ Hours} x100\%$	<=10%	9.61%
	$\frac{Operational\ Delays\ Hours}{Drilling\ Hours} x100\%$	<=10%	18.31 %
	$\frac{StandBy\ Hours}{Driling\ Hours} x100\%$	<=10%	9.03%
BIM	Time for the receiving of drilling reports	<=15min	9 min
ICE	$\frac{\#Fullfilled\ Proposals}{\#Received\ Proposals} x100\%$	=100%	100%

As shown in Figure 9, the DE-140 drilling rig drilled 2,349.35 meters, exceeding the goal by 6.79% the 2,200.00 meters goal and abiding by the explorations department's order, while the DE-130 drilling rig only exceeded its monthly goal by 0.05% (Figure 10). Both DE-140 and DE-130 drilling rigs worked simultaneously during September 2022.

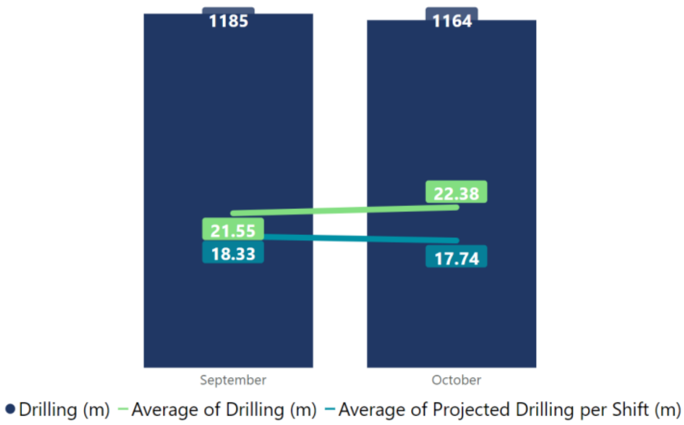

Figure 9: DE-140 drilling rig performance

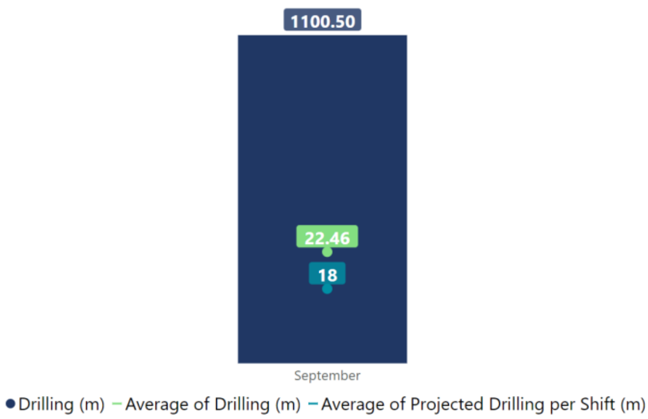

Figure 10: DE-130 Drilling rig performance in September

VDC implementation on this project focused on time optimization. With the identification of each variability source, the project stakeholder discussed and proposed improvement measures during ICE sessions to reduce those sources of variability. Some of the proposals received during ICE sessions were related to integrating stakeholders, and some were related to increasing staff. Considering that some proposals demanded an increasing budget, they had to be revised and analyzed.

CONCLUSIONS

The VDC implementation helped surpass the client's and project objectives as well as the ICE, BIM and PPM objectives except for the operational delays vs. drilling hours one. Although the drilling campaign was projected to be completed above the minimum target due to the performance in the first 5 months, the DE-140 drill rig, which was the subject of the investigation, managed to exceed its target by 6.79% for September and October 2022. The main difference in conditions between the two machines is the number of drilling hours achieved, with the DE-140 machine having a total of 319 hours of drilling and the DE-130 machine a total of 260 hours, equivalent to a 23% difference between both machines, which allowed that, despite the presence of the sources of variability, the DE-140 drilling machine achieved a higher production since its sources of variability were identified and controlled.

It can be concluded that the implementation of the VDC methodology was successful, with the DE-140 drill rig having shown higher production compared to a similar rig under the same conditions. In addition, compliance with the VDC production objectives indicates adequate project progress toward the client's and project objectives.

Finally, further investigation could be carried out considering the automation of entering information into the database and digitalizing the drilling reports.

ACKNOWLEDGMENTS

We would like to express our sincere gratitude to Silver Mountain Resources Inc. for providing us with all the information and resources essential for our research’s success. Their generosity and commitment to our research have been invaluable and greatly appreciated. Furthermore, we would like to thank Alfredo Bazo for his invaluable advice and expertise in the field. His contributions have been instrumental in achieving our objectives. Additionally, we would like to express our heartfelt gratitude to Franklin Rodriguez for his technical and methodological support. We would also like to thank Mariana Herrera for her support in compiling sources. We are deeply grateful for the collaboration and support we have received, which has been crucial to the completion of this research.

WORKLOAD LEVELING METRICS FOR LOCATION-BASED PROCESS DESIGN

Vishesh V. Singh[1], and Iris D. Tommelein[2]

ABSTRACT

Process design can help to meet project deadlines and ensure a smooth workflow. While work structuring (WS) is commonly used to design processes as linear flows, doing so may not account for 2-dimensional spatial variation in work and such variation can disrupt the flow. To limit disruption, takt production and the Work Density Method (WDM) have been developed, but metrics are yet needed to gauge and visualize the quality of workloads to achieve the desired flow. This paper presents multiple perspectives to assess desired outcomes of workload leveling and formalizes them into optimization objectives. It proposes nine metrics, grouped into seven types, to measure the success of achieving these objectives. The value of these metrics is illustrated using XLWoLZo, an Excel-based tool with an off-the-shelf genetic algorithm (GA), to solve a toy problem. The paper compares XLWoLZo's results obtained with the suggested metrics to the results of the metric used in existing models, examines how the resulting values of metrics compare to one another, and assesses their impact on desired outcomes. The paper concludes that no single "best" metric exists and suggests combining metrics to balance conflicting objectives. Finally, the paper discusses limitations and offers future research directions.

KEYWORDS

Process, Location-based planning, Takt planning (TP), Flow, Variability

INTRODUCTION

Process design (aka. process planning) matters to scholars and practitioners engaged in work structuring (WS) and production system design (e.g., Ballard et al. 2001a, 2001b). The aim is for process- and operation design to be aligned with product design. WS includes designing the "chunks" of work to be assigned, deciding their sequence and their release from one production unit (PU) to the next with or without decoupling buffers, and scheduling when they are to be done. A work chunk is "a unit of work that can be handed off from one production unit to the next" and a PU is "an individual or group performing production tasks" (Tsao et al. 2000). Thus, process design includes deciding what steps to include in a process, determining what work to assign to each step and who will do what, sequencing steps, and defining handoffs between them. In addition, it includes deciding what- if any buffers are needed between processes.

WS is commonly used to define construction processes as linear sequences of steps, thereby abstracting them to resemble line flow systems (e.g., manufacturing assembly lines). This abstraction can also be useful when studying the flow of crews. However, construction

[1] Ph.D. Candidate, Engineering and Project Management Program, Civil and Environmental Engrg. Dept., Graduate Student Researcher, Project Production Systems Laboratory, University of California, Berkeley, USA, mvisheshvs@berkeley.edu, orcid.org/0000-0002-6999-9727

[2] Professor, Civil and Environmental Engineering Department, Director, Project Production Systems Laboratory, University of California, Berkeley, USA, tommelein@berkeley.edu, orcid.org/0000-0002-9941-6596

processes have work that depends on the 2-dimensional (and 3-dimensional) spatial characteristics of the project. Ignoring spatial variation of work can affect the quality of the assumed linear flow.

Location-based methods including takt production (aka. takt- or takt-time planning and control) (e.g., Bulhões et al. 2005, Fiallo & Howell 2012, Frandson et al. 2013, 2014, Haghsheno et al. 2016, Lehtovaara et al. 2021, Tommelein 2017, Theis et al. 2017) emphasize concern for space use in production system design. In the planning part of takt production, the aim for process design is to designate zones (work areas or locations) on a construction site where crews will work successively, one at a time, and complete the work in their step within a fixed amount of time (called the takt). The desire to plan work in different zones to a takt is difficult to satisfy because the quantity and complexity of construction work, and consequently the time needed to do that work, tends to be distributed non-uniformly in space.

To characterize non-uniformity, location by location, of the time needed by trades to complete their work, Tommelein defined the concept "work density" and developed a planning method based on it, called the Work Density Method (WDM) (Dunnebier et al. 2014, Tommelein 2017). The objective of the WDM "is to create one-piece process flow based on space use by zone, with the handoff being a zone and occurring at specified points in time" (Tommelein 2022). The WDM describes a numerical way of zoning a workspace while minimizing the workload peak across zones and steps to meet the desired takt (Jabbari et al. 2020, Tommelein 2022). In contrast in this paper, we view workload leveling from multiple perspectives, not only that which aims to reduce the workload peak. We identify metrics that measure, describe, and visualize the "levelness" of a workload, and accordingly define workload leveling.

The next section of this paper reviews literature on process design specific to takt planning, flow, and the WDM, and literature on a problem that is somewhat similar to workload leveling, namely resource allocation and leveling for construction scheduling. The section thereafter introduces desired outcomes of process design and suggests metrics to be studied as performance indicators towards achieving these outcomes. A section on research implementation presents the computer-based tool developed using an off-the-shelf genetic algorithm (GA) to optimize a toy planning problem so that the results from the optimizations according to the suggested metrics can be evaluated and discussed. This paper concludes with recommendations for metrics to enhance process design methods and suggests future research.

LITERATURE REVIEW

TAKT PLANNING AND FLOW

Construction project management has traditionally focused on transformation at the activity level, ignoring handoffs between activities (Ballard and Howell 1998). In contrast, Koskela (2000) acknowledged that transformation-, flow-, and value views on production systems are complementary and must be considered together to improve production more holistically. Therefore, and among other things, flows must be identified and measured.

Given that most construction activities have varying durations and work spread out unevenly in space, it is difficult to identify workflow. Irregular and erratic workflow translate into incomplete work and untimely hand-off of space. Process design with workflow in mind must ensure that the scope of work is well defined by process step and location so that the assigned work can be completed and handed over within the allotted time. Spatial continuity and timely completion tend to reduce the share of non-value-adding activities and reduce the degree of control complexity (Alves and Formoso 2000).

The term workflow has been widely used in the Lean Construction literature, but different authors have used it to refer to different types of flows. Among them, Shingo (1986) described production in terms of two types of flow: process flow and operation flow. Processes represent what happens to raw materials (and pieces of information) as they flow through the project and become finished goods, with work done stepwise by different crews. Operations represent what people with tools and equipment (referred to as crews or production units) do to products. Tommelein et al. (2022) differentiated flows in construction from a location-based planning perspective while recognizing their two-dimensional nature. They defined process location flow as synonymous with process flow and trade location flow synonymous with trade flow.

Process flow determines how long it will take to get a product to the customer. This duration is called the process cycle time and it relates to the system's speed (aka. throughput rate). Since a process comprises steps of work performed by crews, the durations of these steps (the step cycle time or workload) define the throughput rate. An objective of production system design is to match its throughput rate to the customer's demand rate (Hopp and Spearman 2011). The maximum amount of time allowed for producing a product (supply rate) so that it will meet the customer's need is called the takt. Using takt planning, a process can be designed so that each step of work can be completed reliably within the allotted time by crews following each other sequentially while going from one zone to the next.

The literature on flow and methods for takt planning in construction (cited previously) highlight different perspectives on what is considered a good takt plan. They consider process flow as well as trade flow and other flows, and trade-offs between them. The WDM for example (described next) allows planners to objectively balance process flow with trade flow.

WORK DENSITY AND WORK DENSITY METHOD (WDM)

To improve the quality of production plans (e.g., takt plans) in terms of achieving a shorter duration and higher workflow reliability, a goal is to reduce variability in the system. In construction processes this can be done by standardizing work, instilling regularity of work location and timing, and defining clear hand-offs between crews, thereby reducing the requisite amount of control and coordination between them.

Rather than zoning a work space by simply dividing space according to physical features of the structure being built, the WDM performs both workload leveling and zoning. The idea is to define zones so that number of work hours are similar for all steps of trades moving from one zone to the next (Frandson et al. 2013). Specifically, the WDM defines zones while minimizing the peak workload across all zones and all trades.

For a given work scope and trade crew working in a certain unit of space, and associated work structuring specifics, "work density" describes the unit of time the crew will need to complete that scope. Work density captures what work will be done, by whom, where, and how (Tommelein 2017). For projects with repeating architectural features in their product design (e.g., modular hotel rooms), planners can define Standard Space Units (SSUs) (Binninger et al. 2017) and repeated reliable handoffs of more-or-less similar workloads to be completed within a takt. Even for projects without such architectural features, i.e., where handoffs of similar workloads are not obvious, Jabbari et al. (2020), Singh et al. (2020), Diab and Tommelein (2020), and Tommelein (2022) were able to apply the WDM as the method takes as input a work density map for each step in a process. The map represents how much time the crew will need to complete their work across the work space, granularized cell by cell. Tommelein (2017) and Singh et al. (2020) detailed processes for creating work density maps.

The WDM supports process planning for a linear sequence of steps (a process) using a work density map for each step. Work space is divided into zones (that are mutually exclusive and collectively exhaustive) by assigning cells from work density maps to each zone. Then, step by step, the work densities of cells in each zone are added. The resulting cumulative work density, called the step cycle time or workload, describes the time a crew needs to complete their step-worth of work in the given zone.

The workload distribution across zones and steps visualized on a workload histogram or Yamazumi chart helps planners see if a given process design meets their desired outcome(s). If not, the planner may use various throttles (e.g., changing zone boundaries, modifying process steps, changing resources or means and methods available to the crew) to modify the plan. The characteristics that make for a desirable process plan can change with the situation and may require trade-offs. For example, a common trade-off in location-based methods involves reducing the time 'workers wait on work' (crew flow) versus 'work waiting on workers' (process flow) (Linnik et al. 2013).

RESOURCE LEVELING IN CONSTRUCTION PROJECTS

The workload leveling problem is similar to resource leveling and resource-constrained project-scheduling problems (RCPSPs). Resource allocation methods ensure that resources required for a plan do not exceed resource availability constraints (e.g., Colak et al. 2006, Davis 1974, Liu et al. 2005). Although in the basic RCPSP model reduction or minimization of the project duration remains the single most studied objective, several extensions of RCPSP consider other objectives or combinations thereof, such as variabilities in the project environment and resource capacity (Chakrabortty et al. 2017, Hartmann and Briskorn 2010).

Some resource leveling methods try to reduce fluctuations in the number of resources used, while others strive for continuous use of resources to improve productivity and reduce cost (e.g., El-Rayes and Jun 2009, Hegazy 1999). The mathematical formulation of these methods may use one or multiple objectives similar to workload leveling, i.e., to minimize resource fluctuations or lower resource peaks. Examples include the minimum moment method (Harris 1978), the PACK method (Harris 1990), the double moment method (Hegazy 1999), and the entropy maximization method (Christodoulou et al. 2010).

Since these methods are typically used in transformation-based optimization models (exemplified by the Critical Path Method (CPM)) (Brucker et al. 1999), the differences with flow-based process planning methods (exemplified by the WDM) must be highlighted. Resource allocation methods may prioritize critical activities over others when allocating resources. When multiple activities require the same resource, different methods may prioritize them differently. Resource leveling methods tend to prioritize the use of resources required for critical activities by scheduling those activities at their earliest possible time. They minimize resource fluctuations by shifting noncritical activities within their available float to keep the project duration of the original early schedule unchanged, if possible (El-Rayes and Jun 2009). In contrast, in takt planning, there is no prioritization for resource allocation or leveling as all activities (i.e., steps in a process) are critical. In that sense, steps within a process have no float. However, each step has a capacity buffer to ensure enough people on the crew are at the ready so that, in case work takes slightly longer than anticipated, they will be available and able to complete their step within the takt. In addition, takt plans include buffers between processes and at the end of processes. The judicious use of buffers prevents delays that could reverberate through the schedule (Dlouhy et al. 2019).

Flow-based planning methods are relatively new compared to the extensive body of knowledge that exists for transformation-based methods. A missing piece for their broader adoption pertains to metrics: there is a lack of metrics that characterize qualities of flows. In the next section, we discuss objectives and desired outcomes for location-based process design methods, and we then propose several workload leveling metrics.

WORKLOAD LEVELING

OBJECTIVES AND DESIRED OUTCOMES

In lean production, takt plays a key role in synchronizing processes and operations. The workload for a step in a given process may be less than, more than, or equal to the takt imposed by the customer on the process. By matching workloads to the takt, planners can eliminate waste, such as waste stemming from unevenness and overburden (Frigon and Jackson Jr. 2009). In construction, this is done (1) at the strategic level to meet the project deadline and (2) at the operational level to meet phase- or process milestones and objectives such as generating evenness in workflow and avoiding trade stacking.

Workload leveling tries to achieve a steady flow of work for processes, trades, crews, etc. With that said, to define metrics that measure success towards achieving these outcomes, we first define desired outcomes:

O1. Meet customer deadline (phase/process duration) by meeting the customer's takt or by reducing the duration by increasing concurrency.

O2. Achieve constant crew size (Ballard and Tommelein 1999) by reducing the variation of workloads across zones, thus improving trade (location) flow (Sacks 2016).

O3. Increase worker utilization (reduce the time workers wait on work) by providing timely hand-offs of zones and reducing the need for inter-trade coordination.

O4. Increase space utilization (reduce the time work waits on workers) by reducing the variation of workloads across steps in each zone and designing for spatial continuity (Alves and Formoso 2000), thus reducing overproduction waste (Linnik et al. 2013) and improving process (location) flow.

O5. Reduce workload variability by reducing the variation of workloads across steps and zones.

O6. Reduce process step variability by standardizing work and adding a capacity buffer (underloading) to an individual step.

We next identified metrics to measure success in achieving these outcomes.

METRICS FOR WORKLOAD LEVELING

To evaluate and compare the quality of levelness of workloads to meet the desired outcome of a process design, planners need metrics. Different planners may desire different outcomes and thus need different metrics. To accommodate trade-offs and gauge different outcomes, this paper suggests nine metrics, grouped into seven types as Metrics M2 and M4 each have two parts, a and b. These metrics are:

M1. Workload Peak is the maximum workload considering all steps and all zones. The objective is to minimize this peak. This metric is illustrated by the dashed red line vs. the tallest bar in Figure and 2.

M2. Average of Ranges is the average (aka. mean) value of the ranges of workloads, i.e., the difference between the maximum and the minimum workload, but workloads can be grouped in two ways:

M2a. Grouped by Zone: When workloads are grouped by zone, the range of workload is calculated for each zone, and then, the mean of ranges across zones is calculated.

M2b. Grouped by Step: When workloads are grouped by step, the range of workload is calculated for each step, and then, the mean of ranges across steps is calculated.

The objective is to minimize this range. This metric is illustrated by the gap between the solid red line and the solid green line in Figure and 2.

M3. Workload Range is the difference between the maximum and the minimum workloads across all zones and steps. The objective is to minimize this range. This metric is illustrated by the gap between the dashed red line and the dashed green line in Figure and 2.

M4. Range of Averages is the range of the mean workloads per zone or each step. The objective is to minimize this range. This metric is illustrated by the flatness of the purple line in Figure and Figure .

M4a. Grouped by Zone: When workloads are grouped by zone, the mean of the workloads for each zone is calculated and then the range is calculated between means for all the zones.

M4b. Grouped by Step: When workloads are grouped by step, the mean of the workloads for each step is calculated and then the range is calculated between means for all the steps.

M5. Peak to Average Ratio is the ratio of the maximum to the mean of workloads across all zones and steps. The objective is to minimize the ratio between the maximum and the mean of all workloads.

M6. Standard Deviation is the statistical property that measures how dispersed workloads are relative to the mean. The objective is to minimize this standard deviation. A low value means workloads are clustered around the mean. A high value means they are spread out.

M7. Moment is the sum of squares of centroids (= height/2) of all bars in the histogram, i.e., workloads across all zones and steps. The objective is to minimize the moment by reducing workloads or redistributing them.

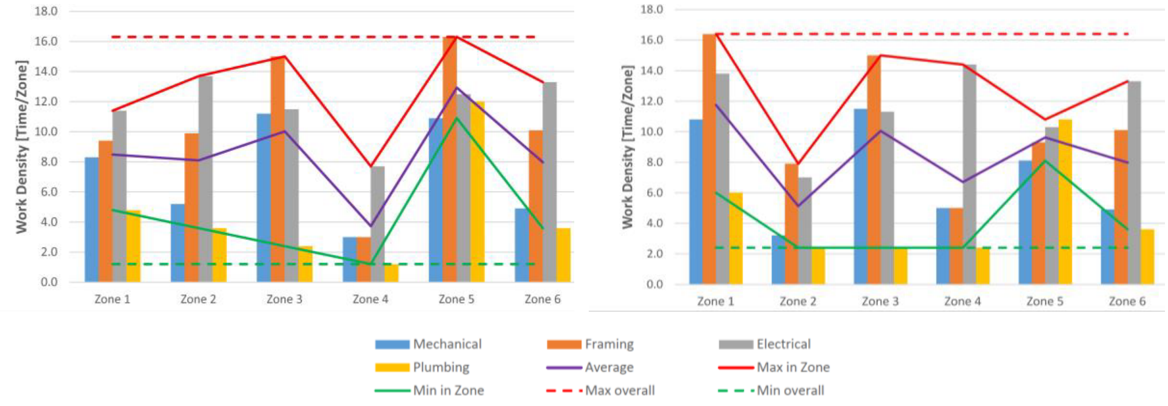

Figure 1: Workload histogram by zone for objective M1 (left) and objective M2b (right)

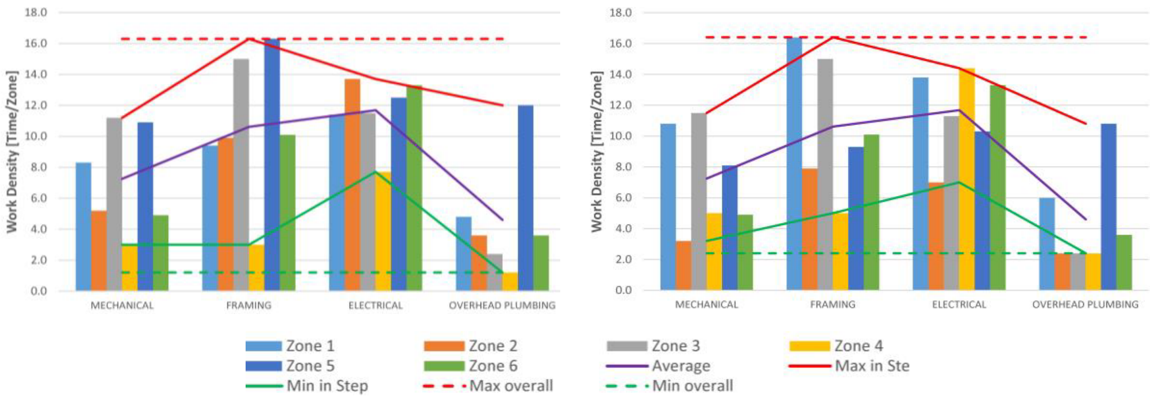

Figure 2: Workload histogram by step for objective M1 (left) and objective M2b (right)

Figures 1 and 2 illustrate the workload histogram after optimization using M1: minimizing workload peak (on the left) and M2b: minimizing the average of ranges grouped by step (on the right), grouped by zone and step respectively. To compare these metrics, we implemented an optimization tool and programmed the metrics as objective functions, as is discussed next.

MODEL IMPLEMENTATION

TOY PROBLEM

Using a GA-based model applied to a toy problem, we programmed the aforementioned metrics one at a time to be the objective function and ran the model to find the optimal solution. The toy problem includes work done by four different trade crews, namely (1) Mechanical, (2) Framing, (3) Electrical, and (4) Plumbing (Figure 3). As these crews are assumed to be working in a linear sequence, each crew's work density map represents a step in the process.

This problem stemmed from a pilot project conducted by Frandson and Tommelein (2014) and Dunnebier et al. (2014) and was also used to illustrate new planning methods including WoLZo developed by Jabbari et al. (2020) and GAWoLZo by Diab and Tommelein (2020).

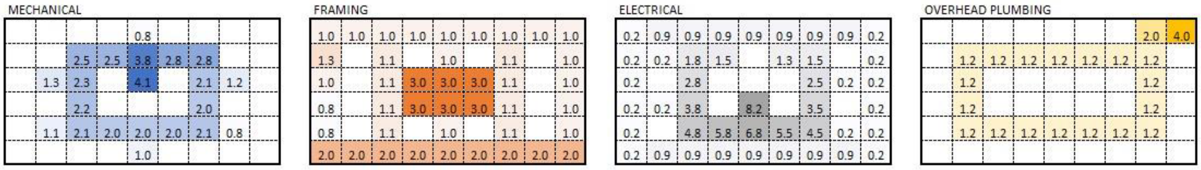

Figure 3: Work density maps for crews in toy problem (part of Fig. 3 in Jabbari et al. 2020)

EXCEL IMPLEMENTATION AND GENETIC ALGORITHM (GA) APPROACH

The toy problem was programmed as a Microsoft Excel based tool, called **XLWoLZo**, which stands for e**X**ce**L** **Wo**rkload **L**eveling and **Zo**ning. The optimization uses the off-the-shelf Microsoft Excel add-in called Solver, provided with the parameters and constraints for work density and zoning as input. The complexity and quality of the problem definition affect the Solver's ability to find a solution. In our case, the problem formulation includes a mixture of continuous decision variables (e.g., the work density in each zone for each step) and integer variables (e.g., zoning grid size). This makes it a mixed integer linear programming (MILP) problem.

In problem formulations where objectives and constraints are non-smooth and non-convex functions of the decision variables, and formulations that use Excel formulas like "IF", both of which are true for this problem, obtaining global optima is unlikely. For such problems, Solver Optimization Methods (2023) recommends using the Evolutionary method, a type of GA. This method provided a solution in a sufficiently short computation time (on the order of several minutes when running Microsoft Excel 365 (v. 1904) on an Intel Core i7-8550U CPU).

The constraints are that zones must be convex, non-overlapping, and non-empty. Recognizing the limitations of Excel to program complex constraints, XLWoLZo constrains zones to rectangles. For example, to divide the work space into six zones, the evolutionary solver first tries to draw a horizontal zone boundary (arrow 1 in Figure 4, where the boundary can be at the bottom of row 1, 2, 3, 4, or 5), thereby dividing the work space in two parts, and then for each part draws two vertical zone boundaries (arrows 2 and 3 at the top in Figure 4, and arrows 4 and 5 at the bottom) resulting in a total of 6 zones.

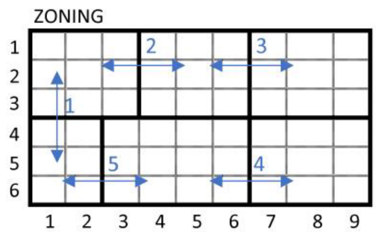

Figure 4: XLWoLZo zone boundary movements

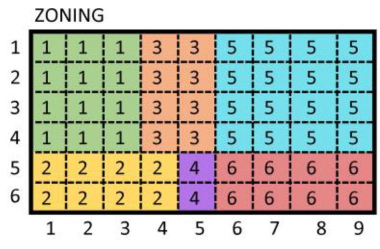

Figure 5: XLWoLZo solution layout for Z = 6 while minimizing workload peak (M1)

The GA moves the zone boundaries until it reaches a solution that it cannot improve upon (based on its convergence parameter or the pre-set computational time limit). Figure 5 shows the zoning solution reached for Z = 6 and the optimization objective set to minimizing the workload peak (M1).

XLWoLZo was run with each of the nine metrics as the optimization objective, one at a time. For each one, the resulting zoning layout and corresponding workload distribution, the values for all 9 metrics were calculated. The results were depicted in workload histograms grouped by zone (e.g., Figure 1) or grouped by step (e.g., Figure 2). Figure 1 shows, when the objective is M1, that the workload for Mechanical trade in Zone 1 is 8.3 time units. This value 8.3 is computed by adding the work density from the Mechanical work density map (Figure 3) for cells that are in Zone 1 (Figure 5). The results from these computations are discussed next.

DISCUSSION

WORKLOAD LEVELING MODEL COMPARISON

The toy problem was solved using WoLZo, GAWoLZo, and XLWoLZo with the number of zones ranging from two to six. In WoLZo and GAWoLZo, the objective was to minimize the workload peak across all the steps in a process according to the WDM (Tommelein 2022). Minimizing the workload peak typically results in minimizing the process duration, barring some exceptions (Jabbari et al. 2020). For XLWoLZo, the model was run 9 times, once for each of the 9 objectives.

As these three models impose different constraints on the geometry of zones, the results they obtain vary in zoning and, correspondingly, application of the metrics gives different results. XLWoLZo has the most restrictive geometrical constraints on zones and therefore produces results that are worse than those of the other two models. The WoLZo Model R divides the work space into rectangular zones, achieving its optimal value of 15.20 time units, which is 7.2% better compared to XLWoLZo's value of 16.30 time units. The WoLZo Model L and GAWoLZo allow non-orthogonal zone shapes and thus result in even better values, respectively 12.30 and 13.50 time units. Admittedly, the geometric constraints imposed by each of these models result in zoning layouts that may not be practical in real-world scenarios. Future research can focus on allowing other zoning geometries and better optimization algorithms.

COMPARISON OF NINE OBJECTIVE FUNCTIONS

Each of the 9 metrics, one at a time, was programmed to be the objective function in XLWoLZo. For each optimal zoning obtained, XLWoLZo also assessed the values of the 8 other metrics. E.g., when optimized for M1 (workload peak), resulting in M1 = 16.30 (Figures 1 and 2), the other metrics have as values M2a = 8.48, M2b = 9.58, M3 = 15.10, M4a = 9.20, M4b = 7.08, M5 = 1.91, M6 = 4.44, and M7 = 1101.88. Conversely, using each of the other 8 metrics as the objective function, resulted in M1's values of 24.30 for M2a, 16.40 for M2b, 16.30 for M3, 22.60 for M4a, 24.10 for M4b, 16.30 for M5, 16.40 for M6, and 16.40 for M7.

Numerically comparing results across all metrics per each objective, the scores for metrics **M2b, M6, and M7** (average of ranges grouped by step, standard deviation, and moment) performed the best in terms of also providing relatively good values for the other metrics. Metrics **M2a, M4a, and M4b** (average of ranges grouped by zone, range of averages grouped by zone, and range of averages grouped by step) performed the worst. Metrics **M1, M3, and M5** (workload peak, workload range, and peak to average ratio) fell in between.

Several metrics are clearly correlated.. M6 and M7 (standard deviation and moment) are both calculated as the product of a constant to the square of each workload and thus their result gives the same results. Standard deviation is not a square but is calculated using variance, which is dependent on the square of workloads.M1 and M5 perform similarly, as mathematically they are the same. Both functions are dependent on the peak, as the average calculated in M5 remains the same for any distribution of workload. This is true in the case of our implementation but can change if a throttle is used to change the underlying work density values (e.g., increasing crew size reduces work density). Strong correlation between metrics show they are interchangeable.

METRICS AND OUTCOME RELATIONSHIPS

In a real-world situation where multiple parties work with conflicting objectives, there is a need to understand the impact of the metrics on different performance outcomes. Balancing between different desired outcomes can be improved by understanding their relationship to the metrics being used to measure them. From the results of XLWoLZo, we observe that:

M1 measures workload peak. Lowering this indicates the possibility of lowering the takt and process duration. Assuming no variation, when M1 <= takt, the process will meet deadline (**O1**).

M2a measures the variation of workload across process steps in each zone. A lower M2a indicates better process (location) flow (**O4**).

M2b measures the variation of workload across zones for each trade or step. A lower M2b indicates better trade (location) flow (**O2, O3**).

M3 measures the variation of workload across all steps and zones. A lower M3 indicates reduced production variability(**O5**). It also improves process (location) and trade (location) flow, but its impact on either is lower than M2a and M2b as it is not biased towards either.

M4a and **M4b** indicates similar effect as M2a and M2b respectively but perform worse.

M5 indicates a very similar effect as M1, and both perform average.

M6 indicates a similar effect as M3 but performs much better due to quadratic versus linear relationships respectively.

M7 indicates a similar effect as M1 but performs much better due to quadratic versus linear relationships respectively. Due to its dependence on the square of workloads, it is reducing higher workloads more than smaller ones.

Takt planners can use capacity buffers to absorb process variability by underloading steps, e.g., to 70-80% of their capacity (Frandson et al. 2015). Thus, sizing of each trade's capacity buffer becomes part of the workload levelling process, as step cycle times need to be lower than the takt. Planners need to balance workers waiting on work (idle time), by providing timely hand-offs of zones, while also underloading to absorb variability. These metrics suggest a distribution of workload values, and with a given target takt, can be used to allocate capacity buffers (**O6**).

Reducing workload variation (by controlling underloading and overburdening) and keeping step cycle time below the takt (with a capacity buffer), results in (1) reduction in work (zones) waiting on workers (steps), in turn improving spatial continuity, and (2) reduction in workers waiting on work, in-turn suggesting timely hand-offs of zones. Achieving both results together is difficult however as one tends to counter the other. This was observed with metrics **M2** and **M4**, both of which are grouped by zone and step. When optimized for grouping by zone, the performance of grouping by steps is poor, and vice-versa.

General contractors (GCs) and trade partners have different priorities as they manage crews between a portfolio of projects. GCs tend to favor process (location) flow, whereas trades favor trade (location) flow, while both manage the related buffers (Frandson et al. 2015). To understand the trade-off between the two desired outcomes we can use a combination of metrics.

Solutions can be employed to deal with these effects, e.g., if a trade is greatly underloaded in specific zones, then the remaining time needs to be planned for the workable backlog, skill development, improvement studies, etc. Another way of understanding the interaction between these two sides involves visually reading the workload histograms. Typically, these histograms are generated with workloads of steps grouped by zones (Figure 1). This makes seeing the variation in workload distribution across steps in a zone easier as opposed to the variation between zones for a step. Thus, to better understand the visual implication of a metric on the workload histogram, we plotted them grouped by zones (Figure 1) and by steps (Figure 2).

To incorporate the trade-offs in real-world scenarios, further study of multi-objective optimization is in order. This may include pareto optimization or creating an aggregate objective function by assigning weights to objectives depending on their relative importance to define an.

We suggest incorporating several metrics on dashboards to support management decisionmaking pertaining to work structuring, zoning, crew sizing, etc.

CONCLUSION

This paper presented an overview of workload leveling for location-based process design using the work density construct, describing various desired outcomes and how they can be measured. Existing models use only the workload peak metric for process optimization. Using metrics described in the literature on resource allocation and leveling in project scheduling as a guide, the paper proposed 9 workload leveling metrics, including workload peak, average of ranges (grouped by zone and step), workload range, range of average (grouped by zone and step), peak to average ratio, standard deviation, and moment.

The identified metrics were programmed for a toy problem on Microsoft Excel (XLWoLZo) as the objective function for a GA to optimize. As expected, the results indicate that there is no single "best" metric for workload leveling. The choice of metric(s) will depend on a multitude of constraints and preferences from the physical site and the project team. Metrics merely provide a quantitative assessment to compare performance toward a desired outcome. Thus, the suggested metrics are later matched with common desired outcomes of location-based process design, and the choice of using a metric is left to the reader. Several objectives (**M1** and **M5**, and **M6** and **M7**) indicate similar outcomes and thus generate similar solutions. These can be used interchangeably and should not be used together when considering different perspectives. Instead, some metrics that indicate opposing outcomes (**M2a** with **M2b**, and **M4a** with **M4b**) should be considered for trade-offs. Overall results and their relationships with desired outcomes showed that metrics **M2b**, **M5**, and **M6**, though meant to measure performance for certain outcomes, can do their work while also balancing other outcomes.

For future research, these objectives can be incorporated into optimization models such as WoLZo or as metrics to support manual workload leveling and zoning using tools such as ViWoLZo. To incorporate the real-world trade-offs, further work may focus on pareto- or other multi-objective optimization, or show metrics on management dashboards for collaborative decisionmaking.

In summary, this paper provides insights into the selection of metrics for workload leveling in planning methods, and it highlights the importance of considering the specific context and objectives of the planning scenario when choosing a metric.

COMPARISON OF TAKT PLANNING METHODS USED ON PROJECTS OF DIFFERENT TYPES

Iris D. Tommelein[1] and Jon Lerche[2]

ABSTRACT

Takt planning has been used to deliver projects of different types and in different industry sectors. We presuppose here that the methods used to develop project takt plans therefore must vary. To test whether this presupposition holds we consider two different project types (wind turbines and healthcare facilities) and compare sample projects of these types in terms of the rationale that was applied when developing their takt plans. We show that the rationale takes into account the relative cycle times and associated resource costs of individual steps in their production processes, considering the dependencies between those steps and between processes. Little has been written in the literature to date about the relative costs of process steps in takt plans, and how these costs affect the opportunities planners have and choices they make when leveling workloads to determine the so-called "operable" takt time. That is done here. This paper contributes to the literature on takt production used to deliver construction projects by describing theoretical concepts that help to differentiate takt planning methods used to plan projects of different types.

KEYWORDS

Production system design, takt production, takt planning, work structuring, flow, complexity, cycle time, cost, Critical Chain, Theory of Constraints

INTRODUCTION

Takt planning has been used to deliver construction projects and phases of work within projects of different types and in different industry sectors, such as multi-family housing, healthcare, and manufacturing plants. Project types can be differentiated based on characteristics such as their complexity, size, spatial features (e.g., location, horizontal vs. multi-story, onshore vs. offshore), and supply chain ecosystem (e.g., supplier and subcontractor availability and capability), and phase types can be differentiated likewise within projects. Recognizing variation by project- or phase type, one might expect that methods used to develop project takt plans will vary. This expectation is in line with Shenhar's (2001) argument that "one size does not fit all projects," i.e., that different types of projects should be managed in different ways. While Shenhar (2011 Table 1) labels all construction projects as "build to print" and lumps them together in the Low-Tech bin, within this bin further distinctions can certainly be made. With this in mind, we start this paper from the presupposition that the methods used to develop project (takt) plans therefore must vary.

[1] Distinguished Professor, Civil and Environmental Engineering Department, Director, Project Production Systems Laboratory, University of California, Berkeley, USA, tommelein@berkeley.edu, orcid.org/0000-0002-9941-6596

[2] PhD, Dept. of BTech., Aarhus University, Birk Centerpark 15, 7400 Herning, Denmark, jon.lerche@btech.au.dk, orcid.org/0000-0001-7076-9630

To test whether this presupposition holds we consider two different project types, namely wind turbines and healthcare facilities, and compare sample projects of these types in terms of the rationale that was applied when developing their takt plans. The rationale is based on relative cycle times and associated resource costs of individual steps in their production processes, considering the dependencies between those steps and between processes. To ground this paper's contribution in prior work, we next review literature related to takt production used to deliver construction projects, and scheduling-related topics including the Critical Chain method (CC) based on the Theory of Constraints (ToC). We then explain the perspective we adopted for our analysis, that considers the relative costs of process steps in takt plans, and how these costs affect the opportunities planners have and choices they make when leveling workloads to determine the so-called "operable" takt time. That section is followed by the presentation of Project Type 1, a wind farm infrastructure project, and Project Type 2, a healthcare facility project. Each one includes a description of the rationale applied in planning these projects. The paper ends with a discussion and conclusions.

LITERATURE REVIEW

PROCESS STEP DEPENDENCIES AND INTER-PROCESS NETWORK DEPENDENCIES

Before talking about process steps in takt plans, it is worth separating the functions of planning and scheduling. According to Kelley & Walker (1959), planning is defining what activities have to occur and their order of occurrence based on technical or logical relationships (the topology of the network); scheduling further adds the dimensions of time and cost to these activities (the geometry of the network). The critical path method (CPM) highlights the sequence(s) of activities having the longest duration. A CPM schedule does not depict the possible occurrence of variation in duration or timing of activities, or the existence of alternative activities. A manifestation of variability (e.g., uncontrolled stoppages) may result in delaying the project.

Since the inception of CPM, a variety of other and often-times related network scheduling methods have been developed (e.g., Russell & Wong 1993). Location based scheduling (LBS) explicitly depicted location-dependent logic (Willis 1998, Harris & Ioannou 1998, Kenley & Seppänen 2010, Lerche et al. 2019). Takt planning further introduced into the plan a given beat (the takt) and the direction of the flow of work, as will be elaborated on in the next section. The Critical Chain (CC) method with its drum-buffer-rope concept defined the slowest process step as the drum and based on that drum paced the other process steps (Goldratt 1999).

Whether to use CPM, LBS, Takt, or CC as methods for planning needs to be decided judiciously in order to match the project requirements and opportunities provided by their context. Any one or several of these methods can be used within the Last Planner® System (LPS), where the work structuring of activities is based on principles applied to logical layers of planning (Ballard 2000, Ballard & Tommelein 2021). LPS focuses on how to plan in light of what to accomplish with the plan, rather than on the specifics of what a plan consists of (Lerche et al. 2020b). The LPS does not single out the use of any method in particular.

When scheduling, activities are aligned according to their technical or logical relations. Howell et al. (1993) defined these as degrees of linkage (from loose to tight) between processes. Hopp and Spearman (1996) found these linkages to have dependent or independent demands. Bølviken et al. (2015) defined relationships between processes as dependencies that can turn into constraints, either physical or non-physical. For example, a physical constraint arises when a component or prefabricated unit's physical characteristics (weight, dimensions, etc.) exceed the crane capacity (e.g., Taghaddos et al. 2018). Protecting the schedule (or production plan) from variability requires the discipline of actively removing or limiting such constraints (e.g., through work structuring and make-ready planning when using the LPS).

Using CPM, buffers may be introduced within and between activities to allow time or resources to mitigate the risks of being delayed from such constraints. LBS further allows for location buffers, and CC looks to create a buffer of inputs needed by the drum. Goldratt (1999) defines a system constraint as what prohibits the system from achieving higher performance, something that is not an act of God and can therefore be handled. This could be true for example in case of the crane, but then raises the questions "What are the tradeoffs?" and "At what cost?"

TAKT PLANNING

Researchers have described theoretical constructs and applications of takt planning or, more generally speaking, takt production (e.g., Frandson et al. 2013, Linnik et al. 2013, Binninger et al. 2019, Gadbois et al. 2018, Lehtovaara et al. 2020, Jabbari et al. 2020). As is presupposed here, takt planning methods will differ as the project types differ but research in this area is lacking. Barring exceptions such as Tommelein's (2022) detailing of the Work Density Method (WDM), we have found few papers that actually spell out the specifics of any method used to develop the takt plan. Nevertheless, at heart the methods include the following procedural steps:

1. Identify a sequence of steps that make up a linear process. Alternatively, linearize a process that has concurrent steps by sequencing its steps so that they have a one-on-one finish-to-start relationship with at most one other step, or by performing concurrent steps off-takt, that is, removing them from the process under consideration. To illustrate, each square in Figure 1 represents a process step and its color refers to a specific trade. One trade may perform different steps in the process either with the same crew or with different crews.

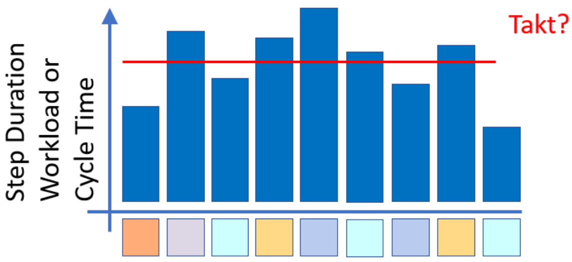

Figure 1: Workload histogram for a linear process
(aka. cycle time histogram or Yamazumi chart)

2. Based on the demand for the process deliverable, calculate what the takt should be (shown by the red line in Figure 1). "Takt Time [is] the pace that exactly meets customer demand given available production time. This is a customer-focused metric" (Moran 2022).
3. Determine the duration of each step. This duration is called the workload or cycle time. It is shown in Figure 1 by a blue vertical bar for each step.
4. The peak of all steps' cycle times must fall below the takt or the process will not be able to fulfil its customer's demand. That peak defines the "Operable Takt Time [which is] the pace you can actually achieve with your current process and equipment. This is a manufacturing-focused metric."[3] (Moran 2022).
5. If the operable takt exceeds the customer's takt, then lower the blue vertical bars until they all fall below the takt (red line). The difference between the two serves as a capacity buffer needed to absorb duration variability. Protecting the takt plan from variability is commonly

[3] Jabbari et al. (2020) used the notation T(Z) to refer to the peak workload in a workload histogram. This peak defines the operable takt time of a process, although they did not use that term. Z is the number of zones (locations where work is done) into which the work space is divided. T(Z) is a function of Z because the operable takt depends on how the workspace is divided into zones due to the fact that workloads may vary by trade and by zone.

done by underloading resources (i.e., creating a capacity buffer) or by allocating time- or space buffers (Frandson et al. 2015).

A blue vertical bar (including the tallest one called the peak workload that defines the operable takt) can be lowered by adjusting one or several “throttles” or “adjustment mechanisms” (Binninger et al. 2017) available to planners in general, namely: (1) Modification of product- and component characteristics, (2) Use of alternative breakdowns of the scope of work, (3) Resequencing of work and addition or removal of work from a process sequence, (4) Selection of alternative means and methods used by a trade, and (5) Development of worker- and crew trade skills, and selection of the number of trade resources that can be assigned.

Such throttling can make use of lean methods, such as:

- Single Minute Exchange of Die (SMED): a method to reduce changeover and exchange times between different components in a manufacturing setting. Some people spell out this abbreviation as Simplify, Move, Eliminate, or Delegate.
- Sort, Straighten, Shine, Standardize, and Sustain (5S): a method to increase work space efficiency.
- Plan Do Check Act (PDCA) aka. the Shewhart- or Deming cycle: a method for action learning, which in this context may be used to understand the conditions of process steps relative to each other. Workload leveling between process steps while aiming to achieve the takt (as is illustrated in Figure 1 with the red line) will require changes in cycle times: some will need to be reduced whereas others could be increased and still fall below the takt.

THEORY OF CONSTRAINTS

An alternative to using a method for takt planning is to apply the Critical Chain (CC) method based on the Theory of Constraints (ToC) (Goldratt 1999). The ToC starts by recognizing the slowest step (bottleneck) in a process. The bottleneck is designated as the drum or pacesetter for the process. Steps upstream of this bottleneck are paced using a pull mechanism called a rope that is tied to the drum. A buffer is intentionally built up before the bottleneck to prevent that bottleneck from starving. This explains the drum-buffer-rope method.

The drum-buffer-rope method can be applied to construction settings. However, its shortcomings must be addressed as well. Roser (2014) mentioned two. First, the rope ties the steps upstream of the bottleneck to that bottleneck, but the ToC is silent about how to manage the steps downstream. These downstream steps—like all other steps in the process—must be considered in any production system’s design. Second, a process may have, not one, but multiple bottlenecks and those may shift over time (Roser et al. 2002).

Lerche et al. (2022a) illustrated how a combination of takt and kanban thinking could be applied to protect the process steps deemed bottlenecks. The kanban (like the rope in the ToC) adds a pull link between process steps in the takt plan to prevent any process step from commencing when its preconditions are not met, or the previous task is not finished.

COST

As mentioned, an objective in takt planning is to make the operable takt less than the customer’s takt and this is done by lowering workload peaks or using other throttles. An issue not previously discussed is that the application of a throttle has not only cycle time- but also cost implications. When looking at only direct costs, in certain situations it may be reasonable to claim that there is no extra cost for using the throttle of speeding up or slowing down work. For example, assume that the cost to perform a step with a certain quantity of work (e.g., 60 units in a zone) can be computed by multiplying a production rate (e.g., one worker can install 5 units/hour) by the number of resources at their cost rate (e.g., a worker is paid $100/hour) (or some other function, but ignoring any non-linearities in the cost function that may arise for example from overcrowding). Using these example numbers, the duration of the step when performed by one worker is 60 units / (5 units/hour) or 12 hours and thus the cost of the step in this zone is $1,200. Using two workers, the duration is cut in half to 6 hours but the cost is still $1,200. Other considerations come into play in the throttling process especially when considering cost, such as:

- A cost penalty will be incurred when the workload is highly variable and unevenly distributed from one zone to another, as this makes it difficult for a trade to maintain a constant crew size. This is not to say that crew sizes cannot change over time, but it is the case that keeping people working together for a longer time results in better performance.
- Some workload variability could be absorbed by engaging multi-skilled workers, but they are likely paid more than less-skilled workers.
- Some resources are very expensive compared to others and may be available only in limited numbers. Throttling up may therefore be cost prohibitive or impossible altogether.

RESEARCH PERSPECTIVE

The research method follows a case study approach with multiple embedded units of analysis. The first unit of analysis is the case description in terms of context, process, and cost drivers. The second unit of analysis investigates the takt planning method as previously described with procedural steps 1 through 5.

PROJECT TYPE 1: WIND FARM INFRASTRUCTURE

PROJECT SCOPE

The construction of wind farm infrastructure combines multiple technical modules, to result in a power plant with a life time exceeding 20 years based on the turbines' end-of-life expectancy. Wind farms are often divided in two systems: (1) the transmission system (housing of electrical power transmission equipment or cabling) connecting the power plant with a national grid, and (2) the power generating system (cable connections, wind turbine generator structures) harvesting the wind's energy. The module assembly strategy follows what Peltokorpi et al. (2018) calls "sectional," leading to interfaces having clear technical dependencies.

PROCESS

As the wind energy industry is rapidly developing both onshore and offshore, modules are increasing in power output capacity and physical size (Enevoldsen and Xydois 2019). At the highest level, a wind farm can be broken up into separate packages, pertaining to grid connection points, cables, transformer stations, foundations, and wind turbines. Each of these packages then contains sub-systems or modules, e.g., the wind turbines package consists of the tower, nacelle, and blades. Lerche et al. (2022) revealed how the process time for an offshore cable termination is related to the design choices made not only for the cable itself but also for its support structures. They reported how the offshore wind farm infrastructure is assembled in accordance with its technical dependencies, and noted that technical dependencies appear to make the ordering of processes predictable and replicable. This is the case especially for installation processes that require equipment (e.g., cranes, purpose-built vessels, or underwater robotics) (Barlow et al. 2018), which might explain why offshore installation in particular has been planned using CPM (Lerche 2020). When a technical dependency is broken, schedule adjustments can be made, e.g., if a foundation is installed but cabling is not complete, the turbine can be installed but not commissioned, and temporary power generators would be required to sustain its product integrity (lifetime expectancy) until the cabling is completed.

Cost

The tradeoffs made by the infrastructure developers are related to the cost of installation versus the cost of maintaining power production, while accounting for the financial incentives for finishing early or at least on time that stem from the opportunity to start generating power and earn revenue (opportunity cost). Sovacool et al. (2017) described the difference between onshore and offshore in terms of the risk associated with the cost of the equipment, in particular purpose-built vessels used for offshore installation (Barlow et al. 2014). Installation vessels being the main cost driver, with an average rate of €250,000/day, has made both developers of offshore infrastructure and their supplier pool of manufacturers (cables, transformer stations, foundations, and turbines) conscious of vessel capacities and costs. Consequently, they have shifted their focus to limiting the time spent offshore (Lacal-Arántegui et al. 2018; Lerche et al. 2020, 2022). Although onshore wind farm infrastructure development and project execution use less expensive equipment, the relative cost of equipment is still considerable.

Defining the Takt

The technical dependencies provide clear direction for the linearity of process steps between trades. Wind farm infrastructure installation requires only a few trades, electrical and mechanical trades being the primary ones, where specialized resources for specific process steps are seen as 'off-takt'. Lerche et al. (2020, 2022) defined process steps according to module type and trade required (Figure 2):

1. For the main module process steps where the use of highly specialized equipment is essential (e.g., a crane with exceptionally large reach or hoisting capacity), these can be determined by contractual terms for either the equipment or for the assembly crew. It could also be determined by what durations to handle given modules are practically feasible for the equipment. Process steps preceding and succeeding these then either align with the drum (as mentioned in the ToC) or planned to a different takt. For process steps without such equipment requirements, the durations could be organized according to location or trade as is the case when developing a (takt) plan for building construction (Lehtovaara et al. 2020).
2. Considering large equipment for handling the modules (installation processes here) to be the drum, this sets the takt for up- and down-stream process steps. The takt is then calculated according to the beat of procedural step 2. Lerche et al. (2020) found that installation vessels set the beat, providing pre-assemblies with a turnaround rate that could be divided by the number of modules in a batch. Such a calculation would also apply in case additional units of large equipment (e.g., purpose-built vessels) are introduced.

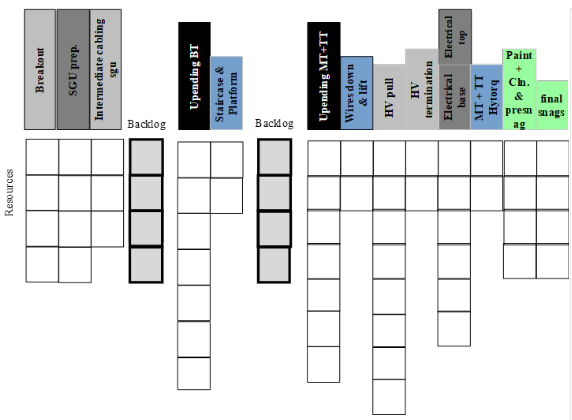

Figure 2: Process steps with resource requirements (Lerche et al. 2022)

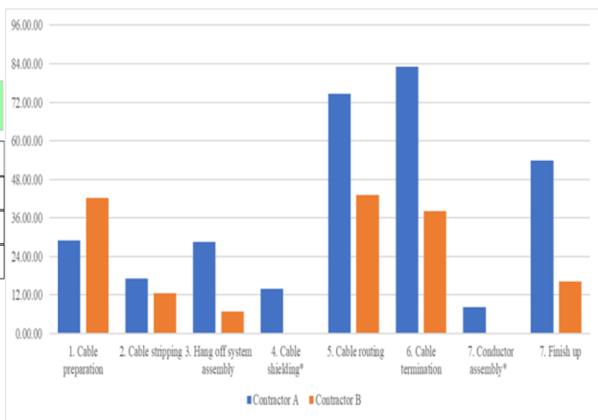

Figure 3: Comparison of process step durations between two contractors (Lerche et al. 2022)

3. Capacity buffering with resources allows for leveling the process steps durations, those process steps with high technical dependencies or equipment constraints require alternative solutions as design changes, or capacity improvements to the equipment. Simultaneous work of different trades is commonly used for offshore commissioning, allowing the trade to finish a location one at the time.

PROJECT TYPE 2: HEALTHCARE FACILITIES

PROJECT SCOPE

The construction of a healthcare facility comprises multiple project phases pertaining to the building's core-and-shell and fit it out (site work, foundations, structure, exterior cladding, interior rough-in, finishes, commissioning). Healthcare projects require the installation and commissioning of complex mechanical-, piping-, electrical-, fire-life-safety- and other systems each of which must meet stringent performance requirements (seismic safety, sustainability requirements, etc.), and all are packed together in a limited amount of building space designated to utilities. Therefore, these projects are considered complex when compared to commercial building or housing projects, for example.

Here, we focus specifically on a later phase of project delivery, namely interior work (rough-in and finishes), during which many trade specialists are involved. Because of interdependence between the trades' work, judicious coordination of that work can significantly help to speed it up. Therefore, not surprisingly, in healthcare- and laboratory projects such work appears to have been planned more often using takt (e.g., Linnik et al. 2013, Frandson and Tommelein 2014, Gadbois et al. 2018) than has been the case for earlier work (e.g., foundations).

PROCESS

Interior work is typically not dependent on a single, pacing resource (in contrast, e.g., structural steel erection may be paced by a tower crane). Due to its relative complexity, it is quite common to have ten if not more specialty contractors involved, all requiring access to and sharing site space, material hoists, as well as other resources. In addition to space and the aforementioned resource dependencies, the work of one trade often forms the substrate for the work of the next trade (e.g., framing must precede hanging drywall, priming, and painting).

For certain scopes of work, there is a natural flow to doing building construction work (Riley et al. 1995) and work will proceed in a Parade of Trades. However, that flow can be flexible: some work can be done out of order without becoming cost prohibitive. Dependencies exist but can be modified, e.g., while it is preferrable to paint walls before putting flooring in a room, if flooring needs to come first then protection can be added to avoid paint spilling on it.

COST

For each trade, the cost of an activity is a function of worker pay based on their skills, and the cost of materials, tools, and equipment (plus overhead and profit). Worker costs (as opposed to equipment costs in wind farm projects) are relatively high compared to the other costs. At the risk of overgeneralization, the resources required for healthcare project delivery are not as capital intensive as those required to deliver wind farm infrastructure.

Furthermore, the cost of work in a process, step-by-step, is relatively speaking commensurate across trades. To achieve schedule milestones, crews may be doubled up and work in different locations concurrently with no cost penalty (as explained earlier). Shared resources (e.g., material hoists and manlifts) may be expensive and scarce, but of note is that many trades take turns using them so that potentially many process steps are impacted by them (unless their use can be scheduled off-takt).

DEFINING THE TAKT

The customer process of rough-in and finishes, the commissioning phase, involves numerous systems (heating ventilation and air conditioning, potable and perhaps also grey water, medical gasses, building controls, etc.). Upon project turnover, the move-in phase involves getting people to occupy and use the building. The costs arising from missed handoffs between those processes and opportunity costs are high. A goal of takt planning therefore is to hit the project commissioning and turn-over milestone dates and to do so reliably.

DISCUSSION

UNDERSTANDING THE THROTTLES

Lowering of process-step cycle times can be done by applying throttles, as previously mentioned (also see Lerche et al. 2020, 2022, and Tommelein and Emdanat 2022):

1. Apply PDCA to reduce the cycle time of a process step (but do not confuse fundamental improvements with learning curve effects) as well as reduce its cycle-time variability.
2. Use technical solutions to reduce assembly durations, e.g., replace slower mechanical or hydraulic tools with faster electrical tools to shorten the duration of bolt tightening in module joints. Find alternative tool solutions to improve installation process steps (Zhao et al. 2018). Redesign work processes.
3. Crew up (or down) when worker availability is not a constraint (as may be when highly specialized workers are required, such as unique equipment operators) and sufficient work space is available.
4. Add equipment capacity to expedite work.
5. Divide process steps into smaller ones, esp. those with few technical dependencies and not requiring heavy equipment. E.g., if the crane is the drum, then try to remove steps that require crane use in order to alleviate its workload. Use a small crane for assemblies up to a defined height, before using the main crane for higher lifts.
6. Take some scope out of a process step and perform that scope at another time.
7. Pre-fabricate assemblies. As when working with larger modules being fabricated elsewhere, move assembly upstream from the construction site to a manufacturing site.
8. Design fewer process steps into the product, e.g., the cable case in Lerche et al. (2022).
9. Change the product design but be mindful that this can affect individual process steps positively or negatively (e.g., Figure 3 illustrates step durations of two contractors who completed similar processes but chose different designs).
10. Eliminate interface assemblies by "thinking in" the assembly process, e.g., apply mistakeproofing by using electrical plugs on both sides instead of hard wiring (e.g., Figure 4 in Tommelein 2008).
11. Add buffers to protect the bottleneck step in a process (i.e., ensure its efficiency and effectiveness), e.g., build up an inventory buffer of modules at quay side, ready for vessels to carry them offshore in order to protect the installation process step.

    Of note is that in the offshore literature there is a tendency to focus on the transport of personnel (Lerche et al. 2022), optimizing the use of vessels that are not directly involved in process steps (Petersen et al. 2016) and are not a process bottleneck. This practice merely reduces flow-variability but does not improve process performance.

Decisions in this regard must be made early enough to be most effective, however, even when made at the last minute they can still be beneficial to process performance.

IMPLICATIONS FOR TAKT PLANNING

Based on a project's type (Table 1) some throttles for takt planning are used more easily and cost-effectively than others. Steps for constructing wind farm infrastructure have numerous technical- and key resource dependencies; they involve expensive and unique equipment. As the dimensions of prefabricated units get larger, opportunities to devise alternative plans and flexibility in planning tend to diminish (you cannot beat physics). One runs into limitations on available equipment sizes and highly skilled operators, on allowable loads on bridges, overhead obstructions, ground pressures, allowable truck loads and volumes (weight per tire, weight distribution), etc. Equipment (the drum) determines the operable takt. It may be that one piece of equipment is available, but no additional one is readily available or affordable. In situations like this, planners must first resort to using SMED to improve drum throughput.

Table 1: Takt planning comparison

Case 1	Case 2
STEP IN TAKT PLANNING 1. Step and process definition: Dependencies define process step sequencing, Space, Steps in the process	
a. Dependencies express technical execution strategies. b. The dimensions of the modules determines the need for space (location), and what can be done in adjacent spaces. c. Requires fewer different trades (e.g., electrical and mechanical) with fewer and 'bigger' steps. It is clear who you need when and in what sequence.	a. Dependencies are based on choices related to logical sequencing of work, and there is some flexibility in that (e.g., paint walls before putting in flooring or vice versa, though the former may be preferred) b.. Work can be broken into "chunks" of various sizes which creates flexibility in deciding what to do where. c. Numerous specialist trades are needed and must coordinate their shared use of space (especially on 'fast' projects where concurrency can be achieved).
2. Customer takt	
Customer demand for speed is based on the business case but constrained by what is feasible given available equipment capacity (e.g., large vessels).	Customer demand for speed is based on the business case and drives the determination of production rates (quantity installed per crew hour) and resource loading.
3. Individual step cycle time	
Step cycle time may be on the order of hours, driven by equipment costs.	Step cycle time may be on the order of a fraction of one day to a few days, typically less than the time window covered in a weekly work plan.
4. Process operable takt	
Specialized equipment defines operable takt (and cost), i.e., drum (in CC). Lerche et al. (2020) revealed how the industry's tendency to focus on the drum beat defined by costly equipment.	Work density and resource availability defines operable takt (e.g., how many electricians can productively work in an electrical room?).
5. Process operable takt	
Protection of the drum by buffering with inventory (e.g., stage 2 or 3 times more modules than will be transported on any one vessel).	Use capacity buffering and workable backlog.

Planners can view processes from both a design- and commercial perspective. When engaged early in design they can balance these perspectives, whereas later that becomes increasingly difficult. When balancing is accomplished to the extent possible, they can design the takt plan based on the drum's beat and synchronize other process steps based on the drum.

In contrast to equipment-intensive work (e.g., foundation piles, segmented bridges, or wind turbine towers) that is dominated by the pace at which that equipment can "go," processes for healthcare project delivery have more substrate- and fewer technical dependencies. Worker-intensive work presumably has flexibility in crewing up or down. It is relatively easy to get more people and not too costly to provide the crew with needed tools and equipment.

Before construction starts, Case 1 has shown that actively thinking of repetition in design can be beneficial. Such repetition is also beneficial as the modules are prefabricated. Prefabrication means taking work out of a (site) process or moving work to another process in order to reduce a given step duration(s) and therefore the corresponding process duration. Case 2 can also benefit from prefabrication. In addition, Case 2 can benefit from designs that use multiple smaller components distributed in space, rather than a few larger ones focused in one area, when this leads to a decrease in work density by zone.

During construction, both cases benefit from conducting first run studies and designing operations, defining standard work, and mistakeproofing to help achieve reliability in step execution. While case 1 further can take advantage of repetition, it can further strengthen the effect from the other throttles, as the modules introduce limited variation. This also means that Case 1 can seek improvement through tool selection due to high repetitions, e.g., moving from slowly rotating hydraulic tool heads to electrical. Process step improvement for Case 2 relies on trades judiciously choosing the “best” trade tools.

Both cases reveal that increasing resource capacity can lead to process improvement, this is presumed easy for both cases, while Case 1 has a limitation of geographical space or work location constraints. Secondary around the resources, Case 2 also shows that scope of a step can be combined vs. divided and/or reallocated to other steps within limits of constraints imposed by numerous trade jurisdictions. As Case 1 dominantly require mechanic or electrical resources, the use of multi-skilled trades is possible, this is supported by the offshore settings being less restrictive in terms of labor union jurisdictions.

CONCLUSIONS

By means of two samples of projects of different types, we illustrated that takt planning methods vary due to consideration given to relative cycle times and associated resource costs of individual steps in their production processes, while accounting for the dependencies between those steps and between processes. The costs associated with the use of various throttles to change workload peaks play a role in the planning process. To our knowledge, little has been written to date about the relative costs of process steps in takt plans, and how these costs affect the opportunities planners have and choices they make when leveling workloads to determine the so-called “operable” takt time. We found that the CC method stemming from the ToC offers useful perspective on methods for takt planning especially in cases where a single, expensive resource or step clearly defines the process bottleneck, and the bottleneck’s cycle time well exceeds the cycle time of other process steps. More in-depth study is in order of how cost considerations affect the choice of a takt planning method.

INTEGRATION AND DEVELOPMENT MODEL FOR SUPPLIER RELATIONSHIP MANAGEMENT IN CONSTRUCTION

Andreas Lepold[1], Marco Binninger[2], and Oliver Wolfbeiß[3]

ABSTRACT

The construction industry faces the challenge of selecting and developing partners for its projects. Although partner selection models and criteria have been extensively studied, the construction industry does not yet have optimized tools for selecting partners. Partner development is becoming increasingly important in the context of Lean Construction, which encompasses both Takt Planning and Takt Control (TPTC) and Last Planner System (LPS) approaches. To solve this challenge, a comprehensive literature review identified methods for partner selection in both the stationary and construction industries. The selection of the partners to be developed was presented using a best-practice example from the automotive industry. With the help of expert workshops, a model tailored to the selection of partners to be developed in the construction industry was developed and necessary criteria identified. The resulting conceptual model was tested through case studies and found to be effective. The selected criteria can be flexibly varied and adapted to the corporate strategy. The model was successfully applied to different partners of a general contractor with the help of case studies. The model is currently being tested in practice at a general contractor in an extended project scenario.

KEYWORDS

Supply chain management (SCM), Supplier relationship management, collaboration, trust, integration

INTRODUCTION

The application of lean management to construction was first introduced with the Egan Report Rethink Construction in 1998 (John Egan, 2014). The Lean approaches gained wider dissemination through the efforts of the International Group for Lean Construction and the successful implementation of the Last Planner System approach in 2000 (Ballard, 2000). However, the practical implementation of these approaches has been limited to project-based processing, which is characterized by a long start-up and run-down curve and no constant performing phase (Fagerlund et al., 2021). The focus has been on collaboration and cooperation both in practice and theory, and this project-based mindset is evident in approaches like the Last Planner System or Target Value Design, which are examples of lean construction implementation.

Newer approaches, such as Integrated Project Delivery (Bayazit et al., 2006) or Takt Planning based on the 3-level model (Dlouhy et al., 2016), take the concept a step further by

viewing a project as a whole system. However, they are still primarily focused on single project execution, as this is the norm in the construction industry.

Continuous improvement is a crucial element of successful production systems, and cross-project learning is a key component of this process (J. M. Clark & K. E. Stecke, 1997). When projects are viewed as part of a larger system, they become interdependent and can be compared with one another. This approach can lead to advantages such as overlapping start-up and run-down phases, greater scaling effects, and a faster learning curve between projects. However, it can also lead to negative effects if approaches and problem-solving processes are not sustainable. The bullwhip effect, caused by a lack of stability, can have a significant impact on the overall system.

To address these challenges, new ways of thinking are necessary. In particular, the interaction between the implementation partners General Contractor (GC) and Subcontractor (SUB) must be considered more closely, as stability is largely generated by their collaboration. This interface between the micro and norm levels in the 3-level model (Dlouhy et al., 2016) is crucial to optimizing performance across projects. When both parties work together and share similar interests in the production system, the interface can be optimized to promote stability.

The construction industry can learn from other industries that have faced similar challenges in transitioning to production systems, and adopt the approach of systematic supplier relationship management (SRM) as part of supply chain management (SCM). This involves developing and integrating partners into the production system in a mutually beneficial manner, creating a win-win situation. While supplier selection methods are already applied in the construction industry (Cengiz et al., 2017), the SRM approach has yet to be widely adopted.

This paper applies the SRM approach, specifically the identification of developable partners, to the construction industry. The term "supplier" is used broadly in this context and includes subcontractors, craftsmen, planners, and all partners of a GC. Examples from the stationary industry are used as a basis for a model for the application of SRM in the construction industry. The research question addressed in this paper is: "How can the interaction between GC and other partners (Sub, craftsmen, planners, or suppliers) be developed sustainably on a micro level to positively influence stability?" By answering this question, the paper provides insights into how the construction industry can improve its production systems through the adoption of an SRM approach.

THEORY AND AS-IS SITUATION IN CONSTRUCTION

PRODUCTION SYSTEMS

The following chapter emphasizes the significance of partner management in a production system, drawing on the development of SRM in other industries and literature. Production systems refer to the comprehensive organization of production and comprise all the concepts, methods, and tools that contribute to the effectiveness and efficiency of the entire production process (Schuh & Stich, 2012). Contemporary production systems, such as the Toyota Production System, are founded on horizontal and vertical networking. Supply chain management, on the other hand, pertains to the management of the entire value chain (Wieland & Buchholz, 2011). The integration of external partners is particularly essential in the vertical value chain. For instance, Daimler and Bombardier have a vertical integration of up to 20% (Helmold & Terry, 2016). SCM can be segmented into customer relationship management, which defines the customer relationship from the GC's perspective, and supplier relationship management, which optimizes the relationship with the supplier (Wieland & Buchholz, 2011). Other industries have already recognized the following aspects related to SRM as they become a production system:

- Entering into and managing long-term relationships is becoming increasingly important in modern markets (Riemer, 2008)
- Relationship perspective instead of transaction-oriented views (Riemer, 2008)
- Traditionally the purchase range was regarded almost exclusively under cost aspects. The role of the procurement in the enterprise changes however and experiences increasing attention by the management (Stuart, 1997)
- A goal is thereby the structure of complex relationship networks with mutual information flows to a optimization of the entire creation of value chain (Riemer, 2008)

A key goal of SRM is to systematically evaluate and segment suppliers based on their current and future economic importance to the company (Dangelmaier et al., 2004). It is important to distinguish between partner relationships that primarily serve operational purposes and those that can help the company build strategic competitive advantages (Stuart, 1997). Figure 1 illustrates the evolution of SRM from a supplier as a procurer in the 1980s to a value creator in the present time. A clear example of this change can be seen in the automotive industry. In 2002, the car manufacturer, specifically the Original Equipment Manufacturer (OEM), produced 55% of the body of a car. Today, the industry average is 29% (Mercer Management Consulting & Fraunhofer-Institut, 2015). Similarly, BMW had a development depth of 70% in 1985, which decreased to 30% in 2007 (Richter & Hartig, 2007). At SMART in Hambach, suppliers contribute 75% of the product development and value creation (Wieland & Buchholz, 2011).

Figure 1: Evolution if the SRM (Helmold & Terry, 2016)

As a result, supplier management has become an integral function of transferring quality, cost, and delivery targets to the external value chain and synchronizing them with it (Helmold & Klumpp, 2011). The shift in value chain shares and consolidation has led to the concentration of competencies that were previously held by manufacturers with key suppliers, increasing the market power of these suppliers. Automotive manufacturers have responded to this trend with strategies such as "mega-supplier" or "key-supplier" approaches (Dölle, 2013). Additionally, early and systematic development of potential alternative suppliers is critical, as these suppliers can be integrated into cross-company processes through collaborative optimization (Helmold & Terry, 2016).

AS-IS SITUATION IN CONSTRUCTION

The construction industry is known for its project-specific execution and a highly fragmented and small-scale contractor market. In the German market, for instance, most contractors employ only a few individuals (Schul et al., 2007).

To secure subcontractors for a project, tendering and market comparison are usually the preferred methods, which can take up a considerable amount of time. While price is often the main criterion in the selection process, it is essential to consider other factors that may impact the total cost of ownership, such as rework, complaints, or failure (Helmold & Terry, 2016).

Project-specific processing has its own set of challenges. Companies collaborate for a limited time and then go their separate ways. During the initial stages of a project, friction can arise, which can either decrease or lead to a premature end of the partnership. Moreover, there is limited post-reflection or lessons learned, which does not promote the need for long-term and sustainable cooperation (Ferrada et al., 2016)

In practice, project-specific collaboration is governed by a contract that defines the technical and organizational framework conditions. The order is processed based on this contract, with the goal of achieving cost efficiency and minimizing interfaces. Most decisions are cost-driven, and there is a tendency to continue working together despite challenges due to time constraints.

As a result, large projects often experience budget overruns, delays, and a bad reputation, leading to legal proceedings and high insolvency figures (Ferrada et al., 2016; Narayanan et al., 2018).

METHOD

The procedure of the present article is based on two basic methods, namely literature research and expert workshops, which are discussed in more detail below.

In the first step of the literature research, the ideal process of partner development is presented based on the current standard literature. Based on this, the search for best practice examples will be conducted. The focus is on the automotive industry, which has been following the SRM approach for many years. The method of literature research was selected because it is a valuable tool for developing theoretical frameworks. The literature review was following the steps of selecting relevant sources, analysing, and synthesizing the information, and presenting the findings (Tranfield et al., 2003). Based on the partner development process and the preparation of the expert workshops, a comprehensive literature research identifies existing criteria for supplier selection. This research includes over ten relevant papers from 2009 to 2022. Based on the literature research, expert workshops are conducted in which the relevant criteria for partner development are identified and transferred to the construction industry.

Building on these criteria, further expert workshops will derive a model that can be used to identify the current maturity level of the partner as well as the need for development. The expert workshops will be conducted in collaboration with a GC. On the one hand, so that the developed model can be quickly transferred into practice, and on the other hand, to compare the criteria with the corporate strategy. The expert workshops as a method were chosen because it is an effective way of collecting knowledge (Bogner, 2005). Experts in our term are department leaders and specialists of a GC located in the German construction market. The experts were selected focusing on their role, market understanding, experience (over ten years average) as well as representing different perspectives e.g. project control, tendering, site management.

Subsequently, the capability of the model will be validated by means of six case studies to show the practical use of the model.

LITERATUR RESEARCH

IDEAL PROCESS OF PARTNER DEVELOPMENT AND BEST PRACTICE

In the chapter "Production Systems", it is evident that industries beyond the construction sector have reconsidered their approach to selecting partners. Furthermore, the manufacturing depths of companies in the stationary industry are approaching that of a general constructor. As such, this chapter presents a standardized supplier management procedure from the stationary industry, and emphasizes the successes achieved through the implementation of SRM. Figure 2 illustrates the supplier management process according to Hofbauer (2016), which comprises four sub-processes that are explained in greater detail below.

Figure 2: Supplier process (based on Hofbauer, 2016)

Supplier selection: At Audi AG, supplier selection serves to identify new and potential suppliers. The aim is to maintain and improve the supplier pool at the same level. The focus of supplier selection at Audi AG is on innovative and technology-driven suppliers. By collecting supplier information centrally, Audi AG achieves transparency throughout the company with regard to the market. Another advantage for Audi AG is the early identification of technological trends (Hofbauer, 2016).

Supplier evaluation and classification: As supplier evaluation (Wildemann, 2008) summarizes all processes, which serve for the production, selection and preparation as well as the evaluation of supplier information (Wildemann, 2008, p. 157). The aim is to verify that supplier performance meets defined requirements (Glantschnig, 1994). The supplier evaluation consists of the definition of the criteria as well as the quantitative and qualitative evaluation of the suppliers according to these criteria (Hofbauer, 2016). Audi AG conducts supplier evaluation not only at the time of award, but throughout the entire collaboration. The results of these evaluations are communicated to the supplier. Thus, a continuous improvement is achieved at the supplier. The classification of the suppliers serves to carry out a comparison with the corporate strategy and thus to identify the strategically relevant and irrelevant suppliers. The strategically significant suppliers are developed (Hofbauer, 2016).

Supplier development: Supplier development includes both the further development of existing suppliers and the qualification of new suppliers. It thus also supports supplier development. The aim is to increase the capabilities and performance of suppliers. This includes cooperation on a collaborative level as well as the transfer of know-how. At the same time, supplier development increases the competitiveness of suppliers among each other and thus reduces the dependency of the client. (Hofbauer, 2016). BMW and Porsche see supplier development as a core task. Development here extends to supplier academies and the secondment of experts. To develop its suppliers, Porsche also actively intervenes in the corporate policy of the partner (Helmold & Terry, 2016).

Supplier integration: Helmhold & Terry describe supplier integration as integrating the supplier into the existing product development process. Furthermore, it implies the use of the partner's know-how and the coordination of processes and systems. The aim is to minimize waste in the collaboration (Helmold & Terry, 2016).

EXISTING CRITERIA FOR SUPPLIER SELECTION

In the construction industry, supplier selection is a crucial activity, much like in other industries. However, the construction industry faces unique challenges due to three main factors: the type of collaboration, friction caused by a lack of development, and a lack of trust. The selection of suitable partners is thus critical for achieving economic success. (Bayazit et al., 2006; Zulficar et al., 2022)

Thanaraksakul and Phruksaphanrat (2009) examined 76 papers in a study for significant criteria for supplier selection and assigned a rank to each of the 33 criteria (Thanaraksakul & Phruksaphanrat, 2009). Helmold & Terry (2016) list ten criteria for supplier selection. In addition, Wieland & Buchholz, (2011) describes seven criteria for the type of cooperation between partners. Harshad et al., (2022) identified 21 criteria from the perspective of the lean, agile, green, and sustainable paradigms (Harshad et al., 2022). Kshaf et al., (2022) 19 factors that will improve the interaction between the subcontractor und the main contractor (Kshaf et al., 2022). Nath et al., (2021) identified ten project level enablers of collaboration (Nath 2021). Taherdoost & Brard (2019) identified 25 criteria in his study (Taherdoost & Brard, 2019).
In addition, Taherdoost & Brard make it clear that a company should only choose the criteria that are in line with the expectation of future suppliers (Taherdoost & Brard, 2019).

DERIVATION OF THE MODEL FOR PARTNER MANAGEMENT BASED ON EXPERT WORKSHOPS

The previous chapters demonstrated the effectiveness of an SRM model in other industries. In chapter "As-Is Situation in Construction the need for such a model for the construction industry was demonstrated. In this chapter, the methodology for building a partner model in the construction context is explained. The structure of the model is based on a maturity matrix. The rows represent the categories and the columns the degree of development.

THE CATEGORIES OF THE MODEL

Table 1: Example derivation of the subcategories for the partner model (Expert workshop, Nov. 14, 2022)

Attributes from supplier selection	Influence of the attribute on a service to be provided, a product or an activity (in the construction context)	Derived subcategory
Quality, Delivery, Performance. Reliability	Influences the control effort of the partner	Focus on the control

Table 2: Overview of the ten derived categories for the partner model and the respective definition (Expert workshop, Nov. 14, 2022)

Attributes from the supplier selection	Sources	Subcategory of the model	Definition
Quality, Delivery, Performance, Reliability	(Becker, 2014); (Thanaraksakul & Phruksaphanrat, 2009); (Helmold & Terry, 2016); (Taherdoost & Brard, 2019); (Nath et al., 2021)	Focus of the control	Degree of control effort of the partner based on quality and on-time delivery
Mutual trust and easy communication	(Taherdoost & Brard, 2019); (Nath et al., 2021)	Know-How Transfer	Degree with which knowledge is shared between the parties
Warranties and claim policies	(Thanaraksakul & Phruksaphanrat, 2009); (Taherdoost & Brard, 2019)	Contract type	Degree of mutual dependence
Desire for Business, Management and Organization	(Becker, 2014) (Thanaraksakul & Phruksaphanrat, 2009)	Time commitment	Duration of cooperation
Professionalism, Attitude and strategic fit, Communication system	(Taherdoost & Brard, 2019) (Helmold & Terry, 2016), (Nath et al., 2021)	Level of cooperation	Degree of efficiency of cooperation
Flexibility and Reciprocal arrangement	(Taherdoost & Brard, 2019) (Becker, 2014) (Thanaraksakul & Phruksaphanrat, 2009)	Scope of service	Degree of the partner's own product development
Innovation and R&D, Personal trainings and development, willingness of innovation	(Taherdoost & Brard, 2019) (Thanaraksakul & Phruksaphanrat, 2009) (Helmold & Terry, 2016)	Optimization and development	Degree of partnership business development
Production, facility and capacity, technology aspects	(Taherdoost & Brard, 2019) (Thanaraksakul & Phruksaphanrat, 2009) (Helmold & Terry, 2016)	Standardization	Degree and scope of standardization
Financial status, cost management and transparency, financial strength of the supplier including payment modalities	(Taherdoost & Brard, 2019) (Thanaraksakul & Phruksaphanrat, 2009) (Becker, 2014)	Willingness to invest	Monetary importance of a decision for the partner
Other criteria	(Hofbauer, 2016)	Strategic relevance	Strategic importance of the partnership

In chapter "Existing criteria for supplier selection" more than ten relevant papers and over 80 criteria were identified. The following model is intended to solve the construction-specific problems of the partner selection. Additionally, the model is intended to be applicable to all partners and not limited to suppliers of physical products. Therefore, the criteria are used as bases for the categories of the following model and specifically adapted. To adapt the categories to the construction sector, the influence of each attribute in the construction context on a service, product, or activity to be performed was investigated. Table shows an example of this adaptation. In addition Table 1 shows which of the supplier selection attributes serve as the basis for the subcategories. The definition of the 10 derived subcategories can also be taken from (Expert workshop, Nov. 14, 2022).

THE FOUR STAGES OF DEVELOPMENT OF THE MODEL

From a broader perspective, there are two stages of development within the system: "in" and "on" the system. "In" the system refers to partners who are functioning within the production system, but who do not have a strong interest in further developing it. These partners can be elevated to the next level through targeted development efforts. The more advanced stage is "on" the system, where partners with a higher level of development can be identified and have a vested interest in contributing to the production system.

To provide more detail, the system can be divided into four levels. Level 0 is the starting point, which all partners must reach. Levels 1 and 2 can be achieved independently, but Level 2 requires that all criteria be met in order to gain a holistic understanding of the system. This approach helps to prevent a single criterion from disproportionately influencing the allocation of resources. Level 3 represents an ideal situation, but no partner has yet reached this level in practice (see Figure). It represents the aspiration for a perfect partner.

In summary, the system has two stages of development: "in" and "on" the system, and is divided into four levels, with each partner starting at Level 0 and aiming to progress to Level 3. (Expert workshop, Nov, 14, 2022)

THE MODEL

In order to classify partners and identify their development potential, each level is defined in relation to the respective category. With ten categories and four levels, a 10x4 matrix is created. Level 0 represents the minimum requirement in the corporate context, while level 3 represents an idealized, maximum possible state. The definitions for levels 0 and 3 serve as the framework for the definition of intermediate levels 1 and 2. These definitions are chosen in such a way that from level 2 onwards, the categories are correlated with each other. The goal is to ensure that partners are selected holistically and developed across multiple categories, rather than only within a single category. Figure 4 shows the model with the development stages and the ten defined categories. (Expert workshop, Nov. 21, 2022)

For the further development of partners, two categories play a special role: investment will and strategic importance. If a partner reaches a defined threshold in these categories, the company will have the will to develop the partner. The action portfolio based on strategic importance and investment will is shown in Figure . (Expert workshop, Nov. 21, 2022)

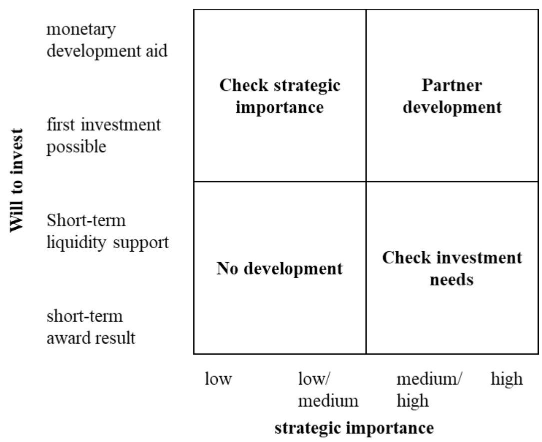

Figure 3: Recommendations for action on partner development based on strategic importance and willingness to invest (Expert workshop, Nov. 14, 2022)

CASE STUDIES

In the following, the applicability of the model for the classification of partners as well as for the development of the same is examined. As part of the expert group, six scenarios for the classification of partners and six scenarios for the development of the partners were examined. Two case studies for Classification of Partners and one case study for Development of the Partners are explained below as examples. (Expert workshop, Nov. 21, 2022)

APPLICATION OPTION 1: CLASSIFICATION OF PARTNERS

Due to the clever choice of categories, the model can be applied universally for partnerships. From the classic SUB to the material supplier and to the planning partner. This is illustrated below in two examples for the respective level (see Figure).

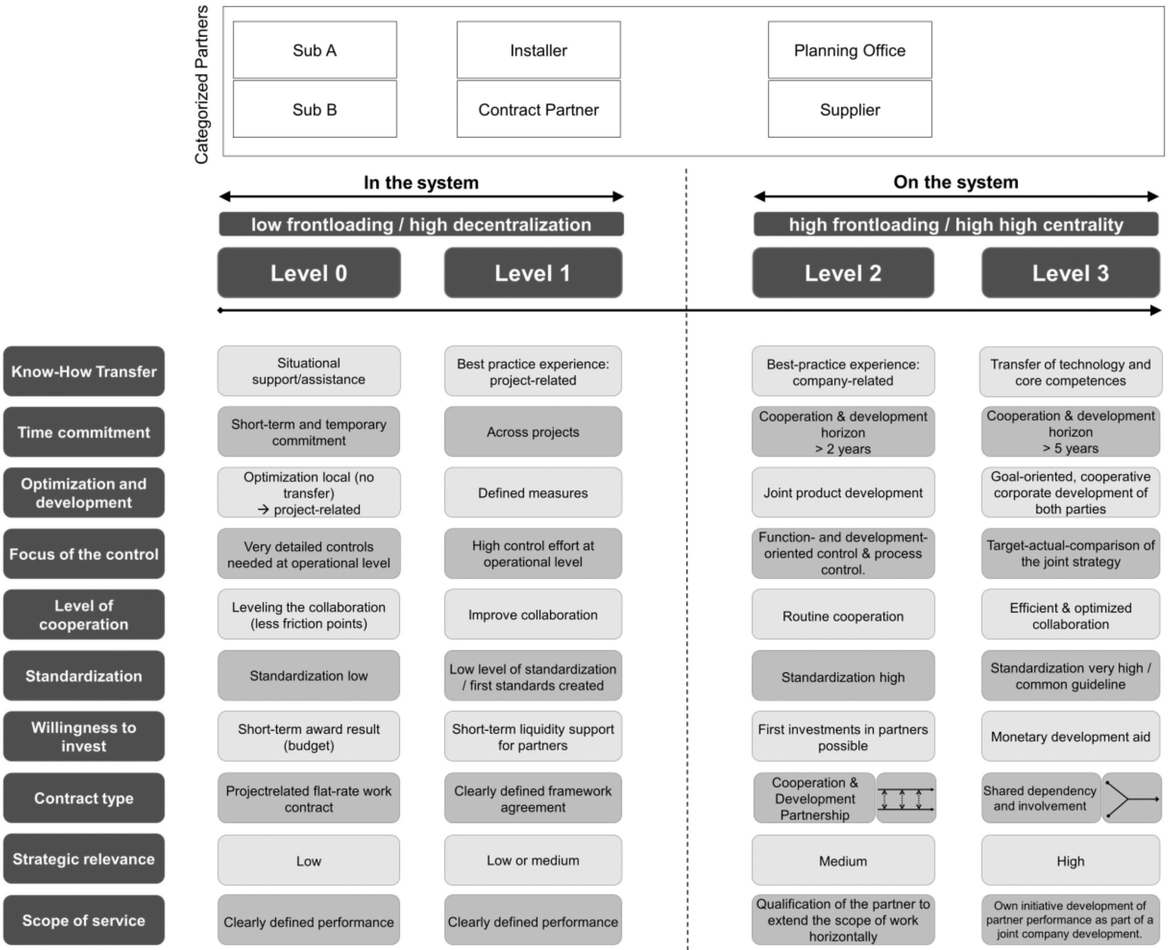

Figure 4: Partner selection, integration and development model (Expert workshop, Nov. 21, 2022)

Example Stage 0, Subcontractor A and B:

A su at Level 0 requires close quality control, as well as monitoring of quantity, adherence to schedules, and location. Know-how is transferred unilaterally, with the GC providing information to the subcontractor. Due to the nature of the contract, which is typically a project-related lump sum contract, the cooperation is limited in time. The collaboration is based on aligning the respective tasks, which is possible because the scope of the service is clearly defined and the contractor is not expected to develop the product independently. As a result, the subcontractor may optimize their work but without considering subsequent trades. The contractor's approach may not be highly standardized, and their relevance to the company's success is typically low, allowing the focus to be on the award result. (Expert workshop, Nov. 21, 2022)

Example Stage 2, Planning Office and Supplier:

Only partners who demonstrate a willingness to work on the system are placed in Stage 2. These partners have proven or can demonstrate that operational level control is unnecessary, and thus the focus of control shifts to development and process levels. Know-how transfer is not limited to individual processes or projects but encompasses all affected areas. The cooperation between the two partners is formalized by entering into a cooperation and development partnership with a commitment of over two years. Due to the long-term commitment, the cooperation is focused on routine and efficiency. The development partnership makes it possible to support the partner in horizontally expanding their scope of tasks, with a joint development of the product towards a high level of standardization (both physical and digital products). Achieving these objectives may require an initial investment in the partner (e.g. expanding the service infrastructure at the partner), which can only be justified by a medium strategic relevance of the partner. (Expert workshop, Nov. 21, 2022)

APPLICATION OPTION 2: DEVELOPMENT OF THE PARTNERS

Based on the practical examples, it is shown how a partner can be developed.

Scenario 1 Partner needs to be developed, Subcontractor A from level 0 to level 1:

Changes in environmental conditions can lead to the need for partner development. For example, if a supply deficit increases the strategic relevance of a subcontractor from low to medium, it becomes necessary to develop this subcontractor into a framework contract partner and bind them across projects to minimize production risks (Figure). To successfully develop the partner, it is important to improve the cooperation with them, creating a basis of trust for project-related exchange of know-how. At the beginning of the partnership on level 1, a very detailed control is still necessary, and the optimization or development takes place within a narrow framework, requiring short-term liquidity support. (Expert workshop, Nov. 21, 2022)

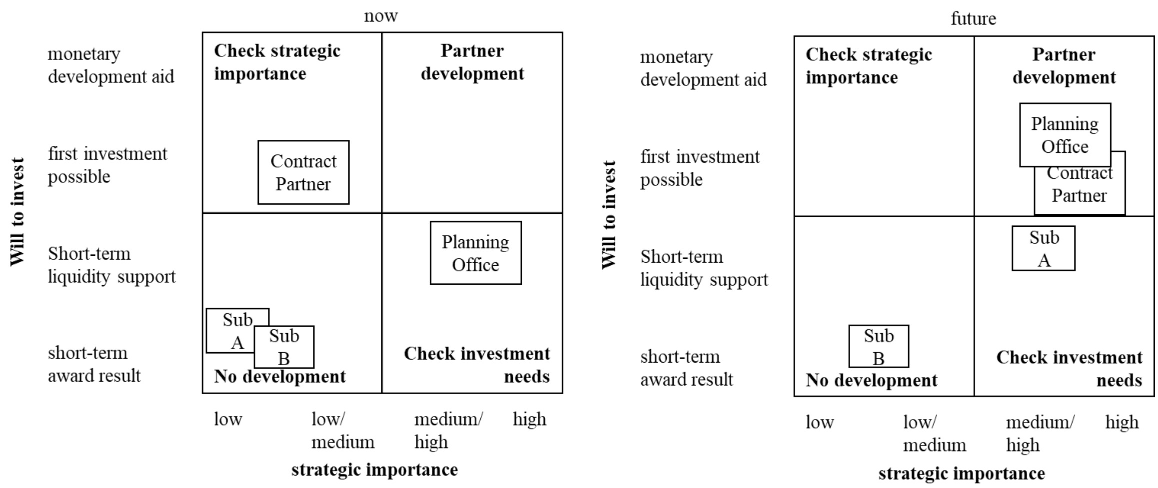

Figure 5: Example scenarios for the classification of partners in the event of a change in strategic importance and the willingness to invest (Expert workshop, Nov. 21, 2022)

CONCLUSION

Many industries have transitioned from a purely cost-driven approach to a holistic approach when selecting partners. The construction industry needs to follow this trend. The article compares the automotive industry to the construction industry, where project-specific execution, a fragmented and small-scale contractor market, and a focus on cost-efficiency and short-term partnerships have hindered the development of effective SRM. To boost production efficiency and effectiveness in the construction market, a viable solution may involve shifting its focus towards forging long-term, sustainable relationships with suppliers and partners. The paper presents a model for classifying existing and potential partners. Practical scenarios from a GC show that development stages can bring transparency for both clients and partners. The model shifts procurement from a best-price approach to a sustainable development approach for partners. Parties can use the model to decide whether and how they can deepen the partnership. Additionally, the model supports management in categorizing partners by maturity level. By creating a long-term development perspective, partners are bound to each other, promoting common understanding of goals, joint learning, and sustainable interaction. It is theoretically proven within the case studies, that the research question can be confirmed. The developed model is the base for the interaction between the GC and other partners and has the focus on developing a sustainable and stabile partnership between the parties.

This concept paper was developed in collaboration with a GC, and the model is currently being tested in practice.

DISCUSSION AND OUTLOOK

To answer the research question "How can the interaction between GC and other partners (Sub, craftsmen, planners, or suppliers) be developed sustainably on a micro level to positively influence stability" a model for partner selection has been successfully developed and tested in the case studies. The model enables the GC to choose the project partner in the right way and even develop him in a long term. Also the model proves to be a fast and efficient method to create an overview of the current partners. The case studies have shown that the model can be applied to suppliers of physical products as well as to subcontractors, planning offices and other partners of a GC for effective supplier management and thus supports the critical phase of partner selection (Bayazit et al., 2006; Zulficar et al., 2022). In accordance with the best practices from the automotive industry (Hofbauer, 2016), the clear criteria and the classification of the partners create transparency about the current development status of both parties. The model makes it possible to identify a partner's development potential in advance and to continuously track and control its development. By promoting transparency and recognizing development potential, the stability of the partnership can be positively influenced. Although the model has been successfully tested in the case studies, its effectiveness has yet to be tested in practice. In this work, the criteria were chosen according to the strategy of the general contractor (Taherdoost & Brard, 2019). It is therefore necessary to examine how the selected criteria fit the entire construction industry.

The model is currently in an initial testing phase and has yet to be extensively tested in practice. It is necessary to verify its applicability during the practical phase, which precludes final evaluations currently. Additionally, the practical phase will determine whether the selected categories require supplementation or adaptation. In further investigations, the model's impact on the entire construction industry should be examined, possibly through surveys of partners.

To select the best option from multiple alternatives, a metric should be developed and a threshold defined. As the model includes both quantitative and qualitative criteria, it would be useful to investigate the effectiveness of decision models from multi-criteria-decision-making (MCDM) such as the Analytic Hierarchy Process (AHP) (Thomas Saaty, 1980) or the Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS) (Wang et al., 2009).

To define and track partner development, the experiences from the stationary industry suggest creating a catalog with measures for partner development up to the partner academy. Through a portal access, partners can monitor their current evaluation and goals required for further development. This approach will enhance transparency, interaction, and communication among stakeholders.

UTILISING DESIGN THINKING TO REFINE CUSTOMER REQUIREMENTS – A CASE STUDY USING THE CONCRETE SUPPLY CHAIN AS AN EXAMPLE

Jan Wolber[1], Diego Cisterna[2], Özgür Tercan[3], Shervin Haghsheno[4], and Svenja Lauble[5]

ABSTRACT

The concrete supply and value chain in Germany is characterised by a large number of project participants and, as a result, numerous interfaces must be regulated continuously in every building project. The industry's high degree of fragmentation leads to a situation where information must be prepared and transferred from one system to another with a great deal of manual effort. However, initial attempts to establish a continuous information chain using digital technologies did not bring the desired success. It became clear that the past attempts placed an excessive emphasis on technological aspects and neglected the needs of the actual users. This paper describes a human-centred research methodology that puts the human being and therefore the ultimate customer more in the foreground and actively involves the person in the development of solution concepts. The aim is to reduce waste as well as repetitive and unnecessary activities for those involved in the concrete supply chain. For this purpose, the Design Thinking method is used and adapted to the current context. Summarized this paper contributes an exemplary procedure on how to use Design Thinking to refine customer requirements using the concrete supply chain as an example.

KEYWORDS

Collaboration, customisation, logistics, Design Thinking, concrete supply chain.

INTRODUCTION

The German construction industry is highly fragmented. According to the Federal Statistical Office (2020), 99.9 % of the companies in this country have fewer than 250 employees and 90 % of the companies have fewer than ten employees. In addition, the German construction industry is characterised by a high degree of complexity, which is increased, among other things, by a large number of project participants from different disciplines. This constellation leads to a heterogeneous use of software and hardware and thus to insufficiently interlinked knowledge silos, with many media and information breaks. (Shen et al., 2010)

This paper deals with a specific area within the German construction industry, namely the concrete supply and value chain. Like the construction industry, this sub-sector is also highly fragmented. According to the annual report of the Federal Association of the German Ready-Mixed Concrete Industry (BTB, 2020b) the German ready-mixed concrete industry consists of 535 companies with 10,590 employees and a total of 1,880 ready-mixed concrete plants.

This situation is particularly problematic for the flow of information between the process participants. In the supply and value chain of concrete, information must be collected at different process steps and permanently documented (cf. DIN EN 206 , DIN 1045-2). This process is currently carried out manually and need to be connected and documented afterwards in a complex manner. For example, the delivery of concrete from the mixing plant and its arrival at the construction site must be documented. The risk of information errors due to the "human factor" is particularly high here (Lanko et al., 2018). At the same time, the communication channels in the supply chain of building products are often limited to conventional telephone calls, emails or faxes (Li et al., 2015). This circumstance makes an automatic exchange of information and easy traceability very difficult.

Various organisations have already attempted to develop a solution to this problem in the past (BTB, 2020a; edr software GmbH, 2019). However, the systems developed were only used in closed ecosystems limited to a few project participants. A large-scale application failed not because of a faulty system, but because of the acceptance of the users. A closer look at the systems reveals that the focus in the development of the solutions was on the technology and not on the customer. In a round of interviews with experts from the concrete industry, the system failure was identified as the result of incomplete collection of user/customer requirements and its lack of incorporation into the solution design (SDaC, 2022).

The aim of this paper is to examines the problem more closely and focusses on the customer requirements with the help of a human-centred research approach. For this purpose, a human-centred research method was selected and used, adapted, and extended to the present situation.

In the further course of the paper, the literature review to human-centric Design is presented. Afterwards the basics of the Design Thinking method are first discussed, before the actual procedure is presented. This section forms the main part of the paper. The individual steps in the process are explained in detail and examples of interim results are given. Finally, an outlook and a critical appraisal of the results are provided.

LITERATURE REVIEW

System development used to be based on predefined process steps that did not involve the user much, if at all. In the 1980s, the cost of computer hardware dropped significantly, giving many people access to computers. The problem, however, was that computers were difficult to operate. Therefore, with the involvement of users, new systems were developed that were simple and easy for everyone to use. This laid the foundation for the involvement of users in the development of systems and products.(Cockton et al., 2016)

User-centered design puts the user and their relationship to technology at the forefront of an application's development process (Zhang et al., 2020). Understanding the characteristics and needs of people leads to technologies that create added value for them. Additionally, understanding the customer results in a more usable product, financial savings by avoiding bad investments, and safer systems. A method to achieve an understanding of the user is, for example, to ask the following questions of Ritter et al. (2014).

- What do people do? Methods for gaining knowledge from data are used for this purpose.
- Why do people do what they do? Insights are gained into people's unconscious and conscious motivations.
- When are people likely to do something? Patterns of human behavior are identified.

- How do people decide to do things the way they do? An understanding is built up about people's possibilities for action, limitations, and resources.

While user-centered design examines the interaction of the user with a system, human-centered design focuses more on the abilities and characteristics of the people who are influenced by the system. The human being is considered the central element of the system (Spitler & Talbot, 2017). Nowadays, more and more systems are being created in which humans no longer interact with technology only as users but in a mixed human-machine interaction. Nevertheless, this can be influenced by new technologies. This makes it necessary to consider humans and their effects on development. Human-centered design takes into account both immediate and long-term points of contact between the human and the system. (Ritter et al., 2014)

To create user-centric design, there are several methods and approaches that designers can use. Personas are fictional representations of users based on research that help guide design decisions by providing a clear understanding of users' needs and goals (KSRI, 2020). User journey mapping is another method that involves visualizing the steps a user takes to accomplish a task, which can identify pain points and opportunities for improvement (Lewrick, 2018). Wireframing is another technique where low-fidelity visual representations of a user interface are created to explore different design options (KSRI, 2020). Prototyping is a critical step in the design process, where high-fidelity mockups of a product or service are created to test with users and refine the design (Uebernickel et al., 2015). Usability testing is another essential step to evaluating the usability of a product or service by testing it with representative users (KSRI, 2020). Co-creation is an approach that involves engaging users and other stakeholders in the design process to ensure their needs and ideas are incorporated (Schallmo & Lang, 2020). Design thinking is a problem-solving approach that emphasizes empathizing with users, defining the problem, ideating potential solutions, prototyping, and testing (Schallmo & Lang, 2020; Uebernickel et al., 2015). This approach ensures that the design is centered around user needs and goals. Agile development is a methodology that emphasizes collaboration, flexibility, and continuous improvement (Lewrick, 2018). This allows designers to iterate on the design based on feedback and new information, leading to a more user-centric design. Overall, these methods and approaches help designers create solutions that are centered around the needs of the users (Uebernickel et al., 2015).

For this study, the design thinking method was chosen to investigate the problem described in the introduction. Among other methodologies, design thinking is very customer-centered and has already been successfully applied in the past in various studies in the construction industry (Spitler & Talbot, 2017; Zhang et al., 2020). In addition, other methods, such as developing personas and forming hypotheses, can be included in the process. In the next chapter, the methodology is presented and the essential features are discussed.

METHOD

Design Thinking is used to create customer-oriented products, services, and processes, and to align them in the most customer-centric way feasible (Schallmo & Lang, 2020). Instead of developing solutions for which suitable areas of application still need to be found, Design Thinking offers a method for examining the problems and developing human-centred solutions. According to Erbeldinger et al. (2015) Design Thinking focuses on inventive thinking with a radical customer or user orientation. The methodology requires several iterations that serve to successively gather user feedback and consequently generate new knowledge and develop more appropriate solutions (Schallmo & Lang, 2020). In addition, an interdisciplinary team is used, which deals intensively with the issue over a period of time (Plattner et al.; Schallmo & Lang, 2020).

In the context of this work, the Design Thinking Microcycle according to Uebernickel et al. (2015) was chosen and combined with the procedure according to Schallmo and Lang (2020). The Design Thinking Microcycle consists of the following five steps (Figure 1):

1. **Step 1: Problem definition**
   Initially, it is important to look at and examine the problem as neutrally as possible and with a broad field of vision. In particular, a common understanding and a common perspective should be created within the team working on the problem. In this phase, it is important to deal intensively with the user and to understand the needs. This can be achieved through a lot of personal contact in the form of discussions or workshops. It is also very helpful to take on the role of the user for a few days and, for example, to carry out the work yourself. This approach gradually increases the knowledge about the user and his problems.
2. **Step 2: Need finding**
   The relevant conclusions are then collected, analysed, and interpreted. This procedure makes it possible to develop a user profile that demonstrates characteristics, needs and problems.
3. **Step 3: Ideating**
   The next step is to gather possible ideas for solutions based on the knowledge already collected. The ideas aim to fulfil the identified needs of the user. Relevant ideas are identified through a selection process.
4. **Step 4: Prototyping**
   Afterwards the collected ideas need to be transformed into testable prototypes as quickly as possible. The level of detail of the prototypes increases with each iteration loop. The aim is to identify the best properties of the prototypes quickly and without much development effort, and to improve them continuously in the following iteration loops.
5. **Step 5: Testing**
   In a test phase, the prototype is presented to its future users and checked for practicality. Prototypes that are not suitable are already dropped in early iteration loops. This allows the development team to concentrate on particularly promising prototypes or functions.

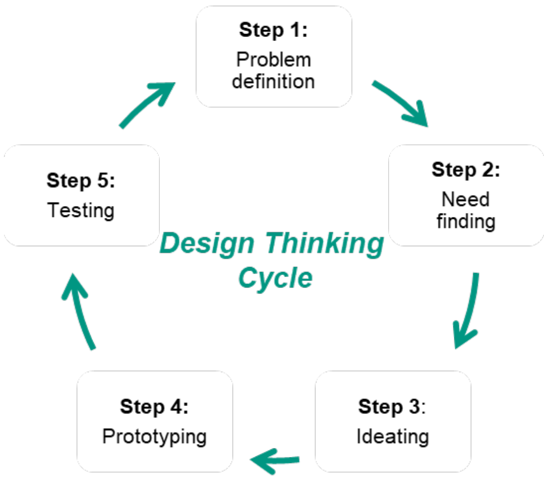

Figure 1: Design Thinking Microcycle according to Uebernickel et al. (2015)

As already mentioned, the Design Thinking Microcycle takes place in several iterations. Once an iteration has been completed, the cycle starts again from the beginning by revising the problem definition and adapting it based on the findings. This procedure makes it possible to quickly produce presentable results and to further concretise them after each iteration loop. In the next chapter, the Design Thinking Microcycle is applied to the concrete supply chain. The actual procedure and the methods used are described. In addition, exemplary results are shown.

RESULT

PROBLEM INVESTIGATION (STEP 1-2)

The case study started with arranging ***a panel of* experts**. As part of the Smart Design and Construction (SDaC) research project and in cooperation with the German Concrete and Construction Technology Association (in German: Deutschen Beton- und Bautechnik-Verein E.V. - DBV) and the Community for supervision in construction (in German: Gemeinschaft für Überwachung im Bauwesen E.V. - GÜB), a working group was initiated. The SDaC project is a research project funded by the Federal Ministry of Economics and Climate Protection of the Federal Republic of Germany, with the aim of developing a platform for Artificial Intelligence (AI) applications in the construction industry. The interdisciplinary consortium with numerous partners is led by the Institute for Technology and Management in Construction at the Karlsruhe Institute of Technology (KIT). DBV and GÜB are domain experts and active in the field of concrete construction for several decades. The expert panel is in turn composed of representatives of the concrete value and supply chain and most recently consisted of 28 people from 20 different organisations. The expert panel forms the group of people in which ideas and approaches were later presented and discussed. For this purpose, the current state of development was presented to this group at short intervals. The form and methods used will be explained further below.

To learn more about the participants in the supply and value chain, ***personas*** representative of each user group were developed. The identified relevant user groups are: concrete distributor, concrete mixer driver, shell construction manager and quality supervisor. Creating a persona is a method used to represent a fictitious user as authentically and realistically as possible. The persona represents a member of a real focus group. In the representation of the persona, individual characteristics, wishes and tasks of a user are considered. For example, it represents the age, gender, possible family relationships, personality, desires (“gains”) and frustration (“pains”) as well as tasks ("job-to-be-done"). The information on the persona is based on conclusions drawn from recordings, experiences and our subjective perception and thus represents how the user would behave from our point of view. (Lewrick, 2018) A persona from the concrete supply and value chain is, for example, the shell construction site manager. The persona of the shell construction foreman developed in the case study is shown in Figure 2.

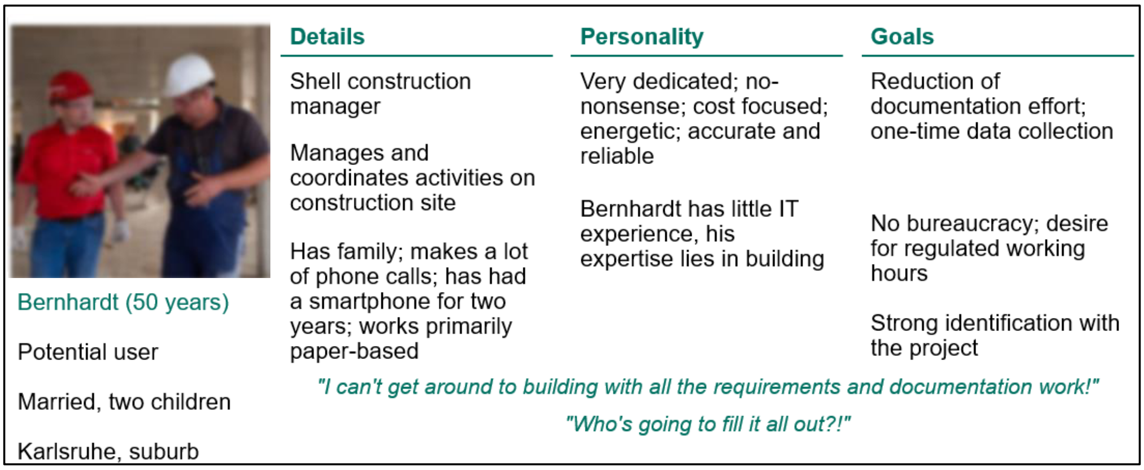

Figure 2: Persona shell construction manager

The developed personas were regularly reviewed and adapted within the Design Thinking cycle. For this purpose, expert interviews and on-site observations were used. This procedure successively sharpens the image of the potential users with each iteration loop and thus leads to regular insights into the behaviour of the users.

In addition to the personas, hypotheses were formed to add information. The hypotheses serve to make the knowledge gained tangible. The development and verification of hypotheses is oriented towards the three steps according to Kornmeier (2018). The three steps can be iteratively repeated as often as desired according to the Design Thinking cycle.

1. A hypothesis is formed about a causal relationship that requires explanation. The hypotheses describe a problem or a situation but can also represent a proposed solution at the same time. In relation to the shell construction manager, for example, a hypothesis is: "The site manager does not have enough time to carry out careful documentation. A simple, quick process is necessary".
2. The hypothesis is tested against reality through conversations or observations and falsified if necessary.
3. This process of constantly forming and testing hypotheses is repeated regularly until statements are found that best represent reality.

Figure 3 shows examples of hypotheses for the persona of the site manager. In addition to the actual hypothesis, the figure also describes how the hypothesis can be tested.

Hypothesis	Assumption	Measurement
Hypothesis 1	The construction manager does not have enough time to carry out careful documentation: A simple, fast process is needed.	Required time, number of errors
Hypothesis 2	The user has little prior knowledge of the requirements for the delivery. This results in insufficient / incorrect testing.	Years of professional experience of the tester, number of errors
Hypothesis 3	The matching of delivery bill to order form is insufficient. A daily updated and supporting digitalisation would be ideal.	degree of documentation, interviewing persons concerned
Hypothesis 4	External data (e.g., weather data) are not considered during the ordering process: Integration can optimize or facilitate ordering and documentation.	Data reconciliation
Hypothesis 4	Documents for documentation (individual documents) are not linked to each other: The same information must be entered in several places.	Number of multiple accesses to information, single documents with the same information

Figure 3: Hypotheses on the persona of the shell construction manager

The development of personas and hypothesis has created a sharper picture of the actual clients of a later solution. In particular, the problems and difficulties of each group of people have been addressed. One conclusion from this process was, for example, that the site manager is not averse to using digital technologies in principle, but that he hardly has time to deal with them during his working day. The development team was not previously aware of this connection in this much detail, and it was only highlighted through the development and validation of the personas.

SOLUTION DEVELOPMENT (STEP 3-5)

With a deeper understanding of the customer requirements (compare step 1-2), it is now possible ***to develop ideas and suitable solutions (step 3)***. One idea that quickly emerged from the intensive examination of the problem situation is the two-step approach. The two-step approach is particularly interesting because it quickly improves the current situation. The quick improvement of the current situation was one of the customer requirements identified earlier.

The two-step procedure is illustrated in Figure 4. The first stage is using an Artificial Intelligence-based scan function to extract machine-readable data from the delivery notes as quickly as possible and therefore at short notice, to circumvent the digital-analogue media breaks. The necessity for this first stage is the high fragmentation of the concrete supply and value chain. The high number of different companies makes a direct standardisation of a digital exchange format extremely time-consuming due to the necessary agreements. The Design Thinking Microcycle in connection with the presentations of personas and hypothesis have confirmed this fact. For this reason, the development of a digital interface is not planned in the long term until stage 2.

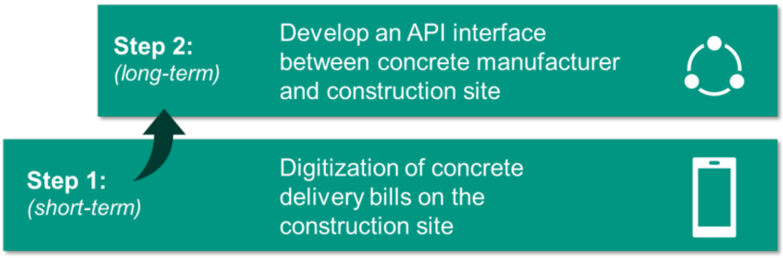

Figure 4: Graduated implementation model for a continuous information chain

After a suitable idea was identified, the team started with ***prototyping (step 4).*** The aim was to design a technical concept for each stage as quickly as possible for the software development later. To this end, conceivable technical approaches were quickly converted into testable prototypes using ***Mock-Ups.*** A Mock-Up gives the user an overall impression of the planned system without necessarily actually functioning (Lewrick, 2018). The future customer of the software application is placed at the centre of the development. Mock-Ups are ideal for expert interviews to convey ideas and approaches to the interviewer, visually and in a way that is easy to understand. For the presentation of the Mock-Ups, three levels of presentation were chosen: low, medium and high resolution (KSRI, 2020). Each level was ***tested through several iterations (step 5)*** in user interviews. The difference between the individual stages is the increasing level of detail of the prototype. By doing so the interviewer automatically focuses on the feedback of the viewer. Too specific content or a high-quality design can distract the viewer and therefore influence the feedback. For example, in an early phase of the Mock-Up development, it is not necessary to gather feedback about design aspects such as the button size or the colour scheme, but rather on the actual functionalities. The three levels are exemplarily shown in Figure 5.

Figure 5: Three levels of Mock-Ups according to KSRI (2020)

1. ***Low Resolution:*** This level shows the ultimate user flow in the application. Individual pages in black and white represent the necessary steps that a user must go through to achieve the desired result. The user flow thereby determines the number of pages and the click sequence in the later software.
2. ***Medium Resolution:*** At this stage, the first basic elements within the pages are defined and mapped. The resulting wireframes are already clickable but still in black and white. The focus of the feedback at this stage is on the completeness of the required functions. The design and layout do not play a role at this stage.
3. ***High Resolution:*** This third level already shows all details of the later application. This impression is created by a graphically appealing design with a high level of detail. The viewer may not be able to tell the difference between the Mock-Up and the final application.

After finishing the third level of the Mock-Up development, the final software development had to be carried out and the Artificial Intelligence-based scanning software and the API interface had to be created. The respective Mock-Ups provide a clickable prototype for this, which only needs to be technically replicated. Due to the short-cycle and the human-centred Design Thinking approach, the ***agile software development method is*** used for the development. Unlike, for example, the waterfall model or the Rational Unified Process (RUP), which tend to be considered less effective, heavyweight and unable to deal with short-term changes. The goals set were readjusted or completely redefined in each sprint by means of evaluated feedback (Martin, 2020). The four guiding principles and the twelve principles from the Agile Manifesto were used for orientation (Beedle et al., 2001) which according to Bergsmann (2018) form the cornerstones of practically all agile approaches.

DISCUSSION

The primary goal of any business is to satisfy its customers by providing products and services that meet their needs and requirements. However, determining what customers want and need is not always a straightforward process. Customer requirements can be complex and multifaceted, and understanding them requires a structured approach. In recent years, Design Thinking has emerged as a popular approach for solving complex problems, including those related to customer requirements. This paper discusses the use of design thinking to refine customer requirements, using a case study of the concrete supply chain as an example.

The concrete supply chain is a complex and multifaceted system that involves many stakeholders, including contractors, suppliers, and customers. To better understand the customer requirements in this supply chain, a Design Thinking approach was used. The process involved several steps, including the development of personas, hypothesis, and mock-ups. Design Thinking is a human-centered approach to problem-solving that highlights empathy, experimentation, and iteration. At its core, Design Thinking is about understanding the needs and wants of users and using that understanding to create innovative solutions that meet their needs. When it comes to customer requirements, Design Thinking can be a valuable tool for businesses. By using Design Thinking, businesses can gain a deeper understanding of their customers' needs and use that understanding to develop products and services that better meet those needs.

The Design Thinking process used in the case study resulted in several insights and improvements for the concrete supply chain. For example, the process revealed that customers in the supply chain were concerned about the quality of the concrete they received and the reliability of the delivery process. As a result, the developed system was reorganized to improve quality control and delivery scheduling. Additionally, new services were added to the process to help customers track their orders and communicate with suppliers.

The implications of these findings extend beyond the concrete supply chain. By using Design Thinking to refine customer requirements, businesses can gain a deeper understanding of their customers' needs and develop more effective solutions to meet those needs. This can lead to increased customer satisfaction, improved products and services, and ultimately, a more successful business.

CONCLUSION

The supply and value chains examined in this case study demonstrate significant possibilities for digitalisation. The application of the Design Thinking method within the framework of the research methodology proved to be very beneficial. Particularly during the phase of the problem investigation, the approach enabled an in-depth examination of the problem. Instead of focusing directly on a solution and working it out with the participants, a significant amount of time was spent in an early phase, analysing the problem in depth. Leading by this procedure, a two-stage solution implementation approach was formed. The use of Mock-Ups in the phase of the solution development also proved to be very helpful. The visualisations increased user understanding by giving the user a general understanding of the solution that have been presented. In comparison, it would have been much more difficult to present concepts to the future user only through explanations, text documents or similar. The three stages of Mock-Up development ensured that the focus of the feedback was targeted.

This article provides, for the first time, a customer-centric approach to analyse system requirements. The requirements obtained in this way can then be transferred into a type of requirements specification. Due to the fixed implementation time, only a limited number of methods could be tested and applied. Within the framework of the Design Thinking approach, however, there are many other methods (cf. job-to-be-done, stakeholder map, data canvas or similar) that can be integrated into the procedure as desired. For future work, it is recommended to also test these methods. Furthermore, the procedure presented in this paper has so far only been applied in the supply and value chain of concrete. For this reason, this case study doesn't create a representative sample size and should be applied to other disciplines and industries.

A FRAMEWORK FOR OPTIMIZING MATERIAL MANAGEMENT PROCESSES IN OIL AND GAS EPC PROJECTS

Mahmoud Daghlas[1], Rachad Bou Nasser Eddine[2], Michel Tabet[3], and Mayssa Kalach[4]

ABSTRACT

In the specialized engineering, procurement, and construction (EPC) oil and gas industry, the monetary value of procurement equates to more than engineering and construction combined. However, material management processes are yet to evolve from conventional push systems to more efficient ones. The application of lean concepts to eliminate the waste embedded in the material flow processes of construction projects has become a proven practice for reducing cost overruns and schedule delays. To this end, the objective of this study is to develop a framework relying on just-in-time delivery and pull systems to enhance material management processes in EPC projects. Namely, the proposed framework introduces changes to the responsibility matrix and sets time limits for the concerned material flow stages based on data analysis for electrical and control equipment of an oil and gas EPC project in the Russian Far East. The framework is then tested using a probabilistic Monte Carlo simulation. The results show a significant decrease in the storage cost, as an example of waste reduction. The framework provides a practical material management solution for EPC companies that minimizes non-value-adding durations and ensures a continuous material flow with continuous feedback and accountability loops.

KEYWORDS

Supply chain management, design science, flow, integration, waste.

INTRODUCTION

Construction projects are getting more complex, uncertain, and quick with a growing competitive market. This is coupled with an increased client's demand for lower project costs and faster project completion. In the specialized engineering, procurement, and construction (EPC) oil and gas industry, the monetary value of procurement equates to more than engineering and construction combined where the cost of supplies and equipment accounts for roughly 60 to 70 percent of the overall direct cost of construction (Patel & Vyas, 2011). Traditional construction industry material management practices are push systems that depend on pre-set deadlines for releasing work into the following activities (Alves, Tommelein, & Ballard, 2006). As a result, these processes have typically been associated with ineffective results including large inventory buffers, cost overruns, lower safety standards, or even a lack

of necessary items on site. This is mostly due to the fact that the material operations are frequently separated from the real workflow and dispersed across various departments (Arbulu et al., 2005). For instance, the planning team is in charge of creating baseline schedules that drive procurement operations, but the procurement team is responsible for making sure that items are on-site when needed.

Offsite and onsite material logistics are the two primary divisions of construction logistics. Offsite material logistics are dependent on numerous companies cooperating in the form of a network with the goal of moving material efficiently to cut costs and time and increase customer value (Hamzeh et al.2007). However, because temporary facilities are frequently housed on-site, onsite material management tries to lessen site congestion (Said & El-Rayes, 2013). Moreover, by designating places for resource delivery and optimizing storage, onsite material management tends to decrease non-value-adding material transportation (Thomas et al. 2005). Offsite material management received a lot of attention in the literature. For instance, the use of the Kanban system was highlighted by Arbulu et al. (2003). The idea of supplier Kanban is to replenish the site with a small selection of limited range, made to stock products. They discussed the positive effects of this process-driven lean strategy on productivity and time reduction and concluded that ordering small quantities rather than large batches is essential for the strategy's success. They also suggested a new position called a supply chain integrator to concentrate on the value stream of the supply chain. Other initiatives to connect supply and manufacturing have been made. As an example, Arbulu and Ballard (2004) used a web-based tool incorporated with the Last Planner system to reach this goal. This is accomplished by using that technology to manage daily production in order to improve workflow dependability and reduce demand fluctuation. Arbulu et al. (2005) differentiated themselves by using lean tools and concepts like Kanban and pull systems based on a just-in-time approach as well as Standard Procurement System (SPS) Production Manager and SPS Material Manager as software tools to improve the dependability of production level workflow and material supply. Hamzeh et al. (2007) also approached the issue differently by putting more emphasis on logistics centers. They emphasized that supply will be highly variable because it depends on hazy construction schedules. This will result in mismatches in supply and demand, driving up costs and lengthening processing times. Based on that, they used simulations to demonstrate the potential benefits of logistics centers in dealing with supply changes and portrayed these facilities as superior options to site inventories due to the issues the latter have.

On-site material logistics, however, did not receive as much attention in the literature. In order to address this issue, Ghanem et al. (2018) made the case that prior studies only treated the site storage area as the final destination of supplies, failing to account for the possibility that issues would arise when moving goods to the actual construction site. Congestion on the site is a drawback of poor site material management, which will harm worker productivity and safety measures (Singh 2010; El-Gohary & Aziz 2013). Furthermore, by examining elements that are associated to productivity, Seppänen et al. (2016) examined how onsite logistics will impact worker productivity. In order to examine the impact of onsite material management on building projects, Patil and Pataskar (2013) applied inventory control approaches. They discovered that the inability to get materials on site in a timely manner is one of the main reasons for project variation, accounting for 5% of all project variations. They suggested implementing a reward system to encourage staff employees to sign up for construction material management training, so they become aware of material planning and scheduling at every step. Additionally, they suggested adopting ABC and Economic Order Quantity analyses for annual inventory control. The former is a method of inventory management that categorizes items based on their importance and is also known as Pareto Analysis or the 80/20 rule. The latter is a mathematical formula used in inventory management that takes into account the cost of ordering, the cost of holding inventory, and the demand for the product to determine the optimal order quantity that minimizes the total cost of ordering and holding inventory. Abou Dargham et al. (2019) sought to apply lean thinking to create, simulate, and model an efficient and dynamic site plan that will result in a seamless flow of materials on site, minimizing time and expenses. By using a pull-based supply chain of Glass Reinforced Concrete units and integrating some process activities, the results indicated a 16% decrease in the overall cost and a 15% reduction in the overall simulation time compared to the base model of the process under consideration.

It becomes evident that the application of lean concepts is key to eliminating the waste embedded in the material flow processes and reducing cost overruns and schedule delays. However, no study was found to explicitly focus on the application of lean concepts to improve the overall material management process and its impact on project performance, in particular in the specialized oil and gas EPC industry. By analyzing real project data, this study aims to identify the bottlenecks in the material management process of EPC oil and gas projects and develop a framework for a lean material management process relying on just-in-time delivery and pull system.

METHODOLOGY

The objective of this study is to develop a framework that can be applied by EPC contractors to reduce the waste embedded in the material management process of oil and gas EPC projects. This is achieved by following the design science research methodology. Namely, the problem is first identified by surveying the conventional flow of material along with the material management procedures of an international EPC contractor. The material management procedure is a set of guidelines and steps that defines the sequence of material flow from suppliers bidding stage up to delivery and handling on site; it also defines a set of key documents issued with regards to each stage of material movement. Data corresponding to each of the material flow involved stages of an oil and gas EPC project executed by the same contractor was extracted from multiple delivery reports exported from the Site Material Management System (SMMS). This system is a tool used to track material delivery, receipt, and issuance. In particular, the extracted data corresponds to the electrical and control equipment installed in an electrical substation of and oil and gas project in the Russian far east and include key dates in the flow of material, which provides an overview of the material management process. The dates were used to estimate the durations of each stage. Following that, an analysis was conducted on these durations and compared with the baseline schedule to identify the bottlenecks and the waste embedded in the process. A framework that targets those bottlenecks was then developed. Finally, the framework is tested on the project data using a probabilistic Monte Carlo simulation to show the magnitude of storage cost reduction as an example of waste minimization providing an illustration of the optimized material management process.

DATA COLLECTION

In a typical EPC project, the process of material management includes five main stages: bidding, manufacturing, shipping, storage, and erection/installation. Figure 1 shows the flow of material starting from the receipt of the material specifications from the Client up to their onsite erection or installation; each stage is mapped along with its responsible manager(s) and their interface with other functions managers. A solid line represents a direct reporting protocol, and a dotted line represents an indirect reporting protocol; for instance, in email communication terms, a solid line reflects “from / to” email communication(s) and a dotted line reflects a “cc” in an email communication. Stage 1 starts when the contractor prepares and sends requests for quotation (RFQs) to the potential approved suppliers (vendors); this process is directly managed by the procurement manager (PRM). Upon receipt of RFQs, the suppliers compile and submit to the contractor their technical and commercial offers; these undergo a thorough review process (i.e., bidding negotiation and technical clarifications) that allows the contractor to identify the best bidder technically and commercially. Once a bidder is selected, the contractor issues a purchase order (PO) to the supplier to start manufacturing, signaling the end of Stage 1. The bidding negotiation process is managed by the PRM and supported by the Engineering Manager (EM).

The contractor, being responsible for the material, deploys resources to the supplier premises to ensure the quality of the material. Upon the completion of the manufacturing stage, the contractor conducts routine testing and issues an inspection release notice (IRN) to declare the material is of good quality, signaling the end of Stage 2. The supplier then prepares the material for shipping and requests the contractor's approval to ship, which is usually in the form of a shipping release note (SRN). Stage 3 corresponds to the shipping stage; the material is shipped through regulated logistics routes (e.g., sea freight, air freight or land freight). Upon receipt on site, the contractor checks the quality of the received material, and the site team issues a material receipt voucher (MRV) and transfers the material to the site store. The material remains in store until the responsible subcontractor requests it; the store then releases the material through a material issuance voucher (MIV), signaling the end of Stage 4. Once an MIV is issued, the material is cleared to be erected on site.

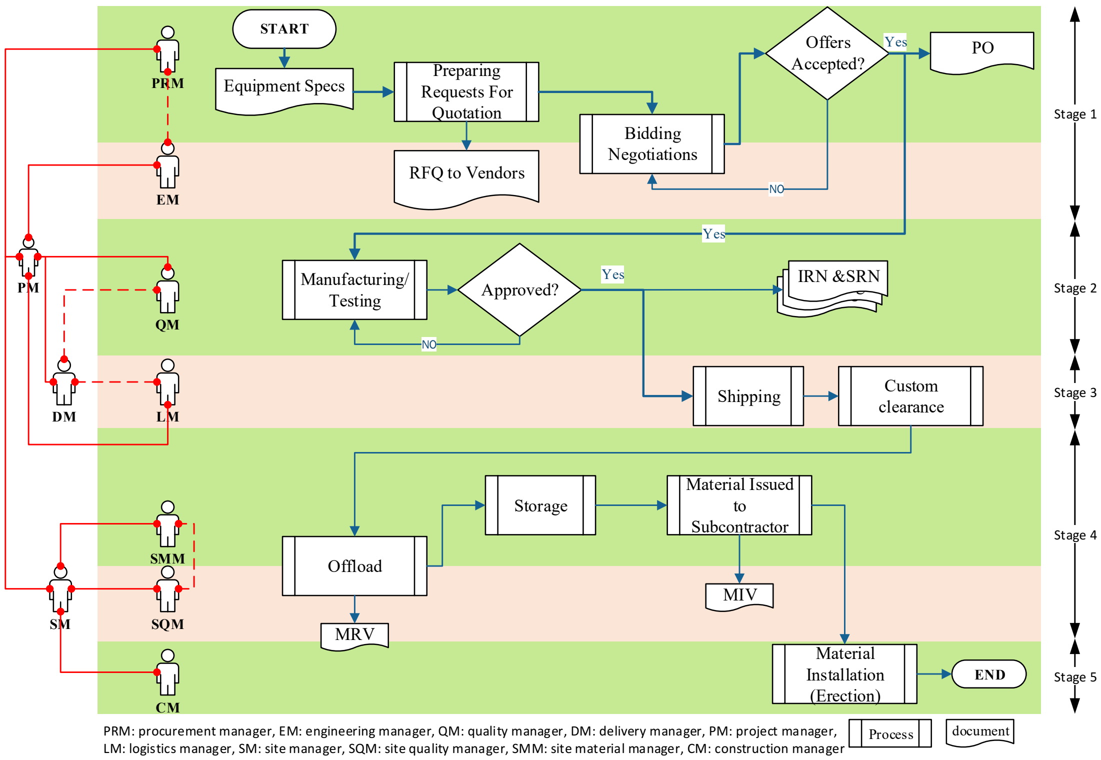

Figure 1: Material Management Process Flow Chart

To illustrate the waste embedded in the material management process, data was collected for 147 equipment installed in the electrical substation of an EPC oil and gas project in the Russian Far East. These were selected because they are tagged items that can be tracked efficiently. The selected equipment include electrical transformers, high voltage switchgears, uninterrupted power supplies (UPSs) and low voltage power panels, and cabinets for distributed control system (DCS), emergency shutdown system and fire and gas system. For each equipment in the substation, the dates corresponding to the RFQ, PO, shipping, site receipt, and erection milestones were extracted to calculate the duration of each stage in the process. The averages of these durations are illustrated in Table-1.

Table 1: Collected Data

Stage	Average Duration (Days)
Bidding	26
Manufacturing	71
Shipping	73
Storage	239

DATA ANALYSIS

The collected data show an alarming waste in the contractor's material management process. The root cause analysis of this data revealed three major bottlenecks. Starting with the bidding stage, an average of 26 days is a long time considering that the suppliers are familiar with the equipment and are able to submit the techno-commercial offers in less than two weeks. After a root cause analysis of this waste, the delay in this process is found to be caused by the heavy bureaucracy in the communication protocol whereby each revision of the offers must go through a lengthy approval process although the technical aspects are not time consuming (this is the first bottleneck). The second waste is illustrated in the manufacturing stage which takes up to 70 days on average. The analysis revealed that the equipment goes through quality checks prior to shipping from the supplier, which results in a substantial amount of rework to rectify the contractor's comments as the contractor inspects the equipment post-manufacturing (this is the second bottleneck). The shipping stage is considered within limits given the project's location.

The third and major waste, however, is manifested by the storage (idle) time on site (i.e., 239 days). To better analyze this waste, the progress of material arrival to site (i.e., cumulative percentage of total metric tonnage as a function of actual dates) is plotted along with the planned erection progress and the actual erection/execution progress of material (Figure 2). First, the figure shows a large gap between the material arrival and its planned erection. It could be argued that during the year between April-2020 and April-2021, the COVID-19 pandemic had a major influence on the workflow (the flow of both construction material and construction crew) which was the main cause for the piling of material at this time and also in pushing the execution of the project. However, this does not negate the fact that the erection was planned to take place starting Apr-2021 while the material arrival to site started in Apr-2020. This means that the equipment was going to be idle in the warehouse according to plan and that the erection activities were planned independently from the delivery plan. In other words, the procurement function's key performance indicator (KPI) being independent from the construction progress, there was no added value in delivering the equipment in Apr-2020 while the installation is only needed in Apr-2021, which indicates a major flaw in the management process (this is the third bottleneck). By analyzing the storage inventory area over time, it was found that the maximum inventory floor area was about 500sqm, which indicates the need for a storage facility for this substation to accommodate that area. Another observation from Figure 2 is the gap between the planned erection and the actual execution in terms of dates and durations as well (i.e., the planned duration is 81 days and the actual duration is 244 days), which can be traced to many intertwining factors. The actual execution matches with the planned execution, both of which are a year into the pandemic. However, during the pandemic, a significant shortage of workforce and material was experienced on site (although the case study equipment were already on site prior to the pandemic shutdowns, a lot of other material were obstructed). Therefore, the work that was supposed to be executed during the pandemic was heavily affected, and consequently, by Apr-21 although the erection works of the case study equipment commenced within planned time, priorities have changed due to the work obstructions during the pandemic and the pace of execution could not keep up with the plan. Another reason for the execution deviation can be traced to the manpower mobilization shortages from subcontractors due to financial issues.

To further illustrate the negative repercussions of the inventory waste, the storage cost is calculated. Based on actual storage cost data, and the fact that the selected equipment contains high quantity power electronics that need to be kept in a heated and well-preserved warehouse, the average cost of power requirement to preserve 1m^2 of floor area in a site warehouse in the project site in the Russian Far East was found to be \$1.55/m^2 per day. This cost covers the electrical power, manpower, and preservation costs. Considering each equipment floor area over its storage period, the total power cost to store all the equipment for their respective storage durations is found to be around \$204,000. In fact, the analysis revealed that this range of storage duration is very common due to two main reasons. First, given that material delivery to site is the main milestone to claim payment from client, contractors tend to push material to site as soon as they can to collect cash payments. The second major factor is that site management and site material management are under pressure to handle piling quantities of arriving material whether these are needed at that time or not. This is mainly because the delivery manager and procurement manager's KPI is to deliver the material to site as soon as possible since they lack a direct reporting protocol with site management. It is noticed that a recurring theme in the bottlenecks is the fact that each function manager acts to achieve their KPI on priority, and sometimes in isolation, without consideration to other functions which leads to a local optimization. Therefore, any attempt to improve the flow would not be as effective without changing the KPIs.

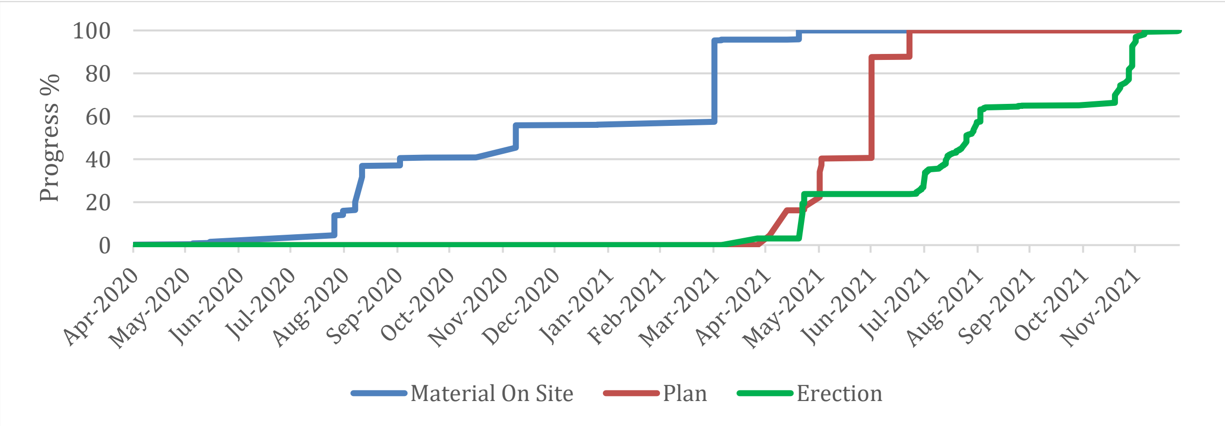

Figure 2: Material Delivery Vs. Erection Plan (measured in metric ton)

DEVELOPED FRAMEWORK

Based on the analysis of the data collected, three bottlenecks are found to impede the flow of material and its management process: the bidding bottleneck, the manufacturing bottleneck, and the storage bottleneck. These are viewed to negatively impact the project performance and are a critical indication for a substantial needed process improvement. The proposed framework is based on a pull system and a just-in-time material flow to reduce the process waste by introducing changes to the responsibility matrix and setting time limits based on data analysis. Namely, an enforceable timeline is introduced to managerially deal with each bottleneck. The timeline is determined based on oil and gas EPC industry best practices and may change depending on the industry and type of equipment/material. Starting with the bidding process, the timeline is set at 14 days with continuous communication between the engineering function and the procurement function and monitoring of the suppliers. This time limit is based on the activities of procurement in this project (2 days for floating the request for quotation to suppliers, 5 days for suppliers to compile and submit their offers, and 7 days for reviewing the offers and issuing purchase orders). Any delay in this process will be monitored by the project manager. Then, the manufacturing process timeline is set to 30 days. As described in the analysis section, a lot of the manufacturing time waste is due to rework resulting from the comments received during the inspection stage. Finally, the storage process timeline is set to be in the range of (0 to 7) days; this process is the most challenging bottleneck in the material flow due to the prolonged idle times of material in the warehouse. To this end, a pull system is implemented to regulate this process by signaling to the logistics teams the shipping date of the equipment that ensures its arrival at the site by the time it needs to be installed.

Moreover, the proposed framework includes changes to the responsibility matrix to ensure that the reporting structure supports a collaborative effort rather than being solely based on the achievement of individual milestones. Figure 3 illustrates the updated responsibility matrix and the newly introduced lines of communication (illustrated by solid lines) between different functions managers in addition to introducing the durations allowed to several activities to guide the process and make it more systematic. Namely, the proposed framework introduces the following changes:

- Adding a direct communication line between procurement manager and engineering manager for bidding process.
- Adding a direct communication line between delivery manager and quality manager for expedited manufacturing and testing at vendor sites.
- Adding a direct communication line between site material manager and site quality manager.
- Adding an indirect communication line (illustrated by dotted line) between site manager and procurement manager to initiate the procurement process in a timely manner.
- Adding an indirect communication line (illustrated by dotted line) between site manager and logistics manager to ensure material is delivered within a week of construction readiness based on the schedule.

To ensure the framework is followed and any deviation is escalated and consequential, new KPIs are introduced:

- Procurement manager: ensure the bidding process is done within 14 days - accountable for any excessive time.
- Delivery manager: ensure manufacturing is done within 30 days - accountable for any excessive time.
- Logistics manager: ensure delivery within 60 days.
- Site manager: timely signals to procurement and logistics (percentage)

Moreover, to maintain a feedback loop for any material that exceeds the 7 days limit, a root cause analysis must be conducted and reviewed by the site manager. However, given that the KPIs are not reviewed regularly, the material flow process needs to be monitored in the weekly inter-disciplinary meetings and to be continuously signaling to function managers. This process can be maintained using a frontend user friendly interface that takes the inputs from expediters or project engineers and sends alert signals to responsible managers based on the following questions represented in Figure 3:

- Are offers received and reviewed within 14 days?
- Is the shipping schedule within 60 days?
- Is the delivered equipment ready to be installed (logistics input)?
- Is equipment spending more than 7 days in the store?

The frontend interface will derive its protocol from Figure 3 and is illustrated in Figure 4.

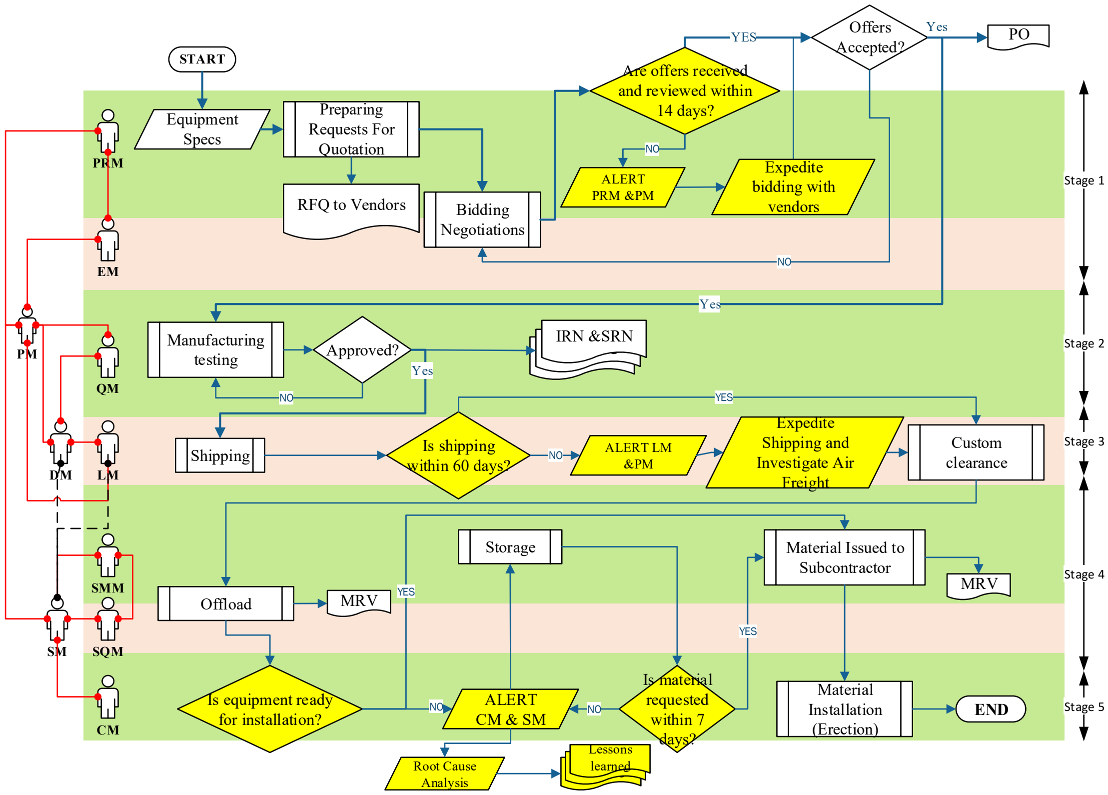

Figure 3: Flow of Material in the Proposed Framework

The input to the interface illustrated in Figure 4 is under the responsibility of the quality engineer, package engineer or material controller. The alerts will be sent automatically when the dates conflict with the set time limits. The alerts will be in the form of high priority emails to the respective function manager and will be raised in the weekly meetings. The number of alerts will be a key measure to determine the performance of each manager against the proposed KPIs.

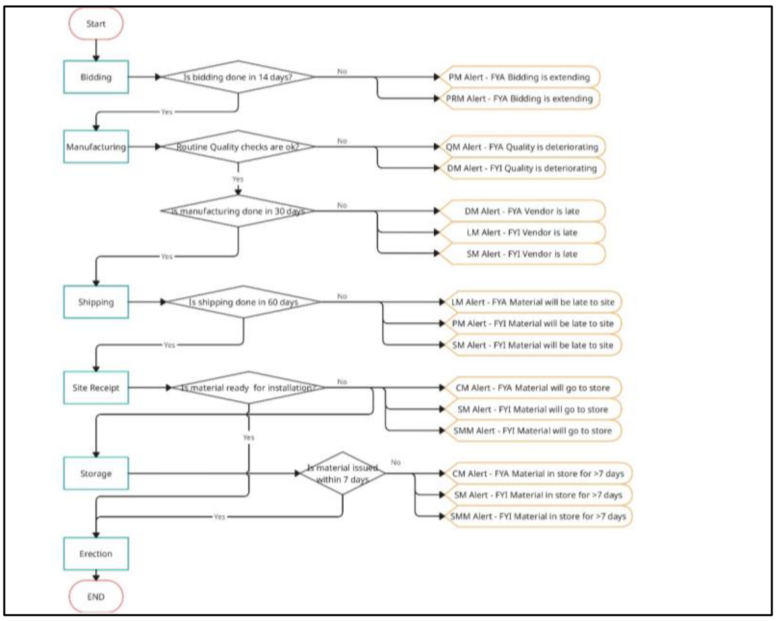

Figure 4: Frontend Interface for Material Tracking and Alerts

APPLICATION OF THE PROPOSED FRAMEWORK

To illustrate the enhanced material management process, the proposed framework is applied to the project data to show the magnitude of storage cost reduction (as an example of waste reduction and improved performance). To this end, a probabilistic model was built to measure the change in storage cost. The model considers an ideal scenario where the flow of material is not interrupted and the material arrives at site on time, and a worst-case scenario where the material remains in store for 7 days. The analysis was conducted using MS Excel and Palisade @Risk probabilistic tool. To check the effects of the proposed framework on the storage cost, the proposed system assumes that the material will ideally not spend any time in store, and if it does, it should be in storage for a maximum of 7 days. This was represented as a discrete probability density function with an 80% probability that the equipment will be erected within the same day of arrival without any time at store and a 20% probability that the equipment will be at the warehouse for 7 days as a worst-case scenario.

Using the $/sqm estimation calculated from the actual data, the output of this analysis is the summation of the storage cost for all items. This output is compared to the original storage cost of $204,000. The simulation was done using a Monte Carlo Simulation for 10,000 iterations. The results of the simulation for storage costs are illustrated in Figure 5.

Figure 5: Simulation Results for Storage Costs

Figure 5 shows that there is a 90% probability that the storage cost will be less than $1,800. This figure represents a massive improvement compared to the original cost of $204,000. The simulation was repeated at different test conformity levels (50% and 30%). The results of the simulation are summarized in Table-2 and show the expected storage cost with a probability of 90%.

Table 2: Storage Cost Simulation Results

Conformity Level	Storage Cost at 90% Confidence
80%	$ 1710
50%	$ 3511
30%	$ 4489

The proposed system redefines the warehousing strategy and ensures equipment remain in the warehouse for the minimum days. This is almost a total elimination of the inventory waste in the warehousing system. Another important improvement can be noticed at the level of inventory management. The previous analysis showed that the inventory in the warehouse kept piling up for almost a year until it reached a maximum of about 500sqm floor area in the warehouse. Based on the new proposed framework, an inventory model was built considering the worst-case scenario of all items spending 7 days in the store, the inventory curve is shown in Figure 6.

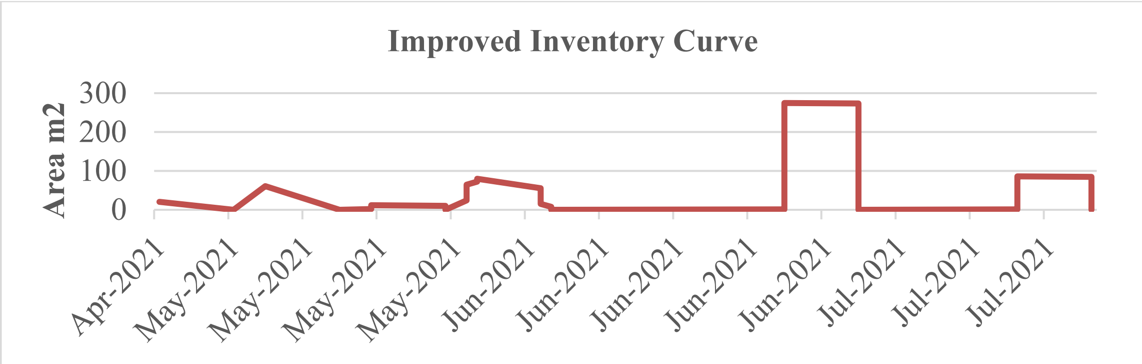

Figure 6: The Improved Inventory Curve

Figure 6 illustrates that the inventory is levelled at about 80sqm and keeps on emptying from the warehouse without piling up. This is a very good indicator that the system is effective in eliminating inventory waste. A spike is observed in June-2021, this is due to a large delivery lot. Although this would need a warehouse, it could be mitigated by renting space in the available warehouses on site to avoid the need for a new warehouse. For the other inventory peaks (May-21) the scenario can be eliminated by using other warehouses or simply by keeping the material in the truck for a couple of days to reduce handling cost and storage cost.

DISCUSSION

The simulation results provide an example of waste reduction as an illustration of the improved performance of the material delivery and management process. The simulation model derives its variables from the set time limits; these are project-specific and, therefore, are not rigid. Namely, the location of the case study was the driving factor in setting the time limits. The proposed framework, however, can be applied to other EPC projects since the material flow process is similar, but with necessary adjustments to the time limits and the KPI's derived from them. Additionally, the results illustrate an ideal scenario where unforeseen conditions are not affecting the erection of material. For instance, one of the reasons for the prolonged erection duration in the case study (244 days) is the breakout of the Covid-19 pandemic and lack of workforce on site. Should the proposed framework have been in place at that time, it would have helped in mitigating the delays and facilitating the implementation of a quick mechanism to compress the schedule due to the accountability loops. Moreover, beyond improving project performance in terms of schedule and cost reduction, the smooth and continuous flow of material is viewed to also ensure less material handling and congestion on site, therefore it is expected to improve the safety performance. However, a deeper investigation of these impacts presents an interesting future research opportunity.

CONCLUSION

The construction industry is witnessing an increased client's demand for a lower project cost and a faster project completion. In an EPC project, the monetary value of procurement contributes to more than engineering and construction combined. However, material management is yet to evolve from the conventional push system to a more efficient one. Following an analysis conducted on real EPC project data, the study shows that the flow of material in a conventional material management process is plagued with excessive waste. In-depth analysis of the waste embedded in each stage resulted in the identification of three major bottlenecks in the bidding, manufacturing, and storage stages. Accordingly, a framework based on a pull system and a just-in-time material flow is proposed. The framework aims to reduce the various waste embedded in the process by introducing changes to the responsibility matrix and setting time limits based on data analysis. Namely, an enforceable timeline is introduced to managerially deal with each bottleneck. The framework is tested using a probabilistic Monte Carlo simulation. The results show a significant decrease in the storage cost, as an example of waste reduction, providing an illustration of the enhanced material delivery and management process. The framework provides a practical solution to EPC companies that minimizes non-value adding durations and ensures a continuous material flow with continuous feedback and accountability loops.

A THREE-LAYERED APPROACH FOR A LEAN SUBCONTRACTOR PROCUREMENT PROCESS

Karen El Zind[1], Salam Bakesmati[2], and Mayssa Kalach[3]

ABSTRACT

It is generally recognized that subcontractors execute significant parts of construction works. This makes the subcontractor procurement process − from packaging to delivery method selection, budgeting, candidate selection, and so on − a cornerstone for the successful completion of construction projects. While the focus of the extant literature has been mainly steered towards the process of subcontractor selection and its related criteria, little emphasis has been placed on the procurement process itself and its implementation by general contractors. The main purpose of this paper is to develop a comprehensive lean methodology that may be applied by general contractors to improve subcontractors' procurement processes. To do so, a three-layered approach is proposed involving the realignment of steps within the process, the application of the choosing-by-advantages methodology, and the introduction of a digitalized subcontractor rating program. Then, the proposed approach is tested on a typical subcontracting procurement process adopted by a well-established construction contracting firm in the Middle East. Results show a significant reduction in the overall duration of the subcontractor procurement process. The offered methodology is viewed as a roadmap that can be generally adopted for reducing rework, eliminating waste, and enhancing the subcontractor selection methodology.

KEYWORDS

Lean construction, standardization, process, supply chain management.

INTRODUCTION

It is widely recognized that general contractors look to specialty contractors, or subcontractors, to perform specific tasks on construction projects. Hinze and Tracey (1994) mentioned that, particularly in building projects, it is common for 80-90% of the work to be performed by subcontractors. Subcontractors may provide specialized trade work such as painting, carry out specialized services such as electrical and mechanical, or provide labor services such as skilled craftsmen (Mbachu, 2008). Additionally, specific design works may be subcontracted to specialized firms. This reliance on subcontractors is rooted in several reasons. Bennett and Douglas (1990) argued that tasks in construction are specialized in such a way that no one firm can perform them all; therefore, many specialist contractors with specific expertise are required to meet the industry's complex demands. Additionally, Hsieh (1998) suggested that general contractors use subcontracting to allow the downsizing of their firms and to ensure better handling of unstable market conditions. Furthermore, operations of the average general

contractor are not sufficiently extensive to afford full-time employment of skilled craftsmen in each of the several trade classifications needed in the field, nor is it feasible for these companies to own, operate, and maintain specialized equipment that may have only limited use during a project, as presented by Arditi and Chotibhongs (2005).

Typically, in building construction, there is a need for involving many specialized trades; this dictates the extent to which work packages are subcontracted and, therefore, leads to general contractors initiating frequently one or more subcontractor procurement process. Given the time-limitation characteristic of construction projects and the importance of making informed decisions within short time frames, the application of lean principles can be beneficial in ensuring their success from time, cost, and quality perspectives by facilitating the selection of the right subcontractor to execute the works. This study aims to develop a comprehensive lean methodology that may be applied by general contractors to improve subcontractors' procurement processes by reducing the overall process duration, limiting rework, and improving the quality of the decision-making approach.

LITERATURE REVIEW

One of the most significant factors affecting the costs of construction projects and the entire construction industry is the efficacy of subcontracting procurement processes (Yin et al., 2014). In the extant literature, the focus has been mainly steered towards the process of subcontractor selection and its related criteria, subcontractor rating methodologies, and the relationship between general contractors and subcontractors. For instance, according to a study by Arditi and Chotibhongs (2005), the process of bid shopping by general contractors is one of the problematic issues in subcontracting and may cause detrimental consequences on the overall performance of the project. Possible solutions are therefore presented based on the input of surveyed professionals, including owners requiring general contractors to provide bid listings and subcontractors refraining from providing contractors who shop bids with quotations. Other issues in subcontracting practices are also addressed in their study including payment timeliness, provision of construction insurance, site safety issues, and productivity issues (Arditi & Chotibhongs 2005). Ulubeyli et al. (2010) discussed the subcontractor selection practices of Turkish contractors in international construction projects. Their study reports that, although most contractors employ previously known subcontractors, no systematic processes nor models are put in place as a means for making an optimal selection. It is also highlighted that subcontractors are frequently selected based on the decision-makers' own experience rather than via a selection process and suitable evaluation technique (Ulubeyli et al., 2010). In another study that forms part of the ongoing discussion around partnering and subcontractor selection, Hartmann and Caerteling (2010) discusse price and trust as subcontractor procurement mechanisms and explore how the interaction between the two is important in the selection of subcontractors. Abbasianjahromi et al. (2013) proposed a model for subcontractor selection based on the fuzzy preference selection index. The value of their model lies in eliminating the weighting criteria phase in selecting the optimal subcontractor where weighting attributes is a challenging task. Polat et al. (2015) used the genetic algorithm technique as a methodology for selecting subcontractors for all work packages in a construction project considering time, cost and quality performances. El-Khalek et al. (2019) identified subcontractor prequalification evaluation criteria and their impact on project success. Among the evaluated criteria, on time delivery of materials, failure to complete contract due to financial problems, subcontractor's difficulty in reimbursement, reputation, and tender price were found as the most influencing ones.

On the other hand, the implementation of the choosing-by-advantages (CBA) as an alternative method of subcontractor selection has been heavily explored in the construction industry literature. Notable recent publications include Demirkesen and Bayhan (2019) in which twelve factors for evaluating alternatives are presented and connected to a seven-step CBA procedure. The result is a selection which ranks highest importance of advantages and lower cost of advantages. El-Kholy (2022) presents a rigorous analysis of the proposed technique using CBA and explores an illustrative case study for testing. It is concluded that the proposed methodology takes into account aspects of decision-making that are not considered in traditional methods and paves the way for further exploration in the literature. Limited studies are found to tackle the analysis of traditional procurement procedures and the presentation of innovative processes. Yin et al. (2014) presents a procurement process that is mapped against the seven types of waste which forms the basis of lean theory. It discusses how traditional procurement methods for subcontracting tend to bound opportunities for price negotiation, constructive contractor relationships, and the avoidance of future problems such as waste, risk in construction, and engineering interface (Yin et al., 2014). In an attempt to address this, a Lean Subcontracting Procurement Process (LSPP) is presented which is initiated by a subcontracting plan based on a seven-arrangement operation plan that is aimed at eliminating various types of waste in construction projects, and which involves four types of operating flows. The implementation of this LSPP in its collaborative nature resulted in cost reduction and shortened construction time (Yin et al., 2014). Suresh and Arun Ram Nathan (2020) discuss lean procurement in construction projects using the total interpretive structural modeling (TISM) approach to classify readiness factors and build a model which helps construction companies in India to begin the implementation of lean production. They focused on material procurement which is very similar to that of subcontractor procurement in construction sites. The model analysis identifies the techniques of awarding purchase contracts, checking material specifications, negotiating with suppliers, and subtracting the cost of material as the model's driving forces. The change of these four factors has gained importance in Lean procurement execution as they directly affect other sections of the organization.

The focus of the construction industry literature has mainly been directed towards the process of subcontractor selection, the criteria used in the decision-making process, and the drawbacks of these traditional methodologies. Little emphasis has been placed, however, on the subcontractor procurement process itself and its implementation by general contractors. This study presents an in-depth analysis of the steps involved in the subcontractor procurement process in a typical building construction project and proposes a three-layered approach rooted in the application of lean principles to achieve a shorter and more efficient process.

METHODOLOGY

This study follows the Design Science (or constructive) research approach which entails the creation of a solution for a practical field problem (Rocha et al., 2012). Namely, this study aims to propose a comprehensive lean approach that may be adopted by general contractors to reduce the waste embedded in the subcontractor procurement process. The problem is identified through direct observations of the subcontractor procurement process followed by a well-established general contracting firm in the Middle East. The solution artefact is developed through a multi-stage process that includes data collection, data analysis, and the proposition and evaluation of a three-layered lean subcontractor procurement process. In the first stage, data with respect to the steps followed during the subcontractor procurement process in three recent tower construction projects was collected through surveying procurement records such as internal communications, exchanges with subcontractors, and meeting records, and through discussions with team members that were involved in the projects of interest. For the purpose of this research, the three selected projects have been awarded following the design-bid-build approach to project delivery. This is important because, under more collaborative project delivery methods, the structure and the timeline of the procurement process would be completely different. The three projects are of similar value (around $70 Million) but with different scope of work. More importantly, these projects are relatively in the same location and were undertaken within the same timeframe; this is of particular importance in eliminating external factors such as the effects of economic instability on the decision-making process and consequently on the procurement strategy as a whole. The location of the projects is also of importance as it plays a major role in the availability of subcontractors to choose from. Accordingly, the current state of the typical procurement process followed by the general contracting firm is mapped along its corresponding data. Then, the analysis stage of the data collected allowed the identification of the waste embedded in the process and also unveiled opportunities for improvement. Finally, a three-layered process is developed and includes incorporating the CBA decision-making process and integrating lean concepts with digitalization techniques to form a comprehensive lean subcontractor procurement process.

DATA COLLECTION

The contractor's typical procurement procedure adopted on various projects, and particularly on the three building construction projects of interest to this study is explored by identifying and mapping the various involved stages of the complete process starting with a subcontracting plan and ending with a signed subcontract. The flowchart in Figure 1 reflects the current state map of the typical subcontractor procurement process and depicts its various stages along with the various departments involved, each according to its role within a stage. These include a total of 6 stages (sequenced horizontally, left to right) and involve several departments as well as external stakeholders (displayed vertically); particulars of these parties and their functions within the subcontractor procurement process are detailed in Table 1.

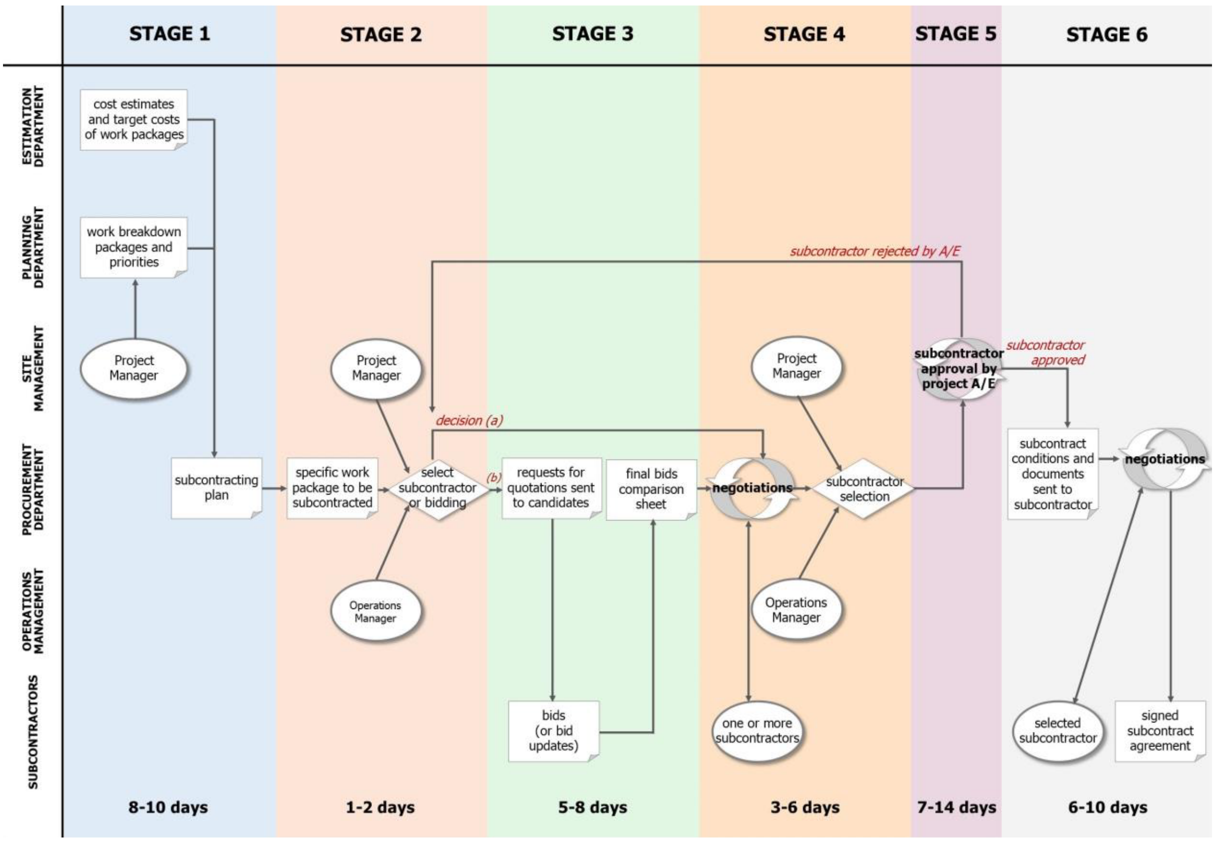

Figure 1: Flowchart of the Typical Subcontractor Procurement Process

The procedure is initiated in Stage 1 by a collaboration between the estimation and planning departments in direct coordination with the project manager and the procurement department, which produces a subcontracting plan that will form the starting point of any and all process initiation. Stage 2 is then started with a specific work package that comprises a target cost and a target schedule. It's important to note that, in this case, stage 2 is instigated purely based on the subcontracting plan and does not take into account any project delays or schedule changes. The procurement department shortlists a number of subcontractors who are suitable candidates for completing the subject works from whom they may or may not have received prices during the tender stage and presents them to the project manager and operations manager in a strategic decision-making meeting. During this meeting, a decision must be made on whether negotiations shall be made with a single suitable subcontractor (i.e., decision "a") or else to proceed with bidding (i.e., decision "b"). The former decision is normally a result of the scope complexity and characteristics of the subject work package, combined with the availability of specialized subcontractors in the market. The factors affecting the decision and the implications of the decision-making methodology will be discussed in subsequent sections.

Table 1: Parties Involved in the Subcontractor Procurement Process

Party	Internal/ External	Stages Involved	Main Role in the Process
Estimation Department	Internal	Stage 1	Provide information about the pricing strategy used during tender and the target cost of each work package to preserve planned profits.
Planning Department	Internal	Stage 1	Provide required information regarding the deadline for procuring a subcontractor for each work package (priorities) as well as the completion date for each work package.
Site Management Team	Internal	Stages 1, 2, 4, 5	Project Manager provides their opinion and guidance on the whole process concerning their preferences for the packaging of the works as well as specific subcontractor preferences. Site team is also in charge of the process of getting the A/E's approval on subcontractors (this may include iterations).
Procurement Department	Internal	Stages 1, 2, 3, 4, 6	Starting with a subcontracting plan, the goal is to ultimately produce a subcontract agreement with the selected subcontractor.
Operations Management	Internal	Stages 2, 4	Offer strategic planning, guidance, and judgment regarding subcontractor selection in line with the firm's business plan.
Subcontractors	External	Stages 3, 4, 6	Compile and submit bid prices and, if selected, provide their company profile for approval and, once approved, sign a subcontract agreement with the contractor.
Project A/E	External	Stage 5	Consent to the appointment of subcontractors.

In the case of decision (a) being made, stage 4 is initiated which will be discussed shortly. In case of decision (b), stage 3 commences with requests for quotations sent to candidate subcontractors. These candidates may have previously submitted their bids during the tender stage or may be newly invited. Once all bids have been received from the candidates, a bid comparison sheet is prepared showing an item-by-item comparison of the priced Bills of Quantities (BOQ), noting that some subcontractors may choose not to submit a bid for many reasons such as poor previous experience with the contractor, project location not being suitable, project scope being too risky for their business, and many others. Before making a final decision, stage 4 begins with a round of negotiations with either the selected subcontractor(s) from stage 2 or those whose bids were the lowest in stage 3. This step is purely commercial, whereby the price is negotiated in order to reach the target price; it may however be omitted if the presented bids already meet the target price presented at the beginning of the process by the estimation team. Once this step is completed or omitted a decision is made, and a subcontractor is selected with the guidance and judgement of the project manager and the operations manager.

Before proceeding with the subcontract preparation, and should the main contract conditions stipulate this, the subcontractor's details, profile, and previous experience are submitted to the project's Architect/Engineer (A/E) for their consent. Should the subcontractor be rejected, stage 2 is reinitiated in order to make a new selection. Otherwise, a subcontract is prepared and sent to the subcontractor for review and signature. Typically, a round or two of negotiations take place regarding the conditions of the subcontract, and, in rare cases, subcontractors may impose an addition to their price to bear the risks stipulated in the subcontract. Finally, once the contractor and subcontractor reach common grounds regarding the subcontract conditions, an agreement is signed, and the subcontractor proceeds with the works. The complete subcontractor procurement process, as presented in its current state and including all 6 stages, is found to take a minimum of 30 working days to be completed and a maximum of 50 working days, assuming that the first decision is (b) and that the subcontractor is approved by the project A/E from the first round.

DATA ANALYSIS

The collected data clearly show big room for improvement. Given the extent to which work packages are typically subcontracted on building construction projects, a total duration of 30 to 50 days per package could potentially cause major delays. Below are the various types of waste identified in the process:

The inherent push system based on which the initiation of stage 2 is made: The subcontracting plan, which is the basis for initiating a procurement process, is prepared in the first weeks of the project life. As such, it does not take into account any schedule and priority changes or the progress of procurement itself, which may cause a figurative inventory of packages that are not required to start just yet. Scope modifications, schedule delays, or other adjustments may require certain work packages to be procured in a sequence that is different from that of the subcontracting plan.

Major rework is embedded in the process, particularly with the subcontractor selection process. Holding two decision-making meetings with various parties, as well as having to restart the process of selection in case the project A/E does not give their consent are two major forms of waste. Additionally, leaving subcontract negotiations until the last stage also causes unnecessary rework; this could easily be avoided by providing the subcontractor with a draft agreement earlier on in the process to make them aware of its conditions.

The decision-making process is plagued with human error. With no specific decision matrix, it is purely based on the opinions of the procurement department, the project manager, and the operations manager. For instance, previous experience with subcontractors, a major contributor to the selection process, is not referred to or well-documented in order to be used as a benchmark.

PROPOSED THREE-LAYERED APPROACH

To address the identified flaws in this subcontractor procurement process, a three-layered approach aimed at reducing rework, eliminating waste, and enhancing the subcontractor selection methodology is proposed and is illustrated in Figure 2. The first layer involves a change in the way a new process is instigated as well as a simple realignment of processes at two levels of the procedure, namely the process of securing the project A/E's consent on the subcontractor and the process of negotiations of the subcontract conditions between the contractor and the subcontractor. With regards to the process initiation, and in order to address the issue of frequent changes in construction projects, a pull system by which work packages are only sent to the procurement department for action at the last responsible moment is proposed; this allows them to sign the subcontract before the works are due to be commenced (plus enough lead time to allow subcontractors to procure the materials needed). In addition to ensuring the right work packages are procured at the right time and with the most up-to-date project information, the adoption of this lean principle allows the workload to be pulled in such a way that ensures no package is procured too soon, and hence the possibility for abortive works is reduced.

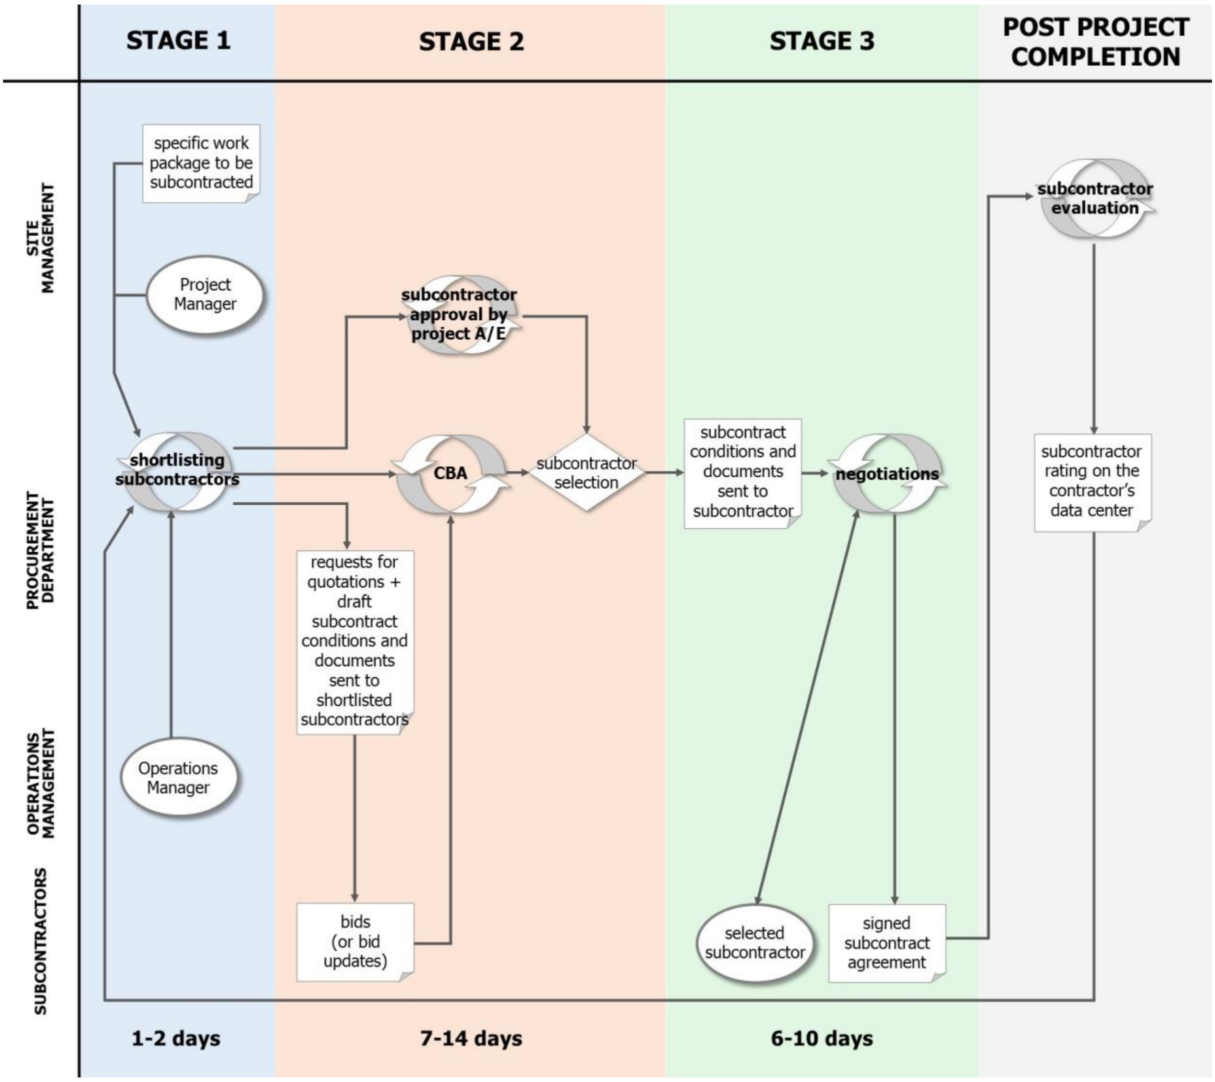

Figure 2: Proposed Three-Layered Subcontractor Procurement Process

In order to avoid possible rejection by the A/E after having invested time in selecting and negotiating with a selected subcontractor, it is proposed to submit for approval the details of shortlisted subcontractors from the optimized stage 2. By doing this, time is saved by initiating this process in parallel with the decision-making process of selecting a subcontractor in addition to avoiding rework in case consent is withheld by the A/E. At another level, it is also suggested to provide the shortlisted subcontractors with a draft of the subcontract conditions and documents along with the request for quotation in stage 3. This allows subcontractors to be aware of these conditions and account for any risks in their prices, hence avoiding disruptions in the process or possible price changes prior to signing the subcontract.

The second layer addresses the subcontractor selection phase of the procurement procedure. As discussed, the current state not only necessitates iteration by having two decision-making processes running at two different stages, but it also leaves much room for human error as it is purely based on opinion and advice, albeit being from professionals and stakeholders in the project. The choosing-by-advantages (CBA) is proposed as a method for enhancing the decision-making process by using multiple qualitative and quantitative criteria. The CBA framework proposed by El Kholy (2022) is proposed to be adopted as a means for enhancing the decision-making phase of the subcontractor procurement process. The main advantages of the CBA method are (a) its ability to accommodate the comparison of multiple alternatives (subcontractors in this case) over several factors, (b) its ease of use by creating a straightforward matrix structure using simple software which may be used with any work package on any project, and (c) reducing the possibility of human error of judgment through its scientific basis of calculation, which in turn reduces cycle time and minimizes the amount of coordination required between departments.

The third and final layer is related to the shortlisting of subcontractors and the use of historic data in such a manner that allows for continuous improvement and learning. An online-based subcontractor rating program within the contractor's Enterprise Resource Planning system is suggested in which data about subcontractors' expertise, contact details, as well as performance history is compiled. This stage requires project managers to rate subcontractors at the end of every project against a set of pre-determined criteria from technical, commercial, and time perspectives. The subcontractor rating stage takes place beyond the procurement process, long after the subcontract agreement is signed. It forms an integral part of the procedure enhancement by creating a feedback loop essentially based on the principle of continuous improvement. Namely, it paves the way for sustained benefits as a result of recurrently examining the performance of subcontractors and, in turn, the efficiency of the subcontractor procurement process itself. By having all this information readily available to the procurement department, a shortlist of potential candidates for the performance of any work package is easily created, which will form the basis for starting the CBA decision-making process as well as sending out requests for bids. This list of subcontractors may also be submitted to the project's A/E for approval in order to save time and reduce reiteration. It should be noted that this may not be accepted by all A/Es. However, by adopting the previously suggested rating system, one of the criteria could be the previous consent by A/Es to the specific subcontractor. As such, the shortlist will take this data into account by eliminating those that have previously been rejected by the specific A/E on the project.

DISCUSSION

The application of the proposed three-layered approach resulted in reducing the overall duration of the subcontractor procurement process from 30-50 days to just 14-26 days and in reducing the need for the involvement of many different parties. The subcontracting plan is now considered to have been completed prior to the initiation of stage 1 and the trigger for the procurement process becomes a specific work package requested by the site team in coordination with the planning department. The underlying reason is, as previously discussed, the application of a pull system that is based upon real-time project requirements, therefore allowing for better time management and reducing the need for rework.

The governing factor in determining the duration of stage 2 is the period stipulated under the main contract for the A/E's reply to submittal, assumed to be anywhere between 7 and 14 days typically. This is the longest of the durations among the three activities taking place simultaneously during this stage, namely (a) the request and receipt of bids from shortlisted subcontractors, (b) the setting up of the CBA framework, factors and determining criteria with their weights, and (c) the consent of the A/E. In this case, since a list of subcontractors is submitted (or in the case discussed earlier of the A/E rejecting this setup, the historical data will lead to the submittal of a subcontractor likely to be consented to by the A/E), the risk of rejection is very low, and rework is highly unlikely. As such, the longest among the durations of Stages 3, 4, and 5 of the conventional procurement process was adopted as the governing duration for Stage 2.

The final stage of subcontract conditions negotiations is considerably shorter than in the current state map since the subcontractor has already been made aware of them when requesting new bids in stage 2. By doing so, the subcontractor would have the opportunity to make allowances for the mitigation of any risks they deem necessary. While there will still be conditions and details to be negotiated at the final stage prior to subcontract signature, the extent of these will be limited to those of which the subcontractor deems completely unacceptable to them.

Finally, the proposed approach, having been developed based on a main contractor's adopted procedure in building construction projects, is particularly applicable to such projects. However, this methodology is indeed applicable to any project that is awarded following the design-bid-build approach to project delivery and that entails a need to go through a subcontractor procurement process. What makes it appealing in building types of construction is the high volume of work that is typically subcontracted, and which is commonly more extensive in building construction than other types of construction projects and where the number of work packages sub-let to specialty subcontractors is more sizeable, leading to many more instances of running the process.

CONCLUSION

Depending on the level of complexity and time limitation of the construction project at hand, contractors may decide to execute the various work packages of the project either in-house or with the help of subcontractors.The subcontractor procurement process is a complicated procedure involving input from different parties and encompassing several stages where decision-making takes place. Given the extent to which work packages are subcontracted on building construction projects, the selection of the right subcontractor and having a signed subcontract at the right time is of paramount importance. While the extant literature has thoroughly examined the issue of subcontractor selection, little emphasis has been placed on the procedure adopted by contractors to turn a work package into a subcontract agreement. This study aimed at closing this gap in the literature by examining a typical subcontractor procurement process of six stages, with potential judgement-related risks, and proposing a three-fold enhancement rooted in the application of lean principles to achieve a shorter, more efficient process. Namely, the proposed approach involves realignment of the steps within the subcontractor procurement process, coupled with the application of choosing-by-advantages methodology and a digitalized subcontractor rating program as a means for achieving a process with limited non-value-adding activities. The offered methodology is viewed as a roadmap that can be generally adopted by general contracting firms to reduce rework, eliminate waste, and enhance the subcontractor selection process.

The limitation of the study is that the process mapped reflects the typical process followed amongst general contractors of similar size undergoing building construction projects in the same region. It is recommended for future studies to have the same process studied with multiple contractors and on other types of projects such as infrastructure projects. Furthermore, while this study paves the way for examining the effectiveness of existing procurement processes adopted by contractors and how the application of lean principles can be of benefit, further research would be helpful in bridging the gap between available subcontractor rating criteria and digitalization by developing industry tools that allow the implementation of those criteria into an innovative subcontractor rating mechanism.

CONSTRUCTION SUPPLY CHAIN PRODUCT DATA INTEGRATION FOR LEAN AND GREEN SITE LOGISTICS

Fabrice Berroir[1], Magdalena Pyszkowski[2], Omar Maatar[3], and Nico Mack[4]

ABSTRACT

Supply Chain Management using Construction Consolidation Centres, kitting and Third-Party Logistics were proposed to streamline material flows in construction and reduce costs. Studies also highlight potential mitigation of the environmental impacts of the Construction Supply Chain but, despite the climate emergency, these solutions struggle to become industry practice. Digitalization, especially with Building Information Modelling based processes, appears as a key enabler for this transition, but it is hindered by heterogeneous data between construction companies and suppliers (made of manufacturers and resellers). Therefore, semantic Digital Twins, that can use Product Information Management, and recent norms on Product Data Templates have been proposed, but they need to be studied through practical cases from both construction site and supply chain perspectives. Consequently, this study applies a Design Science Approach involving 3 pilot projects, a manufacturer and digital supply chain experts around the development of a proof of concept of a Digital Twin tool for Lean and green logistics in construction. We identify what limitations of classical technologies used in the pilots could be addressed by a Digital Twin, we define what product data is needed for such a use case, and we compare practical scenarios for sharing and storing this data.

KEYWORDS

Supply Chain Management (SCM), Logistics, Digitization, Digital Twin, Product information management (PIM).

INTRODUCTION

Inspired by Toyota Production System's Just-In-Time production and logistics, Supply Chain Management (SCM) is a key topic for Lean Construction since the years 2000 (Vrijhoef and Koskela, 2000; Arbulu and Ballard, 2004). The uncontrolled flows of materials in the construction sector cause many inefficiencies on site such as repetitive handling or losses, with a direct impact on productivity and costs reported by many authors (e.g., Mossman, 2008; Dakhli and Lafhaj 2018). Health impacts for workers are also considerable, for example the French health insurance office estimates that material handlings cause at least 48% of work-related accidents on construction sites (Assurance maladie, 2021). Lastly, the environmental impact of construction material flows is significant, with about 20-35% of all urban freight traffic caused by the construction sector in Europe (Brusselaers et al., 2020). In the Netherlands,

27% of all greenhouse gas emissions in 2015 are attributable to construction logistics (encompassing infrastructure, buildings for construction companies and building materials supply). In the context of environmental emergency, the concept of Green Lean Approaches (e.g., Rosenbaum and Gonzales, 2012) requires these issues not be treated in isolation, since improvements in the productive process can also lead to reduction of environmental impacts. These considered, supply chain management and logistics are of prime interest.

In previous research, Vrijhoef and Koskela (2000) pointed out the "myopic control" of the supply chain in Construction. Practical solutions were proposed with benefits reported both from an environmental and from a productivity perspective. For example, Mossman (2008) reported building costs at 80% of industry benchmark and a 73% reduction in CO2 emissions of material transportations thanks to the London Construction Consolidation Centre. The concept of Construction Consolidation Centre (CCC) also called Construction Logistics Centre (CLC) has since become more applied/researched (e.g., Guerlain et al., 2019; Brusselaers and Mommens, 2022). This may be used in combination with kitting where the material is delivered in batches at the exact workspace resulting in a productivity increase (Elfving et al., 2010; El Moussaoui et al., 2020; Tetik, et al. 2021). Lastly, the logistics operations may be performed by a specialized Third-Party Logistics (TPL) operator as described by Ekeskär and Rudberg (2020). Despite some differences in scope, methods, or equipment, all the examples above are similar by the fact that (1) they break existing silos within the Construction Supply Chain, or between Construction Supply Chain and construction site(s), and that (2) digitalisation is stated as key when developing/deploying these solutions.

Therefore, this article aims to investigate product data integration from the construction supply chain for lean and green logistics. Specifically, it develops its practical implications for both construction sites and manufacturers.

LITERATURE REVIEW

The combined application of Building Information Modelling (BIM), Lean and Supply Chain Management can guide the whole sector towards improved procurement and execution performances (Le et al., 2018; Guerriero et al., 2018). While BIM does not only include geometric information, more and more data related to the processes and detailed product specifications are covered under standards such as the Industry Foundation Classes (IFC) (BSI, 2013). The BIM is complemented by the Digital Twin (DT) concept, which has the potential to enrich existing BIM data with dynamically sensed datasets, leveraging on real-time monitoring and the synchronicity of the cyber-physical bi-directional data flows (Boje et al., 2019). More specifically semantic-based digital twin applications promise the ability to link heterogenous datasets. This could be applied to link data silos between construction supply chain actors (manufacturers, resellers, etc.) and thus facilitate a shift towards BIM-and DT-based processes.

According to Peltokorpi and Seppänen (2022), Product Information Management (PIM) is a core component in achieving this shift. The study identifies use cases and proposes an applicable process for PIM where product data comes from manufacturer as 'standard' data and is enriched with 'instance' and 'process' data. Consequently, systematic PIM is stated as an essential part in the effort for lean construction. Notably regarding logistics, PIM allows better coordination of material supply using identification codes such as Global Trade Identification Number (GTIN) from GS1 (Daskalova et al., 2019) with tracking tools and linking product libraries and project data. To provide product data in a structured and standardized way, manufacturers need to know what information they should provide and how it should be presented. Hence, Product Data Templates are suggested (Meda et al., 2020). They are defined by product type based on ISO 23386 and ISO 23387 (International Organization for Standardization, 2020) in compliance with ISO 12006 and they enable the identification of properties and groups of properties. To maintain classifications and property sets, buildingSMART offers an online service called buildingSMART Data Dictionary (bsDD) (Buildingsmart, 2021). However, according to Peltokorpi and Seppänen (2022), “more practical research is needed to test the process and integration of the solutions”. Most notably, further research should study how to efficiently link product standards, instance and process information with BIM and test the applicability of product Data Templates from a supply chain and construction material provider’s point of view.

Consequently, this paper investigates how PIM and the Digital Twin concept can contribute to supply chain integration and logistics optimisation in construction. We assume that breaking data silos is a first necessary step to break decisional silos between the construction sites and their supply chain and that it will serve a lean and green perspective. We investigate in practice, from both the construction sites and the supply chain perspectives, how product data integration from the manufacturer could be used to support and upscale Supply Chain Management methods for reduced costs and environmental impacts of construction logistics.

METHODOLOGY

To cover practical implications and perspectives of product data integration from both sides of the supply chain, a Design Science Approach was chosen. With the participation of site managers from several case studies, a global construction product manufacturer and Supply Chain digitalisation experts, it aimed to develop a Proof of Concept (PoC) of a semantic Digital Twin for construction logistics optimisation. Therefore, this research was conducted as a use case of the Digital Supply Chain in Built environment group (Daskalova et al., 2019). Created from a memorandum of understanding between BuildingSMART and GS1, this consortium involved Construction Supply Chain companies to promote data driven collaboration.

The overarching research is tackled by the following questions (fig.1):

- Why Digital Twin and PIM are important for lean and green logistics on site? (Q1)
- What data is needed from the manufacturer to enable logistics optimisation? (Q2)
- How can this data be efficiently provided by manufacturers? (Q3)

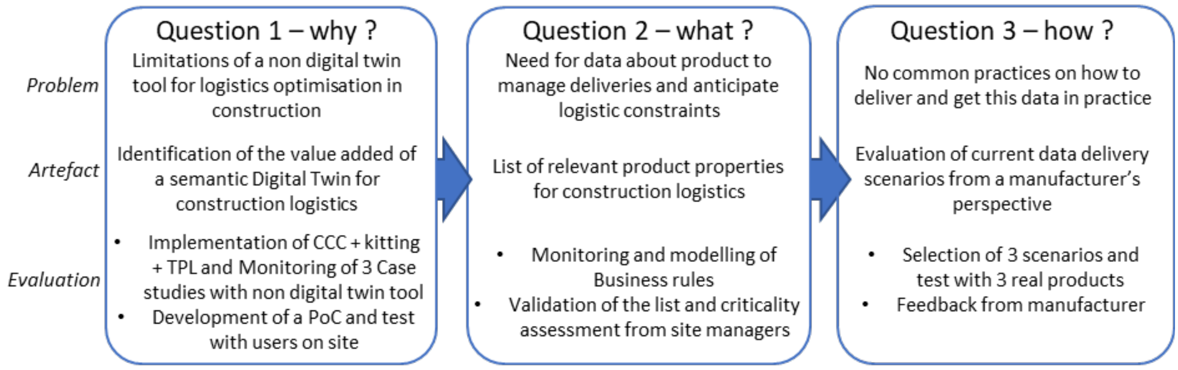

Figure 1: Research process with a Design Science Approach

As illustrated in figure 1, the questions were treated sequentially, and the DSA framework was applied for each question to deliver specific and replicable artefacts for the various stakeholders of the construction supply chain. Question 1 aimed to allow construction companies, logistician, and related practitioners to identify some expected value added of a PIM and Digital Twin tool towards Lean and Green logistics compared to a standard web platform. Therefore, innovative supply chain management methods were implemented by a General Contractor in Luxembourg (CLE- Compagnie Luxembourgeoise d’Entreprises) on 3 projects described in table 1. Previous publications about this project confirmed the strong potential for cost reduction and environmental impacts mitigation of a Lean Supply Chain Management while also emphasizing the key role of digitalisation (Berroir et al., 2021 and Maatar et al., 2022). The limitations faced by the teams with the web data platform used were collected through interviews. A PoC based on the digital twin concept (Boje et al., 2019) was designed to answer these limitations, and developed so that it could be tested on site with site managers (for predefined scenarios).

Question 2 aimed to provide to manufacturers, digital supply chain experts, standardisation bodies and researchers a set of product properties that are relevant for construction logistics based on the pilots. Therefore, logistic constraints on site (e.g., if an operator must unpack a package because it is too wide to cross a corridor) were collected during the monitoring of the pilots and modelled as a logical sequence, forming a so-called business rule. Accordingly, the product properties needed by these business rules could be listed, cross-checked with several existing classifications, and reviewed with sites participants for validation.

Lastly, based on this list of properties, question 3 aimed to provide practical feedbacks on data sharing and storing. 3 scenarios were identified and compared for 3 products from Knauf Insulation with the support of digital supply chain experts and BIM consultants.

CASE STUDIES DESCRIPTION

The 3 pilots involved overall 15 General Contractor's managers (from superintendent to director) from 2019 to 2023. More details on the projects are available in the following table:

Table 1: Description of the 3 case studies

Project	AUREA (in Differdange – LU)	OMNIA (in Esch-Belval – LU)	GRAVITY (in Differdange – LU)
Description	14 floor residential tower with 138 apartments	15 floor residential tower with 106 apartments	4 residential buildings (of 6 to 15 floors) with 205 apartments
Timeline	11/2019 to 07/2020	04/2021 to 05/2022	10/2021 to 03/2023
Trades involved	Tilling, floors, HVAC, bathtubs/showers, sanitary eq., joineries	Tilling, HVAC, bathtubs/showers, sanitary eq., plasterboards	
SCM/logistics innovations tested	Kitting, CCC, TPL	Kitting, CCC, TPL, multisite roundtrip with reverse logistics and some material picked up at close supplier	
Number of kits	1100	850	~1800 (ongoing)
Nb. of product types (references)	~900	~700	~300
Product choices	(Almost) fully flexible choices from the buyer		Choices from a shortlist
Digital tool and delivery management process	A Customized web data management platform on the software Airtable enabled to manage lists of kits and deliveries and to link it with files, photos, status, and planning on the cloud in real time. (See Maatar et al. 2022). It was used as a support for Last Planner System's meetings (Make-ready process).		

A benchmark conducted by the research team showed that most construction logistics software found on the market were focused on managing a delivery planning and on booking storage capacities or resources on site. This has little to do with enabling the detailed inventory of kits and the distributed management of deliveries between a logistic operator and the construction site(s). Thus, the general contractor designed and implemented its own web data platform for the pilots using the software Airtable. The detailed pros and cons of this precise software are not relevant for this study. The point is that, similarly to the other software found, it was representative of a "non-digital Twin" tool in the sense that it had no real-time (at least partly) automated data collection from the real world, no automated feedbacks to the real world, no simulation/problem solving capacity and no machine-readable product data integration.

RESULTS

EXPECTED VALUE ADDED OF A DIGITAL TWIN FOR LOGISTICS ON SITE (Q1)

As reported by Maatar et al. (2022), site managers were able to manage deliveries in kits with such a platform. Although preparing and maintaining the platform was time consuming, measurement showed that this outweighed the time that they usually lose in firefighting activities related to logistics.

However, in absence of machine-readable data, the web platform was not suitable for detailed product management inside kits and for multi-project and multi-criteria optimisation: the Omnia and Gravity sites were relatively close from each other (5km), but managers and logisticians couldn't plan complex roundtrips with the level of information they add and tended to schedule separate deliveries. Moreover, delivery times were often miscalculated because of unchecked delivery constraints (especially for products such as plasterboard). These limitations reported by site managers through interviews are summed up in the table 2. As proposed by Boje et al. (2019), a semantic Digital Twin may answer them. A PoC called TWISCO was designed to specifically illustrate how the DT concept can overcome these limitations. Tests on site (with tests data sets) confirmed the relevance of these features for site managers (fig. 3).

Table 2: Proposition of a Digital Twin application for Grean + Lean Construction logistics

Main limitations of web data platform used in pilot projects	**Features implemented in the TWISCO Proof of Concept (PIM + Digital Twin)**
Construction site's stakeholder and TPL operator need to know in detail what needs to be packed together, how and what are the characteristics of each package (e.g., weight)	A Kit management view allows to manage separate instances of products in each kit with their own properties and to manage and calculate the properties of the resulting kit.
Consistency between deliveries coming to the CCC and kit to be delivered need to be checked	Unique tracking of product instances in the kits using serialized GTIN (sGTIN) from GS1
Construction site's stakeholder and TPL need to assess when a kit should or not be delivered and what would be the impacts?	Planning integration + Space status management (may be automated with sensors) *Example: if there is humidity in the apartment delivery of wooden door should be postponed.*
As operators have a limited window of time to perform deliveries, delivery time need to be calculated considering constraints on site	Customizable constraint modelling through a "Business rules engine" *Example: a kit is too wide to cross a corridor, operator will lose time to unpack it and carry in separate batches*
TPL operator needs to be able to minimize both cost impacts and environmental impacts of complex multi-site roundtrips	Optimisation module with multicriteria optimization (using Genetic Algorithm)

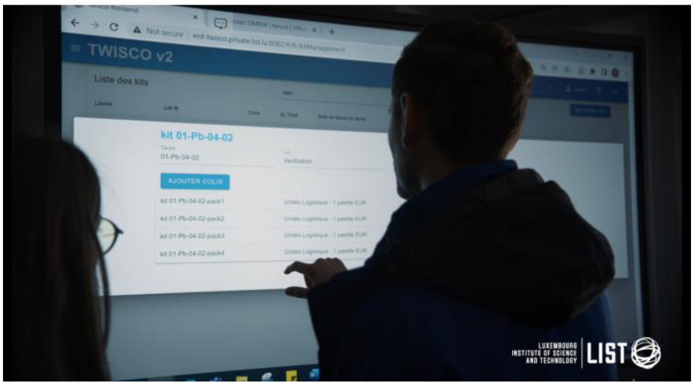

Figure 2: Testing on site of the TWISCO Proof of Concept

PRODUCT PROPERTIES FOR CONSTRUCTION LOGISTICS (Q2)

As a practical contribution to the 'Coordinating material deliveries on site' case for PIM stated by Peltokorpi and Seppänen (2022) and to enable tests with actual products, a list of the relevant 'standard data' for construction logistics was needed. The business rules, used to model the logistic constraints reported on the pilots, had product properties as a parameter, that could be extracted towards a first data model. With the support of experts from DSCIBE, it was crossed with existing standards such as ETIM and Peppol (OpenPeppol, 2017), which resulted in the list of properties hereafter. This list did not aim to be exhaustive nor definitive, but to contribute to the elicitation of key product data and to be representative of the type and amount of data needed to implement a semantic Digital Twin concept in practice. This list was submitted to the site managers to check the alignment with the characteristics they had to consider during pilots. Not all properties were of the same importance according to the feedbacks: While some characteristics such as weight or GTIN were mandatory to the concept proposed, other were situational. Accordingly, 'Must have' properties were highlighted by site managers, that encompass the most impacting problems faced. To help readability and future uses, the list was split in several sub cases ('purpose') and further explanations are proposed in description.

Table 3: Product Data for Construction Logistics: General data

Property	Purpose	Criticality	Description
Product identification (GTIN)	General	**Must have**	Global Trade Identification number 13-digit code
Seller Identification	General	Nice to have	GLN number of the company.
Manufacturer Identification	General	**Must have**	GLN or identification number
Key words (synonym)	General	Nice to have	Plain text
Product category	General	**Must have**	Categorization of the product type (e.g., windows). Should refer to existing categories in IFC, GPC or UNSPSC class.
Description	General	Nice to have	Plain text
Name	General	Nice to have	Plain text

Table 4: Product Data for Construction Logistics: Ordering, accounting, and kit definition

Property	Purpose	Criticality	Description
Ordering unit	Ordering, accounting, kit definition	**Must have**	Unit in which the order is expressed (square meters, linear meters, kg, pieces, …)
Minimum ordering quantity	Ordering/ accounting/ kit definition	Nice to have	If a threshold is defined for orders
Minimum package per pallet	Ordering/ accounting, kit definition	Nice to have	Minimum number of instances of the product type that can/must be stacked on one pallet (of the defined pallet type)
Maximum package per pallet	Ordering, accounting, kit definition	**Must have**	Maximum number of instances of the product type that can be stacked on 1 pallet.

Table 5: Product Data for Construction Logistics: Handling and transport

Property	Purpose	Criticality	Description
Gross product weight	Handling, transport	**Must have**	Value in kg. May include packaging
Net product weight	Handling, transport	Nice to have	Value in kg without packaging (useful only if packaging is a big part of the weight)
Pack quantity	Handling, transport	Nice to have	The number of packed units that are in the orderable unit. E.g., if the orderable unit is a pallet that contains 30 boxes then the packed units are BOX and the packed quantity is 30.
Roll diameter	Handling, transport	Nice to have	Specific to cylinder products
Product density	Handling, transport	Nice to have	Only useful to determine weight if not given.
Product volume	Handling, transport	Nice to have	Relevant for truck optimisation with stackable products
Product length (packaged)	Handling, transport	**Must have**	Deep dimension of the packaged product
Product width (packaged)	Handling, transport	**Must have**	Latitudinal dimension of the packaged product
Product height	Handling, transport	Nice to have	Needed when products can be stacked or to check if product can go through some doors/lifts
Numeric pack size	Handling, transport	Nice to have	Consumable unit quantity Specifies the number of consumable units that are in each orderable unit. E.g., if the orderable unit is a pallet that contains 30 boxes, then the packed units are box and the packed quantity is 30 and the numeric pack size 30*orderable unit
Type of handling unit	Handling, transport	**Must have**	Type of pallet used (pallet EUR, destructible pallets, no container, other (e.g. backrest pallets)
Handling instructions	Handling, transport	**Must have**	Plain text: comments of the manufacturer on how to use / or manipulate the material
Is it fragile	Handling, transport	**Must have**	Boolean, high risk of breaking

Table 6: Product Data for Construction Logistics: Installation

Property	Purpose	Criticality	Description
Vapour permeability	Installation	Nice to have	If available, can be used to determine the sensitivity to humidity. Potentially useful for further Use cases other than logistics
Thermal resistance	Installation	Not relevant for logistics	R-value, if necessary, a use or storage temperature should rather be given
Use temperature	Installation	Nice to have	Range of acceptable temperature for using the product as intended
Storage temperature	Installation	Nice to have	Range of acceptable temperature for storage

Table 7: Product Data for Construction Logistics: Installation

Property	Purpose	Criticality	Description
Maximum storage humidity	storage	**Must have**	Maximum humidity conditions before risk of degradation / property losses for the product
Maximum storage temperature	storage	**Must have**	Maximum temperature conditions before risk of degradation / property losses
Minimum storage temperature	storage	**Must have**	Minimum humidity conditions before risk of degradation / property losses for the product.
Sensibility to sun light	storage	Nice to have	Some material might be for example discoloured if they are left exposed to the sun

Table 8: Product Data for Construction Logistics: Reverse, Waste management

Property	Purpose	Criticality	Description
Packaging plastic sheet	Reverse, waste management	Nice to have	Amount of plastic with usual packaging. Can be useful for reverse logistics
Packaging wooden pallets	Reverse, waste management	Nice to have	Amount and type of wooden pallet with usual packaging. Can be useful for reverse logistics

PRODUCT DATA DELIVERY FROM THE MANUFACTURER (Q3)

In the 3 pilot sites, only the "must have" properties of the products managed would represent more than 20 000 values. For a construction company, filling and maintaining such a database is unrealistic and cost-ineffective, even if data would come in a machine-readable format. Particularly in these cases where product choices validated by the buyer at a very late stage of the project. This responsibility falls then on manufacturers, but from a supplier's perspective, knowing how to provide the data requires tackling practical questions 1° and 2° below, that were tested for 3 products from Knauf Insulation (e.g., https://knauf.be/fr/produit/acoustifit).

1° Where to store data so that it can be managed in time, at minimal cost?

The purpose of these experiments was not to find the best solution on the market from an economical or technical perspective, but to compare several approaches different by nature from a supply chain perspective. Accordingly, three patterns were identified and tested: data can be stored in common data bases/databanks (1), data can be stored in the BIM objects (2), or data can be piggybacked to e-procurement messages (3).

Using a common product data bank (GDSN)

An approach based on National databases is emerging in many countries especially regarding standardized Life Cycle Assessment Data (e.g., https://www.oekobaudat.de/). For the tests, a product data base called "GDSN" (which was originally designed and used for food) was used.

Pros: - Minimal needs in terms of software or pre-existing data (apart from a GTIN) from both sender and receivers' point of view

- Consistency with GS1 regulations (for the case of GDSN)

Cons: - The system was closed, meaning that adding properties or bypassing asked fields was not possible. This might not be the case for all solutions of type "databank"/common database, but the flexibility of the system raises questions in front of unanticipated data need or changes in the standards raises questions.

Integrating all (the required) properties in the BIM file

Alternatively, several big manufacturers provide access to BIM libraries where an IFC file (or other BIM formats) can be downloaded for each product (e.g., bimlibrary[5] from Saint-Gobain). In some cases, it is even possible to generate BIM file for a system of several products assembled including products of other manufacturers as for example in Knauf Insulation (2022).

Pros: - All information is standardized.

- Fully customizable within available properties at manufacturers level. Example: https://test.hybrid.pl/knauf_insulation/bim/bim_generator/form.php?id=7977
- Considered as more convenient from a (big) manufacturer's perspective

Cons: - May be less effective procurement-wise
- Requires having BIM libraries of the products
- May restrict the access to data for software outside of BIM environment

Sending data (and some potential meta data) as a message for e-procurement (Peppol)

Peppol allows a network of eProcurement partners to be connected and exchange standard-based documents (OpenPeppol, 2017). Thus .xml files can automatically be sent by any internal system and 'translated' at the receiver's level with customizable integrators.

Pros: - Considered as more convenient from a procurement and multi-level supply chain, - Natively supports logistics workflow

- Data to deliver is easily customizable, and can be aligned with Data Templates

Cons: - At receiving end, using Peppol may entail to maintain multiple copies of the same product data instead of maintaining a single catalogue of product types

- Harder to implement on manufacturers side (new system of data sharing)

2° How to structure data in sync with existing classifications to ensure interoperability?

In all three scenarios above, the key to identify a property is its Uniform Resource Identifier (URI), identified thanks to data templates through the bsDD. Every property in the list (Tables 3 to 8) were looked after in the bsDD, in some of the main product data classifications available (ETIM, eClass) and in the Peppol standards as shown in table 9.

Table 9: Identification of targeted data in current classification

	number of properties	bSDD	ETIM	eClass	Peppol
All properties	34	71%	42%	32%	84%
Only "Must have"	14	73%	45%	36%	100%

The percentages in table 9 indicate that as new use cases or applications are developed, a significant amount of the properties might be out of available classifications. More importantly, these properties were spread in several classifications, which made their identification tedious and thus, limited replicability and efficiency from a manufacturer's perspective.

DISCUSSION

Construction Logistics and Digital Twin on site

Although TWISCO was usable for tests and demonstrations, it is still a PoC with a TRL5 (Sadin 1988). As such it is not fully functional, and the value added of the Digital Twin Concept proposed in table 2 needs to be confirmed and potentially extended with its full implementation

[5] https://bimlibrary.saint-gobain.com/

in real conditions. TWISCO's business rules engine could be used as a framework for bottom-up identification of logistic constraints through new case studies. These should also consider the potential limitations of Digital Twins in construction regarding the human related aspects highlighted by Noueihed and Hamzeh (2022). Sensor's implementation on construction sites and automated tracking from the supplier proposed by the TWISCO PoC should also be more studied. Indeed, these technologies may contribute to the Last Planner System by enabling a more trusted Make Ready Process. Moreover, the environmental impact mitigation from a multi-site delivery optimisation algorithm should be demonstrated in practice as well.

Predefined Group of properties in the Product Data Templates for specific use case

Product data templates are defined by product type. Based on current work, authors call for more generic predefined group of properties based on use cases such as "logistics". This paper is a contribution towards such a standardized set of property for construction logistics. Authors emphasize that such a group of properties should not be restricted to the "handling or transport properties" as other aspects were identified as necessary to optimize logistics based on Just-in-time principles (for example installation aspects). This list is however preliminary and limited in scope. More project types, product types, and logistics scenarios (e.g., multi modal logistics optimization, reverse logistics, logistics for reused materials) need to be investigated. Other similar applications such as the circular economy with the 'Product Circularity Data Sheet' (Mulhall et al., 2022) may benefit from such a standardization effort.

Manufacturer's perspective on PIM

To encourage manufacturers to openly give access to their data, there is a need to either set regulatory obligations or clarify the business model and competitive advantage. Therefore, understanding and awareness should be raised in the industry. From the manufacturer's perspective, this might require simplifying and clarifying the concepts used (standards, data formats, data templates, data sheet, data sets, classifications, norms, data dictionary, properties, attribute, etc…). Moreover, this study indicates that there might not be a "silver bullet" solution, but different options depending on the type of products, experience with BIM and PIM, the number of reference or ERP system used, etc. This should be elaborated in further studies.

CONCLUSIONS

This paper investigated how data continuity may be achieved in construction and how it could support data driven logistics aiming at reduced environmental impacts and costs. Based on operational feedbacks from 3 projects with almost 4000 kits delivered from a CCC, limitations of a classical web data platform were identified and a proof of concept of semantic Digital Twin was proposed to answer them. This PoC enables to manage 'instance data' of products (e.g., unique reference of material within a delivery) which facilitates kit management. It can be subsequently linked with 'process data' (e.g., delivery status) which are essential to manage the process in the sense of Lean Construction and to integrate 'standard data' which encompasses physical characteristics of a type of product (e.g., weight). What standard data should be exchanged and how it can be practically delivered was studied with real products from both ends of the supply chain. Accordingly, this research contributes to Lean Construction by identifying some potential benefits and perspectives of Digital Twin and PIM for SCM. It contributes to the fields PIM, BIM, and Digital Twin by presenting use case of these technologies with concrete implication in the execution phase, by comparing several patterns for delivering the data and by reporting a limit in current definition of Product Data Templates. Thus, authors advocate for predefined sets of properties for specific use cases such as logistics or circularity in the Data Templates (that could be built upon the list proposed in this article) and highlight the need to raise awareness amongst the industry through more practical cases.

STRATEGIC PARTNERING BETWEEN CLIENT, CONTRACTOR, AND SUBCONTRACTOR

Herman Kvale Ferstad[1], Atle Engebø[2], Paal André Slette[3], and Ola Lædre[4]

ABSTRACT

The concept of strategic partnering has recently gained significant attention in the Norwegian construction industry. Strategic partnering is a project delivery method that emphasizes a more collaborative approach than traditional delivery methods. It shares similarities with a Lean project delivery approach, as both seek to optimize and create more collaborative projects. In this paper, strategic partnering is broken down into three key elements of Lean Construction: contractual, organizational, and relational elements. Through this, the paper aims to contribute to understanding strategic partnering between a client, general contractor, and a key subcontractor by addressing the following research questions: 1) How is strategic partnering practiced in Norwegian construction projects, and 2) What are the experiences of practicing strategic partnering in Norway?

An in-depth case study was conducted to investigate ways to enhance strategic partnering in future projects. A combination of a literature review and semi-structured interviews were used for data collection for this paper. The findings show that using strategic partnering improved project outcomes, with trust, early contractor involvement, contingency of key participants, and problem resolution being crucial aspects of the collaboration. However, more attention should be paid to evaluating the other parties in the context of the strategic partnership.

KEYWORDS

Strategic partnering, strategic alliancing, project delivery models, Lean construction, collaboration.

INTRODUCTION

As building projects become increasingly complex, alternative project delivery methods are becoming more prevalent in the construction industry (Engebø et al., 2020). The new delivery methods seek more integration in the construction process by involving key parties in the early stages and forming an integrated project team. A core driver for this change can also be found in the lean community through the emergence of lean project delivery with its emphasis on establishing a collaborative project organization, relational contract, and lean operational system to align and integrate key participants and encourage a collaborative environment (Mesa et al., 2019).

Nevertheless, there is a need for further research in the area of collaborative project delivery. Partnering is one such method, which can take the form of a strategy or a practice of different

versions. According to Lahdenperä (2012) partnering can also be viewed as a philosophy. Bennett and Jayes (1995) define partnering as a management approach in which two or more organizations utilize each other's resources to attain specific goals. This form of collaboration is particularly useful in complex projects with a high degree of uncertainty and a need for collaboration among the parties (Eriksson, 2010).

In the literature, there are commonly two forms of partnering that occur: project and strategic partnering (Beach et al., 2005). Project partnering is limited to a specific project and aims for short-term effects (Bygballe et al., 2010). On the other hand, strategic partnering can span over several years and projects, and seek long-term gains (Beach et al., 2005; Cheng et al., 2004). Both forms are relatively less prevalent in project-based industries compared to production-based industries where they have existed for a longer period (Bygballe et al., 2010).

Strategic partnering can be a way to implement Lean principles as the collaboration lasts for a prolonged period and the relationships between the parties are strengthened through collaboration. In other industries, there has been found that strategic partnering has a positive effect on lean strategies, lean manufacturing, and lean design (see for example, Jayaram et al., 2008). In other words, the concept should be transferable to the construction industry in line with the lean philosophy's approach to continuous improvement, efficiency, and value creation.

Sundquist et al. (2018) and Zheng et al. (2020) emphasize the need for further research to comprehend the concept of strategic partnering. Additionally, case studies on strategic partnering are necessary, as the previous research has primarily consisted of cross-sectional studies (Zheng et al., 2020). According to Bygballe et al. (2010), there is little documented research regarding strategic partnering between multiple actors. There is also a knowledge gap in the literature about the experiences and effects of strategic partnering, especially in the Norwegian construction industry. However, this does not imply that strategic partnering is not practiced in the construction industry. It is therefore of interest to gather and collect experiences from parties who practice strategic partnering in their projects. Lately, there has been a study about strategic partnering between a contractor and a designer in Norway (see Paulsen et al., 2022).

The purpose of this paper is to identify the success factors of strategic partnering in Norwegian construction projects. Additionally, it will investigate the experiences of partnering across multiple projects. It will be based on relevant literature and two case projects. The following research questions (RQ) have been developed for this in-depth study:

- RQ1: How is strategic partnering practiced in Norwegian construction projects?
- RQ2: What are the experiences of practicing strategic partnering in Norway?

This study examines two building projects that utilize a Design-build contract that features predefined criteria for collaboration. The main focus of this research is on the relationship among the client, the contractor, and the subcontractor, as the same partnership is tracked throughout the entirety of the first project and the early stages of the second. The general contractor was engaged in the design phase together with the client and the electrical subcontractor was engaged before commencing construction.

THEORETICAL FRAMEWORK

Strategic alliances have a central place in the lean philosophy. For Toyota, partnering in the supply chain was one of the four core processes. Garnett et al. (1998) believe that a premise for a lean construction process is that alliances, operationalized through the project team, work on a series of projects, continually developing the product, applying quality improvement and waste reduction techniques, and incorporating arrangements for learning and continuous improvement.

COLLABORATIVE PROJECT DELIVERY METHOD

Miller et al. (2000) describe a project delivery method as «a system for organizing and financing design, construction, operations, and maintenance activities that facilitates the delivery of a good or service». According to Klakegg (2017), some will argue that adapting the project delivery model to the specific project will be most appropriate. Others will argue that a standardized project delivery model will contribute to less misunderstanding and disagreements from project to project. To handle projects with higher risk, uncertainty, and complexity collaborative project deliveries can be a preferred option (Tadayon, 2018).

There is a distinction between hard and soft elements in collaborative project delivery (Wøien et al., 2016). The hard elements can be found in the contract, while soft elements are the outcome of using process-oriented methods during the project. The findings by Engebø et al. (2019) conclude that the most important soft elements were top management support, openness/transparency, trust, shared goals and motivation, and attaining the right people. Whether the client's management can provide continuous support lies on the client's resources and is considered a critical success factor.

STRATEGIC PARTNERING IN THE CONSTRUCTION INDUSTRY

The literature review indicates a clear distinction between project partnering and strategic partnering (Beach et al., 2005; Bygballe et al., 2010). Project partnering is a method that is specific to a particular project, focuses on short-term effects, and is more results-oriented (Beach et al., 2005). On the other hand, strategic partnering is geared towards achieving long-term effects of collaboration between various parties. This delivery method lasts for multiple years and projects and is more process-oriented than project partnering. Establishing trust, shared objectives, and commitment among project members are important factors for a long-term relationship between involved parties (Bygballe et al., 2010). According to Koolwijk (2018), strategic partnering is a delivery method in which the owner, contractor, and key subcontractors enter a long-term partnership. Additionally, contractors and subcontractors are allowed to work on follow-up projects if they meet predefined criteria set by the owner. Characteristics of strategic partnering include open-book accounting, shared risk and reward, and open communication. According to Zheng et al. (2020), transitioning from project partnering to strategic partnering poses a substantial challenge with a focus on the institutional environment, organizational structure, and team dynamics. Furthermore, previous research suggests that a more strategic approach to project partnering can enhance projects in the construction industry (Moller & Bejder, 2004).

There have been successful examples of strategic partnering, but these are mainly restricted to client-contractor (Shimizu & Cardoso, 2002). However, there is a need to explore the phenomena all through the supply chain. To increase productivity in projects, contractors should improve their relationship with subcontractors and provide feedback and evaluations (Eom et al., 2008). A case study by Beach et al. (2005) found that the majority of interviewees from the general contractor believed that a long-term partnership with subcontractors would provide better support throughout the project. It is also emphasized that the benefits of collaboration will be apparent after several years of collaboration between the parties. The key to success in collaboration is the development of a shared understanding of expectations, shared visions, and a common goal for the project. A case study by Crutcher et al. (2001) found that the strategic partnership between an electrical subcontractor and supplier led to increased productivity and efficiency in material handling. A long-term partnership, based on principles that benefit both parties, will most likely be beneficial for all parties involved in the execution.

A LEAN PERSPECTIVE ON STRATEGIC PARTNERING

Oakland and Marosszeky (2017, p.21) propose that for lean construction to be successful, project delivery should emphasize the creation of an integrated organization with the commercial interests of the parties aligned around the efficiency of the project as a whole. A lot of attention in lean management has been aimed at collaboration and partnering between different parties to enhance value creation (Jylhä & Junnila, 2014). Research has shown that combining Lean principles and partnering can create positive synergies (Falch et al., 2020). According to Karanjawala and Baretto (2018), the implementation of Lean Construction in partnering has resulted in more open communication, trust and transparency, and identification of constraints and non-value adding activities. The concept of strategic partnering corresponds with the Lean philosophy of continuous improvement as it aims to achieve learning outcomes both at the organizational level and across different projects (Paulsen et al., 2022). Furthermore, since strategic partnering is lasting for more years and over several projects, it can be easier to implement Lean principles in the involved organizations.

THE KNOWLEDGE GAP

Most of the literature regarding strategic partnering has been limited to either client-contractor, contractor-subcontractor, and a few contractor-designer. However, few publications examine strategic partnering with multiple actors, such as client-contractor-subcontractor, and this aligns with the findings by Bygballe et al. (2010). In general, both Sundquist et al. (2018) and Zheng et al. (2020) state that it is a research gap regarding the concept of strategic partnering and that more case studies should be conducted.

METHODOLOGY

This study employed a qualitative research design by combining both a literature study and a case study. The literature study was based on the prescriptions of Arksey and O'Malley (2005) and the case study was designed based on the methods outlined by Yin (2018) for single-case studies. The goal of this research was to examine the phenomenon of strategic partnering between a client, contractor, and subcontractor in the construction industry in Norway.

The literature study was conducted to provide a comprehensive overview of the existing knowledge on strategic partnering in the construction industry. A structured search of relevant literature was conducted using various databases such as Scopus, Web of Science, IGLC, and Oria. After the literature search was reduced to a manageable amount the sources were evaluated by predefined criteria. The sources were evaluated by criteria such as the title, relevant keywords, abstract, conclusion, and an overall assessment of the publication. If the publication met the criteria mentioned above, reliability and credibility were considered.

The case study was conducted to provide in-depth insights into the phenomenon of strategic partnering in the construction industry in Norway. The case chosen for this study was two building projects within the same geographical region, and the same organizations participated in both projects. Table 1 shows some information about the two projects which were analyzed. Having been established for some time, it was possible to gather more detailed and nuanced information about the strategic partnership through different parties.

The primary method for data collection applied in the case study was in-depth semi-structural interviews. The selection of participants for the study was based on their roles in the projects. A total of ten informants from the client, general contractor, and main subcontractor were selected from the case projects. All ten interviewees participated in the first project while seven of these were also participating in the second project. The semi-structured interviews were conducted digitally. A list of open-ended questions was used as a guide for the interviews within the following main categories: contract, organization, and relations. The interview questions were tailored to the research questions and for each subcategory, the participants were asked about their actions, experiences, and suggestions for what could have been done differently. The interviewer was also able to follow up on any additional points that arose during the interview. All interviews were recorded and transcribed for analysis. An example of an interview question was: “How would you describe the level of trust in the projects?”.

Table 1: Facts about the two case projects.

	Project A	**Project B**
Location	Oslo, Norway	Oslo, Norway
Building type	Rehabilitation and new-built school building	New-built office-building
Contract type	Design-build with collaboration	Design-build with collaboration
Building dimension	ca. 17.000 m^2	ca. 24.000 m^2
Start of construction	Q2 2019	Q2 2022
Takeover	Q2 2021	Q2 2024
Sustainable goal	BREEAM[1] Excellent	BREEAM[1] Excellent

[1]BREEAM stands for Building Research Establishment Environmental Assessment Methodology.

The data collected from the literature study and the case study were first analyzed separately, but afterwards they were analyzed against each other. The literature study data were analyzed using thematic analysis. The data collected from the case study was analyzed using a process of coding according to contractual-, organizational-, and relational elements.

FINDINGS AND DISCUSSION

This chapter presents findings from interviews in the case study and evaluates them using the case study and theoretical framework. The chapter is structured into sections on contract, organization, and relations.

CONTRACTUAL ELEMENTS

The contract plays a vital role in any construction project. Even if the partnering concept emphasizes collaboration and building a relationship beyond the formal contract, there must nevertheless be a contractual relationship that ensures the foundation of the strategic partnership. In the case projects, the most important contractual relationships were between the general contractor and the client, and between the general contractor and the electrical subcontractor. In the early stages of the first project, the client made a strategic decision to procure a contractor who had the capacity and competence to partake and collaboratively develop the project together with the client. Key contractual elements identified were the following:

Design-build with collaboration was the preferred contract between the client and contractor.

Procurement not just on lowest price: Several different criteria were used. The competence of the contractor’s personnel was a vital factor in collaborative project delivery.

Incentive model: where both client and general contractor worked towards a target price.

The parties did not prepare a formal agreement in advance that established that the partnership should continue through all the projects. The lack of an up-front strategic alliancing agreement seems to be in line with previous research (see for example Paulsen et al., 2022). An explanation may lie in the nature of projects. In contrast to industrial production, where the alliance will continue to produce the same product repeatedly, the parties will produce unique products repeatedly. For the parties, it would therefore be too great a risk and uncertainty associated with formalizing the strategic collaboration at such an early stage (i.e., before the first project). Instead, they seek to use the first project to build a relationship and see if they can achieve some partnering effects that can form the basis for further collaboration.

The importance of selecting people who can collaborate and see both sides of an issue is emphasized, and it puts high demands on project management. In sum, the client allocated a lot of resources to the contracting process as their objective was to establish a strategic partnership with the contractor if the collaboration in the first project succeeded. As a supplement to price, experience, competence, and references were considered important criteria for selection, especially for complex rehabilitation projects. For the selection of an electrical subcontractor, the main criteria are based on price. However, it is pointed out by the subcontractor that the relationship and experience from previous collaboration could have influenced the choice of the electrical subcontractor.

In both projects, an incentive model was used where both client and general contractor were involved with a target cost contract, as described in Zimina et al. (2012). If the final cost was below the target price, the profit was shared between the parties. This also applies to overruns up to a certain amount. If the costs exceeded a certain percentage of the target price, the contractor had the risk. The contractor was awarded if they made good purchases that didn't affect the required quality. Furthermore, the design and target price were developed in parallel in this project. This allows the client to make more optimized decisions, increases and extends project flexibility, and reduces and shares risks between the parties. On the other side, late changes in the project can lead to more stress and friction in the design group managed by the general contractor. There was no further incentive in the contract, but based on the performance of the first project there was no doubt that the contractor would get the second project. For the subcontractor, there were not used any contract nor cost-related incentives.

According to the interviewees, there were some formulations in the contract regarding how the collaboration through the project should be. However, all interviewees state that it can be difficult to appraise if formulations, such as trust, comply with the contract during the project. To make strategic partnering work every party must put in the effort and integrate themselves within the project organization. The issue of productivity within the construction industry has been a longstanding concern, and therefore this was addressed in the interviews. The first project was delivered ahead of schedule, with a finished product that met the client's expectations and demands, with a few minor discrepancies. Additionally, the project was completed within the target price agreed upon by the client and contractor. Given the complexity and short implementation period of the project, the subcontractor deemed the overall productivity to be high. This corresponds with the findings of Kubal (1996) where strategic partnering between the client, contractor, and subcontractor improved the project results.

ORGANIZATIONAL ELEMENTS

In both projects, it was important for the client with early contractor involvement. The contractor was involved in the predesign phase in both projects. The first project was priced based on the completed pre-project, typically at the frame application level. The electrical subcontractor was involved early after the general contractor was chosen, as a part of the contractor team. The interviewees presented a nuanced view of the early involvement of the contractor as they listed both advantages and disadvantages. In the early phase of the project, it can be difficult for the client to assume or foresee how much different operations will cost during the project and how long it will take to complete each operation. With early involvement, the contractor will be able to contribute with knowledge of the constructability (Tadayon, 2018).

Early involvement of key parties can also lead to increased trust between the key parties over time and improve efficiency. The involvement of subcontractors before the commencement of construction allows for better preparation and increased preparedness for the project (Nevstad et al., 2018). As Beach et al. (2005) describe, the subcontractor will be able to provide better support if they are involved at an early stage. However, both the general contractor and the electrical subcontractor state that too early involvement of contractors can lead to higher uncertainty and more confusing surroundings. There should be some goals and objectives developed by the client before contractors get involved. For example, the tenant joined the project late, with the result that significant changes to the design were required. If the involvement of different parties isn't strategically assessed in advance, it could result in wasteful activities such as rework on the design of the project. Reflecting on the first project, it may have been beneficial for the tenant to have been involved earlier, or the design team could have made their solutions more flexible. If the solutions are being locked at an early stage, it could lead to waste because changes require redesign.

During the first project and the current early phase of the second, there were very few conflicts among the parties involved. There was a clear strategy and mutual understanding among the different parties that issues or disagreements should be addressed at an early stage and a project level. One of the reasons for this approach was to prevent the history of the conflict from being forgotten in case it was prolonged. This can be said to be in line with the partnering philosophy as one seeks to overcome disagreements or conflicts not by contractual clauses but by their shared commitment and interest in the project. One interviewee stated: "There were no conflict or bigger disagreements between the client and the contractor throughout the projects". However, another interviewee stated: "Between the contractor and the subcontractor, there may be a few more disagreements". This is because the execution phase is more dynamic than the early phase, and multiple disciplines needs to be coordinated.

If a resolution could not be reached between the client and the tenant, it was then brought to a steering group composed of representatives from the client's organization and the tenant's organization. If they were unable to reach an agreement, the matter was escalated to a dispute or legal action. The client evaluated both the progress and the economic impact of the case before making a final decision. According to the interviewees, there were minimal conflicts and no unresolved cases. There is a mutual understanding among the interviewees that disagreements primarily occur during the construction phase, whereas the pre-project phase is relatively static.

In the transition from the first project to the second, considerations were made regarding the transfer of key personnel. One interviewee stated: "The most important element is to transfer key personnel from the previous project". Continuity among key project participants is an important factor for achieving success in a long-term partnership (Black et al., 2000). The general contractor plans to transfer four out of eight individuals from the project team, while the electrical subcontractor transferred all their personnel from the first project to the second. This continuity can create synergies for the upcoming project as the trust and relationships between the participants have already been established through the previous project. This aligns with the findings of Sundquist et al. (2018), where relationships developed through project partnering can be extended into strategic partnering. According to an interviewee, the upcoming project may be vulnerable if the key participants are not transferred. The level of uncertainty is reduced by the parties becoming familiar with one another and having a clearer understanding of each other's methods and performance capabilities. This corresponds well with the findings of Bresnen and Marshall (2002), where a lack of continuity of key personnel and relationships can lead to problems for the long-term collaboration and transfer of knowledge between the parties.

Table 2 presents experiences within organizational elements. An interviewee noted that productivity was deemed satisfactory in the project due to two key factors. Firstly, swift decision-making by the client, contractor, and tenant regarding any possible changes to the building helped maintain an optimal workflow in the project. The strong trust and relationship established among the parties facilitated an efficient decision-making process. Secondly, the project's progress plan was well-conceived, resulting in minimal delays caused by the need to wait for other contractors to complete their work.

Table 2: Summary of experiences within organizational elements.

Element	Good experiences	Bad experiences
Early contractor involvement	Enables better preparation and increased understanding of the project; enhances trust between the parties; increases efficiency	Too early involvement may lead to more confusion and uncertainty; can lead to more waste if solutions are locked in too early.
Conflict resolution strategy	Having a clear strategy and mutual understanding, disagreements or issues can be addressed at an early stage	If a resolution can't be reached, disputes can escalate to legal action
Continuity of Key Personnel	Can reduce uncertainty and create synergies; companies become familiar with each other's working methods and capabilities.	If there is a lack of continuity of key personnel, long-term collaboration and knowledge transfer can be more difficult

RELATIONAL ELEMENTS

Throughout the first project and early phase of the second, all interviewees reported that the level of trust between the parties was sufficient and increasing. By understanding each other's working methods mutual trust developed throughout the projects. In a rehabilitation project, such as the first one, uncertainty can be a challenging factor and difficult to control. According to all interviewees, trust is a prerequisite for collaborative project delivery and a successful strategic partnership. As one interviewee stated: "Trust is essential in this collaborative model. Without it, such contracts do not function properly". According to another interviewee, it typically takes around one year to establish a trustworthy relationship. Trust between the parties is crucial during chaotic periods. As Chan et al. (2003) describe, uncertainty can be an underlying challenge in building trust between parties. This is also acknowledged by the interviewees. However, due to the early involvement of both the contractor and subcontractor they were able to start building trust and relationships between the project participants at an early stage. Koolwijk et al. (2021) state that trust is one of the success factors for strategic partnering. It is noteworthy that trust naturally develops when the project results are positive (Beach et al., 2005). However, incidents that threaten the trust between the project participants on a larger scale than in the first project can occur. As this was a complex and large-scale building project, late changes from the tenant could have been challenging for the trust between the parties.

Throughout the projects, there have not been implemented dedicated evaluation meetings regarding the partnerships. However, there has been some evaluation ongoing through the general contractor reporting on quality, economics, and progress. The feedback the contractor receives from the client will indicate the client's satisfaction. A similar report is done by the subcontractor at the same time. The interviewees state that it is common to conduct an internal evaluation of the projects. However, according to an interviewee, it is not common to conduct other forms of project evaluations during or after projects. There is mutual consent among the interviewees that evaluation meetings are something they should establish between the parties, especially at the end of projects. Often it can be challenging to change the scope and take a step back when you are in the project. One should ask what went well and what could have been done better. Since the pre-project for the second project was underway while the first project was in the final phase, the client did not want to disturb the contractor with heavier evaluations. Such a period can be very hectic for the contractor, but the client still believes it could have been done at a later time. Given the lack of formal agreements for the strategic partnership between the parties, the continuity of key participants and transfer of experiences was important.

This kind of knowledge transfer could have contributed to fewer mistakes in future projects. According to the findings of Cheng et al. (2004), conducting evaluations of internal performance within the organization is important for achieving success with strategic partnering. This aligns with the execution of the first project, where internal evaluations were carried out by all three involved parties. However, the general contractor should have conducted a more comprehensive evaluation of the electrical subcontractor to create a win-win relationship in the long term (Eom et al., 2008). Given that the subcontractor has worked with the general contractor previously, it could be beneficial to conduct evaluations to further develop the partnership and at the same time identify opportunities for improvement. One interviewee explains that collaboration combined with predictability is essential for delivering good results. Key relational elements were identified:

- The level of trust between the involved parties was sufficient and increasing throughout the first project and through the start of the second.
- Trust is a prerequisite to successful strategic partnering and collaborative project deliveries.
- Evaluation of the project and collaboration should have been carried out, especially at the end of the projects.

A successful strategic partnering relies, among other things, on effective collaboration between the contractor and subcontractor. Research indicates that by developing a positive relationship between them, productivity can also be enhanced (Eom et al., 2008). Additionally, the electrical subcontractor plans to use the same supplier on the second project and this could lead to more productivity according to Crutcher et al. (2001). However, it can be quite challenging to quantify whether productivity was good as there is little comparison basis.

CONCLUSIONS

This study analyzed two case projects to identify the presence of contractual, organizational, and relational elements in strategic partnering. Furthermore, it contributes to research on Lean construction by exploring strategic partnering as a collaborative project delivery method. The examination included an examination of the client, general contractor, and electrical subcontractor. This study provides a detailed and in-depth examination of strategic partnering, and as such, the results should not be considered representative of the broader phenomenon. Rather, the findings may offer a more in-depth understanding of the topic and be of use to individuals and organizations who consider strategic partnering in their projects. Furthermore, this research may also contribute to the existing knowledge about strategic partnering. The study reveals that many principles and characteristics outlined in the existing literature regarding strategic partnering were also present in the case projects. It was found that spending excessive time formulating collaboration specifications is an unnecessary and non-value creating activity. Project participants in the first project experienced improved productivity, aligning with the Lean philosophy of creating value for the client. The essential part of the collaboration between the parties is that each participant commits and dedicates themselves to the partnership.

The client and contractor developed a target price to ensure shared risk and reward, which can be important in collaborative project deliveries. Additionally, this study found that early contractor and subcontractor involvement is an important success factor in strategic partnering. It contributes to both establishing a relationship between the parties and building trust at an early stage. At the same time, the contractors are more prepared to commence the execution phase. Furthermore, a clear hierarchy for conflict resolution is emphasized through strategic partnering. There was a clear understanding between all project participants that any conflict or disagreements should be resolved at the project level. Continuity among key personnel in all parties throughout the projects was an important factor because replacing one of the main participants would require building new relationships from scratch. The following critical success factors were identified throughout the projects in a non-specific order.

- Target price development
- Early contractor involvement
- Building relationships at an early stage
- Conflict resolution strategy
- Contingency of key project participants
- Evaluation between projects

So far, the case study reveals that there is currently a lack of established best practices for evaluating each other's performance within the strategic partnership. To ensure the implementation of Lean principles, such as continuous improvement, it can be beneficial to arrange meetings where collaboration between the parties is evaluated. This can provide useful information about potential changes for both the pending and upcoming projects throughout the whole supply chain. To create a deeper understanding of the effects and benefits of strategic partnering in the construction industry further research is needed, including case studies and interdisciplinary studies.

SLACK: WHAT IS LACKING ON SUPPLY CHAIN RESILIENCE STRATEGIES?

Fernando Pereira[1], Marcus Fireman[2], and Bernardo Etges[3]

ABSTRACT

In complex systems, supply chains are more exposed to variability and uncertainties that lead companies to suffer negative effects on their performance and may even collapse. The civil construction sector is seen as a complex socio-technical system, therefore it must consider strategies that deal with these disturbances. Slack and resilience in the supply chain are topics that have already been discussed in several sectors of the industry and deal with these variables, however the literature is recent for the civil construction sector. It is understood that Slack can provide an improvement in the effect of supply chain resilience, however, there is no theoretical discussion that points out similarities and complementarities between slack and the concept of resilience in the supply chain to shed light on the uses and limitations of the practices. The study in question makes a theoretical discussion based on a literature review about these systems, compares their practices and strategies, similarities and complementarities and finally proposes future research. Findings of this study shows that one of the strategies like flexibility is more advanced on strategic issues such as pricing and flexible contracts in supply chain resilience theory than on slack theory. Other contributions are discussed for collaboration, social capital, margin of manoeuvre, agility and redundancy strategies.

KEYWORDS

Supply chain resilience, slack, strategies.

INTRODUCTION

Disruption in the supply chain is a phenomenon related to the interruption of the supply flow due to an unexpected event, usually having a high negative impact on the performance of organizations (Azadegan et al., 2021). Costs, revenues and deliveries can be harmed (Hendricks and Singhal, 2013; Ponomarov and Holcomb, 2009; Stecke and Kumar 2009; Ponis and Koronis, 2012), in addition to the possibility of losing market to the competition (Rezapour et al, 2016) or even collapse (Xu et al, 2014). With globalization, increased competitiveness, climate and environmental changes, as well as government and economic crises, supply chains have become more complex (Hendricks and Singhal, 2005; Pettit, Fiksel and Croxton, 2010) making disruptions frequent (Resilinc, 2018). At this point, in a recent study by McKinsey (2020) executives reported that they suffered on average a severe disruption in their supply

chain every 3.7 years and that every decade, a decrease in annual profit of around 45% can be expected.

Civil construction is a system with complex characteristics, which means that it is exposed to several social and organizational factors that can lead to instabilities, (Formoso et.al, 2021; Saurin, 2017) and, therefore, it is also subject to disruptions in the supply chain. It is therefore necessary to propose systems that are able to absorb variations and uncertainties, responding to the disturbances generated in order to minimize or even nullify the effects of these disturbances (Böhle et al 2016; Tukamuhabwa, 2015). Although little has been said about the disruption in the civil construction supply chain, showing that there is a knowledge gap that needs to be filled (Ekanayake et. al, 2021).

The phenomenon of supply chain resilience is a concept that precisely contemplates dealing with the challenges of disruption and has evolved in recent decades not only to propose ways to avoid or mitigate the effects of disruption, but to make it possible to learn from the process and in some cases allow progresses to a more efficient operational future state than the original (Shuai, Wang and Zao, 2011; Mandal, 2012; Pettit, Fiksel and Croxton, 2010, Melnyk et al. 2014). In recent years, studies in the area have identified the existence of a group of strategies that, when adopted help to mitigate the risks of disruption or to have faster and more effective responses to any disruption after it occurs, these strategies are classified into: Redundancy, Flexibility, Collaboration, Agility and Social Capital (Sawyer and Harrison, 2019; Polyviou, 2019; Pettit, et al. al 2019; Tukamuhabwa, 2015). The theme of supply chain resilience has gained space in the literature referring to several industrial sectors, however it has still been little discussed in civil construction (Ekanayake et al., 2020).

Recently, the concept of Slack was pointed out as an asset for resilience in complex systems, such as civil construction (Righi;Saurin, 2015). Bourgeois (1981) defines slack as a reserve of current or potential resources that allow an organization to successfully adapt to internal or external changes. Formoso et. al (2021) highlights that Slack has been used in the literature to describe a broad set of strategies to deal with complexity, Saurin; Werle (2017) corroborates this thought and highlights those slack strategies provide resources to adjust performance and maintain the "vital" functions of the operating system during expected and unexpected events. Fireman et al (2022) presented, from two pilot studies, a set of slack strategies applied in projects that went through a phase of disruption in the supply chain, however the study was more focused on investigating the strategies that were managed by planning and production control.

This paper aims to add clarity to the relationship of slack and supply chain resilience to answers the research question: "What are the strategies of slack and supply chain resilience theories that aim to avoid, mitigate or eliminate possible disruptions in the supply chain? Are there differences, similarities or complementarities between them?". This study is based on theoretical discussions coming from a literature review of the main papers that address strategies used in each system, highlighting similarities and complementarities so that companies can choose and apply the ones that best suit for their business environment context. Although the authors recognize that there are limitations in the literature reviews, which may not have addressed all strategies or theoretical definitions of the concepts. Finally, from the perspective of theoretical discussion, the paper provide guidance on future research on topics for the civil construction sector.

RESEARCH METHOD

The search to foster the theoretical discussion of supply chain resilience strategies consisted of finding the main systematic reviews of the literature in the last ten years using the Web of Knowledge and Google Scholar databases, for the advanced search the search string was used 'supply chain resilien* AND literature review', from the reading of the abstracts 13 papers were selected for the complete reading. Common themes of ways to perform in supply chain resilience appeared in these surveys: collaboration, flexibility, redundancy, agility and social capital. The authors then decided to explore each one of them, forming a base of 67 papers.

To verify what has been studied about supply chain resilience in the civil construction sector, the search string 'supply chain resilien* AND (civil construction OR construction industry)' was used, where only 28 relevant papers were found, indicating a possible line of research to be developed.

In the case of slack theories, the first search was carried out in the IGLC bases with the search string 'slack' resulting in 9 papers, of which 5 were selected after reading the abstract. To complement the search, the Web of Knowledge and Google Scholar databases were used again, with the strings 'slack AND (civil construction OR construction industry)', an extensive reading of the abstracts of 42 papers was made to select only 12 papers. Once again, themes common to the papers were found with regard to theoretical discussions of strategies to use slack: redundancy, flexibility and margin of manouvre.

As the two searches resulted in strategies to avoid disruption of the supply chain, so it was decided to investigate whether there are similarities, differences or complementarities between them and finally and propose a theoretical discussion.

LITERATURE REVIEW

SUPPLY CHAIN RESILIENCE

The concept of supply chain resilience has been studied with the aim of dealing with the challenges of disruption, where companies must avoid or respond quickly to disturbances and return to operational normality (Melnyk et al., 2014; Rice and Caniato , 2003) and even learn from the process and progress to an even better operational future state than the original (Shuai, Wang, and Zao, 2011; Mandal, 2012; Pettit, Fiksel, and Croxton, 2010, Melnyk et al. 2014) .

In the last two decades, studies have shed light on strategies to support supply chain resilience, whether reactive or proactive, depending on the application context (Tukamuhabwa, 2015). Sawyer; Harrison (2019); Polyviou (2019) and Pettit, et. al (2019) highlight the role of four main categories of strategy: Flexibility, Redundancy, Collaboration and Agility.

Redundancy

Redundancy is an element of the supply chain resilience strategy that involves the selective use of spare capacity and inventory to deal with supply shortages or demand variations (Parast and Shekarian, 2019). These spare capacity can be reserve stocks (Datta et. al, 2007; Pereira et. al, 2014); multiple supplier options in cases of low reliability (theme that can also be found in the flexibility strategy, but with regard to redundancy, it is related to having supplier options beyond the necessary demand and not just sharing capacity delivery between two or more suppliers, for a given demand) (Sheffi, 2001; Feng and Shi, 2012); reserve capacity of facilities, employees and modes of transport (Linnenluecke, 2017; Sheffi and Rice; 2005; Rezapour, Farahani and Pourakbar, 2016; Ponomarov and Holcomb, 2009).

Flexibility

Flexibility is a category that includes strategies that allow organizations to manage risks in the supply chain by adapting to changes in market demand or supply, causing resources to be reallocated quickly in turbulent scenarios and still maintaining performance in service levels (Tang and Tomlin, 2008; Stevenson et. al, 2008; Erol, Sauser and Mansuri, 2010; Christopher and Holweg 2011; Tukamuhabwa, 2015). Pereira et.al (2008) also points out that flexibility is a decision-making structure that allows responsiveness in the dynamics of environments.

Several strategies involving the concept of flexibilities are addressed in the literature, Tang and Tomlin (2008) list flexibility strategies in three dimensions: supply risks; process risks and demand risks. Supply risks involve multiple-supplier strategies to reduce dependence on a limited number of suppliers and flexible contracts for eventual demand adjustments, which allow changes in quantity orders between suppliers or over time (Li et. al, 2020; Wu et. al, 2019), another example can be strategies contemplating multi-modal transport (Tang, 2006). Process risks consider the flexibility of manufacturing processes or resources, such as production route alternatives due to the multi-purpose machine or even the adoption of multifunctional workers (Sheffi and Rice, 2005; Ekanayeke et al, 2021; Tang and Tomlin, 2008). Demand risks, on the other hand, are related to the flexibility of postponing production (Datta et. al, 2007) and product pricing (Zhanhai and Zhipeng, 2019).

Collaboration

Collaboration can be defined as the ability to work efficiently with other stakeholders to achieve common benefits by sharing risks, resources, information and knowledge (Parast and Shekarian, 2019; Scholter and Schilder, 2015). The collaboration strategy can contribute to reducing uncertainties inherent in the supply chain, as well as ensuring recovery in the face of a disruptive event and providing speed and agility to decision-making due to consensus between the parties (Scholten et.al, 2014).

In recent studies Duong and Chong (2020) gathered 157 literatures in a systematic review to confirm the hypothesis of the positive impact of collaboration for the recovery and response to disruptions, several collaboration mechanisms were pointed out in the authors' review, including contractual and economic practices, practices joint planning and control, relationship management, information and technology sharing, governance practices, supply chain design, and assessment and feedback practices in the post-disruption period.

A well-known example of collaboration is the case at Toyota, when Aisin Seiki's, one of Toyota's main suppliers responsible for supplying proportioning valves used in the brake system of all vehicles, suffered a serious fire. Due to just-in-time (JIT) principles, only about two or three days' worth of inventory was available. Toyota group companies, together with some external companies, immediately set up alternative production factories. The result was a feat, it was expected that the production of Toyota vehicles would stop for weeks, in just two days the plants started producing again (Nishiguchi and Beaudet 1998).

However, like most of the studied strategies, trade-offs are expected even in supply chain collaboration, Choi; Krause (2006) alert to horizontal collaboration and the risk of collusion between the parties, Jüttner; Maklan (2011) point out that there may be risks of sharing confidential information, sometimes strategic for companies.

Agility

This strategy revolves around the concept of rapid response to unpredictable changes in demand or in the supply chain (Christopher and Peck, 2004) in order to adapt, give pace and speed in the recovery of risk events (Shekarian et.al, 2020; Tukamuhabwa, 2015; Jüttner and Maklan 2011, Erol et.al, 2010).

Recent studies address the issue of technology as an increase in resilience performance through increased agility, involving blockchain, network inventories and real-time analysis, big data analytics and monitoring tools to increase supply chain visibility (Li et. al, 2022). Visibility is a key concept in the agility construct that helps to quickly identify the status of the chain and possible vulnerabilities (Tukamuhabwa et.al, 2015; Jüttner and Maklan 2011), it is closely connected with visual management and Lean Construction practices for problem solving (Saurin et al, 2021).

Social Capital

Polyviou (2019) conducts a study to explore strategies that allow small and medium-sized companies to be resilient, the author argues that companies of this size often do not have enough resources or power to use the strategies proposed so far, such as raising levels of safety stock, negotiate with multiple suppliers, and increase space, workforce, and equipment capacity. The analyzes of the study reveal other strategies in addition to those studied for large companies and that are linked to human resources, more specifically to social capital. In this point, Adler and Kwon (2002) define social capital as links or relationships between individuals or cohesive groups that seek the same goals.

The construct of social capital is formed by three dimensions: *structural capital*, *cognitive capital* and *relational capital* (Ghoshal, 1998). *Structural capital* is related to the links between actors in a given network and the patterns inherent to the links (Nahapiet and Ghoshal, 1998), examples of structural capital factors are the geographic proximity between decision makers and network size and hierarchy, in this case, the smaller the size of the network and the more horizontal the organization, the greater speed in decision-making, that is, it favors structural capital (Whittington et al., 2009; Inkpen and Tsang, 2005). *Cognitive capital* is related to the time of experience and knowledge of employees (Fischer and Pollock, 2004), and *relational capital* to team commitment, mutual respect and proximity in relationships (Nahapiet and Ghoshal, 1998).

SLACK

Slack is defined here as a reserve of resources that exceed or not the minimum necessary and that can be reallocated to support organizations to adjust performance in the face of expected and unexpected events (Fireman et al. 2022; Formoso et al. 2021; Saurin; Werle , 2017). It is possible to identify in the literature the existence of two dimensions of the slack concept, the first of which refers to which resources are being applied as slack (eg: time, equipment, projects, procedures, materials, etc.) while the second dimension is strategy-related how slack resources are being employed (Fireman et al., 2018). This paper seeks to address the second dimension, which brings the categories of strategies for the application of slack (Formoso, et al. 2021): Redundancy; Flexibility; Margins of Manoeuvre.

Redundancy

It is a category of strategy in which the resource is provided above the minimum amount necessary to perform a specific function (Nonaka, 1990), or when more than one resource performs the same function (Azadeh et al., 2016). As examples of this strategy are the redundant procedures for checking materials that must be sent to the project (Fireman et al., 2022); stock of materials (Formoso et al., 2021); and more than one foundation project considering different types of soil (Saurin et al., 2021).

In the literature on Slack, it is possible to identify four subcategories of redundancy (Formoso et al., 2021; Saurin and Werle 2017; Fireman et al.; 2022): (a) standby redundancy – strategy that deals with the adoption of resources that are not involved immediately in the running task; (b) active redundancy – when the applied resources are involved in the task; (c) redundant procedures that apply to specific cases of redundant procedures; (d) finally, the work-in-progress category, which adopts the strategy of using a backlog of available work areas (in the case of construction) or stock of semi-finished products.

Flexibility

Flexibility is seen in the literature on slack as a strategy related to the use of resources in diverse and adaptable ways (Formoso et al., 2021). At Toyota, workers' multifunctionality is naturally encouraged to absorb deviations in the production line (Shingo, 1989). Other examples of flexibility are multi-purpose equipment, flexible plant layout or even alternative sequence of production routes. The flexibility category is the most recent slack category presented in the literature (Formoso et al., 2021; Saurin, et al., 2021) which explains the low number of examples or the current lack of subcategories.

Margins of Manoeuvre

The third strategy, margin of manoeuvre, is considered a combination of the two previous strategies (Formoso et.al, 2021). It addresses the creation or maintenance of margins and additional resources that allow the system to continue to function despite unexpected demands (Saurin; Werle, 2017). Examples of this application can be seen in the study by Fireman et al (2022), which brings examples such as design changes to simplify connections in metallic parts in order to increase assembly speed; use of a reserve shift for production to correct line delays; contingency margins in the budget of suppliers. Stephens et al (2011) highlights the existence of three types of margins of manoeuvre: defensive – restrict actions of a unit or borrow margins from another unit; autonomous – local reorganization or adaptation of resources in cases of need; coordinated – creation of features that can be shared by two or more units.

DISCUSSION: SIMILARITIES AND COMPLEMENTS WITH SLACK STRATEGIES AND SUPPLY CHAIN RESILIENCE STRATEGIES

There are common points between the main strategies listed in the literature regarding slack and supply chain resilience, Table 1 represents strategies that are used for each concept. Of the six strategies presented, two themes studied are explicitly common to the slack and supply chain resilience literature: Redundancy and Flexibility. However, despite seeming to converge, apparently there are differences in the focus of action that will be commented further.

Table 1: Supply Chain Resilience and Slack Strategies

Strategies	Slack	Supply Chain Resilience
Redundancy	X	X
Flexibility	X	X
Collaboration		X
Agility		X
Social Capital		X
Margins of Manoeuvre	X	

Redundancy is a strategy that appears to have a greater degree of convergence between the two themes, it is mainly about maintaining a contingency of resources whether active or standby, as proposed by the slack literature. In the literature on supply chain resilience, although there are no clear subcategories, there are more popular examples such as capacity reserve, safety stock, backup facilities. There is a divergence regarding the role of procedural redundancy, a subcategory presents in the slack literature, but which is not identified in the supply chain resilience literature. In some situations, double-checking a critical process or supplier can be important to mitigate possible disruptions. Another important point is that the focus of slack literature has been on combating production uncertainties and not necessarily preventing a disruption in the supply chain. Examples of this are given in Saurin et. al (2021) utilizing foundation project redundancy or even reserve staff on important equipment. Fireman et. al (2018) and Saurin (2017) discuss the use of WIP (work-in-process) to have stocks of materials in different manufacturing stages, kit centers or distribution centers shared between construction trades can be examples of WIP to protect the flow production when there is instability in the production flow. These redundancy utilization strategies are more connected to production planning and control rather than supply chain resilience.

Flexibility: strategy that considers the adaptation of changes with existing resources in the company. At this point, supply chain resilience studies seem to be more advanced with regard to strategic issues to deal with supply chain demand variability and disruptions. For product pricing flexibility, for example, Tang and Tomlin (2008) cite the case of Dell, where the factory of one of its main suppliers suffered from an earthquake that compromised the delivery of components for a certain line of computers, Dell's response outside of lowering prices on other computers that did not depend on that supplier's components and thus altering demand. Behzadi et al, (2017) proposes a mathematical modeling on the multiple-sourcing strategy in the agriculture sector and concludes that this is efficient to avoid financial losses, but does not have a good performance to avoid climatic risks of harvests. Li et.al (2020) study two types of flexible contracts for risk sharing, one with the possibility of changing quantities and another with capacity reserve, they conclude that when there is no coordination in the supply chain ie - when the decentralized system does not make profits equivalent to the centralized system, these contract models perform better than contracts with less flexibility. As for issues involving operational problems, they converge in slack and the literature of supply chain resilient, such as developing skills in teams, relocation of workers to higher priority jobs, creation of alternative layouts, flexibility in changing processes to meet critical change scenarios (Saurin et.al 2021; Fireman et. al, 2022). Once again, as in the case of the redundancy strategy, the flexibility strategies used in slack seem to be more focused on the concepts of production planning and control and not on supply chain resilience. On the other hand the literature of Slack presents procedures redundancy as a subcategories of redundancy, but it is not presented on supply chain literature. Figure 1 shows the subcategories of flexibility and redundancy in the slack and supply chain resilience literatures.

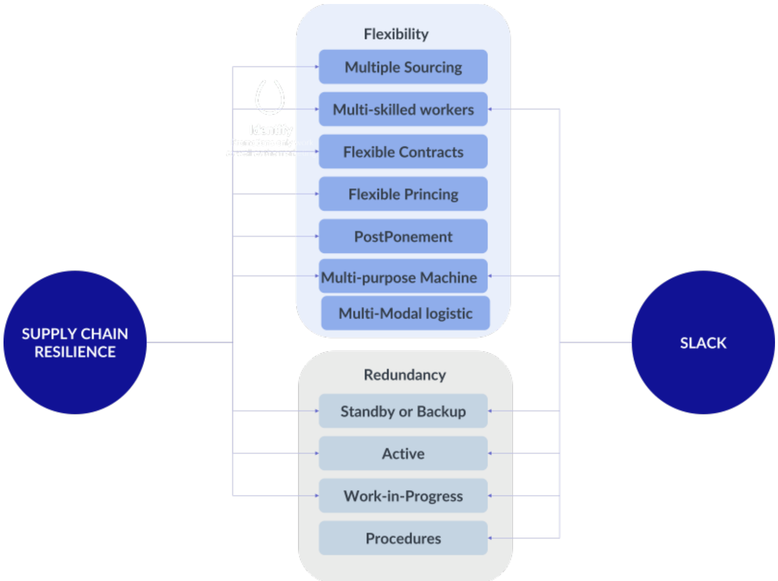

Figure 1: Redundancy and Flexibility Map

Collaboration and Margins of Manouver: It is possible to verify that there is a certain relationship between the two strategies, since the subcategories margins of manouver defensive or a coordinated it is possible to identify that there is an implicit model of collaboration, whether achieved through borrowing or sharing resources. However, the collaboration strategy has a greater focus on the supply chain external to the production environment (factory or, in the case of civil construction, the construction site), its networks of connections and development of trust, risk sharing, predictability of delivery, knowledge exchange, and postponement and resource sharing. A relevant theme for case studies involving the civil construction sector is the deepening of the trade-offs pointed out in the cited literature, to study the extent to which collaboration can be used, for example: is there any kind of conflict of interest when integrating a certain part of the supply chain? What company information can be shared with a certain network of suppliers that does not compromise the strategic advantages over the competition?

Agility: theme correlated with the use of visual management and indicators for the quick perception of problems related to suppliers, in order to detect possible threats in the chain. In the slack literature related to the civil construction sector, they point out themes that can be considered agility strategies inside other strategies, such as Saurin et al (2021) put examples of importance of daily meetings where employees detect problems to propose quick solutions and sometimes reallocated resources between teams, as defined in the flexibility strategy. Saurin and Werle (2017) still argue that visibility, a nomenclature used synonymously with agility, is a way of classifying resources.

Social Capital: strategy that enters the field of behavioral studies of human resources, there is also similarity in these resilience strategies in the supply chain with what is discussed in slack. In this point, the initial study related to slack on complex socio-technical systems presented by Saurin and Werle (2017) pointed out that discuss problem-solving techniques were classified as a category os slack strategy known as cognitive diversity. So, there is convergence with the strategy of Cognitive Capital pointed out by Polyviou et.al (2019), which aims to share knowledge of experienced employees for others. Means of measuring the performance of these strategies are still scarce in civil construction studies, as well as frameworks and case studies that shed light on how to develop these skills in human resources, with the scope to improve the effect of supply chain resilience.

CONCLUSIONS

The concept of slack is still not widespread in the civil construction sector, as well as strategies to improve aspects of supply chain resilience. Disruptions in the supply chain can be caused by external factors such as catastrophes and wars, although we must remember that these disruptions are also frequent in characteristics internal to the context of the business model, such as competition, new demands for products, relationship with the supplier network, among others. It is therefore inferred that there is a knowledge gap that needs to be taken advantage of to make companies more efficient in relation to supply chain resilience in the civil construction environment, and that they are able not only to pass unscathed through turbulent times, but that they are able to develop new ones. opportunities from them.

There are several similarities between the studies of slack strategies with supply chain resilience, theoretical definitions and discussions should be improved in order to facilitate the understanding of the topics, so companies can choose which methods and how much resources they should employ in the solutions theories without misunderstanding of concepts and duplication of applications. The present study demonstrated that there is a wide field of study on slack strategies related to flexibility, since in the resilient supply chain literature there are important subcategories that have not yet been addressed in slack studies as multiple sourcing, flexible contracts, flexible princing, postponement and multi-modal logistic. On the other hand the literature of Slack presents procedures redundancy as a subcategories of redundancy, but it is not presented on supply chain literature.

Another important point of the paper was to bring more clarity about the differences between the redundancy and flexibility strategies, which currently prove to be very close to the performance limit of each one. In this regard, it is possible to note that there is greater clarity in the supply chain literature on the difference between the two, since while the redundancy strategy seeks to work with an excess of capacity than necessary to respond to disruptions, the second has as its main objective to create capacities in existing resources to promote adjustments as demand changes occur (Xu, 2008; Datta et.al, 2007).

Finally, this study sought to confirm the importance of slack in the effects of resilience in companies, more specifically in supply chain resilience. It should also be noted that future research should study the trade-offs listed in this study to optimize their applications and choices in the desired context.

FUTURE RESEARCH

Below are some suggestions for possible future research:

- Case studies involving the application of resilience and slack strategies and lean construction mediating theses strategies.
- Performance measurement of strategies in different contexts.
- Frameworks for implementing supply chain resilience concepts adapted to the civil construction supply chain in different sectors: SMEs, infrastructure works, construction buildings, etc.

RESEARCH LIMITATIONS

Theoretical discussions are limited to current research and literature review, other concepts and discussions may not have been addressed.

Few case study examples are placed in the AEC industry, which may hinder the practical interpretation of supply chain resilience strategy concepts

SUCCESS IN INTERRELATED SUPPLY CHAIN: AN ANALYSIS OF THE HUMAN BEHAVIOUR UNDER CRISIS

Mani Poshdar[1], Rodrigo F. Herrera[2], and Vicente A. González[3]

ABSTRACT

A wealth of studies is available on the key success factors of managing interrelated projects in a construction supply chain. The human factor, however, is often overlooked in normative success solutions. According to classical management theory, individuals are expected to act rationally and maximise their utility. Although, due to an individual's computational and cognitive abilities, decision-makers often choose the first satisfactory course of action rather than searching for the optimal course of action, particularly during times of crisis. This study adopted a surrogate model to conduct a series of laboratory simulations that involved human behaviour. A comprehensive literature review was conducted to determine the experiment design, followed by sixteen hours of experiments that spanned two countries investigating decision-making behaviour within two prominent management models: the traditional and collaborative models. In order to identify patterns in the perception of the participants regarding real success factors, a content analysis was performed on their questionnaire responses. This analysis identified three key characteristics of construction success and the top characteristics required to succeed under each model investigated. By sharing these insights and lessons learned, teams can gain a deeper understanding of what it takes to succeed in a competitive environment.

KEYWORDS

Supply chain management, Simulations, Collaborative, Action learning, Collaboration.

INTRODUCTION

In the wake of the COVID-19 pandemic, the "New Normal" is characterised by a crisis-like environment, deep uncertainty, and adaptability instead of stability and long-term planning (Araya, 2021). Consequently, preparedness, recovery, and adaptation decisions must be planned and deployed in the context of concurrent disruptions (Herrera et al., 2022). To date, the impacts of COVID-19 have received considerable attention across a wide range of industries. Nevertheless, the construction sector still has much to learn about the problem and potential solutions (Cherian & Arun, 2022). As with other industries, the construction, procurement, and logistics sectors experienced unforeseen disruptions due to COVID-19's rigorous lockdowns, which also affected supply chain management. It exacerbated the chronic issues of cost

overruns, schedule delays, and low productivity in the construction industry (Doloi, 2013; Herrera et al., 2020; Venkatesh & Venkatesan, 2017). Research indicates that improving the product development process, supply chain coordination, and the standardisation of parts and components can mitigate the impact of these recurring issues. In order to achieve these goals, the importance of improving client-contractor interactions cannot be overstated, particularly through establishing strategic alliances and partnerships that facilitate real collaboration (Chen et al., 2012; Dainty et al., 2001; Engebø et al., 2020; Lahdenpera, 2017; Mesa et al., 2019).

Lean emphasises collaboration, supported by process ontology, to address the interrelationships between tasks (Tzortzopoulos et al., 2020). The success of any collaborative approach depends on the participation of individuals. While normative solutions are often used to achieve operational goals, they tend to rely on simplistic behavioural assumptions that fail to take into account the complexity of human behaviour (Ghodrati et al., 2022; Gino & Pisano, 2008; González et al., 2015). The classical economics theory typically assumes that individuals act rationally and make decisions to maximise their utility (Parnell & Crandall, 2020). However, rationality is bounded by human computational and cognitive capabilities (Selten, 1990). Consequently, decision-making patterns in projects are often inconsistent with normative theories, especially in complex situations (Kahneman et al., 1982). In 1957, the concept of bounded rationality was introduced (Simon, 1957). The approach emphasises effective behaviour rather than an idealised state of perfect rationality. Informational inadequacies, time constraints, and cognitive limitations all contribute to the inability to make perfect, rational, and well-informed decisions. (Diacon et al., 2013). It is, therefore, more likely that in times of crisis, a satisfactory or suitable decision will be reached in which the decisions are adequate but not perfect. (Parnell & Crandall, 2020). When faced with such circumstances, decision-makers often choose the most suitable course of action instead of continuing to search for the optimal course of action (Fox, 2015).

Our primary objective in this study was to explore how behavioural patterns in decision-making can be linked to the construction supply chain dynamics, especially during a crisis. This research belongs to the behavioural operations management field and adopts a laboratory-based experimental strategy applied in a number of social science fields, including economics, psychology and sociology, law, political science, anthropology and biology (Katok, 2019). There is a high cost and/or disruption associated with investigating the influence of human behaviour on collaboration dynamics in a real system under a variety of conditions. A laboratory experiment can simulate a situation while isolating the intended variables from the rest. Laboratory experiments became mainstream research setting in social science in 1875. It was not until the 1980s that operations management research began to take it up. As a result, surrogate models are the preferred approach for laboratory simulations. They allow a complete manipulation of all factors to match the study assumptions (Bolton & Ockenfels, 2008).

RESEARCH DESIGN

The overall research design is presented in Figure 1. The study started with an extensive literature review to identify the experiment design. The experiments were conducted in two countries over four days, consisting of two rounds each day. In the first round, all participants acted independently, simulating the traditional supply chain management model. Participants adopted a collaborative approach in the second round, in which they agreed to work together to achieve a specific objective. The decision behaviour patterns of participants were recorded and analysed based on their perceptions. To obtain participants' perceptions regarding their experiences under each model, a questionnaire was administered after each round. Upon completion of day 4, a content analysis was carried out to identify patterns in the recorded results. By conducting the same experiment in two different countries, we were able to detect any cultural nuances that might have impacted the results.

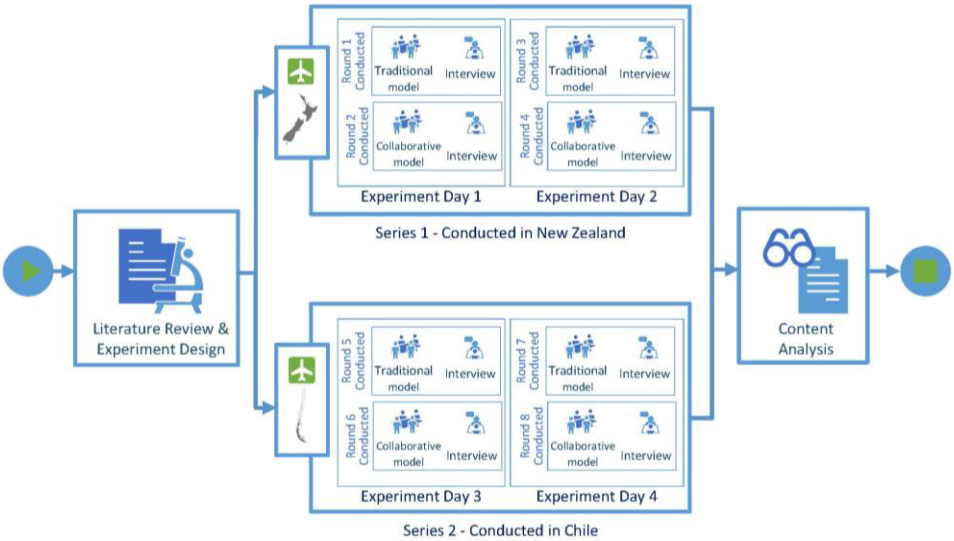

Figure 1: The research design

THE EXPERIMENT STRUCTURE

The experiment simulated a simplified version of the supply chain for five bridge construction projects, including prefabrication and shipping stages. Figure 2 shows the entities and relationships involved in creating a conceptual model of a system according to the standard steps (Abdelmegid et al., 2017; Abdelmegid et al., 2020; Poshdar et al., 2016). A total of six individuals representing key members of the supply chain participated in the experiment.

- Two participants represented the manufacturers responsible for fabricating the structural components (Fabricator 1 and Fabricator 2).
- Two participants represented transportation agencies responsible for delivering prefabricated components to the construction site (Shipping 1 and Shipping 2).
- Two participants represented contractors involved in the construction project (Contractor 1 and Contractor 2).

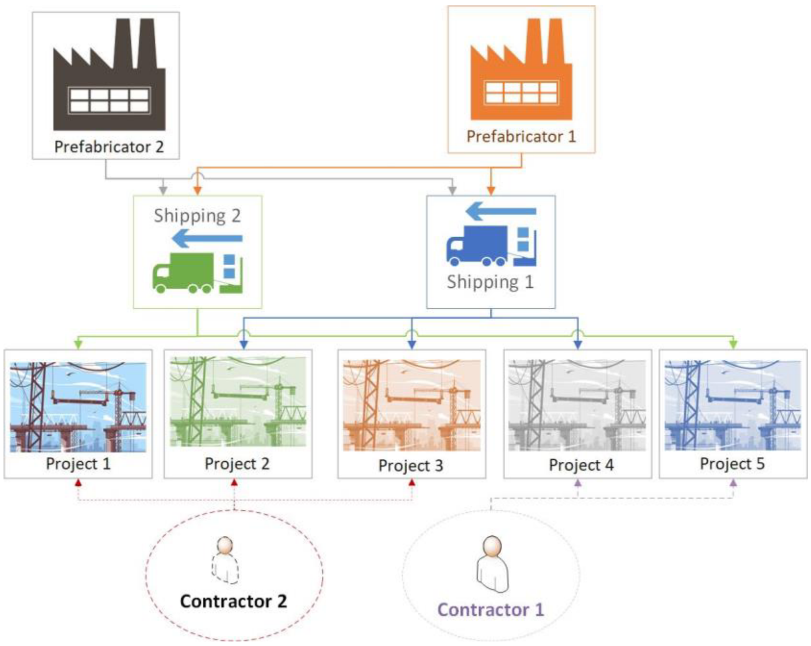

Figure 2: The experiment structure

The bridge components were those recommended by Waka Kotahi, the New Zealand Transport Authority. Detailed information about the simulated projects is presented in Table 1.

Table 1: Characteristics of the projects simulated.

Project #	Number of beams	Type of beams	Span length (mm)	Shipping distance (km)
Project 1	9	Single hollow core beam, 900 mm Depth	25,000	450
Project 2	5	Super T beams	30,000	86
Project 3	4	Single hollow core beam	27,500	242
Project 4	9	Single hollow core beam, 650 mm Depth	18,000	91
Project 5	9	Single hollow core beam, 650 mm Depth	16,000	408

A rough budget was assigned to each activity based on the size of the project and shipping distance (Table 2).

Table 2: Budgets allocated to each activity within the supply chain divided by projects.

Project #	**Prefabrication ($)**	**Transportation ($)**	**Construction ($)**
Project1	277,000	208,000	2,079,000
Project2	277,000	46,000	2,703,000
Project3	185,000	46,000	2,657,000
Project4	277,000	46,000	1,409,000
Project5	277,000	116,000	1,409,000

A 10% contingency was built into the quantity take-off price in the budget. The calculated prices are summarised in Table 3.

Table 3: Summary of activity costs.

Costs Associated	**Prefabrication** ($ Per week)		**Transportation** ($ Per week)	**Construction** ($ Per week)						
	Line set up.	Operations	Operations	Site Establishment	Staging Installation	Precast Beam	Deck	Parapet	Remove Staging	Urban Design & Walkways
Direct cost	8,000	68,000	9,000	120,000	40,000	40,000	70,000	20,000	70,000	30,000
Overhead	2,000	2,000	1,000	10,000	10,000	10,000	10,000	10,000	10,000	10,000
Total	10,000	70,000	10,000	130,000	50,000	50,000	80,000	30,000	80,000	40,000

Each participant could face two types of delays to imitate real-life pressure on a decision-maker.

- Normal delay that its likelihood was between 6% to 10%, which was implemented as a randomly generated number for each activity.
- A pandemic delay would apply a locked-down period with an arbitrary length of between 5 and 10 weeks. The purpose of this study was to examine the decision-making behaviour of supply chain members during times of crisis. Therefore, all experiments involved the delay caused by a pandemic.

THE EXPERIMENT PROTOCOL

Each round of the experiment involved the following five steps:

Step 1 - The facilitator described the experiment structure and rules, allocated roles and funds. The roles were assigned randomly, and participants remained with the same role for the whole experiment. A random number generator was then used to determine the length and the start week of the delay caused by the pandemic. The participants were not informed about this latter information until the due week.

Step 2 – Participants started planning their operations. They could decide when to start each activity to minimise costs and maximise profit. However, once it had begun, they could not stop overhead payments or add additional working shifts to speed things up. The reactive approaches were restricted in order to avoid an overwhelming level of complexity.

Step 3 – The experiment set the time unit of the operations as weeks. The facilitator would announce the start of each week while running a random number generator to identify and inform the participants about the typical delay for each activity. The players would implement their plan accordingly, and the costs were deducted per operating over a week.

Step 4 – A full round of the experiment finished when all participants had their activities completed.

Step 5 – A questionnaire with the following five open-ended questions distributed among the participants. It was used to assess participants' perceptions of the factors that influenced their decision patterns, and those that could contribute to their success under each model.

- Did you find any operational strategy useful to achieve success in the collaborative phase?
- What would you do if, at some point, your profit opposed the team's benefit under the collaborative model? Have you ever encountered such a situation in this experiment?
- What are the top five characteristics that can help a player succeed in a collaborative environment? Why?
- What are the top five characteristics that can help a player succeed in the traditional model? Why?

Although we provided some examples for questions 3 and 4, participants were given the autonomy to include any items they deemed relevant.

The criteria for success in these experiments were defined based on two common Key Performance Indicators (KPIs): time and cost. The measurement of success was based on the achievement of these criteria. In order to create personal incentives, in each round, the participant who could achieve the highest ratio of earnings to the allocated budget would receive a 30$ voucher and a bar of Chocolate.

IMPLEMENTATION OF THE EXPERIMENTS

During April and May 2022, four rounds of experiments were carried out in New Zealand, two simulating the traditional model and two simulating the collaborative model. Twelve undergraduate engineering participants participated in this series. In August and September 2022, the same four rounds of simulations were conducted with 18 undergraduate civil engineering participants from Chile. A random sampling approach was used to select the participants. Since each individual in the population had an equal chance of participating, regardless of their characteristics or traits, this approach ensured a reduced bias in the results.

The experiment took an average of two hours for each round. Thus, a full experiment day took around four hours, and a total of sixteen hours were spent conducting the experiments for this study. All decisions and movements made by the participants were recorded using a spreadsheet. The following is a breakdown of the average completion length (in nominal weeks) recorded for each project: Project 1: 45; Project 2: 41; Project 3: 36; Project 4: 25; Project 5: 31.

RESULTS AND DISCUSSION

The first question invited participants to reflect on their experiences and identify strategies that proved effective in achieving success.

The result: Communication and coordination were among the most frequently recorded success factors. *The Discussion:* Transparent communication from the beginning of projects was indicated to be crucial to planning and minimising downtimes. A well-coordinated strategy is essential for the success of any team effort. In a competitive environment, this is even more critical. Additionally, the participants stressed the importance of teamwork and collaboration when prioritising activities. Working together to identify long-term goals helps ensure that all team members work towards a common goal and can prioritise their activities accordingly (Zulch, 2014). In order to achieve success, the participants also suggested that an initial kick-off meeting could be an instrumental step, as it can enable discussion of strategies and the development of agreements with others. These meetings allow all shareholders to discuss strategies and reach agreements about the common goal.

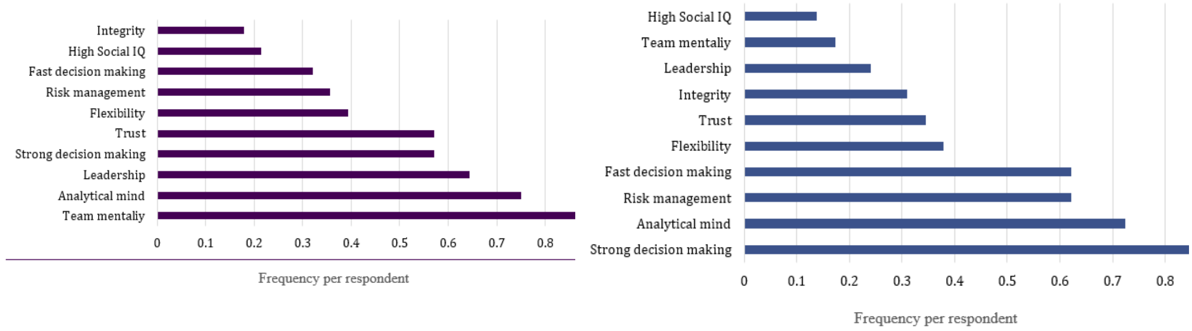
Managing projects effectively requires a global and systemic understanding of operations and supply chain members. With a global perspective, managers can identify areas where costs and delays can be reduced. Additionally, by having a systemic view of the supply chain, they can assess potential risks and plan accordingly to ensure that the project is completed on time and efficiently. To involve a systemic understanding in project management, managers should create a detailed map of the entire supply chain, identify bottlenecks, and analyse the dependencies between each supply chain member. It will help them to identify opportunities for cost savings, as well as potential areas of risk. Additionally, they should create a timeline for the entire project and ensure that all stakeholders and supply chain members know their responsibilities and deadlines (Chou & Yang, 2012).

The result: In addition, the participants stressed the importance of mutual agreement and trust between all parties to achieve success. *The Discussion:* In order to ensure that the project is completed effectively, it is imperative to build trust and establish positive relationships between all parties. It ultimately reduces disputes, reduces costs, and increases overall project success. These relationships should be maintained throughout the project timeline to ensure everyone is on the same page and working towards a successful outcome. Trust can be built through regular meetings between parties to review progress and discuss any potential issues or risks. Additionally, creating a safe and open environment where people can share their ideas, concerns, and feedback is another way to establish trust and build strong relationships (de Oliveira & Rabechini Jr, 2019; Karlsen et al., 2008).

The second question presented a thought-provoking dilemma for the participants, testing the balance between personal gain and team success. Having personal interests that conflict with team benefits is a real-life scenario that can occur in a variety of contexts, including construction.

The result: The answers show that the participants understand the importance of teamwork for achieving success under a collaborative model. Participants prioritised common benefits and collaboration in decision-making, while also emphasising the importance of optimising the global project and synchronising agents. Despite the potential for individual gains, sacrificing personal gain for the greater good of the team was seen as critical by the participants, who displayed a high level of integrity in choosing the team's benefit over their own profit. *The Discussion:* The participants' emphasis on prioritising common benefits, collaborating in decision-making, and sacrificing personal gain for the team's benefit are in line with the literature on effective team dynamics and collaboration. The collaborative model, in which parties share profits, risks, and responsibilities, is becoming increasingly popular in the construction industry as a means of fostering collaboration and improving project outcomes (Anvuur & Kumaraswamy, 2007; Elghaish et al., 2020; Giménez et al., 2022; Lahdenperä, 2012).

It is paramount to possess certain key characteristics to succeed in the collaborative model in the construction and project management world. It led to the third question covering the top qualities of success in the collaborative model.



(a) The collaborative approach

(b) The traditional approach

Figure 3: The perspectives about the success factors

Figure 3 (a) summarises the ideas based on the frequency of occurrence in the responses to question 3.

The result: According to the participants, team mentality and approaching the project as a collective effort were the most relevant characteristics for success in a collaborative environment. *The discussion:* When the team is united, they can share ideas and resources more effectively and better understand each other's strengths and weaknesses. It allows them to better coordinate tasks and collaborate on solutions (Mack et al., 2008).

The result: A strong analytical mind was found to be among the top three important factors to success for participants. It allows them to assess situations, identify potential problems, and make informed decisions. *The discussion:* teams need to understand better the problem and the resources available to find solutions more effectively. Analytical skills can assist teams in resolving problems more effectively, creating a more harmonious environment that facilitates achieving the desired results (Asfar et al., 2021).

The result: Participants ranked leadership as the third most influential factor that would lead to success. *The discussion:* It involves leading the team to achieve common goals, making decisions, and resolving conflicts. Effective leaders can motivate the team, inspire them to work together, and set a positive example. They can listen to the team and consider their opinions when making decisions. They can also manage conflicts effectively and maintain a healthy work atmosphere (Nishizaki & Seed, 2015). There was some difference between the identified success factors of the traditional model and those of the collaborative model. **Error! Reference source not found.**(b) summarises the answers to the fourth question regarding the success factors of the traditional model based on the frequency of items among the responses.

The result: In the eyes of our participants, strong decision-making stood first among all other success factors. *The discussion:* The construction sector often involves a considerable amount of decision-making, risk assessment and quick thinking. It is particularly critical to developing these skills in traditional models. In the model, individuals are valued for managing risks effectively and coming up with smart decisions (Flyvbjerg, 2021). Therefore, it is crucial to have strong decision-making skills, as decisions are expected to be reached quickly and effectively without the support of a large team.

The result: Strong decision-making skills are crucial in the traditional model, as participants are expected to make quick and effective decisions without relying on the support of a larger team. *The discussion:* A strong analytical mind was also listed as one of the three most important characteristics of success in this model. An analytical mind helps individuals better understand the world's complexities, identify patterns, and make informed decisions that can lead to greater success (Alvarenga et al., 2019).

The result: Risk management has been identified as one of the top three success factors in the traditional model. *The discussion:* A thorough understanding of the construction industry and a strong ability to assess risks and evaluate potential outcomes are required for supply chain members to assess risks, evaluate potential outcomes, and make decisions accordingly. Risk management can assist in identifying and resolving upcoming problems before they become issues. Moreover, it can minimise the negative effects of any risks that may occur and ensure that the project remains on schedule and within budget (Micán et al., 2020).

The result: Both the collaborative and traditional models in the construction industry emphasise analytical mind but require different specific traits for success. The collaborative model emphasises team mentality and leadership, while the traditional model emphasises strong decision-making and risk management.

The result: Most participants preferred the collaborative model over the traditional one to achieve success when asked after the experiments. The main reason for this preference was the ability to better coordinate and communicate with their peers, which led them to make more effective and efficient decisions which could result in lower risk-taking. Participants believed collaboration and teamwork could improve workflow, reduce costs, and achieve better results. The collaborative model, according to them, also contributed to more equitable profit distribution and improved performance. Additionally, participants noted the importance of sharing information and risks, as well as enhanced synchronisation, which contributed to their success. Overall, participants reported that the collaborative model provided better coordination, communication, and cooperation among all members, resulting in faster, more efficient, and more successful outcomes.

The result: Although there were some differences in frequency between the two countries, the items and their order followed a similar pattern. It suggests that the findings were largely independent of the work environment in the two countries, providing an accurate comparison for further research.

CONCLUSIONS

Using a laboratory experiment methodology, behavioural operations management research was conducted to examine how decision-making behaviour patterns and crises impact typical construction supply chain members. We conducted four days of experiments in two countries, each with two rounds. A traditional work model was simulated in the first round, while a collaborative approach was tested in the second round. After the administration of a questionnaire and a content analysis, several key points were identified.

When comparing the collaborative and traditional models of managing supply chains in the construction industry, it is evident that both models prioritise certain key characteristics, such as analytical thinking. However, it is imperative to note that each model requires different characteristics to succeed. The collaborative model emphasises team mentality and leadership. In this model, it is essential to have a team player who collaborates with others. Any team member should be able to prioritise the team's benefit over their interests. Additionally, effective team leadership and management practices can facilitate team cohesion and support collaborative project management efforts.

On the other hand, the traditional model emphasises traits such as decision-making ability and risk management ability. In this approach, various stakeholders are expected to work independently. It is essential for individuals to possess strong decision-making skills and manage risks independently. Effective decision-making involves evaluating multiple options and choosing the most appropriate course of action based on relevant information, while risk management involves identifying and mitigating potential hazards and uncertainties.

Sharing insights and lessons learned from these experiments contributed to developing a collective understanding of what it takes to succeed in a competitive environment. Teams seeking to improve their performance and achieve their objectives can benefit from this information.

This study presents the first step in developing a laboratory experimental approach to investigating management strategies. There were some limitations to this study regarding the number of experiments, the number of models tested, and the sampling criteria for participants. Therefore, further research is required to verify the reliability of the results. During future research, experiment sizes will be increased, and new models will be tested using different sampling criteria for participants. Cognitive errors may also have negatively affected the results. For example, trust, team mentality and integrity are three concepts susceptible to being confused in participants' minds. In order to accurately measure data, it is critical to define reliable indicators for each concept. To determine the impact of these factors separately, it would be appropriate to focus on one concept at a time. It would ensure that the data collected is specific to that concept and not impacted by any other concepts being studied. It will help to minimise ambiguity and ensure that the data accurately reflects the intended meaning of the concepts.

ACKNOWLEDGMENTS

We would like to thank Dr Nariman Ghodrati, all participants and the teaching assistants who took part in the simulations. We would also like to thank the Collaborative International Interuniversity Research, Innovation and Development Program of the Auckland University of Technology and Pontificia Universidad Católica de Valparaíso for funding this research project through the CIIRID IDEA Funds.

DEVELOPMENT OF AN OPTIMIZATION MODEL BASED ON BUSINESS PROCESS RE-ENGINEERING TO MINIMIZE CONSTRUCTION PROJECTS DELAY

Muhammad Atiq Ur Rehman[1], Sharfuddin Ahmed Khan[2], Taha Arbaoui[3], Mickael Huot[4], and Amin Chaabane[5]

ABSTRACT

Related decisions can affect project scheduling in a construction supply chain (CSC). After all, the project activities require vital resources and collaboration among project stakeholders. That effects can occur negatively, such as delay, budget overrun, and project performance. These effects are considered wastes in lean construction (LC). The concept of LC is still limited regarding application in CSC. This study aims to develop a decision-making model (LC tool) to minimize project delays using a mixed integer linear programming optimization model. The proposed model is triggered by the business process re-engineering of the scheduling process.

A construction company case example that delivers construction renovation projects to its customers is considered for validation. This approach is applied in two stages. In the first stage, the information process flow of the company is developed to derive the inputs required for the logistics and scheduling optimization model. Then in the second stage, the mathematical model is developed based on the inputs to generate optimal supplier selection, projects schedules, and resource utilization decisions. By using the proposed LC tool, the results show that delays in multiple projects can be minimized. Finally, decision-makers can use this technique to manage concurrent projects and suppliers that leanly provide essential resources to these projects.

KEYWORDS

Lean Construction (LC), Construction Supply Chain (CSC), Optimization, Offsite Construction, Scheduling

INTRODUCTION

Lean construction (LC) or lean manufacturing focuses on the constant effort of removing waste, meeting or exceeding all customer expectations, focusing on the entire value chain, and

increasing efficiency or productivity in the execution of a construction project or manufacturing process (Eldeep, Farag, & Abd El-hafez; Mossman, 2018) and (Zimmer, Salem, Genaidy, & Shell, 2008). The lean theory has five fundamentals: value, value stream, flow, pull, and perfection. The lean philosophy aims to increase customer value while eradicating waste. Lean construction considers the construction processes as a flow of activities, and all non-value-adding activities are considered as "waste" (Eldeep et al., 2022).
The objective of lean philosophy is to minimize waste. In LC, the activities or events considered as "waste" are defects, overproduction, waiting, over-utilized talent, transportation, inventory, motion, and extra processing (Igwe, Hammad, & Nasiri, 2022). Therefore, any approach or tool that minimizes these wastes can be considered an LC tool. Based on the literature, LC tools for construction supply chain management (CSCM) can be qualitative such as just in time (JIT), or only quantitative such as mathematical optimization (Uriarte, Ng, & Moris, 2018), or hybrid method (Li, Fan, & Wu, 2010).

CSCM manages communication and actions among project stakeholders who collaborate to ensure appropriate responses to the varying demand and supply signals across supply chain functions (Mello, Gosling, Naim, Strandhagen, & Brett, 2017). An efficient construction supply chain (CSC) enables cost savings, schedule compression, decreased material lead time, and high-quality construction projects (Le, Elmughrabi, Dao, & Chaabane, 2020). CSCM is a promising approach to successfully integrating several internal and external players (suppliers, designers, vendors, contractors, subcontractors, and internal and external clients) (Le, 2020).

Lean supply chain management is an important field of research. Different frameworks have been proposed and applied successfully in many industries (automotive, retail, etc.) and service sectors (healthcare, financial, etc.) (Jasti & Kodali, 2015). Lean and construction supply chain management needs a better understanding ((Le & Nguyen, 2022) ; (Zimmer et al., 2008)). More research will help develop LC tools that improve CSC at different construction project phases and deal with CSC issues, such as delays in projects in both breadth and depth (Liu & Lu, 2017). Therefore, this research proposes a lean construction tool to minimize delays in construction project scheduling activities by combining two Lean supply chain management pillars: business process re-engineering (Information technology) and logistics optimization (Logistics Management).

LITERATURE REVIEW

CSCM is a popular and emerging topic. A recent literature review study shows six established research clusters: logistics and SCM for prefabricated construction, construction procurement, CSC integration, green construction SCM, reverse logistics in construction, and onsite construction logistics (Nguyen & Le, 2022).

Hatmoko & Scott (2010) defined construction SCM as a system where suppliers, contractors, clients, and their agents work together to install and utilize information to produce and deliver materials, plant, temporary works, equipment, labor and/or other resources for construction projects. The concept of the construction SCM implicitly provides the opportunity for substantial improvements in client and stakeholder value through a strategic look at profitability. Lean construction is more effective if it integrates with supply chain collaboration, especially long-term collaboration. In other words, supply chain collaboration facilitates lean application and accelerates lean transformation (Meng, 2019)

Lean construction(LC) provides principles and tools that support companies to recognize and remove non-value addition activities or tasks from processes, improve productivity, and provide value to customers. Optimum results could be obtained by continuously striving for improvement (Plenert, 2011). LC can work with other construction technologies, and there is an increase in the integration of (LC) and Building Information Modelling (BIM) to derive benefits(Marte Gómez, Daniel, Yanquing, Oloke, & Gyoh, 2021). There is little literature regarding applying business process re-engineering and mathematical optimization to achieve lean construction (LC) in CSC. The following table shows the search results of different keywords used in the Scopus database.

Table 1: Search Keywords Result

Query	Keywords	Results
1	lean construction AND supply chain AND scheduling	22
2	lean construction AND supply chain AND performance improvement	30
3	supply chain AND lean construction AND business process AND optimization	6
4	supply chain AND lean construction AND business process AND optimization AND scheduling	2

The two papers combining the fourth query keywords do not focus on CSC, and the papers resulting in the third query keywords combination is six. Out of six, only two were relevant to CSC. They developed a software platform system and integrated project stakeholders and Building Information Modelling (BIM) technology to collaborate to achieve lean construction digitally and improve project performance collectively (Yungui, Kuining, Yongbin, & Tao, 2014). One study proposed a methodology to integrate principles of lean construction and constraints of resource scheduling into a constraint programming optimization formulation to improve construction productivity and logistical efficiency (Liu & Lu, 2017).

Some papers deal with construction supply chain optimization, including supplier selection and minimization of project delays. However, none are linked with lean construction, as evaluated above in the literature search results.

For the mathematical model to give output, it requires input data, which are parameters. This paper applies LC methodology to minimize waste and attain the parameters necessary to minimize project delays. Some papers applied optimization in construction project scheduling and supplier selection.

Mirghaderi & Modiri (2021) developed a heuristic-based multi-objective mathematical model under uncertainty investigated for construction material supply chain design. The considered supply chain comprises a primary supplier and a number of projects (i.e., customers) demanding different construction materials in different periods depending on the technical specifications of the demanded product in terms of lifetime.

A mathematical model is conceived in this study to design and optimize risk-averse logistics configurations for modular construction projects under operational uncertainty. The model considers the manufacturing, storage, and assembly stages, along with the selection of optimal warehouse locations, but supplier selection was missing in their model(Hsu, Aurisicchio, & Angeloudis, 2019).

García-Nieves, Ponz-Tienda, Ospina-Alvarado, & Bonilla-Palacios (2019) proposed a mathematical model that practitioners can easily use to optimize construction schedules considering to the largest extent the time and space conditions repetitive projects offer.

RESEARCH METHOD

This section provides details of the problem and justification of the solution proposed to solve the problem.

PROBLEM DESCRIPTION

A construction consultancy company based in Montreal, Canada, delivers construction projects modular or traditional for Canada based in Montreal. We named the company XYZ in this paper to protect their privacy. The XYZ company provides optimal foundation and structural repair solutions as well. The problem they faced was assigning resources to different projects and managing different project schedules. They were looking for mathematical solutions to optimize their project scheduling and assignment of resources to multiple projects. Initially, they did not have any process mapping of their processes, and many processes needed to be more varied or waste that did not add any value to their work.

SOLUTION APPROACH

The reason for choosing the business process management (BPM) technique to identify redundant processes is that it helps to align your strategic objectives with business processes, demonstrate executive commitment, and empower employees. The chances of improvement in business processes will be amplified (Hung, 2006). The BMP technique helped the XYZ company set its lean objective to minimize multiple project completion times.

To optimize the project schedules, different techniques can be applied. We selected a single-time minimization objective because the single-project approach identifies better solutions than the multi-project approach. (Kannimuthu, Raphael, Ekambaram, & Kuppuswamy, 2020). We selected solver-based optimization over simulation-based optimization for project scheduling because it is fast convergence (for small problems), time constraints modeling, and makes exact solutions possible. In contrast, in simulation, it is slow convergence and not always the optimal solution reached. (Klemmt, Horn, Weigert, & Wolter, 2009).Therefore in this research, we utilize both BPM and mathematical optimization techniques to achieve the best results.

MODEL DEVELOPMENT METHODOLOGY

The mathematical model is developed in two steps to achieve LC (minimize project delay). First, the business process of XYZ is studied and improved based on the information required as inputs to minimize delays in their ongoing project schedules.

After fixing their business process information flow, a mixed integer linear programming mathematical model is developed to minimize the project delays based on supplier selection and project activities optimization. The explanation of these steps is shown in Figure 1.

The first step concerns improving the organization's information flow process to gather inputs for the mathematical model. The second step is related to mathematical model implementation and the generation of optimized schedules.

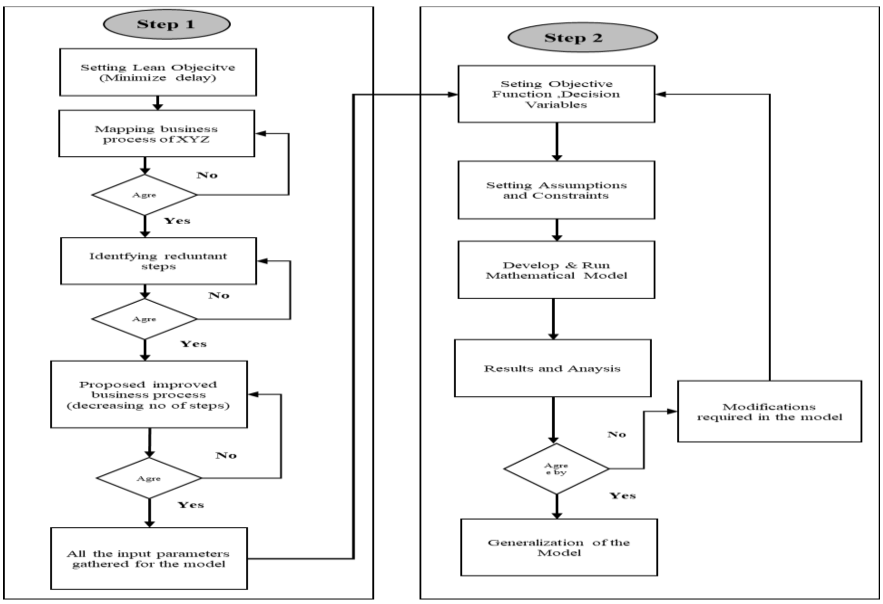

Figure 1: Working Methodology

FIRST STEP IMPLEMENTATION

The company's business process is analyzed and improved in the first step to get the required data to generate schedules. The following figure 2 shows company XYZ's proposed information flow process for managing schedules. There are two departments: administration and technical, along with three people involved in generating and managing schedules of projects. The company manager is from the administration department, and the project manager and team lead are from the technical department. The information flow system is integrated, and the information, whether input or output of the process, is shared by these three people through an IT system named the scheduling system in the figure.

The information generated in these processes includes the number of projects scheduled to optimize, the type of resources required for the project, supplier's information, project activities duration, cost of resources by suppliers, activities precedence to each other, and due date of project completion. These inputs are shown in green borders in the below figure. This input information will be stored in an integrated system that will allow them to manage and view it. The "XOR" gate used in the team lead pool shows the decision he has to take for the resources. If the company has enough resources for the project, it will proceed without suppliers. Still, if company resources are insufficient, he has considered the cost and time associated with suppliers for providing resources. This paper considers projects that require supplier resources for their completion. Then after receiving the input information from the team lead about the projects, the project manager will assign relative importance weights to these projects based on priority. These weights will be critical as the model in the second step will optimize the project schedules based on these weights.

After having this information, the project manager will finally use the mathematical model to generate optimized project schedules in real time. This administration and other departments will receive updated information about the project schedules, as shown in the last process of Figure 2.

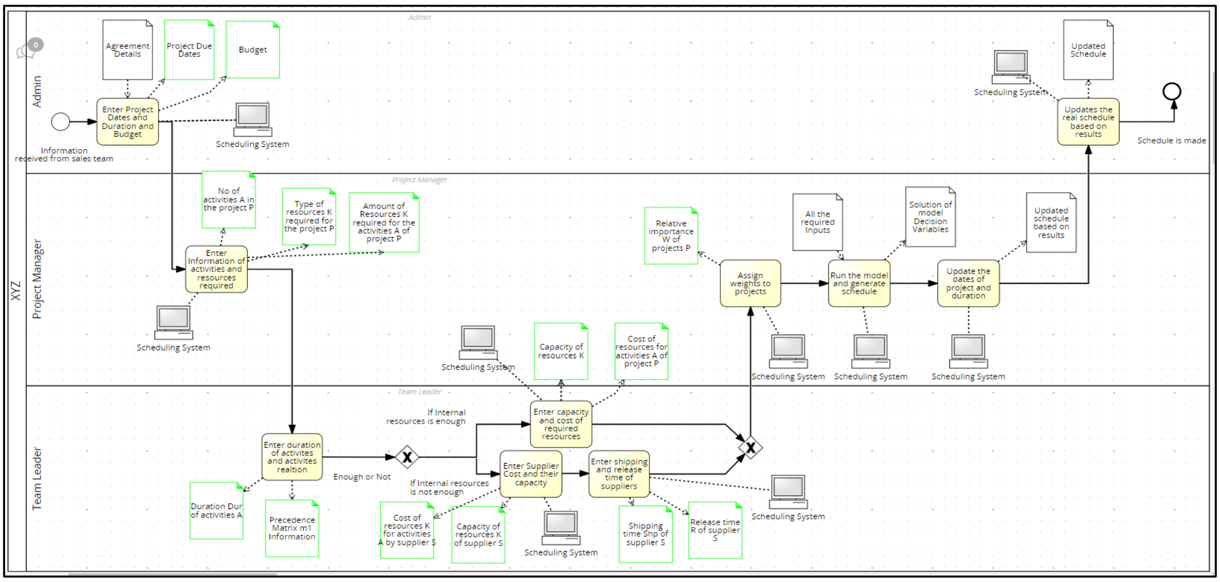

Figure 2: Proposed XYZ Information Flow Process for Managing Project Schedules

SECOND STEP IMPLEMENTATION

A mixed integer linear programming model is developed to optimize project schedules. This model is inspired by the study of (Chen, Lei, Wang, Teng, & Liu, 2018) with small modifications such as adding a precedence matrix approach as a constraint. The assumptions taken for this model include the following: projects are independent of each other regarding activity dependence, but they can share suppliers and resources. No uncertainty factors are included in the model; the raw materials are always available in the right quantities in the supplier's warehouse; they do not produce a surplus, and the elements are transported in shipments whose sizes were fixed before.

The details of the model are given as follows:

Sets)

P	Set of Projects
S	Set of Suppliers
A	Set of Activities within each Project
K	Set of Nonrenewable Resources

Parameters)

Q_{PAK} Quantities required by each activity A of each resource K of each project P

Cap_{SK} Total capacity of each supplier S for resource K

R_{SK} Release time of supplier S for resource K

Shp_{SP} Shipping time of supplier S to project P

Co_{SKA} Supplier S cost of supplying resource K

Dur_{PA} Duration of activity A of project P

W_p Relative weight of project P

DD_P Due date of project P

$Bud = \$10000$

$M = 50000$

m_P The precedence binary matrix for each activity of project P

Decision Variables)

X_{PSAK} Binary variable representing the supplier selection for resource k of activity A of project P

Z_{PSAK} Quantity supply of resource k for activity A of project P by supplier S

ST_{PA} Starting time of activity, A of project P

TD_P Tardiness (delay) of project P

CT_P Completion time of project P

Objective Function)

The objective function is to minimize the delay of multiple projects simultaneously based on their importance weights.

minimize $$\sum_{p} W * P \tag{1}$$

Constraints)

$$\sum_{p \in P} \sum_{a \in A} Z_{pska} \leq Cap_{sk} \forall s \in S, k \in K \tag{2}$$

The equation 2 constraint is related to the capacity of the supplier. Each supplier has different capacity for resource k and its total supply for each resource must be equal or less than its capacity.

$$\sum_{s \in S} Z_{pska} \geq Q_{pak} \forall p \in P, a \in A, k \in K \tag{3}$$

The equation 3 constraint is related with quantity of resources k required by each activity. The total units of resource k supply by supplier S should be greater than or equal to required quantity of activity a of project p

$$\sum Z_{pska} \leq M \times X_{psak} \forall p \in P, a \in A, s \in S, k \in K \tag{4}$$

The equation 4 constraint is related to big M. It implies that the quantity of resources k should only be supplied by supplier s that are selected for that activity a.

$$\sum_{p \in P} \sum_{s \in S} \sum_{k \in K} \sum_{a \in A} Z_{pska} \times Co_{ska} \leq Bud \tag{5}$$

The equation 5 constraint is related with budget of projects. The total cost of resources k required by activity a of project p should be less than or equal to the budget.

$$\sum_{s \in S} (R_{sk} + Shp_{ps}) \times X_{psak} \leq ST_{pa} \forall p \in P, a \in A, k \in K \tag{6}$$

The equation 6 constraint is related to release time, shipping time of supplier *s* of resource *k* and starting time of activity a. The starting time of activity a should be greater than or equal to the summation of release and shipping time of supplier *s* for resource *k*.

$$ST_{pa} + Dur_{pa} \leq CT_p \forall p \in P, a \in A \tag{7}$$

The equation 7 constraint is related to the construction time completion of the project. The starting time of the last activity of project p and its duration must be less than or equal to the construction completion of the project.

$$TD_p \geq CT_p - DD_p \forall p \in P \tag{8}$$

Equation 8 is related to the tardiness of the project. It states the difference in time between the due date of the project(input) and the construction completion of the project (decision variable).

$$ST_{pi} + Dur_{pi} \leq ST_{pj} \forall p \in P, i \in A, j \in A, i \neq j \tag{9}$$

Equation 9 is related to precedence matrices of projects. It provides information on activities dependence on other activities via binary format.

IMPLEMENTATION

All the input parameters are fed into the Python model through Excel sheets. Some of these are shown below. The relative importance weights W of projects chosen randomly as P1 = 0.4, P2 =0.2, and P3 = 0.4. Each project has its precedence matrix, and in Table 2, the precedence matrix, namely "m1" of project 1 is shown below. This table is read as horizontal number depends upon vertical number; for example, in the table, activity 2 is dependent upon completion of activity 1 and similarly, activity 7 is dependent upon all activities from 1 to 6 and will not start until these activities are complete.

Table 2: Precedence Matrix for Activities of Project 1

m1	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
1		1					1											
2							1											
3							1											
4							1											
5							1											
6							1											
7								1										
8									1									
9										1		1						
10											1	1						
11												1						
12													1					
13														1				
14																		
15																1		
16																	1	
17																		1
18																		

Another input Q, the resources required by activities of different projects are shown in Table 3. This parameter is in three dimensions where "A" represents activities of a project, "K" represents resources required for that activity, and "P" represents projects.

Table 3: Resources Required by Activities of Different Projects

		A1	A2	A3	A4	A5	A6	A7	A8	A9	A10	A11	A12	A13	A14	A15	A16	A17	A18
P1	K1	5	4	4	5	4	4	5	4	4	5	4	4	5	4	4	5	4	4
P1	K2	2	6	1	2	6	1	2	6	1	2	6	1	2	6	1	2	6	1
P1	K3	5	0	2	5	0	2	5	0	2	5	0	2	5	0	2	5	0	2
P2	K1	3	4	5	3	4	5	3	4	5	3	4	5	3	4	5	3	4	5
P2	K2	4	8	4	4	8	4	4	8	4	4	8	4	4	8	4	4	8	4
P2	K3	6	0	0	6	0	0	6	0	0	6	0	0	6	0	0	6	0	0
P3	K1	3	4	5	3	4	5	3	4	5	3	4	5	3	4	5	3	4	5
P3	K2	4	8	4	4	8	4	4	8	4	4	8	4	4	8	4	4	8	4
P3	K3	6	0	0	6	0	0	6	0	0	6	0	0	6	0	0	6	0	0

RESULTS

The optimization model for logistics management was implemented using Python and solved with the Gurobi solver. The model generated contains 986 constraints and 1,086 variables (486 binary variables, 972 integer variables, and 372 continuous variables). Solutions for the different cases are obtained within two seconds. The objective function minimizes the total delay of all projects based on their relative importance in the form of weights given as inputs.

Figure 4 shows the number of units supplied (nonrenewable resources) to different projects. Supplier 3 supplies most of the resources in total 315 units, followed by supplier 1, while supplier two supplies the least number of resoruces:206 units. It can also deduce from the figure that for project 1, supplier 1 is the most important; however, for projects 2 and 3, supplier 3 is the most crucial. Figure 4 also shows the amount of nonrenewable resources provided by each supplier. Supplier 2 and Supplier 3 supply zero units of K1, and all the units of K1 are supplied by Supplier 1. Supplier 3 is the only supplier of resource K3 and supplies 114 units of K3 and 201 units of K2, and supplier two only provides 206 units of resource K2. Based on these results, the construction manager can prepare a better collaboration plan with the different suppliers to ensure reliable relationship-building throughout the different projects and avoid delays that might be caused by the lack of flexibility in providing the different resources (e.g., only one supplier selected for K1 and K3)

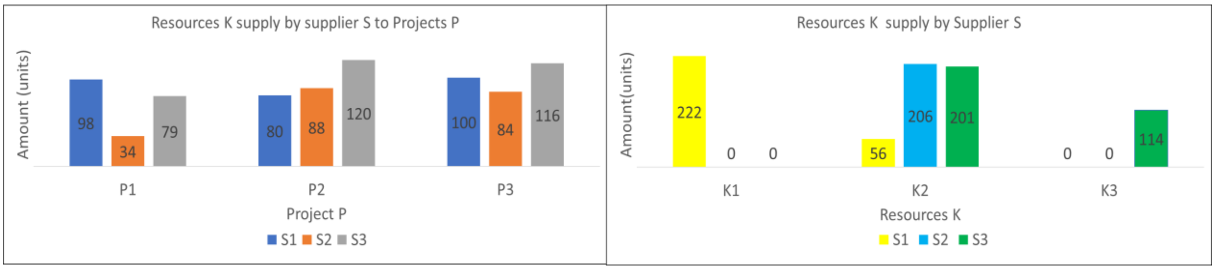

Figure 4: Suppliers "S" Providing Resources Type "K" to Projects "P”

For instance, Figure 5 shows the different suppliers S1, S2, and S3 that have supplied resource types K1, K2, and K3 to different activities of Project 3. The first chart in Figure 5 is for supplier S1, and the second and third charts are for S2 and S3, respectively. For instance, in Figure 5, it can be seen that S1 supplies K1 resources to all activities, S1 supplies K2 resources to some activities: 1, 2, and 8^{th,} and S1 does not supply K3 resources, so there is no grey bar in chart 1 of figure 5. Using the proposed tool, the construction manager can better control the impact of resources on each project's detailed activities and enable efficient management of resources in case of disruptions.

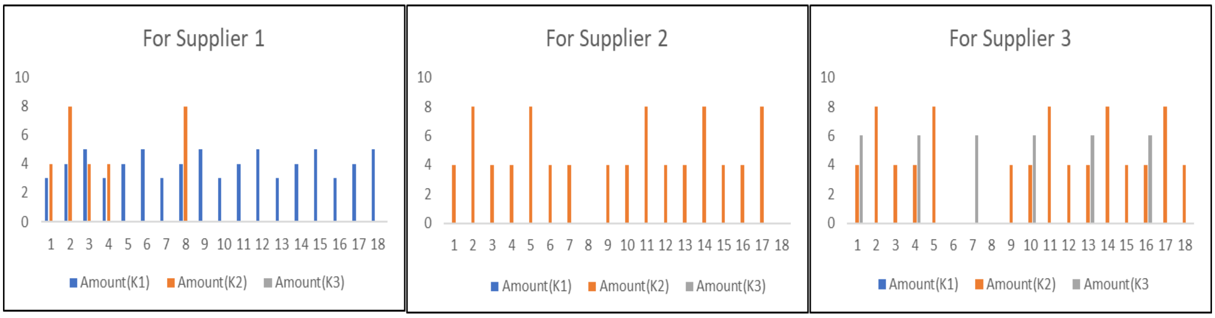

Figure 5: Suppliers Providing Resources K to Activities of Project 3

The model gives the optimal starting time for each activity of each project, and it is shown in Figure 6. Based on the model results, Project 1 should be completed within 12 weeks, Project 2 in 9 weeks, and Project 3 should be completed within 10 weeks. The starting time of activities is also affected because of the difference in precedence relationship among activities of projects.

Figure 6, along with figures 4 and 5, can be utilized collectively to identify the areas to improve decision-making for activities completion time, resources assignment, project idleness, and supplier relationship management.

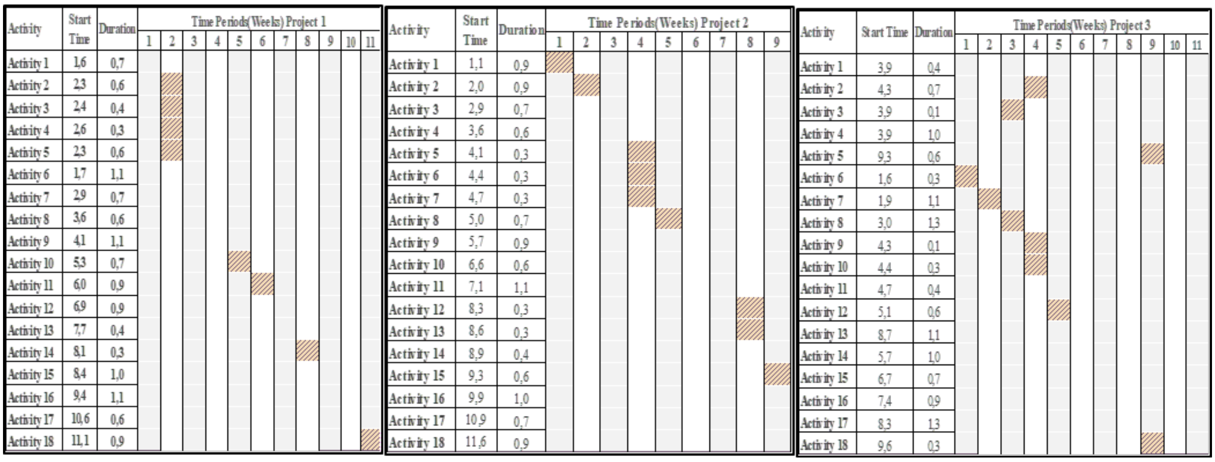

Figure 6: Resultant Gantt Charts of Projects (1,2 & 3)

The completion time and tardiness(delay) of each project are shown in Figure 7. The model can minimize the delay of these projects with respect to the project's due dates. The Project 1 delay is minimized to 2 weeks, the Project 2 delay to a week, and the Project 3 delay to 2.7 weeks. This figure shows the improvement in project time schedules by implementing this model by comparing the before and after conditions.

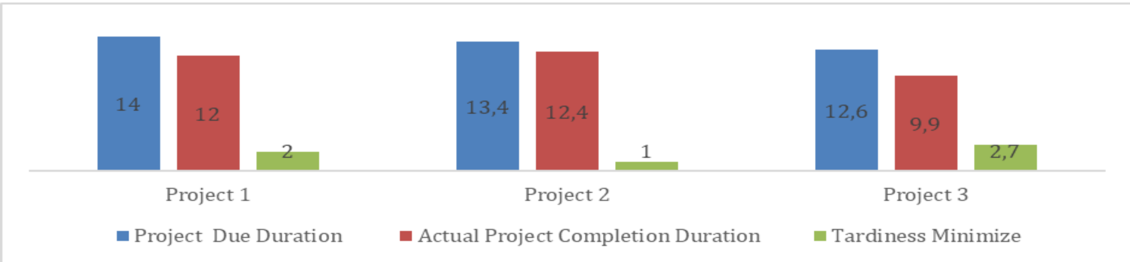

Figure 7: Comparison of Projects Completion Time Before & After Model Implementation (In Weeks)

RESULTS SIGNIFICANCE

The work we proposed here is the interpretation for BPR and logistics optimization to achieve LC. There are many papers available in the literature that provides mathematical optimization solutions for CSC, such as (Zhu, Dai, Liu, Xu, & Alwisy, 2021), (Elmughrabi, Sassi, Dao, & Chabaane, 2020)and (Hsu et al., 2019) but do not provide the way how the mathematical model will be used to achieve LC. By using BPR, we could derive the mathematical model's specifications from reducing waste and facilitating lean practices within CSC (Le & Nguyen, 2021).

Additionally, based on the case study in this paper, the proposed study improves the whole system of a CSC by combining BPM and optimization techniques, which aligns with the goal of lean tools, such as ‘The Last Planner System’ (Daniel, Pasquire, & Ameh, 2014; Le & Nguyen, 2021).

CONCLUSION

This research provides a methodology to minimize the delay (lean) of multiple construction projects simultaneously for the company. This methodology consists of two steps. The first step is related to streamlining the organization's information processes that generate the required inputs for managing and creating schedules. After the generation of these inputs, they are fed to the mathematical mixed integer linear programming model in the second step to give the optimal project schedules and minimize the delay of the projects.

The limitation of this paper is that it only considers nonrenewable resources for projects. Most of the time, real-world projects involve renewable resources such as employees, cranes, and other equipment. Therefore, the addition of these elements to the model will dramatically enhance the capability of the model.

However, this research brings a novel lean methodology that utilizes qualitative and quantitative methods to minimize construction project delays and generate optimal schedules. This will help the project-delivering company manage its resources, project tasks, and suppliers in real-time.

The future steps of this study are to include decisions related to renewable resources in the model and assignment of renewable resources to different activities based on their availability by the model. The decisions related to inventory management can also be included in the model to enhance its capability further.

SUPPLY CHAIN RISK, DISRUPTION AND RESILIENCE; COMPARISON BY SIZE AND INDUSTRY TYPES

Arsalan Safari[1], Vanesa B. Al Ismail[2], Mahour M. Parast[3], Ismail Golgeci[4], and Shaligram Pokharel[5]

ABSTRACT

This study categorizes the types of the supply chain (SC) risk events and disruption and characterizes the plans for SC resilience by firm size and by industry in a holistic framework. We applied systematic literature review and analysis of high quality peer-reviewed journal articles published since January 2000. We collected these articles through three main global scientific databases using relevant keywords. The study maps the sources and antecedents of SC risks and disruption in a comprehensive framework for the six SC risk categories of demand, supply, organization, operations, environment, and network/control. Our findings suggest that the SC resilience plans developed by small and medium-sized enterprises (SMEs) are not necessarily the same as those of large enterprises. While collaboration and networking, and risk management are the most crucial resilience capabilities for all firms, applying lean and quality management principles and utilizing information technology are more crucial for SMEs. For large firms, knowledge management and contingency planning are more important. The resilience plans also vary by industry type as well. Based on our analysis, the authors identify theoretical inconsistencies and knowledge gaps in the literature on SC risks and SC resilience, leading to suggested directions for research in this field.

KEYWORDS

Supply chain disruption risk, supply chain resilience, contingency theory, size, industry

INTRODUCTION

Supply chain resilience is increasingly acknowledged as a critical capability to respond, recover, and adapt in the face of severe adversities and disruptions. Most of the research on SC resilience has focused primarily on various antecedents and consequences of SC resilience (Christopher and Peck, 2004; Jüttner, 2005; Blos et al., 2009; Cao and Zhang, 2011; Zhao et al., 2013; Bavarsad et al., 2014; Chen, 2018; Jajja et al., 2018). This research has underplayed two fundamental elements of SC resilience: the firm's size, and the firm's industry. To adapt to SC disruptions, firms have specific processes, organizational structures, and capacities that differ

[3] Eminent Scholar, Arizona State University: Tempe, AZ, US, mahour.parast@asu.edu, orcid.org/0000-0001-6589-1076
[4] Associate Professor, Aarhus University: Aarhus C, DK, i.golgeci@uea.ac.uk, orcid.org/0000-0002-6853-3255
[5] Professor, College of Engineering, Qatar University, Doha, Qatar, shaligram@qu.edu.qa, orcid.org/0000-0002-7709-7803

by the firms' size and industry; a firm's size and industry have been treated as peripheral factors by most empirical studies and not considered by the systematic literature reviews on SC resilience (e.g., Tukamuhabwa et al., 2015; Ali et al., 2017; Kochan and Nowicki, 2018). The research has typically not provided an in-depth analysis of the impact of firm size and industry type on SC resilience plans, and what has been discovered about the role of firm size and industry remains fragmented. This systematic review analyzes the academic literature to understand SC risk and resilience across different organizational sizes and industries (i.e., manufacturing and service sectors). The service sector includes all service-related businesses and construction. Our literature review and analysis of 224 articles published in a top peer-reviewed journal (at least A-ranked in the journal quality list provided by the Australian Business Deans Council (ABDC) within 2000-2021 - offer an in-depth quantitative and explorative analysis of SC resilience plans that are adopted separately by startups, small and medium-sized enterprises (SMEs), and large enterprises in different industries to mitigate disruptions and ensure business continuity.

Despite the extensive research on SC risk and resilience, understanding how firms' risk management approaches and responses to SC risks and disruptions differ across different firm sizes and industries remains somewhat shallow and fragmented. This systematic literature review analyzes the academic literature to understand SC risk and resilience across different organizational sizes and industries. Our systematic literature review shows that most studies have been conducted without paying enough attention to organizational size and industry. First, our analysis reveals that research on SC risk and resilience for SMEs and startups remains embryonic and needs further development. Second, we find that size is usually considered a control variable in operations and SC management research (Bode et al., 2011; Ambulkar et al., 2015; Bode and Wagner, 2015; Jajja et al., 2018; Azadegan et al., 2019; Parast, 2020). Limiting size and industry only to control variables means the research outcomes cannot easily be extrapolated to different organizational sizes and industries. SMEs and startups usually have capacities, limitations, and priorities that are different from those of large enterprises, emphasizing different practices (Hahn, 2020). For startups, access to funds is the key factor; thus, limited access to funds is a major factor in their SC resilience. For large organizations, access to funds is not critical; process innovation is more important and needs to be emphasized (Golgeci and Ponomarov, 2013; 2015; Parast, 2020). SMEs emphasize agility; large organizations put more emphasis on efficiency (Wieland and Wallenburg, 2013; Thun and Hoenig, 2011).

This paper is organized as follows. We first present the theoretical framework of the study. Section 3 describes the methods used in this study. Section 4 discusses the results; we apply descriptive statistics and analyze the literature using various explorative approaches. Section 5 is the conclusion, including the theoretical and practical implications of this research.

RESEARCH METHODOLOGY

This review focuses only on the structural and systematic analysis of high-quality journal papers from January 2000 to June 2021 using manual screening process, assuming that any prior development in risk analysis would have been considered and updated in the recent papers. The sample was filtered using the inclusion/exclusion criteria shown in Table 1 which were adapted from Liao et al. (2017). This study targeted papers with empirical data or case study analysis. This study excluded conceptual, modeling, and review articles and other types of publications such as theses, books, reports, notes, and news. It is assumed that high-quality research presented in a thesis would have already been published in a high-quality journal.''.

Table 1: Inclusion and exclusion criteria for the systematic literature review

Criteria		Criteria Explanation
Inclusion	Partially related	-The article does not explicitly mention the topic nor uses keywords, but it has the intersection of categories at least in a part/section of the article. - The research efforts of a paper are majorly and deeply dedicated to SC Risk and Resilience.
	Closely related	- The research efforts of the empirical paper are explicitly and specifically dedicated to SC risk and resilience.
Exclusion	Search engine reason	-The article is not written in English, or it was not published in a top peer-reviewed journal (at least A-ranked in the journal quality list provided by the Australian Business Deans Council (ABDC) within 2000-2021.
	Non-related	-The article is not academic (e.g., editorials, newspapers, theses, books, reports, or notes) -the article is a conceptual, modeling, or review article. -The article (topic and keywords) is not related to SC risk and resilience, but to another topic due to homonyms.

According to Podsakoff et al. (2005), papers in high-quality journals can be considered the main source to validate the concepts and impact the subject area. Therefore, this review focuses only on the structural and systematic analysis of high-quality journal papers for the period January 2000 to June 2021, assuming that any prior development on risk analysis would have been considered and updated in the recent papers. This review shows that most of the literature on SC risk and resilience has been developed and published recently. The sample was filtered using the inclusion/exclusion criteria that were adapted from Liao et al. (2017). This study targeted papers with empirical data or case-study analysis. This study excluded conceptual, modeling, and review articles and other types of publications such as theses, books, reports, notes, and news. It is assumed that high-quality research presented in a thesis would have already been published in a high-quality journal. Also, books and reports may have a time lag and are more prescriptive and descriptive; therefore, they are not considered in the review. The focus of the search was limited to ProQuest, ScienceDirect, and Google Scholar databases, as they capture most of the published literature. A correlation between the topic and the journal list mentioned above would help develop a comprehensive list of papers for review.

To search for the relevant literature in the database, publications from leading academic journals were scanned with keywords related to supply chain, risks, disruption, small and medium-sized enterprises, new ventures (startups), agility, and distribution network. Table 2 shows the combination of keywords used in the database search; the approach for selecting these keywords was taken from from Krippendorff (2018). Group A has terms related to resilience as keywords, and Group B has terms related to risk as keywords. Group C has terms related to the combination of resilience, risk, and size of the firm. The keyword search yielded an initial sample of 3,466 publications.

Table 2: Keywords used in the database search

Keywords		
Group A	**Group B**	**Group C**
-Supply chain resilience -Supply resilience -Resilient supply chain -Supply chain resilience distribution networks -Supply chain resilience strategies	-Supply chain risk -Supply risk -Supply chain risk management -Supply chain risk mitigation - Supply chain risk mitigation strategies	-Supply chain risk or resilience - Supply chain and resilience and risk -Supply chain and resilience and risk and SMEs -Supply chain and resilience and risk and large companies - Supply chain and resilience and risk and startups/new ventures

The collected literature was then reviewed for their coverage of supply chain resilience, risk, and disruption domains using Hohenstein et al.'s (2015) definition: "*Supply chain resilience is the supply chain's ability to be prepared for unexpected risk events, responding and recovering quickly to potential disruptions to return to its original situation or grow by moving to a new, more desirable state in order to increase customer service, market share, and financial performance*." This definition captures SC resilience regardless of firm size. Extracting and mapping resilience plans for all firm sizes would help us understand the focus of SC resilience and differences based on company size. For example, startups may have fewer employees and may be more vulnerable to disruptions.

The keyword search yielded an initial sample of 3,466 publications. The collected literature was then reviewed for their coverage of SC resilience, risk, and disruption domains using Hohenstein et al.'s (2015) definition of Supply Chain Resilience. Furthermore, the sample was filtered using the inclusion/exclusion criteria shown in Table 1 which were adapted from Liao et al. (2017). This study targeted papers with empirical data or case study analysis. This study excluded conceptual, modeling, and review articles and other types of publications such as theses, books, reports, notes, and news. From the initial sample of 3,466 publications, 224 (6.5%) publications satisfied all criteria for review. (Appendix A lists the authors of the 224 articles. Appendix B shows the resilience plan themes by firm size. Appendix C shows the frequency of resilience themes.) The theoretical foundations of this study are analyzed on three fundamental approaches: 1) the initial visualization, mapping, and analysis of the literature by size, time, journal, approach, theoretical framework, and variables; 2) exploring, synthesizing, and deeply analyzing the literature, and defining the capacity for resilience; and 3) identifying inconsistencies, gaps, and limitations of the literature and proposing potential research directions to address them.

RESULTS

The results section discusses the differences and similarities of resilience plans developed by startups, SMEs that are not necessarily the same as those of large enterprises, as they usually emphasize different sets of resilience capabilities. Our findings strongly support the value of SC resilience and provide substantial ground for understanding the significant elements of SC resilience across different sizes of firms in different industries. Various aspects of SC resilience have been explored in the literature. The collected literature shows that most of the papers on SC resilience are published in six journals, and only eight journals have published one or more papers from 2016 to 2021. Our data shows that from 2016 to 2021 there is a trend of increased interest in the analysis and assessment of SC resilience and SC risks.

Of the journals in which the 224 reviewed articles were published, 31 journals are identified as A-ranked journals by the Australian Business Deans Council (ABDC). The distribution of risk and resilience articles is highly skewed across journals and does not follow a certain path. About 58% of the publications are published in management journals, and 42% are published in management-related journals.

SUPPLY CHAIN RISKS AND SOURCES

An uncertain event leads to the existence of risk, which can be called a risk event (Manuj and Mentzer, 2008). Our review and analysis of 224 articles confirm that the root causes and antecedents of disruption risk events in an SC can be grouped into demand, supply, organizational, operational, environmental, and network/control risks that may interact; these categories are summarized and explained below. SC resilience is considered in all firm sizes (startups, SMEs, and large enterprises) and many service, construction and manufacturing industries. The service sector includes all service-related businesses and construction.

1. Demand Risks: Demand-related risks are mainly related to the concentration of the customer base, short product life cycles, loss of major accounts, volatility of demand, innovative competitors, forecasting errors, demand fluctuations, risks affecting customers, payment delays, inventory shortages, and technological changes leading to demand changes. Demand-related risks can be addressed through various proactive and reactive policies and solutions such as collaboration, coordination, information and communication technology, and top management support (Manuj and Mentzer, 2008; Christopher and Peck, 2004; Mishra et al., 2021).

2. Supply Risks: Supply risks refer to potential or actual disturbances to the inputs of production of goods or services upstream of the firm. Supply risks include dependence on crucial suppliers, consolidation in supply markets, quality and management issues arising from off-shore sourcing, potential second-tier level disruption, and length and variability of replenishment lead times. Also considered as supply risks are supply chain uncertainties, price and market problems, information asymmetry, and logistics-related issues. Some of the many solutions proposed by researchers are sourcing intermediaries (Vedel and Ellegaard, 2013), integrating external responsiveness and creating dynamic capabilities (Foerstl et al., 2010), and developing effective supplier relationship management (Blackhurst et al., 2011).

3. Organizational Risks: Issues related to the organization are also discussed in the literature. Examples of SC risk events from an organizational perspective are organizational changes, mechanistic systems, employee turnover, employee engagement issues, lack of dedicated resources and training for the SC in the organization, marketing and sales processes, organization finances, and inventory held and managed. Research shows the importance of organizational capability to adopt SC resilience-related measures; the measures could improve flexibility, agility, collaboration (e.g., Jajja et al., 2018; Yang and Hsu, 2018), or integration of digital solutions (e.g., Dubey et al., 2018; Hahn, 2020).

4. Operational Risks: Operational risks are about issues and disruptions in the end-to-end process of producing goods or providing services: receiving inputs; converting inputs to outputs using human resources, physical resources, and non-physical resources; and distributing outputs. The risks include quality-related issues (e.g., defects, errors, discrepancies, reworks, and returns), safety, lengthy set-up times and inflexible processes, manufacturing yield variability, equipment unreliability and breakdowns, limited capacity/bottlenecks, and outsourcing critical business processes. Firms need to be proactive and develop demand forecasting, operation planning, and resource allocation (Zhu et al., 2018).

5. Environmental Risks: Environmental risks include risk events associated with a firm's external environment (natural, political, legal, global, economic, demographic, technological, or socio-cultural) that may directly or indirectly impact the firm's SC networks, marketplace, and ecosystem. This includes natural disasters such as earthquakes, floods, hurricanes, tropical storms, weather changes, and wildfires occurring at any place in the supply chain. Supply chain risks can also be due to the wider level of natural risks such as global pandemics. A few research studies focus on COVID--19-related risks (e.g., Fatemi et al., 2021; El-Baz and Ruel, 2021; Spieske and Birkel, 2021; Pimenta et al., 2022). These papers suggest researching the impact of pandemics on every aspect of supply chains, including inventory management, supplier selection, and SC design.

6. Network/Control Risks: Global supply chains are riskier and more complicated than domestic supply chains because of a variety of links interconnecting a wider network of firms (Manuj and Mentzer, 2008). Ideally, a firm should have an effective awareness system for any potential or actual disturbances to the anticipated flow of product and information from within and between every node or link in its SC networks through which its value stream flows. This might be hard to achieve in practice, but firms should at least strive to familiarize themselves with the details and consequences of these risk events and be more proactive. Every organization has its policies, rules, procedures, and systems that help it govern and control its business affairs and SC-related activities, such as asset management and control, transportation management, and safety stock. Control risk events arise from applying or misapplying these rules and systems (Christopher and Peck, 2004).

QUALITATIVE ANALYSIS

We provide our analysis concerning the two contingency dimensions (firm size and industry segment) examined in the previous sections.

1. Firm size and supply chain resilience

The review provides several important insights related to SC risks and resilience capabilities in startups, SMEs, and large corporations. Because there is only one study related to resilience capability in startups, we provide our assessment for SMEs and large corporations.

We start our evaluation by comparing the common themes in different industry sectors (manufacturing, services and construction) and different sizes (SMEs and large firms). In both groups of the industry size, "collaboration and networking" as well as "risk management" emerge as the most frequently cited resilience capabilities. In summary, in SMEs, collaboration and networking, quality management, risk management, flexibility, information systems/technology, innovation, and supply chain integration are the most highly cited resilience capabilities discussed in the literature in that order. For large corporations, risk management, and collaboration and networking are the most widely cited resilience capabilities, followed by flexibility, contingency planning, information systems/technology, responsiveness, and knowledge management and information sharing in that order. Thus, we see similarities and differences between SMEs and large corporations in terms of resilience capabilities that are emphasized in each group and extracted from the literature. Out of 12 resilience capabilities/ themes listed for both SMEs and large firms, six themes are common between them. However, large organizations tend to be more rigid and hierarchical; they develop action plans and allocate resources for risk management initiatives. SMEs tend to be more organic, agile, and flexible, capitalizing on their organic structure to improve agility, innovation, quality and learning capacities.

2. Industry type and supply chain resilience

Our review of the studies in SC resilience based on the industry type reveals several important insights. First, collaboration-networking and risk management as the most important resilience practices across all industries, followed by a mix of resilience practices such as flexibility, information systems/technology, SC integration, and responsiveness in different orders.

The analysis provides more valuable nuances for developing an industry-specific resilience plan. While flexibility is regarded as an important resilience capability in the chemical industry, information systems are critical to improving resilience in the logistics industry. Agility is an important resilience practice in the manufacturing sector; contingency planning is mostly emphasized in the service industries. Our review suggests that while some general resilience practices are common across industries (e.g., collaboration and networking), the development of resilience capabilities should be based on the nature of the industry.

Regarding resilience capabilities, further analysis suggests a clear distinction between manufacturing industries and service industries. While collaboration and networking as well as risk management are important for both sectors, the manufacturing sector places more emphasis on flexibility and SC integration, and the service sector places more emphasis on knowledge management, information systems/technology, and responsiveness. For manufacturing firms, slack resources are highlighted as a resilience-enhancing capability; for service firms, there is not much discussion on the effectiveness of this capability.

3. Firm size and industry type combination

We previously examined the effect of firm size and type of industry on the development of resilience capabilities separately. It would be insightful for organizations to realize what type of resilience capabilities should be developed based on the overall impacts of these two dimensions of firm size and industry together. This requires a more detailed assessment of the literature to assess the combination of both contingency factors (firm size - industry).

To properly address the combination of size - industry, we identified SC resilience studies that clearly focused on firm size and industry type. We only reviewed articles where these two dimensions were clearly identified. Thus, we excluded studies that used a cross-sectional approach or studies in which firm size was a mix of large and SMEs or not specified. Using this procedure, we identified 96 articles that met our criteria. Table 3 below shows our practical assessment of the size-industry combination. We evaluated the articles based on two dimensions of size (i.e., large and SME) and two dimensions of industry (i.e., manufacturing and service).

Quadrant 1: Large Firms - Manufacturing: The most widely cited resilience practices for large manufacturing firms are risk management plans, collaboration and networking, and knowledge management. The development of resilience capability in large manufacturing firms entails the development of a risk management plan, which includes identifying, assessing, avoiding, mitigating, transferring, sharing, and accepting risk; this encompasses all activities of risk management. Overall, the literature suggests that large manufacturing firms are more involved in risk management plans than their service counterparts.

Quadrant 2: Large Firms – Services: The overall resilience capability practices for large service firms are collaboration and networking, risk management plans, and contingency planning. Large service organizations seem to have a much narrower focus on risk management practices: which consist of identifying steps to be taken if a disruption risk occurs (contingency planning). Such a distinction between risk management and contingency plans may suggest that large manufacturing organizations are exposed to more disruption risks.

Quadrant 3: SMEs - Manufacturing: Our review of the studies in this domain identified collaboration and networking, flexibility, and quality management (i.e., lean, and continuous improvement) as the main resilience capabilities of SMEs in the manufacturing space. The literature suggests that the more resilient manufacturing SMEs require assistance from sources other than banks and government loans and grants. They need to rely on collaborating firms such as large corporations and international financial institutions (Moore and Manring, 2009; Gunasekaran et al., 2011; Pal et al., 2014; Santoro et al., 2020). In addition, manufacturing SMEs should be more organic and flexible and use a significant number of external linkages that can help them become more resilient and more successful at the same time. Applying quality management practices, such as lean and continuous improvement approaches are highly recommended by the literature (Demmer et al., 2011; Pal et al., 2014) and they can help SMEs to be more effective and efficient, innovative and responsive to any changes and disruptions.

Quadrant 4: SMEs – Services: Our review of the studies in this domain identified risk management, information systems/technology, and collaboration and networking as the main resilience capabilities for service SMEs. Collaboration and networking capabilities have the same significance for service SMEs as they have for manufacturing SMEs. To establish resilience at the firm level and the supply chain level, SMEs must incorporate information systems and advanced IT infrastructure for effectively informed decision-making, information sharing, communication and organizational learning (Jayaram et al., 2014; Ali et al., 2017).

Table 3: Resilience capabilities for different size-industry configurations (by priority order)

Industry/Size	Large	SME
Manufacturing	- Risk management - Collaboration & networking - Knowledge management	- Collaboration & networking - Flexibility - Quality Management (lean, continuous improvement)
Service (and Construction)	- Collaboration & networking - Risk management - Contingency planning	- Risk management - Information systems/technology - Collaboration & networking

Table 3 summarizes the resilience capabilities based on the size and industry type. Since there was only one study related to resilience capabilities in startups, we cannot provide a discussion on resilience capabilities in the startup domain. The single study conducted in the startup space discussed the importance of data analytics and the platform economy (i.e., information systems/technology for digital business platforms) for improving SC operational efficiency and productivity (Hahn, 2020).

CONCLUSIONS AND IMPLICATIONS

Our attempt was to answer the research question of "How are SC risk and resilience applied and manifested across different organizational sizes and industries?". The review of 224 articles shows that most SC risk and resilience studies have been conducted without paying enough attention to organizational size and industry. Both the size and the industry of firms are considered control variables in these studies. However, SMEs and startups usually have different capacities, limitations, and priorities from those of larger enterprises. Firms in different industries operate amid different realities and face different internal and external factors when devising their resilience plans and achieving SC resilience. Thus, firm size and industry are likely to have a profound influence on how SC risk and resilience are applied and manifested among organizations.

THEORETICAL IMPLICATIONS

This study contributes to the literature on SC risk and resilience in several ways. First, the study builds upon the relatively dispersed previous research into SC risk and resilience, and it maps the sources and antecedents of SC risks and disruption in a comprehensive framework of six categories of risk events: demand, supply, organization, operations, environment, and network/control.

Second, to the best of our knowledge, this study is the first theoretical assessment for startups, SMEs, and large organizations for understanding the SC risks and disruptions that may be caused by due to various factors discussed above. Our findings suggest that the SC resilience plans for startups and SMEs are not necessarily the same as those for large organizations. While risk management and SC resilience plans require allocating resources and developing an effective action plan, startups and SMEs usually suffer from a lack of sufficient resources. However, larger enterprises can better overcome SC risks and be more resilient. According to our literature review, there is only one study for startups: Hahn (2020) highlighted the importance of data analytics, information systems, and the platform economy (digital platform) for SC resilience in startups. For SMEs, in addition to information systems, collaboration and networking, quality management, risk management and flexibility are more important. Besides collaboration and networking, larger enterprises' risk management, flexibility, contingency planning, and information systems/technology are the most important capabilities for their SC resilience plans.

Our analysis highlighted the SC resilience differences by both size and industry type. According to our result (Table 3), collaboration and networking are the most crucial resilience capabilities for all firms. Firms can be more competitive in the market and more resilient by benefiting from the synergetic effects of collaborative relationships with their SC partners (Ali et al., 2017). These are some of the key suggestions: collaboration with customers (Liu and Lee, 2018); strategic collaborative learning (Hallikas et al., 2005); collaborative efforts to align information and find substitutive parts (Messina et al., 2020); and integrating both configuration and manufacturing flexibilities for better alliances with both new and current SC partners (Huang and Lu, 2020). According to our study, risk management is an effective and popular approach for large firms to be more resilient because of their capabilities and resources for risk management compared with startups and SMEs that face resource and skill shortages. As highlighted by various studies, firms need to be proactive and conduct an SC risk assessment and devise mitigation strategies before facing disruptions (e.g., Thun and Hoenig, 2011; Grötsch et al., 2013; Swierczek, 2016; Rezapour et al., 2017).

Another effective part of a SC resilience plan among large manufacturing enterprises is knowledge management: collecting, managing, and sharing SC knowledge, expertise, and information in organizations. Many SC scholars highlight it as an effective part of a resilience plan (e.g., Hendricks and Singhal, 2005; Essuman et al., 2020; Mishra et al., 2021). Continuity and contingency planning are also effective and most frequently appear in resilience plans for large service organizations that are highlighted in the literature (e.g., Norrman and Jansson, 2004; Davarzani et al., 2015; Lam and Bai, 2016; Islam et al., 2021).

For SMEs, in addition to collaboration and networking, flexibility (i.e., flexibility of operations, changing suppliers, rerouting and alternative shipping paths/methods, input substitutes, design flexibility, manufacturing flexibility, and flexibility in organizational structure) is the most important resilience solution in SME manufacturing sectors (e.g., Pal et al., 2014; Stranieri et al., 2017; Bode and Macdonald, 2017). This is followed by applying lean and other quality management solutions for the manufacturing SMEs (e.g., Demmer et al., 2011; Govindan et al., 2014; Pal et al., 2014). At its core, lean theory identifies eight types of waste, also known as "muda" in Japanese, which are defects, overproduction, waiting, non-utilized talent, transportation, inventory, motion, and excess processing (Liker, 2004). We all know that by applying lean principles to supply chain management, organizations can identify and eliminate waste in all aspects of the supply chain, from procurement and inventory management to production and delivery. This can lead to a more efficient and responsive supply chain, with reduced lead times, lower costs, and improved customer satisfaction. For SMEs in the service sector, in addition to applying effective risk management systems, information systems/technology, and effective collaboration and networking (e.g., Hahn, 2020; Belhadi et al., 2021) are important resilience solutions in that order.

PRACTICAL IMPLICATIONS

This study has some effective practical implications as well. First, SMEs and large organizations should become familiar with the main causes and antecedents of their SC risk events and improve their SC resilience by developing effective *ex-ante* and *ex-post* plans for dealing with disruptions. In addition to responsive efforts to minimize the impacts of disruptions, firms need to be proactive by implementing preventive measures to mitigate SC risks and become more resilient. Second, firms should recognize that their SC resilience plans are not necessarily the same for different industry sectors. Risk management, collaboration, networking, and knowledge management (in that order) are the most important resilience plans/themes in large manufacturing firms. Nonetheless, collaboration and networking, risk management, and contingency plans (in that order) are the most effective resilience plans/themes for large service firms. Both manufacturing firms and service firms need to focus on effective collaboration and networking with their partners and key stakeholders, to mitigate the negative impact of SC disruptions.

Third, manufacturing operations place more importance on identifying, assessing, avoiding, mitigating, transferring, and sharing plans for risk events (i.e., risk management), quality management, and knowledge development and sharing. Manufacturing operations that are less flexible than service operations, which mainly focus on business continuity plans and effective information systems. The nature of manufacturing operations is different from the nature of service operations: manufacturing is a functional, mechanistic, production-oriented model; services are more organic, humanistic, and relationship-based models (Duncan and Moriarty, 1998; Truong and Hara, 2018). Therefore, we expect manufacturers to focus more on risk management and preventive measures compared to service organizations, which mainly focus on the steps to be taken if disruptions occur (contingency planning).

Fourth, business managers need to be aware of the types of SC risk events if they implement preventive measures or responses for those risk events. The likelihood of occurrence of those risk events, the consequences of the occurrence of those risk events, and effective *ex-ante* and *ex-post* resilience plans will vary with the firm size and firm industry. We have listed resilience plans/themes (prioritized by firm size) that businesses can consider in Appendix B.
